There are two main reasons for investors to enter into swap deals. The most important reason is that swaps allow some market imperfections to be exploited. In other situations, needs of an investor may change after the initial investment has been made and the investor may wish to hold an asset (or liability) with slightly different characteristics. A swap allows such a change at a lower cost than the alternative of liquidating the original asset that is no longer desired and acquiring a new one.

Mechanics of an interest rate swap motivated by a desire to exploit a market imperfection are best explained with the help of an example. Let us say that firm AAA plans to borrow $100 million for five years at a fixed rate of interest. At the same time, firm BBB is planning to raise the same amount of funds in the form of a five-year floating-rate loan. Both firms inquire about the rates they will have to pay in the two segments of the financial markets—the fixed-rate market and the floating-rate market—and obtain the following quotes:

	AAA	BBB
Fixed-rate bond	8.8%	9.1%
Floating-rate loan	LIBOR + 0.5%	LIBOR + 1.1%

If each firm were to raise the type of funds it needs, the total annual cost for the two firms would be 8.8 percent (the rate firm AAA would have to pay) plus LIBOR + 1.1 percent (BBB's annual cost for the loan). This total cost adds up to (LIBOR + 9.9) percent. Suppose, however, that the two firms raise the opposite type of funds from what they need. AAA raises floating-rate funds and BBB raises fixed-rate funds. They then "swap" their funds. They agree that AAA will pay BBB the cost of fixed-rate funds and BBB will become responsible to AAA for the cost of floating-rate funds. The total cost in this case would be {9.1 + (LIBOR + 0.5)} or (LIBOR + 9.6) percent—a saving of 0.3 percent per annum between the two firms. A financial institution that would have observed this anomaly would bring the two firms together, convince them to raise the type of funds they do not need and swap their obligations. The savings of 0.3 percent will be divided between the three parties—the two firms and the financial institution. The financial institution will bear the risk that each party fulfills its obligations.

After the swap, the two firms and the financial institution will have the following obligations and cash flows. Firm AAA would have raised the loan at LIBOR + 0.5 percent and hence will have to pay the lender this amount every year. It will also have to pay firm BBB 9.1 percent annually for the fixed-rate bond that firm BBB would have raised on its behalf. In exchange, it will receive, say, LIBOR + 1.0 percent from BBB for the loan. Firm AAA's net cash flow will end up being {–(LIBOR + 0.5) – 9.1 + (LIBOR + 1)} or a new outflow of 8.6 percent per annum.

Firm BBB would pay the bond holder 9.1 percent—amount that it would receive from firm AAA—and will have to pay AAA (LIBOR + 1) percent for the loan. Its new cash flow will end up being (LIBOR +1) percent. In addition, we can assume that firm AAA will pay 0.1 percent to the financial institution for its help in the intermediation process.

The cash flows of the three parties with and without the swap can be compared easily.

	AAA	BBB
Without a swap	8.8%	LIBOR + 1.1%
With a swap	8.7%	LIBOR + 1.0%
Financial institution	–	+ 0.1%

The market imperfection that the parties exploited was that the floating-rate and fixed-rate markets assessed different risk premiums for the two firms. Assuming that the expected value of LIBOR over the life of the contract was 8.3 percent, AAA was assessed the same risk by the two market segments whereas the floating-rate market considered BBB to be riskier than the fixed-rate market.

The Bank for International Settlements estimates that the notional amount of interest rate swaps outstanding in the over-the-counter market at the end of December 2007 was $393 trillion. The largest share of this market was for interest rate swaps in euros ($146 trillion) followed by dollars ($130 trillion) and yen ($53 trillion).

Internal/External

In 1993 Fons Trompenaars and Charles Hampden-Turner identified seven dimensions of culture in a model that they outline in their book *The Seven Cultures of Capitalism: Value Systems for Creating*

Wealth in the United States, Britain, Japan, Germany, France, Sweden, and the Netherlands. Five of the seven dimensions deal with challenges of how people relate to one another. The other two dimensions deal with how a culture manages time and how it deals with nature. This latter dimension the two authors labeled internal versus external control. This dimension examined whether a culture believed that it controlled the environment or the environment controlled the culture. The following examines the cultural dimension of control in more detail and specifies the application of the internal-external control dimension to management decision making in multinational corporations (MNCs).

Trompenaars and Hampden-Turner proposed that one way to examine how multinational corporations control their operations is to identify whether the MNC utilizes internal control or external control in their overall strategy. This concept of internal versus external control is derived from the psychological variable known as locus of control. Locus of control refers to a person's belief about what causes the good or bad results in their life. Locus of control can either be internal—the person believes that she controls herself and her life—or external—his environment, some higher power, or other people control his decisions and his life.

The notion of locus of control was first developed in 1954 by Julian Rotter, who in 1966 developed a scale to measure locus of control. Extending Rotter's work, Trompenaars and Hampden-Turner propose that cultures with internal control believe they can control their own destiny, and that natural systems and events are there to be conquered. Cultures with external control believe that one's destiny is predetermined and that one should focus on how to live in harmony with nature and others.

To illustrate the differences between internal and external control cultures, Trompenaars and Hampden-Turner presented managers from different countries the following statements: "Nature should take its course, and we just have to accept the way it comes and do the best we can" versus "It is worthwhile trying to control important natural forces like the weather." More than 50 percent of the managers from Spain and Cuba agreed with trying to control nature, while only 20 percent of managers from Egypt and Kuwait did so. Additionally, when international managers were asked to choose between the statements "What happens to them is their own doing" versus "Sometimes I feel I do not have control over the directions my life is taking," 82 percent of U.S. managers chose the first statement while only 40 percent of Russian and 39 percent of Chinese managers did. Other countries with internal control include Brazil, Canada, France, and Norway, while Hong Kong, India, and Singapore display external control.

Application

In applying the concept to MNCs, Trompenaars and Hampden-Turner define internal control as an MNC placing its focus on what it does best. At the other end of the spectrum, companies need to know what customers want, which is a focus on external control. MNCs need to give attention to issues of both internal control and external control, but it generally turns out that the corporation emphasizes one type of control over another.

Theoretically, in external control cultures, managers can become fatalistic, believing that situations must be accepted rather than changed. They see luck, chance, and change as powerful and real factors in business success. Conversely, in internal control cultures, managers, confident that they can conquer obstacles, tend to be more proactive. Generally speaking, however, most MNCs are not at the extreme ends of the internal/external control continuum.

For example, those MNCs that focus on internal control often have a dominating attitude toward the environment (sometimes bordering on being aggressive). Management teams in MNCs with a focus on internal control are often uncomfortable when the environment seems changeable, to the point of viewing the environment as out of control. In an internal control environment, conflict and resistance by an individual is seen as a sign the person has convictions. Additionally, an internal control environment has a focus on self, function, one's own group, and one's own organization.

By contrast, in an MNC emphasizing external control, harmony, sensibility, and a flexible attitude that encourages compromise and keeping the peace are desired. Additionally, managers are comfortable with the changes that occur in the environment and see them as natural. Finally, the focus of the business is outward, toward customers and partners.

It follows, then, that internal MNCs are competitive, often playing “hardball” with competitors in an effort to win. Additionally, managers often emphasize authority and dominate subordinates. On the other hand, external MNCs are much more oriented to a win-win strategy, seeing relationships with others as more important than winning. They also stress the team over individual achievement.

Interestingly, the results of a survey of senior professional accountants from the world’s major accounting firms in Australia, India, and Malaysia indicate that Australian accountants perceived whistle-blowing as an internal control mechanism compared to Indian and Malaysian cultures. The findings suggest that internal control cultures believe that reporting on wrongdoing is a viable means of being able to effect change, while external control cultures are much more fatalistic, believing such actions are futile.

Internal Labor Market

Companies with internal labor markets may invest in expensive firm-specific training to develop their carefully selected staff.

An internal labor market (ILM) is an administrative unit within an organization in which the hiring, promotion, and wages of workers are governed by a set of rules and procedures, resulting in a job hierarchy, or job ladder. Three factors lead to an ILM: firm-specific skills required for the ILM jobs; on-the-job training necessary to gain the firm-specific skills; and workplace customs that form to support the ILM. The port of entry into an ILM is typically at the bottom of the job ladder in a relatively low-skilled position, such as management trainee. It is what connects the internal labor market to the external labor market (ELM). The rest of the jobs within the ILM are filled by the promotion or transfer of workers who have already gained entry. When someone at the top of the job ladder leaves, workers in the unit move up a “rung,” which creates a vacancy at the bottom. Competition for these jobs is limited to workers already employed within the firm. This restriction of competition for the upper-level jobs to those already employed in the firm, who might not be the most skilled, is the primary cost of an ILM.

Port-of-entry jobs involve intense competition among applicants because it is an entry to promotions, higher earnings, and job security. The administrative unit also faces competition from other employers for workers at this entry level. For the unit, the decision of whom to hire for these jobs is crucial because the worker will ideally be with the firm for a long time, and the firm will invest in the worker in the form of often-expensive firm-specific training. Firms thus spend much time and money in the selection of workers for these port positions, much more so than for positions without a job ladder in which little or no firm-specific skills and training are required, such as clerical or custodial positions.

Wages for the port positions, as for those jobs without job ladders in which the skills are transferable across employers, are determined by competitive pressures in the ELM. However, since jobs in the ILM are not standardized, wages are more wide-ranging. The upper wage limit is the marginal revenue product (MRP) of the worker, or the value of the worker to the firm in terms of revenue generated. The firm will not pay a wage higher than the worker's MRP—that would mean the extra cost of employing the worker (the wage) would be higher than the extra benefit of the worker to the firm. The lowest wage the firm would have to pay to retain the worker is what the worker would earn in the ELM, which would be much less than what the worker could earn in the current firm because the worker's firm-specific skills would not be as valuable to another firm. If a worker in an ILM were to quit or be fired, he or she would lose the position on the job ladder and have to begin again at a (lower) port of entry at another firm.

The potential earnings loss from quitting an ILM creates lower labor turnover within the unit. This employee attachment to the firm and resulting lower turnover costs is an advantage of ILMs to the firm. Further, ILMs give employers an opportunity to observe productive characteristics of employees, allowing employers to make more informed decisions about whom to retain, train, and promote.

International Accounting Standards Board

The International Accounting Standards Board (IASB) is an independent, privately funded accounting standards agency with headquarters in London. The board members represent nine countries and come from a variety of backgrounds as well as bring diverse credentials and experiences to the board. There are 14 board members, and each has one vote. The board members are appointed by trustees. The board is responsible for developing international financial reporting standards, and it follows an open form of due process in order to get this task accomplished. The IASB's goal is to develop a set of high-quality global accounting guidelines for financial statements that will be understandable and enforceable. The IASB also collaborates with national accounting standards agencies to make sure that everyone is in agreement around the world.

A handbook describes how the International Accounting Standards Board operates and proceeds with due process. The framework of the due process system is provided in the Constitution of the International Accounting Standards Committee (IASC) and the International Financial Reporting Standards (IFRS). The handbook reflects the public consultation conducted by the IASB in 2004 and 2005. The Trustees' Procedures Committee (part of the IASC) has been charged with regularly reviewing and amending the due process procedure. This committee is responsible for amending the procedures of due process based on feedback from the IASB and its membership. In addition, the committee has been charged with reviewing proposed procedures on new projects and the composition of working groups. This handbook was approved on March 23, 2006.

The procedures in the handbook address the following requirements:

- Transparency and accessibility: The IASB is responsible for adding topics to its agenda after it has surveyed the membership and conducted research on the topic. Proposed agenda items are discussed at IASB meetings, which are open to the public. IASB meetings are also broadcast and archived on the IASB's Web site.
- Extensive consultation and responsiveness: The IASB solicits feedback from various constituencies in order to collect information from a wide range of groups. In addition, the IASB arranges public hearings and field visits as well as sets up focus groups to promote discussion. After the IASB has listened to all of these groups, it adopts suggestions.
- Accountability: The IASB explains its reasons if it decides to omit any nonmandatory steps of the consultative process as described in the constitution. The trustees are responsible for reviewing and ensuring compliance with the IASB's procedures and mandate, considering the ISAB's agenda, and conducting annual reviews of the IASB's performance.

According to the *Due Process Handbook*, there are six stages to the process, and the trustees are responsible for ensuring that there is compliance at different points through the process. The stages are as follows:

1. Setting the Agenda—The IASB has to consider the following items when deciding whether or not a proposed agenda item addresses the users' needs. When considering future agenda items, the IASB staff is responsible for identifying, reviewing, and evaluating topics that may warrant the IASB's attention. In addition, there may be new proposals that have arisen as a result of a change in the IASB's conceptual framework. Agenda items are also generated via comments from other interested parties. There are times when the IASB receives requests from constituents to interpret, review, or amend existing publications. The staff is charged with compiling a list of these requests, summarizing major and common issues raised, and presenting them to the IASB.
2. Project Planning—When adding an item to its agenda, the IASB has to determine if it is feasible to conduct the project alone or jointly with another standard-setter. If it is a joint project, similar due process is followed under both approaches. After considering the nature of the issues and the level of interest among constituents, the IASB may establish a working group at this stage.
3. Development and Publication of a Discussion Paper—The IASB normally publishes a discussion paper as its first publication on any major new topic as a vehicle to explain the issue and solicit comments from constituents. If the IASB decides to omit this step, it states its reasons. In most cases, a discussion paper includes a comprehensive overview of the issue, possible approaches in addressing the issue, the preliminary views of its authors or the IASB, and an invitation to comment. This approach may differ if another accounting standard-setter develops the research paper.
4. Development and Publication of an Exposure Draft—Publication of an exposure draft is a mandatory step in due process. An exposure draft is the IASB's main vehicle for soliciting feedback from the public. Unlike a discussion paper, an exposure draft sets out a specific proposal in the form of a proposed standard (or amendment to an existing standard). The development of an exposure draft begins with the IASB considering issues on the basis of staff research and recommendations, as well as comments received on any discussion paper, and suggestions made by the Standards Advisory Council (SAC), working groups, accounting standard-setters, and arising from public education sessions. After resolving issues at its meetings, the IASB instructs staff to draft the exposure draft. When the draft has been completed, and the IASB has voted on it, the IASB publishes it for public comment.
5. Development and Publication of an International Financial Reporting Standards (IFRS)—After

resolving issues arising from the exposure draft, the IASB considers whether it should expose its revised proposals for public comment.

6. Procedures after an IFRS Is Issued—After an IFRS is issued, the staff and the IASB members hold regular meetings with interested parties, including other standard-setting bodies, to help understand unanticipated issues related to the practical implementation and potential impact of its proposals.

International Bank for Reconstruction and Development

The International Bank for Reconstruction and Development (IBRD) has a mission of reducing poverty in middle-income and creditworthy poorer countries. This task is accomplished when the organization promotes sustainable development through loans, guarantees, risk management products, and analytical and advisory services. The organization was established in 1944 in an attempt to assist Europe in recovering from the financial devastation of World War II. It is the original institution of the World Bank Group, and counts itself among the five members. The IBRD has a membership of 185 countries.

The Bretton Woods system was charged with developing and implementing the rules and regulations for global commercial and financial transactions. The International Bank for Reconstruction and Development was established as a result. It was the first effort at creating a system that would govern monetary relations among independent nation-states. It was the first effort at creating a system that would govern monetary relations among independent nation-states.

There was much growth and change in national and international financial systems in the 20th century. During the postwar period, many countries had the opportunity to experience economic growth, low unemployment, and gradual deregulation in their respective financial markets. Positive steps were taken to change the way business was done through acts such as the emergence of the European Union, the North America Free Trade Agreement, and Asia-Pacific Economic Cooperation. In addition, international institutions such as the International Bank for Reconstruction and Development (World Bank), the International Monetary Fund, and the Bank for International Settlements have assisted in the management of the changes that have occurred in the international financial arena.

All of the efforts mentioned above have been an attempt to produce a sound international financial system that will be able to sustain itself over the years. The establishment of the International Monetary Fund (IMF) and the World Bank is probably one of the most important success stories for international economic cooperation. During the last 60 years, there have been many changes in terms of the political and economic climate on a global level, which has caused the world's top international financial institutions to shift in terms of how they operate their businesses. Given the number of financial crises that have surfaced during the last 10 years, many scholars and practitioners in the field have called for reform in how the international financial system is structured. These crises have exposed the weaknesses in the international financial system as well as highlighted the fact that globalization has pros (benefits) and cons (risks).

The IBRD has been given the challenge of raising the bulk of the funds for the world's financial markets. In addition, the agency has become one of the most established borrowers since issuing its first bond in 1947. Through its funding activities, the IBRD has become an entity fully capable of providing financial resources to sustain its existence, which allows it to borrow at low cost and offer clients good borrowing terms.

Although the IBRD provides a solid foundation for the World Bank Group, there are four other member organizations that complete the structure for the group. These organizations are the International Finance Corporation (IFC), which is responsible for securing private sector investments for high-risk sectors and countries and was established in 1956; the Multilateral Investment Guarantee Agency (MIGA), which supports developing countries by providing political risk insurance to investors and lenders and was established in 1988; the International Centre for Settlement of Investment Disputes (ICSID), which is responsible for settling disputes that arise between foreign investors and host countries and was established in 1966; and the International Development Association (IDA), which was established in 1960 and partners with the IBRD to ensure that the poorest countries in the world receive assistance in turning their economy around. It is important to note that the five agencies collectively are referenced as the "World Bank Group," whereas the title of "World Bank" only refers to IBRD and IDA.

Highlights

Although it has been given the name "World Bank," the IBRD is not a bank. Rather, it is a specialized entity with the responsibility of accomplishing the Millennium Development Goals. These goals were established by the United Nations in 2000 as an initiative to reduce the level of poverty throughout the world (i.e., increase school enrollments, decrease child mortality, improve maternal healthcare services, control and eliminate disease levels, and provide access to water by the year 2015). In addition, the agency's activities are monitored by the 185 members who control how the organization is financed and how the money is spent. Its headquarters is in Washington, D.C., and there are approximately 109 offices around the world.

One of the most attractive features of the organization is its ability to offer flexible borrowing terms to developing countries. The IBRD's lending policies tend to allow these countries to have more time to repay loans (i.e., 15–20 years to repay the loan as well as a three-to-five-year grace period before payment begins). These terms tend to be more favorable than a commercial bank, which is why the IBRD has been a key factor in developing countries fueling their economic growth. The World Bank finances these loans through its own funding, which yields billions of dollars each year. Its bonds have an AAA credit rating as a result of the loans being secured by the member states' share capital and borrowers' sovereign guarantees.

The World Bank partners with countries to enforce anticorruption initiatives and has created a structure that prevents corruption and fraud in projects.

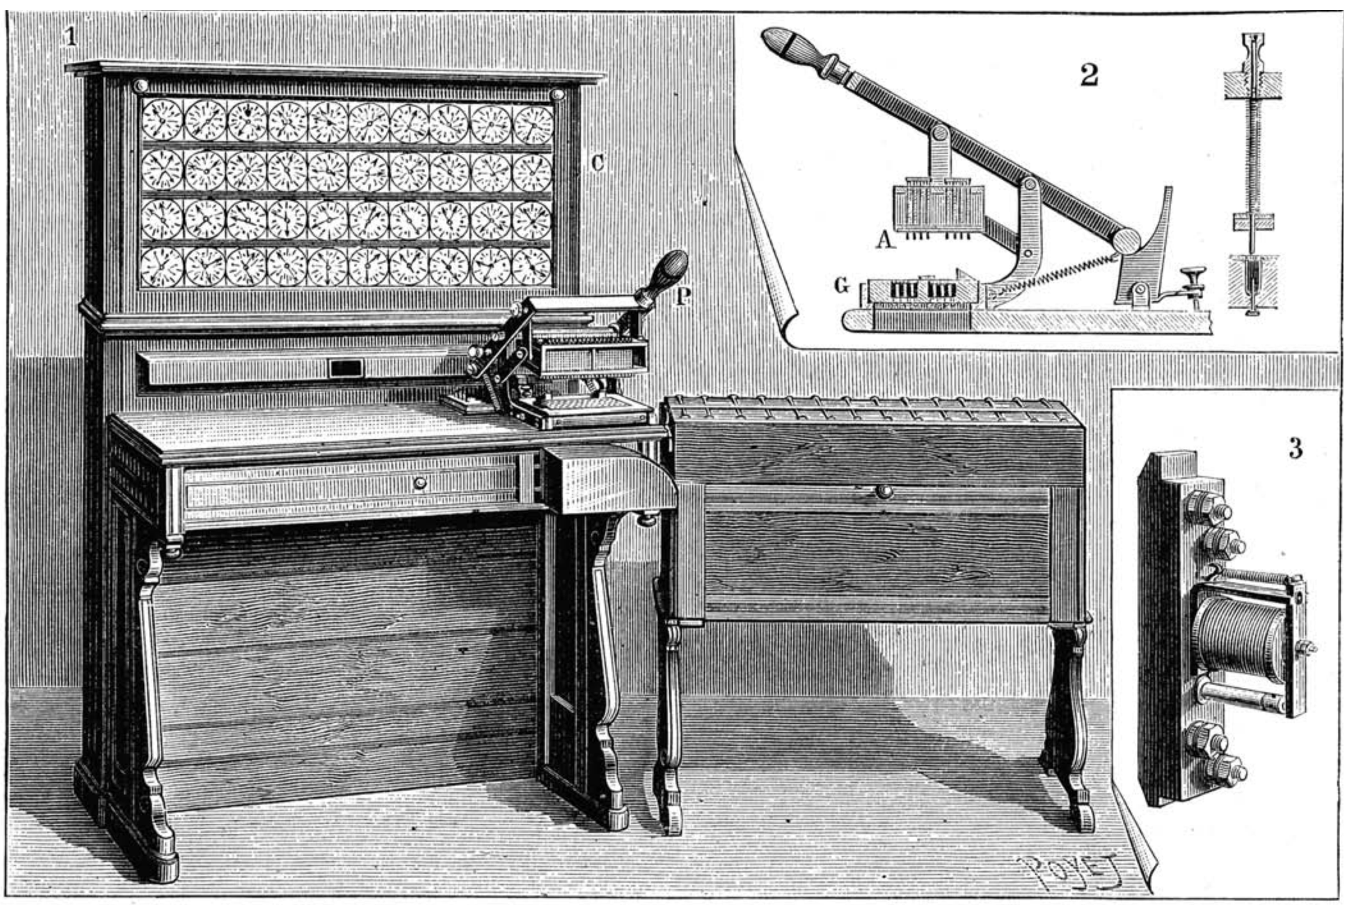
International Business Machines

International Business Machines (IBM) products and services have been a foundation for global business and trade; arguably, without its influence there would be none of the standardization within the information technology (IT) industry so influential in the economic developments of the 1990s. However, IBM has experienced significant losses, notably in 1992, and has had to overcome a cultural and organizational legacy that, although foundational for its growth, had become a barrier to change. This historical legacy runs the entire length of the global IT industry and earlier, with its roots in the activity that even its most sophisticated products still retain: counting.

In the 19th century, at a time of heightened immigration levels in the United States, the U.S. Census Bureau ran a competition to find an efficient way to tabulate census data. This was won by Herman Hollerith, with a punched-card tabulating machine. Hollerith then formed the Tabulating Machine Company (TMC) in 1896. On June 16, 1911, TMC was incorporated in the state of New York as the Computing-Tabulating-Recording Company (CTR). In 1914 Thomas J. Watson, Sr., was recruited from the National Cash Register Company. As company president, he expanded CTR's operations globally, leading to its name change to International Business Machines Corporation on February 14, 1924. During the Depression, Watson counterintuitively produced new machines while demand was low and invested heavily in research and development (R&D). With this excess inventory, IBM was ready when it won the government contract for what was then the largest data processing operation of all time, to maintain all U.S. employment records.

The relationship with the U.S. government proved essential for maintaining IBM's dominance in technological innovation. IBM became a chief contractor for developing computers for the U.S. Air Force's automated defense system. IBM gained access to research being done at the Massachusetts Institute of Technology, working on the first real-time, digital computer. IBM's movement toward electronic computers began with the Automatic Sequence Controlled Calculator in 1944. Increased stability of computers along with other technologies developed with



IBM can trace its roots to the late 19th-century work of Herman Hollerith, whose punch card tabulating machine, a distant forerunner of today's computers, is shown above.

the defense industries during the postwar transition to a civilian economy, combined with the increasing importance of corporate accounting and accountability in U.S. corporations, moved computers into business applications such as billing and inventory control, where IBM already had influence through its tabulating devices.

In 1964 IBM introduced the System/360 product line. In a break from usual practices, IBM unbundled the hardware, software, and service components and offered them for sale individually. In the 1980s, with the Personal Computer (PC), IBM moved into new markets of homes, small businesses, and schools.

However, IBM profits diminished during the global recession of the early 1990s. Mainframe revenue declined due to corporate "downsizing" and the profit margin on microprocessor-based systems was far lower. Louis Gerstner became IBM's CEO on April 1, 1993, and took drastic actions including exiting the consumer business, cutting thousands of jobs, and appointing non–computer industry "outsiders" to key executive positions. Gerstner's successor Sam Palmisano continued this transformation, divesting IBM of its storage, printer, PC, and laptop businesses. As during the Depression and war era, work done in commercially lean times was foundational for success.

When corporate IT expenditures increased during the internet boom and customers were looking for integrated business solutions to contend with new challenges, they required advice as much as technology. Services became the fastest-growing segment of the company. In July 2002 Palmisano purchased PricewaterhouseCoopers's consulting business for $3.5 billion, making IBM the world's largest consulting firm. Despite the emphasis on services, IBM maintains its leadership position in technological innovation, for example, creating the Deep Blue computer that defeated world chess champion Garry Kasparov. The same technology has commercial applications in weather forecasting and modeling financial data.

In 2004 IBM announced the sale of its IBM Personal Computing Division to the Chinese firm Lenovo in a reportedly $1.75 billion deal.

International Capital Flows

International capital flows include all transactions by residents of one country that involve financial claims on and liabilities to residents of another country. International capital flows are divided into various categories, including foreign direct investment (FDI), foreign portfolio investment (FPI), reserve asset flows, and other flows such as bank loans and export and import credits. International capital flows were vigorous before World War I, resumed in the 1920s, came to a virtual stop after the Great Depression, and were restricted under the Bretton Woods system that defined the international economy between World War II and 1973. Since the collapse of the Bretton Woods system, international capital flows have been a catalyst of increasing integration in the world economy.

International capital flows began to play a major role in the world economy during the second half of the 19th century. Britain, France, and Germany were major sources of financial funds to the rest of the world during this period. The majority of international capital flows were in the form of portfolio investment; debt and equity securities financed governments in the periphery as well as large-scale infrastructure projects such as railroad construction. The volume of international capital flows relative to gross domestic product (GDP) was substantial. World War I disrupted this pattern of high capital mobility. International bank lending and portfolio investment resumed in the 1920s under the leadership of the United States. However, the Great Depression put an end to this wave of rising international capital flows. As autarky became the norm in the

1930s, the volume of international capital flows stood at depressed levels.

The international economic system established after World War II (named after the Bretton Woods conference) was hostile to the free flow of capital across borders; industrialized as well as developing countries restricted international capital flows by adopting binding capital controls. Private capital flows resumed only in the 1960s, with the emergence of the Eurodollar markets. As the Bretton Woods system collapsed in 1973, the abolition of capital controls and of restrictions on domestic financial intermediation began in the early 1970s. The United States took the leading role in abandoning capital controls and was followed by other major industrialized countries in the late 1970s and the 1980s.

The growth of international capital flows since the late 1970s has been remarkable. According to the recent studies conducted by the IMF, gross international capital flows stood at approximately 5 percent of world GDP in 1980. While international capital flows have occasionally decreased during times of major financial crises (such as the developing country debt crisis in the early 1980s and the 1994 Mexican crisis), the overall trend has been upward. In 2005 gross international capital inflows were $6.4 trillion, which was close to 15 percent of world GDP.

Due to growing capital flows, international financial integration has risen significantly over the last three decades. As Philip Lane and Gian Maria Milesi-Ferretti showed, the sum of foreign assets and liabilities as a percentage of GDP increased from approximately 50 percent in the early 1970s to more than 300 percent in 2004 in industrial countries. Furthermore, the rate of the increase itself has been rising, with major acceleration of global financial integration in the 1990s and 2000s (despite a brief slowdown after the Asian financial crisis). Financial integration in emerging and developing market economies has also been strong, although it did not reach the level observed in industrial countries. In emerging economies, the sum of foreign assets and liabilities as a percentage of GDP was approximately 150 percent in 2004.

The recent growth of international capital flows was driven mostly by the expansion of banking flows, derivative transactions, and cross-border investment in debt securities. Indeed, these flows now constitute the majority of international capital flows. An important component of this growth is the surge in foreign exchange reserves among emerging economies. These reserves reached unprecedented levels in recent years. The foreign exchange reserves accumulated by emerging market economies are predominantly invested in industrial countries, especially in U.S. Treasury debt securities.

The main implication of this pattern is that emerging and developing economies (especially in Asia) are now the net creditors in world financial markets. Indeed, while emerging and developing market countries receive significant inflows of equity investment (both FDI and portfolio investment in equity securities), the outflow of their foreign exchange reserves to debt securities in advanced industrialized countries (mainly the United States) exceeds capital inflows. In other words, capital flows from less advanced to more advanced countries. It should be observed that the net outflow of capital from emerging and developing economies to industrial economies is a paradox for standard economic theory (because it asserts that capital would flow to places where the rate of return is greatest).

While international capital mobility due to increasing flows of financial funds across borders has been increasing, capital is far from being perfectly mobile across borders. In contrast, the financial assets and liabilities of industrial, emerging, and developing economies show that there is still a marked preference for holding portfolios biased toward domestic debt and equity securities. This well-documented phenomenon is known as "home bias" in international portfolio selection. A related stylized fact is the high correlation between domestic saving and investment (known as the Feldstein-Horioka puzzle), which challenges the expectation of small correlation ratios under high capital mobility. While the findings of Martin Feldstein and Charles Horioka are confirmed in subsequent studies, there are disputes on the methodology of measuring saving-investment correlation and on what this correlation means. Nevertheless, the Feldstein-Horioka puzzle is often seen as a proof of imperfect international capital mobility.

The growth of international capital flows from the late 1970s until recently has been remarkable.

International Centre for the Settlement of Investment Disputes

The International Centre for the Settlement of Investment Disputes (ICSID) is an international organization linked to the World Bank Group, and it is entrusted with the responsibility of facilitating conciliation and arbitration of international investment disputes. The ICSID was established in 1966 following the entry into force of the Convention on the Settlement of Investment Disputes between States and Nationals of other States (Convention). Negotiated under the auspices of the International Bank for Reconstruction and Development (the World Bank), the Convention represented a significant breakthrough in international law, as it effectively granted foreign investors the right to enforce treaties or contracts against a host state in a supranational forum insulated from the interference of domestic courts or diplomatic protection. Since 1978, the ICSID has expanded its reach with the inclusion of the Additional Facility Rules that enable the use of the ICSID machinery by states and nationals of states not parties to the Convention. The Additional Facility is of particular importance for cases under Chapter 11 of the North America Free Trade Agreement because neither Mexico nor Canada have yet ratified the Convention.

The ICSID organizational structure comprises two organs: the Administrative Council and the Secretariat. The Council includes representatives of each contracting party and is chaired ex officio by the president of the World Bank. It meets once a year in conjunction with the World Bank annual meeting and is responsible for the election of the secretary general and the deputy secretary general; furthermore, it oversees the ICSID institutional rules, operations, and budget. The Secretariat, headed by the secretary general, provides a number of administrative functions such as keeping a record of all the panels of arbitrators and conciliators designated by parties, registering arbitration requests, assisting the formation of conciliation commission and tribunals as well as administering the proceedings and costs of each case. The World Bank houses the ICSID and, in accordance with the Convention, it also finances ICSID administrative costs, although the costs of the proceedings are paid by the disputing parties.

Despite being considered a dormant institution for over three decades, the ICSID has recently experienced a surge in interest and prominence. Compared to the 23 contracting states in 1966, the number of parties currently stands at 143, with an additional 12 signatories. Furthermore, between 1995 and 2008 the caseload has also witnessed a dramatic increase as the number of pending cases climbed from 7 to 124. The revival of the ICSID can be most notably explained by the proliferation of bilateral investment treaties (BITs) and multilateral free trade agreements (FTAs), the majority of which stipulate consent to

ICSID arbitrations to resolve disputes arising from the provisions of these treaties. Although other public and private institutions and rules such as UNCITRAL (United Nations Commission on International Trade and Law) and the International Chamber of Commerce are available to resolve investment arbitrations, the ICSID is the most commonly utilized; estimates compiled by UNCTAD, in fact, indicate that two-thirds of all known disputes have been registered with the ICSID.

Proponents of the ICSID arbitration and conciliation facilities have argued that the institution offers a self-contained and neutral mechanism that offers a high degree of competence in investment and trade matters. Additional advantages include the ICSID independence of the parties' willingness to cooperate, the possibility to object to frivolous claims at an early stage in the arbitration, the recognition and likelihood of awards enforcement in the contracting states, and the option to seek annulment of the award. Furthermore, in April 2006, in order to improve upon what some nongovernmental organizations (NGOs) considered an "opaque" arbitral system with potentially significant social and environmental ramifications, the Administrative Council implemented new rules that allow third parties (amicus curiae) with an interest in the proceedings to send to tribunals written submissions and, subject to the disputing parties' consent, attend the hearings.

Critics, however, argue that the ICSID procedures and new rules continue to favor investor's rights at the expense of democracy and human rights, as several notable cases involved disputes over access to water and electricity while others posed significant challenges to environmental regulation. Reformist NGOs and lawyers have suggested that tribunals should be obliged to ensure open hearings, document disclosure, unconditional acceptance of amicus curiae, and have also proposed for the ICSID to consider the creation of an appeals mechanism to permit the correction of legal errors. However, Bolivia's politically charged denunciation of the Convention and Ecuador's notification of restrictions to the types of cases filed under the ICSID have led commentators to assert that the ICSID is heading toward a broader crisis of legitimacy. Confronted with several challenges posed by civil society and the Convention's parties, the ICSID is at a crossroads.

International Chamber of Commerce

The International Chamber of Commerce (ICC) is a nonprofit organization that is made up of member states; it was formed in 1919 for the purpose of promoting open trade and a free financial market. Many believed that there was a need for a neutral entity that could champion corporate responsibility in order to achieve global peace through business transactions. Once the United Nations was formed in 1945, ICC was given the highest level consultative status with the organization and its agencies. The purpose of this move was to ensure that the United Nations was informed of international business views when making crucial decisions during meetings.

ICC's International Secretariat is located in Paris, and the first president was Etienne Clementel. He was a French minister of commerce and has been credited with establishing the International Court of Arbitration in 1923. Originally, the member states were Belgium, England, France, Italy, and the United States.

However, today, the organization represents approximately 140 countries around the world, and national committees are in 84 of the countries.

The ICC is responsible for acting as a catalyst for economic growth, job creation, and prosperity throughout the world. The organization facilitates activities that ensure that global business decisions are in the best interest of economic development throughout the world. In addition, some believe its role is to be a business advocate to governments and intergovernmental agencies. Some of the activities include assisting businesses with self-regulation, working against corruption and commercial crimes in world business, and supporting open trade and marketing a healthy economic system. These activities are achieved through the work of various branches of the organization, including the following:

- International Secretariat—The Secretary General leads this body in an effort to achieve the programs that have been approved by the ICC. This office is the operational component of the organization and responsible for ensuring that the work approved by the World Council is performed.
- Executive Board—The board is comprised of approximately 15–30 members and is responsible for implementing policies approved by the ICC. Each member serves for three years. The chairmanship consists of the present chairman, his predecessor, and the vice chairman.
- International Bureau of Chambers of Commerce—This entity was created in 1951 to bring together the world chambers of commerce in developing and industrial countries. This organization was renamed the World Chambers Federation (WCF) in 2001 during the 2nd World Chambers Congress, held in Korea. WCF is also responsible for administering the ATA Carnet system for temporary duty-free imports.
- International Anti-Corruption Commission—This commission was an attempt by the ICC to create a body that would promote self-regulation against bribery and corruption among businesses. The commission consists of 90 members from 34 countries, and they meet twice a year to discuss issues of interest to maintaining an ethical global business environment.
- Business Action to Stop Counterfeiting and Piracy (BASCAP)—Members of this committee represent organizations that are committed to ensuring that intellectual property rights are respected and protected. Part of their mission is to raise awareness of the social and economic costs of piracy and counterfeiting. These two deviant activities have become a source of concern for many industries around the world (i.e., the music industry). When these actions go uncontrolled, there is a decrease in legitimate employment opportunities as well as tax revenues. BASCAP was formed to connect all of the business sectors around the world in an effort to fight counterfeiting and piracy. Three of the major goals of this group are (1) to increase public and political awareness of these crimes and how the acts can cause economic and social harm; (2) to encourage government action and secure allocation of resources to improve enforcement of policies and laws; and (3) to create an environment where intellectual property is respected and protected.
- ICC International Court of Arbitration—This entity is the oldest established ICC institution, and its main responsibility is to resolve international commercial disputes via the arbitration process. Many companies prefer to use this system because they want to (1) receive a fair trial and avoid potential bias by national courts, (2) avoid bad press and damaging publicity, and (3) maintain confidentiality. In addition, arbitration tends to be less expensive and quicker than litigation.

Arbitration is more flexible than litigation and an organization does not have to be an ICC member to take part in the process. Also, the parties involved in the dispute have the privilege of deciding what form of arbitration will be used to resolve the dispute. They are allowed to select the arbitrators, the location of the arbitration, and the laws that are appropriate. In many cases, the parties can select the target date for completion.

The steps involved in the arbitration process are as follows:

1. The party initiating the dispute submits a request for arbitration to the secretariat of the International Court of Arbitration in Paris. The secretariat is responsible for notifying the defen-

dant of the charges, and the party has 30 days to respond to the accusation.

2. The International Court of Arbitration (ICA) initiates proceedings. At this time, the parties decide whether (1) their dispute will be settled by one or three arbitrators, (2) the International Court of Arbitration will make the selection, and (3) they should select their own arbitrator(s).
3. The arbitral tribunal has two months to draft and forward to the ICA the case's terms of reference. The ICA examines the terms of reference for conformity with ICC Rules. The ICA then takes note of or approves the terms of reference before arbitration can proceed.
4. The second half of the advance is paid and the arbitral tribunal proceeds with the case. The tribunal has six months to prepare and submit a draft award to the ICA.
5. The ICA reviews the award. Once approved, the award is signed by the arbitrator(s) and parties are notified of the decision.

International Commercial Terms (Incoterms)

Commonly referred to as *Incoterms*, international commercial terms are internationally standardized terms of trade that specify the responsibilities of the seller and the buyer in a sales transaction. Incoterms help answer the questions: Which party is responsible for arranging and paying for transport of the goods? Which party is responsible for insurance? Which party is responsible for clearing the goods for export or import and paying duties and taxes? When will transfer of responsibility for the goods take place? Rather than leaving these questions unaddressed or needing to work through each detail for every sales contract, the seller and buyer can select from standard Incoterms that define who bears the cost and responsibility for each of the various activities in delivering the goods.

The 13 standardized international commercial terms have helped facilitate international trade since 1936.

Because they are standardized and have a long history of usage across the globe, Incoterms can simplify the negotiation of sales terms and help the buyer and seller to avoid misunderstandings. Also, because they clarify what is included in the quoted sales price and what additional activities and costs are borne by the buyer, Incoterms help a buyer determine the total landed cost that will be incurred in acquiring and bringing the goods to their final point of delivery.

Incoterms were first created in 1936 by the International Chamber of Commerce (ICC) and subsequently have been revised six times. The most recent version is Incoterms 2000, with the next revision slated for release in 2010. Each of the 13 Incoterms is known by a three-letter abbreviation, with the first letter indicating into which of four groups it falls. While a brief description is given below, it is imperative to reference each Incoterm's full description as provided by the ICC in order to understand and use them correctly.

Origin Terms (E): In this category of Incoterms, the seller's responsibilities are fulfilled when goods are ready to depart from the seller's facility:

- EXW [Ex Works] (named place)

Main Carriage Not Paid by Seller (F): For shipments where the primary or international shipment cost is not paid by the seller:

- FCA [Free Carrier] (named place)
- FAS [Free Alongside Ship] (named ocean port of shipment)
- FOB [Free On Board] (named ocean port of shipment)

Main Carriage Paid by Seller (C): For shipments where the primary shipping cost is paid by the seller:

- CFR [Cost and Freight] (named ocean port of destination)
- CIF [Cost, Insurance, and Freight] (named ocean port of destination)
- CPT [Carriage Paid To] (named place of destination)
- CIP [Carriage and Insurance Paid To] (named place of destination)

Arrival at Destination (D): For shipments where the seller's responsibility ends when the goods arrive at a named place, usually in the destination country:

- DAF [Delivered At Frontier] (named place at border)
- DES [Delivered Ex Ship] (named ocean port of destination)
- DEQ [Delivered Ex Quay] (named ocean port of destination)
- DDU [Delivered Duty Unpaid] (named place of destination)
- DDP [Delivered Duty Paid] (named place of destination)

In actual use, sales documents would reference the Incoterm agreed upon by the seller and buyer by stating the three-letter abbreviation followed by the name of a specific place or port. To illustrate for a Chinese seller and U.S. buyer, "EXW Nanjing, China" would mean that the seller makes the goods available in suitable packaging at its facility in Nanjing and the buyer is responsible for all subsequent activities and costs. "FOB Shanghai, China" means that the seller has accomplished delivery when it has loaded the goods on board the ship in the Shanghai port. "DDU Ogden, Utah, USA" refers to a situation where the seller is responsible for export and import clearances, duties, taxes, insurance, and transportation of the goods to the buyer's named delivery point in Ogden.

Though the Incoterms have standardized definitions that are recognized internationally, U.S. domestic shipments often have used terms of sale with confusingly similar appearances but different meanings. For example, the Incoterm "FOB" is intended for shipments involving ocean transportation in which delivery is accomplished when the goods are placed on board the ship at the origin port. However, many domestic U.S. sales contracts have utilized terms such as "FOB factory" or "FOB origin" to indicate that goods are transferred at the seller's facility (rather than loaded on board a ship), and "FOB destination" or "FOB delivered" wherein the seller is responsible for transport and insurance to the buyer's designated point of delivery.

International Compensation

Compensation is a critical tool to an organization's strategic planning, given its importance to both employees and employers. Research has shown that compensation is a key factor to employee attitudes and behaviors, and can be a determinant in retention of talented employees. Employers have to pay close attention to the compensation program, given the costs that are associated with it. Total compensation, which includes actual pay plus benefits, can be 23 percent or more of a company's revenue. The percentage can vary by industry and geographic location.

Pay decisions can be broken down into two categories: pay structure and individual pay. Pay structures focus on pay level and job structure, whereas individual pay highlights incentives and rewards that are of interest to the employee. Pay level is the average pay (i.e., wages, salaries, and bonuses) of jobs in an organization, and job structure refers to the relative pay of jobs in the organization.

Pay Structure

One of the most popular theories addressing the compensation field is equity theory. Equity theory implies that individuals evaluate whether or not they are being treated fairly by comparing their situation to others. In this scenario, it is common for an employee to compare his/her pay to the pay of other employees, especially those coworkers performing the same duties. Many researchers and practitioners in the field strongly believe that work attitudes and perceptions are based on whether or not an employee believes he/she is being fairly compensated in comparison to the perception of what other employees are being paid. This theory applies to both internal and external structures.

Organizations tend to address these concerns via market pay surveys (external equity) and job evaluations (internal equity). In order to ensure that external equity and internal equity issues are addressed, human resource professionals should consider the following tools when preparing an international compensation package: (1) an international compensation management grading system that is comparable to the domestic grading system; (2) a base salary delivery process that is integrated into the home country's base pay system as well as taking local country laws into consideration; (3) an incentive and reward system that motivates employees worldwide; and (4) a performance management system that rewards employees regardless of their geographic location.

Pay levels are influenced by two factors: product market competition and labor market competition. Product market competition creates a threshold on labor costs and compensation. The threshold can be constrictive when the labor costs are a larger share of total costs and when demand for the product is tied to the price. Labor market competition highlights the fact that the organizations must research and determine what is a competitive salary for positions, especially compared to what competitors are paying for similar positions. In order to compete for talent, many organizations will benchmark against product market and labor market competitions.

Job evaluations are used to measure a position's internal worth. An effective evaluation system is based on compensable factors and the weighing scheme for each factor (based on the factor's importance to the organization). These factors include working conditions, education, experience, and job complexity. Once scores have been assigned to each of these factors, a point factor system is developed.

Market pay structures can differ across borders in terms of their level and relative worth for the job. Some markets may offer lower levels of pay overall and require lower payoff for skills, education, and advancement. In most cases, expatriate pay and benefits will be closely in sync with the compensation structure of the home country. However, this practice is slowly being replaced with alternative practices as more companies begin to implement policies that have pay differentials that are based on geographic location. The pay differentials are used to address inequities that may arise if an employee wants to consider a position in another country that may have a higher cost of living than the home country. Unfortunately, there is a drawback to this practice. It may be difficult to adjust an employee's salary downward if the cost of living decreases and/or the employee relocates to a lower-cost area.

Components of International Compensation

When creating a compensation system for international employees, one must take four basic components into consideration: base salary, indirect monetary compensation (benefits), equalization benefits, and incentives.

The base salary is the foundation of an international compensation system because it represents the minimum rate at which a candidate will work for your company. Some organizations have elected to develop an international compensation system based on the policies and procedures of the parent company's country, whereas others have created an international compensation program based on the host country. Regardless of which practice is utilized, it is important for the compensation professional to consider what happens to the employee's pay once they leave that assignment. On average, the typical international assignment usually lasts from three to five years.

Although most benefits (indirect monetary compensation) packages are the same as offered in the home country, organizations must consider how to address situations where a host country may require certain benefits that are not offered in the home country. It may be in the organization's best interest to consider offering such benefits in order to keep employees motivated and maintain positive attitudes.

Equalization benefits are offered in an effort to minimize any financial hardships that an employee may experience as a result of considering an international assignment. Some of these benefits include housing allowances, educational allowances, language and culture training, employment opportunities for spouses, and emergency leave. Some organizations have found that it is beneficial to offer incentives to expatriates. Some of these incentives include an assignment completion bonus, cash bonuses, stock options, and performance-based bonuses.

International Development Agency

An international development agency is an organization dedicated to designing, implementing, and monitoring humanitarian and economic development–related projects, and in many cases it is dedicated to distributing and managing foreign aid and international assistance programs. An international development agency could be an intergovernmental organization (such as the World Bank, United Nations Development Program, UNICEF, World Health Organization, La Francophonie, Organisation for Economic Co-operation and Development), a governmental agency (such as the United States Agency for International Development, Agencia Española de Cooperación para el Desarrollo, Swedish International Development Cooperation Agency) generally in a developed country, attached to a foreign affairs department responsible for the support of development assistance projects in underdeveloped and developing countries. An international development agency could have the support of a combination of governmental agencies, nongovernmental organizations (NGOs) such as Oxfam and organized civil society actors. Still, at the international level, most of the aid is channelled government to government. The source of the funding could be exclusively from governments, or entirely from private funds, but it also could be a mix of the two.

Overall the objectives of the international development agencies are linked to the United Nations' Millennium Development Goals (MDGs). International development agencies tend to operate under bilateral agreements (country to country); however, there are international development agencies that work under multilateral agreements.

Foreign Aid

The distribution of aid among countries can legitimately reflect multiple aims. Aid may be used to meet humanitarian emergencies, to rebuild post-conflict societies, or to support the commercial, humanitarian, or strategic interests of the donor. Still, the most frequently cited objective of aid programs is economic development.

Although economic development is not the only form of development, it has been identified both as a goal and as a condition for other interrelated development goals such as poverty alleviation, income distribution, debt relief, emergency assistance, food aid, social development, adequate health programs, provision of employment, access to education, gender equality, the spread of democracy, and the provision of a hospitable environment for foreign direct investment. This is the reason why international development agencies depend on foreign aid and why they are focused on economic development. The World Bank (2008) classifies 209 economies. It classifies 49 of them as low income, 54 as lower-middle income, 41 as upper-middle income, and 65 as high-income economies. Of the 49 low income, the vast majority are African countries, a few are Asian, and one of them Latin American (Haiti).

For several developing countries foreign aid represents a considerable component, frequently in excess of 10 percent or more of their national income. However, it is a comparatively small item in the national accounts of the aid-giving countries. Even though the amount and the scope of international transfers toward economic development have increased considerably over the last four decades, the amount of foreign aid differs significantly country to country. For instance, it represents one percent of the gross domestic product of Sweden, the Netherlands, and Denmark. In 2005 the total official development assistance (ODA) rose to a record of US$106.8 billion. Also, the provision of foreign official aid in comparison to private aid varies significantly country to country.

Historical Background

Immediately after World War II, Europe lacked financial capital. The response given by the United States was the Marshall Plan or the European Recovery Program (ERP). The ERP was an initiative for rebuilding U.S.–allied countries while repelling communism from Europe. From 1947 to 1951, US$13 billion was given in economic and technical assistance to the European countries that joined the Organization for European Economic Cooperation (former name for the Organisation for Economic Co-operation and Development). After the Marshall Plan, the participants, with the exception of Germany, surpassed the economic level they had before the war. After the success of the Marshall Plan, attention was turned to developing countries. The Marshall Plan gave rise to many of the elements of foreign aid management and delivery.

International Development Agenda

There are multiple debates on what should constitute the international development agenda. Nonetheless, there are elements that comprise the strategy for development: (1) knowledge and technology transfer from more developed countries; (2) potential role of foreign direct investment (including both long and short term investment); (3) increased role of exports and imports; (4) acquisition of significant levels of resource mobilization; (5) maintenance of a steady macroeconomic environment; (6) investment to dramatically improve social and physical infrastructure (health, transportation, communication, education, etc.); (7) reliance on market mechanisms; (8) well-functioning government institutions; and (9) development of regulatory structures and other market institutions.

Several texts on development have promoted strategic and tactical justification of certain interventions and practices and excluded and delegitimized others. In general, the literature on development is closely related to the literature on apparatuses of power and domination. Development can be autonomous, appropriated, gender conscious, sustainable, or the opposite of all these—the definition depends on the nation, university, policy, or international agencies that define it.

There has never been consensus on the meaning of development. The Westernized idea of development has been used as an agent of economic and cultural hegemony, and some authors argue that development as a construct is used to justify colonization.

Since the creation of Bretton Woods, the idea of development has become fully identified with the idea of economic growth measured as the intensification of production using such measures as gross national product (GNP). The word *underdeveloped* in reference to countries was introduced by U.S. President Harry S Truman on January 20, 1949, in the inaugural speech of the Marshall Plan, introducing a word that labelled and stigmatized those countries that did not fit into the pattern of development dictated by the United States and suggesting it was the "duty" of major nations to improve underdeveloped areas.

Development aid has been a highly controversial subject. Defenders of such aid argue, first, that aid provides emergency assistance and debt relief and that if well administered, its provision can produce long-term improvement in areas such as health, human rights, education, etc.; second, that it can be seen as an exercise of interdependence in which both donors and recipients can pursue their respective interests. On the other hand, the rationale against aid is based on arguments such as (1) aid has been used by authoritarian governments to consolidate their power, meaning it has little effect on the poor; (2) it is used to divert attention from issues such as trade, debt, and the role of TNCs; (3) aid creates dependency, thus weakening the political and economic position of aid recipients; (4) it distorts the free market; (5) aid is often subject to conditions to buy goods and services from the "donor"; (6) the donor-recipient dynamic reinforces stereotypical superiority and racism; (7) aid maintains world inequality rather than challenging it; and (8) aid is often displaced or misused.

International Division Structure

A firm may establish an international division to contain its international activities, thus creating a separation between domestic and international activities. For example, a British food company may have several domestic product divisions to serve customers in its home country, and also an international division to manage affairs in its various international markets. Another variation is where the international division is a mirror image or a miniature replica of the core domestic business, with a mandate to sell the multinational's products to foreign markets.

According to Charles Hill, the international divisions themselves are usually organized by geographic regions—he provides the example of Wal-Mart, which established an international division in the early 1990s from which to manage its global ventures. He further suggests that the managers of foreign subsidiaries report into the international division, and that their role would be to sell the firm's products to their foreign markets. Another structural possibility is whereby the international division has a market structure—i.e., it may be divided into one department that caters to corporate clients, another that serves the retail market, and another that specializes in serving large nongovernmental organizations (NGOs).

The headquarters of the international division are typically part of the corporate headquarters—if not in the same buildings or campus, then at least in the same home country. This may reflect a limited worldview and commitment to international markets. This corporate center also generally remains the center of knowledge creation, certainly at the early stages of internationalization. Thus we would expect the branding, information systems, strategic planning, human resource policies, and financial management to be parallel with those of the core domestic corporation.

The international division structure is generally used in a firm's early-intermediate internationalization process. According to John Stopford and Louis Wells and other authors explaining the structural stages on the path to internationalization, firms tend to begin their international involvement by initially exporting their products and perhaps setting up an overseas sales office. If initially successful, the firm makes structural changes to accommodate their evolving international activities—from international divisions, to area divisions, to a worldwide product division with a global matrix structure, a multidomestic or some global structure.

The international division is thus an intermediate step in reorganizing a firm from domestic to global in scope. As such it is a compromise between home-country orientation and control to realization that the epicenter of the firm has shifted toward foreign markets and a wider worldview. Strauss-Elite, an Israeli food company, added an international division several years ago alongside its domestic coffee, salty snacks, dairy, confectionary, and salads divisions. More recently the structure has been changed to reflect a hybrid global orientation, with two product divisions (coffee and a chocolate company) representing the company's product focus and two geographic divisions (Israel and North America) representing the planned trajectory of market growth.

Howard Perlmutter identifies various mindsets associated with these shifts—including the "polycentric" phase, wherein the firm begins to identify with the foreign markets in which it now operates; and a truly global or "geocentric" mindset. For example, KPMG is a global professional service firm with member firms in 145 countries and a global geographic structure that divides the world into three regions (the Americas, Asia Pacific and Europe, the Middle East and Africa). However, the global firm is divided into three professional practices, namely, Audit, Tax, and Advisory. The emergent matrix structure is at once truly global (or geocentric) in that it enables KPMG to see the world as one market, and at the same time it allows the polycentric specialization in different markets that is essential to the delivery of professional services.

Customer-Focused Structures

More recent work has suggested that the international division structure, along with the other classical dimensions described by Stopford and Wells, has been superseded by approaches that place more emphasis on the customer interface. For example, Julian Birkinshaw and Siri Terjesen suggest that the emphasis has shifted from the classic structures—like product and geographic divisions—to structures that see the world from the customer's perspective. Birkinshaw and Terjesen describe three characteristics of these "customer-focused structures."

First, they include high levels of global integration and coordination to provide service to the customer, for example, using dedicated global customer units to offer a coordinated and higher value-added set of services to key client groups. Second, a high level of value-added through some market-focused structure at the customer interface. And finally, some combination of the integration/coordination unit with the high value-added structure. They call these "true customer-focused structures" and present contemporary examples from IBM, HP, ABB, and EDS that are able to separate between the product-focused business (manufacturing) and the customer-focused structures that give the customer a single point of contact with the firm.

International Finance Corporation

The mission of the International Finance Corporation (IFC), a member of the World Bank Group, is to foster sustainable economic growth in developing countries. IFC focuses its development efforts on the private sector, mobilizing capital in the international financial markets, and providing advisory services to business and governments. IFC emphasizes the actual impact that funded projects will have on the country's economic and societal development.

Since its establishment in 1956, IFC's task has been to work with the private sector to reduce poverty in developing countries. Today, private sector development is seen as the key driver of growth and poverty reduction. IFC supports private companies by providing capital, financial expertise, advisory services, and leadership in setting standards in 140 emerging markets.

IFC provides two main streams of support: investment services and advisory services. Investment services include loans and intermediary services, equity, syndicated loans, structured finance, risk management products, trade finance, sub-national finance, and treasury operations. IFC's advisory services are aimed at creation of a favorable regulatory environment for businesses, providing corporate advice to firms, supporting environmental and social sustainability and infrastructure, and providing access to finance.

IFC uses these services to help companies and financial institutions in emerging markets create jobs, generate tax revenues, improve corporate governance and environmental performance, and contribute to their local communities. The goal is to improve lives, especially for people in developing regions who most need the benefits of growth. These regions include sub-Saharan Africa, east Asia and the Pacific, south Asia, Europe and central Asia, Latin America and the Caribbean, as well as the Middle East and North Africa.

In addition to the direct investments, IFC has substantial impact through its "convening power." This means that when IFC takes the lead entering a new market or offering a new product, other financial institutions often follow along. Accordingly, IFC mobilizes capital through syndications. For many clients, the IFC "seal of approval" for projects is as important as the actual financing.

IFC's largest shareholders include the United States, Germany, Japan, Switzerland, the Netherlands, Australia, Canada, and the United Kingdom. Together the member countries provide IFC's authorized share capital of $2.4 billion, collectively determine its policies, and approve investments.

The president of the World Bank is also president of IFC. IFC's executive vice president and CEO lead its strategy. IFC's corporate governance is vested in a board of governors, whose members are appointed by shareholder governments. The Board of Governors delegates many of its powers to the board of directors, which also represents IFC's member countries. They review all proposed investments. Voting power on issues brought before them is weighted according to the share capital each director represents. IFC's operations are carried out by its departments, most of which are organized by world region or global industry/sector. IFC has over 3,100 staff, of whom 51 percent work in field offices and 49 percent at headquarters in Washington, D.C.

IFC's focus on sustainable economic growth by creating opportunity and improving lives in developing countries sets it apart. Being a member of the World Bank Group, IFC shares the World Bank's commitment to societal development and growth. Investment services focus on long-term partnerships with its clients and sustainable investments. IFC's association with the World Bank allows it to provide a wide range of advisory services to businesses and governments.

IFC promotes investment including microfinancing in frontier markets, those of the poorest countries or in the poorer regions, and particularly industries of middle-income countries. To foster development and growth in these markets, IFC strives to increase private-sector participation in infrastructure, health, and education. In addition, IFC supports efforts to mitigate global climate change by investing in new clean production technologies and providing financing so companies can upgrade to more efficient and cleaner equipment.

International Financial Reporting Standards

International Financial Reporting Standards are accounting rules and principles developed and promoted worldwide by the International Accounting Standards Board. Accounting systems reflect the legislative environments in which they have developed. Consequently, how companies report their financial statements can differ across countries. Faced with such differences, the national accountancy bodies of the world's leading economies in 1973 founded the International Accounting Standards Committee (IASC) to develop and promote internationally recognized financial reporting standards. These standards, the IASC believed, would provide investors and financial analysts with internationally comparable and transparent financial information and enable them to make better economic decisions.

By 2001 the IASC had developed and promoted 41 International Accounting Standards (IAS), providing principles on various accounting topics including the presentation of financial statements (IAS 1), the initial recognition and accounting of property, plant, and equipment (IAS 16), the disclosure of employee benefits (IAS 19), and the reporting of intangible assets (IAS 38).

In April 2001 the IASC was replaced by the International Accounting Standards Board (IASB), which amended some IASs and proposed new International Financial Reporting Standards (IFRSs) on topics for which no IAS standards had previously existed. In 2008, there were eight IFRSs establishing rules for the first-time adoption of IFRS standards (IFRS 1), shared-based payments (IFRS 2), business combinations (IFRS 3), insurance contracts (IFRS 4), noncurrent assets held for sale (IFRS 5), evaluation of mineral resources (IFRS 6), disclosures of financial instruments (IFRS 7), and operating segments (IFRS 8). That same year, nearly 100 countries required, permitted the use of, or had a policy of convergence with IFRSs.

IFRSs have been promoted by a number of different actors. For example, as cross-border financing has grown, multinational enterprises (MNEs) have increasingly used IFRSs to produce comparable and credible financial statements to access international capital markets. In addition, the increased number of nondomestic firms listed on national stock exchanges has been accompanied by an increased number of stock markets that accept financial statements prepared under international standards. In 2008 capital markets in over 50 countries accepted companies who reported their financial statements using IFRSs.

Companies based in developing countries have also driven the application of international financial reporting standards. Eastern European companies, for example, have significantly enhanced their credibility by drawing up their financial statements in accordance with IFRS. The use and stature of IFRS has also benefited from endorsements from political decision makers. For example, the decision by the European Union (EU) requiring all EU-listed companies to prepare their consolidated accounts using IFRSs beginning in 2005 represented a major milestone for the IASB.

Despite the increased use of IFRSs around the world, convergence between IFRS and country-specific accounting principles remains to be fully achieved. The United States, for example, does not plan to implement IFRSs until 2011. Studies have shown that different types of obstacles have impeded the use of IFRSs. Financial costs are one such obstacle because companies consider the transition to IFRSs to be a costly, complex, and burdensome process requiring, for example, investments to update IT systems so that they can handle IFRS financial statements. Another obstacle is patriotism. Some countries, such as France, are attached to their accounting systems and reluctant to abandon them for ones considered to be inferior. Former colonies of imperial powers can also be sensitive to external intrusions. This helps explain why India and Pakistan currently prohibit companies from using IFRS standards.

Culture presents a further barrier to the use of international accounting standards. For example, French accounting principles have historically stressed conservatism and prudence, as shown, for example, by the requirement that companies report their assets at historical cost. This attachment to conservatism can help explain why French accounting companies, banks, and insurers were concerned about problems of earnings volatility and resisted the introduction under IFRSs of fair-value accounting (whereby annual changes in the value of assets are reported in the income statement). It remains to be seen whether the IASB can overcome these obstacles and further increase the use of IFRS standards.

Internationalization

In the past 20 years, an increasing number of firms have changed their orientation from domestic to international marketing and/or production. Internationalization is accordingly when firms extend their products or services in overseas markets, usually from their home country.

Among the foreign market operation modes firms can use for their internationalization are exporting, licensing, franchising, joint ventures, strategic alliances, or wholly owned foreign direct investment (FDI), such as greenfield investments and mergers and acquisitions. Although in the literature, the foreign market operation mode has mostly been regarded as a singular entity, in the more complex business reality, firms often use multiple or mixed modes in the same foreign market.

Possible advantages of internationalization are the extension and expansion of market (e.g., increasing sales in foreign markets), the diversification of the risk of overreliance on the home market, the exploitation of resources in other countries, the taking advantage of economies of scale, the acquiring of economies of scope (i.e., the building and using of foreign market expertise in against your rivals) in R&D, marketing and distribution systems, etc. Because of these advantages, internationalization can lead to higher corporate performance, higher profitability and more stable profits.

Several theories and models of internationalization have examined the timing strategies of firms. Especially, there is ample evidence in support of the so-called stages models of internationalization, such as the Uppsala model. These models view internationalization as a sequential incremental process with a varying number of stages. At first, firms develop products and services for domestic markets. After having grown and being well established in their home market, the firms begin venturing abroad by transmission of knowledge and domestic-based practices to other countries, usually to those that are similar to the domestic market in terms of culture and language—therefore mostly to nearby countries first. In the initial years of internationalization, foreign market entry is a gradual commitment of resources, often beginning with export, thereby gaining first knowledge about and establishing ties (to politics, local business, etc.) in the target. As these ties deepen, more resources are invested abroad, often in form of a marketing subsidiary that is being founded. In a next step, foreign production might be established.

Although widely empirically supported, over the last decade, there has been much debate over the applicability of the stage models of internationalization towards certain firms, especially small firms in the high-tech sectors. Especially with regards to the so-called born globals (or international new ventures), i.e., firms that engage in international operations from the first day of their establishment, conventional stage theories with their gradual establishment of internationalization activities do not seem to be applicable anymore.

Due to the new economic landscape, internationalization has also accelerated among these small and new enterprises, because international markets can represent new entrepreneurial opportunities. Mostly because to their size, these firms display several of the characteristics that are advantageous for internationalization, such as high flexibility and short lines of communication. In the process of internationalization, small and new firms are confronted with the notion that often neither the development of a subsidiary (greenfield investment) nor the purchase of a company in the target market (brownfield investment) represent an attractive or even possible option. Recent literature therefore especially suggests cooperation or joint ventures with local partners as promising internationalization strategies for small and new firms.

Internationalization Model

The internationalization process of the firm has been of interest to researchers for decades. Indeed, the process of internationalization has been the subject of widespread theoretical and empirical research. Over this time, the views about the process of foreign expansion and about drivers explaining the logic of the process have evolved.

One difficulty with scholarship relating to internationalization is that most of the research has concentrated on large firms, using cross-sectional studies or case studies and often focusing on one country of origin. However, the internationalization of smaller firms across different countries and regions has increasingly been of more practical concern to international business. More particularly, small and medium-sized firms (SMEs) and their role in the internationalization process are gaining increasing attention by both academics and the business community. This is so because the fall in trade barriers over the last few decades, the increasing importance for the world's economies of innovation and new technology, and the general expansion in globalization have meant a growing role of SMEs in international markets. While there has been research on the applicability of international models to SMEs, they are decidedly limited. Yet, the internationalization process of SMEs has paramount importance for economic development, especially in smaller economies where local markets cannot by themselves sustain growth. Continued economic expansion in these economies requires their SME population to successfully enter into foreign markets.

Recent investigations that do exist have in particular examined the rise within, and internationalization of SMEs from, a growing range of Asian and eastern European countries. With respect to the situation in eastern Europe, we observe that, as the European Union (EU) has expanded and become more internally integrated, central and eastern European SMEs find themselves with greater access to international markets. Thus attention increasingly has been shifting to how these so-called transition economies—Hungary, Poland, the Czech Republic, the Baltic States, etc.—can effectively compete internationally with western Europe and the United States. The rise of entrepreneurial SMEs in Asia and eastern Europe, and their ability to generate value added by operating in the global arena, is seen as key to the eventual success of these countries.

Over the last three decades, several internationalization theories have evolved. Some have concentrated only on development of exports and on the steps prior to exports. For example, S. T. Cavusgil distinguished five steps or stages involved in the evolution of exporting activity of firms. These various other studies distinguish between "lower," "middle," and "higher" stages of export involvement.

Entry Modes

There have been studies that look at the reasons why SMEs increase the breadth and depth of their exporting activities. When barriers arise to internationalization, these investigations tend to focus on internal problems in a country, such as political instability, decaying infrastructure, and so forth. But beyond this more empirical focus are broader theories that see internationalization as advancing either in increments (staged) or "rapid leaps." In the former case, rapid SME internationalization is assumed unlikely because of financial constraints, the lack of international market experience or information, cultural friction, and other factors. Thus the incrementalists hold that SMEs will internationalize and create value for a country in an evolutionary manner, first undertaking the least complex forms of entry (e.g., exporting) and then evolving into more complicated types of market entry strategies—from the rather passive forms of contracting work (e.g., becoming part of an outsourcing network) to the more active entry modes of licensing, joint venturing, and merging and acquiring.

In 1970s and 1980s, a number of Scandinavian authors published articles on the internationalization process of SMEs that appears to support the incrementalist model. The so-called Upsala School of scholarship suggests sequential modes of entry into successive foreign markets with a progressive deepening of commitment to each market. In these theories, the initial lack of market-specific knowledge and the subsequent need for a gradual learning process are the main assumptions. These theories see firms starting their internationalization process in culturally and geographically close markets. This research focuses on the concept of "psychic distance" as an important factor involved with the gradual approach and examines factors related to the hindrances to the flow of information needed for SMEs to internationalize, such as language differences, differences in culture, political systems, level of education, or level of industrial development. Initial lack of market experience causes firms to be cautious and rather risk averse in their approach to committing resources. As they gradually learn to cope with a target market environment, the perceived threats are reduced and commitment, including financial commitment, increases. Feedback from activities in each subsequent entry mode helps them to advance to the next level; from simple exporting to engaging in wholly owned subsidiaries.

Sharply contradicting these staged-based theories are studies that argue that firms in high-tech industries often have to be global as soon as they enter the foreign market (the so-called born-global model) and that the concept of incremental development does not hold when a firm's owner manager has accumulated market knowledge even before the establishment of the current firm or when demand is inherently global.

It is not clear the extent to which internationalization, once started, continues unabated within a firm or country. There is increasing evidence that the internationalization process contains within it the seeds of its own destruction—or at the least curtailment. Recent studies suggest that, in certain contexts, inward-outward linkages that may initiate the internationalization process can, at a certain point, hinder as well as propel outward international expansion. This has broad implications related to the rate and direction of SME internationalization and, in turn, the ability of an industry to create and capture value added, that is essential in future economic growth.

International Labour Office/ International Labour Organization

The International Labour Organization (ILO) is the United Nations (UN) specialized agency that seeks "to promote rights at work, encourage decent employment opportunities, enhance social protection and strengthen dialogue in handling work-related issues." It was created at the Peace Conference on January 25, 1919, at Versailles, and in May 2008 the ILO counted 181 member states. Since its creation, the ILO has been the single most influential force—both operational and scholarly—in the international world pressuring governments to take a more humane posture on labor.

The ILO has a unique arrangement within the UN system. It has a "tripartite" format in which representatives of governments, employers, and workers collectively discuss and shape policies and programs at the international level, incorporating a multilevel knowledge about employment and work. This tripartisim is encouraged within ILO's member states by promoting social dialogue. The ILO formulates international labor standards in the form of conventions and recommendations setting the standards for labor rights: freedom of association, the right to organize, collective bargaining, abolition of forced labor, equality of opportunity and treatment, and other standards addressing work-related issues.

The ILO has four strategic objectives:

> (1) promote and realise standards and fundamental principles and rights at work; (2) create greater opportunities for women and men to secure decent employment and income; (3) enhance the coverage and effectiveness of social protection for all; and (4) strengthen tripartism and social dialogue.

The main organs of the ILO are the International Labour Conference, the Governing Body, and the International Labour Office, headed by a director general. The national delegations of the ILO member states meet every year in June at the International Labour Conference in the organization's headquarters in Geneva. Each delegation is composed of two government representatives, an employer representative and a worker representative. Also, alternates and technical advisers generally appointed by the cabinet ministers assist government representatives. Consensus in the national delegations is not required, and each representative has one independent vote. Employers and workers are free to express their views and the vote reflects the positions of their organizations. The Conference is the ILO's policy-making and legislative body. It is also an annual space for the discussion of labor and social issues, and it is within the Conference that international labor standards are established and adopted.

The Governing Body is a tripartite body composed of 56 voting members—28 government members, 14 employer members, and 14 worker members. It is the executive council of the ILO and is elected every three years at the Conference, taking into account geographical distribution. The Governing Body generally meets three times a year. Among its functions are the supervision and application of international labor standards; the design of the agenda for the annual Conference and other ILO meetings; the establishment of the budget to be approved by the Conference; monitoring of the decisions taken at the Conference; and deciding on actions to be taken. The Governing Body also has the function of appointing the director general and directing the activities of the International Labour Office.

A worker at a brick factory in Bangladesh. The ILO pressures governments around the world to improve labor standards.

The International Labour Office, located in the headquarters, is the permanent secretariat of the ILO, and it is the focal point for the organization's overall activities. It prepares the background material for the specialized meetings of the organization and the conferences. It also engages in research and education activities, recruits technical cooperation experts, collects information and statistics relevant to the world of work, issues a broad range of specialized publications (studies, reports, and periodicals), provides the secretariat for the conferences, and assists employers, workers' organizations, and government departments in labor and social matters.

The International Labour Office employs around 1,900 officials at the Geneva headquarters. It also engages with 600 experts undertaking missions of technical cooperation around the world.

The director general is the head of International Labour Office. Since its creation, the ILO has had nine directors general: Albert Thomas, France, 1919–32; Harold Butler, United Kingdom, 1932–38; John G. Winant, United States, 1939–41; Edward J. Phelan, Ireland, 1941–48; David A. Morse, United States, 1948–70; Wilfred Jenks, United Kingdom, 1970–73; Francis Blanchard, France, 1973–89; Michel Hansenne, Belgium, 1989–99; Juan Somavia, Chile, 1999 to present.

The ILO also has regional offices located in Abidjan, Bangkok, Beirut, Lima, and Geneva, and they are supported by 40 ILO offices in other countries. The ILO also holds sectoral meetings and committees in order to facilitate views on the problems faced in different economic sectors and explore specific solutions within them. There are 22 sectoral committees in industry, maritime and transport, and public and private services.

International Law

International law should more appropriately be named *transnational law*. Transnational law is defined by Philip Jessup as "all law which regulates actions or events that transcend national frontiers." Transnational law encompasses public international law, private international law, and foreign and comparative law. It includes not only norms that are "international" by their nature, such as treaties or customs, but also domestic rules and principles governing transnational issues, such as Chinese law dealing with foreign litigants or with Spanish business activities abroad. This entry is organized into the three definitional areas: public international law; private international law, including international dispute resolution; and transnational transactions.

Public International Law

Public international law has usually been defined as the law of relationships between "states" (nations or countries). A more expansive definition now in use comes from U.S. law experts: the rules and principles of general application dealing with the conduct of states and of international organizations and with their relations inter se (among themselves) as well as with some of their relations with persons, whether natural or juridical. The sources of public international law include (1) treaties, conventions, protocols, charters of international member-state organizations (e.g., the United Nations), and executive agreements; (2) customary international law; and (3) principles common to major legal systems. Note that no international laws that apply to all nations and citizens of the world are enacted by a supernational body, such as the United Nations. When an issue of international law arises, it may be raised in the courts of a particular nation or in an international forum created by the consent of some or all nations (e.g., the World Trade Organization).

A treaty is an agreement between countries, which can be bilateral (two nations), trilateral (three nations), or multilateral (more than three). There are thousand of treaties in effect globally at this time, covering almost every imaginable aspect of global relations from the law of the sea to human rights to war to commerce. International organizations may also be included in treaties. A convention is also an agreement or compact between nations, often negotiated though the United Nations on a regional or global basis. Protocols are agreements that typically address matters less important than treaty language, but frequently relate to treaty matters. Executive agreements are entered by the chief executive officer of a nation.

In the United States, treaties are recognized in the Constitution, binding on federal and state governments. Some treaties are self-executing, that is, once adopted, these treaties are binding. Executory treaties, on the other hand, need a domestic law enacted by the legislature or an act of the president to be effective. In the United States, executive agreements are as binding as treaties. Some of the agreements can be entered by the president alone, and some are based on congressional authority or a treaty, allowing the president to execute the agreement.

Many treaties affect the conduct of global business and foreign investment. There are numerous intellectual property rights treaties, often bilateral, and domestic laws in various countries which implement the treaties. A summary of the previously informal customary international law that governs all treaties is itself found in a treaty signed by 97 countries: the 1980 Vienna Convention on the Law of Treaties.

Businesses are affected by many public international agreements, especially executive agreements. Trade agreements, the anti-bribery convention, environmental treaties, and protection of intellectual property rights treaties all have a profound impact on international business, be it direct foreign investment, licensing, or importing/exporting.

Trade agreements are often executive agreements that address trade goals, such as liberalizing trade through reduced tariffs or non-tariff barriers, or protecting trade through quotas or tariffs. Trade barriers include tariffs, also known as import duties. Tariffs can be assessed ad valorem (as a percentage of value) or as flat tariffs (based on the number of units). Non-tariff barriers include embargoes and quotas, and indirect non-tariff barriers. Embargoes can dictate a complete ban on imports and/or exports with a foreign nation or a ban on certain goods. Quotas are limits on the number of imports into a country, based on value or quantity. Indirect non-tariff barriers are laws, regulations, practices, and social values that result in reducing the purchase of foreign goods.

Historically, countries have imposed trade barriers for many reasons: tax collection, protection of domestic industry, foreign policy support, national defense, protection of the environment or natural resources, promotion of cultural or religious values, protection of public health and safety, and reciprocation for the barriers of other countries. As countries came to realize that trade barriers may benefit parochial interests, the countries have also determined that barriers damage the international economy. To fully benefit from globalization, most countries are establishing rules to attempt to reduce barriers, notably through the General Agreement on Tariffs and Trade (GATT).

GATT Principles

Almost every industrial sector of the economies of developed countries is now governed by trade agreements. The most significant agreement is the GATT of 1994, which among other provisions, created the World Trade Organization (WTO). The purpose of the original GATT of 1947, signed by 23 countries, was to promote and expand trade between signatory nations by reducing tariffs and non-tariff barriers. Over 125 countries, called members, have now adopted the 1994 GATT, which includes the 1947 provisions, many multilateral trade agreements, and the Uruguay Round Agreements. The Uruguay Round addresses specialized areas of trade relations. GATT requires the domestic trade rules of members to be based on GATT principles.

The WTO sets policies and rules to implement GATT principles and settles trade disputes between nations. It is not, however, a forum for litigation between private parties. The WTO includes about 150 members—all the members of GATT and other countries if two-thirds of the WTO members approve the nation's application.

One critical rule of GATT and WTO is that a nation cannot retaliate against another nation that has imposed a trade restriction. The offended member must proceed through the WTO dispute resolution process. The remedy may in fact include permission to impose a retaliatory trade restriction against the offending member.

Marketing laws come into play when companies hire representatives to promote products abroad. In some countries, such as the United States, there are few, if any, restrictions on the relationship between a company and its representatives. In other countries, local representatives are protected by domestic laws, regardless of a contract between the parties. France, Paraguay, and the European Union, for example, have protectionist provisions for representatives.

Recent Developments in Public International Law

An area of public international law that has gained attention since the mid-1970s has been anti-bribery legislation. Almost every country bans bribery of its public officials. A few countries also ban their citizens from paying bribes to officials in foreign countries. In 1977, the U.S. Congress adopted the Foreign Corrupt Practices Act, the only act of its kind among all nations for 20 years. In 1999, several countries, including all major European countries, adopted the Convention on Combating Bribery of Foreign Public Officials in International Business (CCB). Most of the large international companies are headquartered in nations that have adopted the CCB.

Attention to environmental concerns has grown exponentially in the past half-century. Many laws have been passed by nations, and regional environmental treaties have been adopted addressing some environmental issues. The United Nations adopted the Stockholm Declaration on the Human Environment in 1972, leading to over 30 multilateral agreements. Over 100 nations have adopted the treaty governing transboundary movements of hazardous wastes, the Basel Convention on Transboundary Movements of Hazardous Wastes and Their Disposal. More than 150 nations signed the Convention on International Trade in Endangered Species of Wild Fauna and Flora that governs the import and export of endangered species. The Montreal Protocol addresses the ozone layer and has been very controversial among developed countries. The 1992 Framework Convention on Climate Change and the 1997 Kyoto Protocol have attempted to limit emissions, with no agreement on enforcement mechanisms to date. Businesses will have to take the then-current status of environmental treaties into account when developing locations abroad and at home.

Intellectual property rights (IPRs) include protections for inventions, literary, architectural and artistic works, and words, phrases, symbols, and designs that are eligible for patents, copyrights, and trademarks. Each country grants certain right to the owners of the material. The 2000 GATT Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS) requires its member nations to adopt minimum IPR protections and effective enforcement mechanisms. The signatories must abide by the earlier Paris Convention (patents and trademarks) and Berne Convention (copyrights) that result in foreign IPR holders having the same protection as domestic holders of patents, copyrights, and trademarks.

The 1970 Patent Cooperation Treaty centralized the application process for international protection of patents. The UN World Intellectual Property Organization (WIPO) processes the applications and sends them to countries that the applicant specifies, or to the European Union for its member countries. A similar system exists through WIPO for trademarks. Companies must take care about relying on TRIPS, as various nations are seeking mechanisms to delay compliance or interpret its provisions to protect domestic businesses, rather than foreign holders of IPRs.

A growing concern for global business is the issue of human rights. Nongovernmental organizations (NGOs) and corporations are forming alliances to address human rights in the business setting. Under the auspices of the United Nations, over 60 signatories, including some major global companies, signed a "global compact" in 2000 to support human rights, eliminate child labor, allow trade unions, and protect the environment. Lawsuits have been filed under the U.S. Alien Tort Claims Act, passed over 200 years ago, claiming multinational companies can be liable for human rights abuses by foreign governments that helped the companies, when the multinational knew and condoned the violations. In 2005, Unocal agreed to settle such a lawsuit claiming the oil company encouraged and assisted the rape, torture, and murder of Burmese locals by government soldiers so that Unocal could build a gas pipeline.

Private International Law

Private international law deals with the relationships between parties and conflicts of laws when the parties are in a legal dispute. The relationships are largely dictated by private contracts between parties. There are, however, several treaties and conventions that attempt to introduce common ground for transactions. Notably, the Convention on Contracts for the International Sale of Goods (CISG), adopted by some 64 countries, determines the rights of buyers and sellers of most merchant goods in signatory countries, unless the contracting parties opt out of the Convention or have contract provisions that supersede the Convention. Three large categories of sales excluded from the CISG are (1) consumer goods sold for personal, family, or household use, (2) many labor or service contracts, and (3) stocks, securities, negotiable instruments, and money.

As is the case in most countries, contracts may be enforced under CISG if they were entered (1) by mutual consent, (2) with legal consideration (a bargained exchange, whether goods, money, or otherwise), (3) with legal capacity (not legally incompetent, minors, or under the influence of drugs or alcohol), and (4) for a legal purpose. The Convention addresses contract performance and remedies for breach.

International disputes can be resolved in a number of ways. Diplomatic channels are often the first line of approach, whether nations themselves are involved or citizens and businesses of those nations are in dispute with each other or with a foreign government.

The International Court of Justice (World Court) formed under the United Nations Charter hears certain cases, but only when states are in dispute with each other, or states file a claim on behalf of individual citizens or businesses whose rights have been violated and the complaining state alleges that the violation also infringes on the state itself. Both complainant and respondent are free to submit to the jurisdiction of the World Court, but are not required to do so. For the above reasons, few business disagreements are heard at the World Court.

In the world of commerce, business contracts typically specify how disputes will be resolved, through a choice of court and law, or by alternative dispute resolution, such as mediation or arbitration. A sales contract dispute between a European country and China will be heard typically in the courts identified in the contract, and the law of the country the parties specified will be applied by the courts. The cases can be complicated when a court in a given country must apply law from another country, often involving experts to testify as to what the foreign law provides linguistically and legally. In the absence of contract language, elaborate rules are considered by the courts, such as the legal presence of a litigant in the jurisdiction of the court, which body of law to apply, where the disputed transaction occurred, where the contract was made, where it was to be performed, and other matters.

Issues that often arise in both domestic and international cases are proper jurisdiction and proper forum. Even if parties to a contract agree to use a particular court or court system, a threshold question is whether the court is authorized by law to hear the particular type of subject matter in the case in controversy. In addition to subject matter jurisdiction, the court must obtain jurisdiction over the person or an object in controversy. If an object, such as real estate or personal property, is in the geographic jurisdiction of the court, the requirement is satisfied. If a defending person or business or government is being sued, the court obtains jurisdiction if the defendant has the requisite degree of contact in the geographic locale, and if the defendant is properly served the pleadings filed by the suing party.

In addition to proper jurisdiction, the forum or geographical location of the court must be proper. Often, more than one court has proper jurisdiction, and the proper location must be chosen. A case is eligible to be heard in different courts, depending on the country and state, including where defendants reside, where the cause of action arose, where a contract was made, where a contract was to be performed, or where all the plaintiffs reside. The court can transfer a case, even if venue is proper, if it determines another court would be more convenient for parties and witnesses and justice would be better served. This forum non conveniens principle can apply in any court case, whether criminal or civil. A noted example involved the chemical leak disaster in Bhopal, India, resulting in Indian citizens filing suit in New York federal court against Union Carbide. The judge dismissed the case, in favor of Indian courts, as most of the evidence, records, and Hindi-speaking witnesses were in India, as well as several other reasons that made India the better forum to administer justice.

Once a judgment is entered against a defendant, a problematic procedure arises in the international context. Enforcement of a judgment in a foreign nation presents special problems. For example, if the defendant did not appear in court, he may argue that the method used to serve him was unfair under his own nation's laws. He can challenge the judgment in his country, and if the foreign court agrees with him, it will not honor the judgment and allow collection to proceed. Many countries have signed the Hague Convention on Service Abroad of Judicial and Extra-Judicial Documents in Civil and Commercial Matters, which addresses service, albeit not uniform for the signatory countries.

Foreign and Comparative Law

Where no international agreement controls a particular area of activity, companies are subject to domestic laws, regulations, and customs. Businesses face myriad differences in laws in foreign countries. For example, domestic marketing laws come into play when companies hire representatives to promote products abroad. In some countries, such as the United States, there are few, if any, restrictions on the relationship between a company and its representatives. In other countries, local representatives are protected by domestic laws, regardless of a contract between the parties. France, Paraguay, and the European Union, for example, have protectionist provisions for representatives that override negotiated terms in a contract.

When advertising abroad, nations place a varying degree of control over media and message. In some countries, sexual innuendo or explicit messages might be ignored, while in other countries, severe punishment may ensue, including personal punishment for the company's local representative. The European Union, the United States, and most other countries have bans on false advertising. The interpretation of what constitutes false advertising varies, however. In the United States, for example, false advertising must be a misstatement of fact, not mere opinion or exaggeration. In Japan, exaggeration is also forbidden. Many countries strictly regulate advertising available or aimed at children. The European Union prohibits advertising that directly encourages minors to persuade their parents to purchase the goods or services advertised. Some countries, notably France, ban advertising in any language other than their own languages. Some countries ban advertising of certain products, such as alcohol and tobacco.

The corporation and tax laws of countries can encourage or hamper foreign business. Direct foreign investment in subsidiaries or branch offices is subject to the host country's tax laws, absent a tax treaty. Even with a treaty, definitions of income, allowable deductions and their limits, depreciation treatment, and e-sales treatment are calculated domestically. A home country for a business may have restrictions on tax avoidance by establishing facilities in low-tax-rate countries. All countries control ownership in some or all industries. Foreign investors may have to partner with host companies or citizens to purchase property, enter leases, and operate facilities. A few countries do not allow foreign majority control of any branch or subsidiary.

The history of nationalization and expropriation of assets shows a marked difference among nations in cultural and political treatment of foreign investment. Communist and socialist governments nationalized all domestic and foreign business. In the second half of the 20th century, nations in Latin America, Africa, and Asia expropriated only foreign business assets. The prevailing, although not exclusive, view now is that government has the right to take private property under the condition that the taking is for a public purpose, often hotly debated. Whether compensation is just and prompt depends on the nation taking the property. Investors can purchase political risk insurance, but the cost is often prohibitive or has a considerable effect on the enterprise.

Companies operating offices and facilities in foreign countries are subject to the host domestic labor laws. Employee benefits, such as paid medical leave, will vary. Employee dismissal for no reason will be allowed in some countries, including the United States, unless a union contract is in force, or anti-discrimination laws apply. In other countries, considerable legal restraints and guaranteed employment may govern. Some nations require employee involvement in management by inclusion on the board of directors, sometimes, or other methods. When a foreign purchaser acquires a domestic business, the investor may step into the seller's place with respect to employee rights and union contracts. By contrast, in the United States, when a company is sold, all employees may be terminated unless a union collective bargaining agreement provision has restrictions.

A key consideration for foreign investment is the degree to which antitrust regulations will affect business. Most countries have one form or another of antitrust or competition legislation. Some are detailed, such as Germany's, and some leave much interpretation to the courts, such as the United States and Japan. The basic principle in each law is the prevention or distortion of competition. Vertical arrangements between manufacturers and suppliers, distributors, and customers may all be subject to review in certain countries. Perhaps exclusive distribution agreements are banned; perhaps a company cannot have more than a certain percentage of market share in an industry, perhaps exclusive patent licensing is banned.

Engaging in global business is a complex undertaking, requiring knowledge on many fronts. The legal considerations alone are formidable and demand competent counsel from experienced international advisors.

International Marketing Research

With the fast pace of globalization, the necessity to understand customers in all corners of the globe is becoming imperative. Hence, overcoming the challenges of international marketing research is rapidly gaining in importance in multinational organizations. Information needs are changing and becoming more complex and diverse in a hypercompetitive environment in both developed and developing countries.

Traditional markets in developed economies are now increasingly becoming geographically integrated as direct vertical links and information flows are established between customers, retailers, and suppliers. Consequently, it is imperative to conduct research spanning country boundaries in order to examine the differences between the regional and global market segments.

According to ESOMAR in 2008, the international marketing research turnover was $24.6 billion in 2007, representing a growth of 6.8 percent over the previous year, and a net growth of 4 percent, when adjusted for inflation. The fastest expansions were among the BRIC (Brazil, Russia, India, and China) countries, all experiencing double-digit net growths, along with 19 other markets in the world. Latin America was the fastest growing region with a sharp increase in growth at 17.1 percent (11.3 percent after inflation), accounting for well above $1 billion in revenues. The growth rate remained stable in Europe at 5 percent (2.8 percent after inflation), and in North America at 6.6 percent (3.4 percent after inflation).

Online research has grown dramatically in the last decade, and is now the fastest growing methodology with a total spending of around $3 billion in 2007, an increase of 14 percent over the previous year. The largest absolute increase took place in the United Kingdom (UK), the second largest national research

A Coca-Cola ad in Morocco. International market research helps firms target customers in unfamiliar markets.

market, where online spending almost doubled. The major reasons for the rapid growth of this methodology are speed of delivery and low costs. The most successful companies using this method are mostly focused on providing analytical services to meet client needs, differentiate offerings, and benefit from the ensuing competitive edge.

Most of the world's market research is conducted in Europe with a turnover of $10.6 billion (43 percent market share), followed by North America $8.9 billion (36 percent), Asia Pacific $3.53 billion (14 percent), Latin America $1.22 billion (5 percent), and the Middle East and Africa $.39 billion (2 percent). The largest country markets (growth) are in the United States with a turnover of $8.23 billion (+6.6 percent growth), followed by the UK at $2.4 billion (+2 percent), France at $2.2 billion (+2.5 percent), Germany at $2.2 billion (+5 percent), and Japan at $1.4 billion (+4.3 percent).

The global marketplace is in transition—rapid developments in mass communications technology and global and regional media such as CNN, MTV, CNBC, etc., have apparently created a homogenization of expectations and preferences. It is imperative to collect relevant information to validate such assumptions as whether or not teenagers in a particular market do indeed share similar interests in fashion, music, films, and sports as new trends and related products are rapidly diffusing through the global media. The expansion of modern retailing worldwide incorporating point-of-sale (POS) scanner technologies, and modern merchandising practices have also facilitated the collection of syndicated scanner data in many more countries in the globe. The rapid growth of malls has made it possible to conduct mall intercept interviews. Nevertheless, international marketing researchers also have to address the problems of availability and the use of secondary data in many underdeveloped markets, and the reliability, validity, and the comparability of data across various markets.

International marketing research continues to be driven by a shift in focus to emerging markets, which are increasingly becoming the industry's growth engines, in synchronization with the growing force of globalization. The major research firms within the industry continue to broaden their client base, which seek to outsmart their competitors by identifying the most lucrative opportunities and targets for investments. The most intense competition for market share of research services continues to be in the most mature markets, which enjoy stable overall market growth. The international research firms continue to expand their analytical and consultancy services and growing their innovative products.

International Monetary Fund

The International Monetary Fund (IMF) is one of the international financial organizations that came out of the Bretton Woods conference, and thus a key institutional component of the international economy since World War II. An international lender of last resort (extending credit and assistance when no one else will), it is the closest thing to an international central bank—lacking control over interest rates and the size of the money supply, it lends money to member states in need, seeking to stabilize exchange rates. Countries receiving loans are, when necessary, required to adopt various reforms to reshape their economy to better reflect the economic values and objectives of the Bretton Woods institutions (the so-called Washington Consensus).

The IMF was founded in 1944, after the Bretton Woods Conference at the Mount Washington Hotel in Bretton Woods, New Hampshire—a meeting of the Allied nations to discuss the shape of the international economy upon the end of World War II. It took another year and a half to implement the ideas forwarded at that conference, and when the founding countries—29 of the 45 attending the conference—signed the Articles of Agreement, the IMF began operations at the end of 1945. Membership has increased since, to 185 countries, including all United Nations members except Andorra, Cuba, Liechtenstein, Monaco, North Korea, Taiwan, Tuvalu, and Nauru. What was originally an Allied operation, then, now encompasses former Axis nations as well as nations of the former Soviet bloc.

The United States has exclusive veto power in the decisions of the IMF. The voting weight in other members is determined by its quota, the amount of money it has contributed to the fund, measured in special drawing rights (SDRs). SDRs are potential claims on the currencies in a figurative basket composed of U.S. dollars (44 percent), euros (34 percent), yen (11 percent) and pounds sterling (11 percent), a composition that will hold through 2010. The makeup of the basket is determined by the IMF's Executive Board every five years. The SDR is used for IMF accounting, and to provide a stable standard against which currencies can be pegged (though the euro is quickly displacing it in that role). Sometimes called "paper gold," the SDR was conceived at a time when the gold standard was still a topic of mainstream discussion, and was designed to replace it internationally. At the end of May 2008, the total value of the IMF's quotas was $352 billion; $19.4 billion in loans were outstanding to 65 countries.

The 20 countries with the most voting power in the IMF are (percentage of total votes in parentheses): the United States (16.79 percent), Japan (6.02 percent), Germany (5.88 percent), France (4.86 percent), the United Kingdom (4.86 percent), China (3.66 percent), Italy (3.2 percent), Saudi Arabia (3.17 percent), Canada (2.89 percent), Russia (2.7 percent), the Netherlands (2.34 percent), Belgium (2.09 percent), India (1.89 percent), Switzerland (1.57 percent), Australia (1.47 percent), Mexico (1.43 percent), Spain (1.39 percent), Brazil (1.38 percent), South Korea (1.33 percent), and Venezuela (1.21 percent).

Structural Adjustments

The reforms prescribed by the IMF for nations receiving loans are called "structural adjustments," because they were conceived of as a way to reshape national economies into something more closely resembling the ideal described at Bretton Woods. These adjustments are free-market-minded, focusing on the reduction of trade barriers (such as is encouraged by the World Trade Organization) and the privatization and deregulation of industries. The underlying assumption is that if the borrower nation had implemented these economic changes earlier, it might be less likely to need the loan, but even when that logic does not apply, the conditions are generally imposed; loans are the carrot, structural adjustments the more important goal than simply recouping the loan.

Balanced budgets, a softening or removal of price controls, and the reduction of corruption are all common conditions of structural adjustments, depending on the country. If the nation has a history of protectionism, it will be required to become more friendly to foreign investment and foreign business; in the past, countries were encouraged to open and enhance domestic stock markets, but in the 21st century such exchanges usually already exist.

Naturally, structural adjustments have come under criticism as a breach of national sovereignty—the very reason why the United States refused to ratify the International Trade Organization. The counterargument is that borrowing from the IMF is voluntary; that these adjustments are not imposed on any nation that does not seek help, knowing what the conditions will be. Since the adjustments are tied to the IMF's beliefs about economic health—they are reforms that the institution believes will better enable the borrower to repay the loan—they are intrusive, but not arbitrary.

On the other hand, some adjustments are more intrusive than others, more beneficial than others. The "austerity" adjustment comes under particular criticism, because it requires the borrower nation to reduce its spending on social programs, and usually specifies an amount that needs to be cut rather than recommending particular budget cuts; health and education programs are generally the first to go, and it seems clear that cutting education funding is in fact not in the economic best interests of any country, and furthermore that any country placed on a path of economic betterment through free market initiatives will in the long run have *more* need for a well-educated citizenry, not less.

Though structural adjustments have been part of the IMF's approach since its inception, they have been especially detailed and deep since the 1970s, when stagflation and the oil crises suggested their necessity.

The 2009 G-20 Summit

In the midst of the acute phase of the 2007–09 global economic crisis, the G-20 summit of the world's largest national economies was held among their heads of state rather than their ministers of finance. Going into the summit, the press and several attendees referred to it as "the next Bretton Woods," and the summit later turned out to be largely a planning session for the April 2009 G-20 summit in London. All of the Bretton Woods institutions are to be reexamined. The IMF's articles of agreement have not changed substantially since the fund's inception; some of the G-20 participants have called for a ground-up rethinking of the world's financial environment and the institutions that maintain it, and major changes to the IMF will at least be discussed.

The IMF planned lending up to $100 billion to countries with overall healthy economies that were having problems borrowing in the tumultuous global market conditions.

International Monetary System

The term *international monetary system* refers to the formal and informal arrangements between national governments and financial institutions—private, public, and international—that govern the flow of money and capital between countries. Some aspects of these flows are strictly regulated by domestic and international laws; others are subject to whims and fancies of the market forces often governed by informal agreements and market conventions. Throughout history, there have been epochs when some countries were able to strongly influence the terms under which these flows would take place, and there have been epochs when chaos seemed to reign. The basic purpose of an international monetary system is to facilitate international flows of money and capital in an orderly fashion.

The system must provide a mechanism for payments across countries. Just as the domestic financial system provides very efficient mechanisms (checks, cash, electronic transfers) for transferring purchasing power across entities within the same currency area, an international system must facilitate transfer of purchasing power across countries. This is the easy part—banks have developed very sophisticated mechanisms for converting and transferring value across national boundaries. The foreign exchange market, the largest financial market in the world in terms of daily turnover, allows for efficient conversion of value from one currency to another. Many specialized instruments, for example, acceptance bills, provide liquidity to the market. Governments regulate such transactions merely to prevent payments for illegal and undesirable activities. There is international supervision and regulation of these activities to prevent some forms of systemic risks from spreading from one institution to another. Currencies of many countries have been used over time as international vehicles or reserve currencies to make this task easy and efficient. The challenge for the international monetary system is to ensure that real economic activities take place with minimum resistance arising from the financial transfer that must accompany every real transaction.

Participants in the international monetary system must agree upon a system that determines the values of various currencies in terms of each other—that is, the exchange rates between national currencies. The broad choices for exchange rate regimes are between fixed rates, managed rates, or floating rates. Since changes in exchange rates can have serious impacts upon domestic economies, governments have strong incentives to manipulate their exchange rates to extract some unfair advantages from the global economy. Since such a gain will probably come at someone else's cost, there is a need either for clear international agreements or an international "supervisor" that will ensure that exchange rates are not manipulated and remain with ranges that are justified by economic fundamentals. The challenge for the international monetary system is to ensure that the rules that determine values of currencies are clearly spelled out and there are few incentives for countries to break the rules.

Since countries are often likely to have imbalances in their economic transactions with the rest of the world, the international monetary system must ensure that there are mechanisms to finance such imbalances. While providing temporary relief to finance these imbalances, the system must ensure that incentives exist for countries to take corrective actions, that is, to "adjust" their economies when these balances have not resulted from temporary and reversible shocks. The international monetary system has to ensure that the pool of resources available for financing global imbalances is sufficiently large to meet the needs of countries under normal circumstances.

The international monetary system must provide for an environment in which capital can move from one location to another in response to investment opportunities so as to maximize the global welfare. The international monetary system has to ensure that governments do not impose controls merely to extract monopolistic rents from such flows at the cost of other investors.

Types

Success or failure of an international monetary system depends upon the extent to which it can fulfill these goals without allowing conflicting goals of national governments to undermine the system. While many international arrangements have tried to fulfill these goals over the past century, three systems deserve special mention.

One type was the gold standard (1879–1913). More by convention than through an international agreement, most countries had based their monetary system on gold in the 19th century. Value of a currency was fixed in terms of gold and the supply of a currency depended upon the gold reserves held by a country. Payments between countries were achieved easily through shipments of gold, and exchange rates were effectively fixed as a result of each currency's rigid link to gold. Trade imbalances between countries were paid for in gold that could be shipped between countries without restrictions. An outflow of gold for a deficit country would reduce gold reserves and hence the money supply (automatically). This would put downward pressure on domestic prices, while foreign prices would be rising due to consequences of increased gold reserves in that country. These changes in relative prices set in motion the corrective forces that eliminated the trade imbalances. Free flow of gold also ensured that capital was free to move from one country to another. Indeed, the global economy had reached very high levels of integration under this regime.

The downfall of the gold standard lay in its reliance on gold supplies. It left very little room for governments to play an active role in their economies. With the start of World War I, that objective became more important than maintenance of fixed exchange rates.

Another type was the Bretton Woods system (1945–1972). Experience with the Depression in the 1930s convinced world leaders that self-serving economic policies that attempt to transfer costs of economic hardships to others do not necessarily work. The financial turmoil of the Depression era was replaced by a fixed exchange rate system in 1945 in which the dollar was to acquire a central role. Signatories to the Bretton Woods agreement gave up their currencies' links with gold and established fixed exchange rates against the U.S. dollar. In turn, the U.S. dollar was to have a fixed price in terms of gold and would be freely convertible into gold.

The international monetary system in effect became a dollar standard. The role of the dollar as a reserve and as a vehicle currency increased significantly over the next three decades. The fixed exchange rates could only be changed infrequently with international consultations and only when fundamental economic situations warranted such changes. The International Monetary Fund (IMF) was established to guide countries and to ensure stability in the international financial markets. The IMF also became a source of funds for countries that were facing balance of payments imbalances.

The Bretton Woods system provided an unprecedented stability in the financial markets for war-ravaged countries to rebuild their economies after World War II. The IMF was successful in persuading more and more countries to gradually open their financial markets and get rid of exchange controls. By the late 1960s, however, flaws of this system became increasingly apparent. First, there was a bias in the system against allowing exchange rates to change quickly and by small amounts when economic conditions warranted. This bias had led to a number of speculative runs against a number of currencies as speculators could spot under- or overvalued currencies and could lay bets against those currencies. Second, the resources of the IMF became inadequate as the industrialized countries grew in size and their financial requirements grew far more rapidly than the funds available to the IMF. Third, and most important, the system had left no room for the U.S. economy to adjust should it have balance of payments difficulties. While all other countries could use a change in their exchange rate as a policy tool, the U.S. economy was denied this possibility because it had become the anchor for the international monetary system.

A third system type is the floating rate system (1973–). In 1968, the U.S. government withdrew the promise to freely convert U.S. dollars into gold for nonofficial purposes. A slight adjustment was made to the price of gold in terms of dollars in 1971, and the gold window was completely closed. By early 1973, the fixed exchange rate system was abandoned and most currencies were allowed to float freely. Market participants would determine the values of currencies.

With the exception of the developments in the European Monetary System, most major currencies of the world continue to float. Central banks of some emerging economies "manage" the values of their currencies by intervening in the foreign exchange markets. Some other countries link their currencies to that of a country on which their economies depend heavily. Most industrialized countries today allow unrestricted flow of capital between their economies and the rest of the world.

International Securities Identification Numbering

The International Securities Identification Number (ISIN) is a 12-character alpha-numerical code that identifies uniquely a security (debt instruments such as bonds; share instruments such as equities and collective investments; options; futures; warrants) on the financial markets. This international norm allows a financial intermediary to identify easily the considered security and its associated movements. This identifying number generally accompanies the security description and prospectus.

Confronted with the growing number of financial securities, worldwide organizations decided to attribute a unique number to identify each international financial security. Indeed, the national numbers were generally limited to the considered country and unusable internationally. This standardization enables a uniform and unified financial instruments classification system in order to improve market efficiency (leading to more accuracy and to more effective settlement and clearing). Furthermore, this codification allows the streamlining of back-office routines.

The ISIN does not contain information about the specificities of the considered financial instrument but only identifies the security. However, the securities are not perfectly identified because the ISIN code does not generally specify the exchange place of the selected security (contrary to a ticker symbol).

The Association of National Numbering Agencies (ANNA) was formed in 1992 with 22 National Numbering Agencies. The three main goals of this association, defined in the standard ISO 6166, are to promote, maintain, and develop the ISIN standard. And one of ANNA's key tasks is to improve its general communication to all market investors. ANNA is the registration authority for the allocation of ISINs. ANNA comprises 77 organizations (number of full members in July 2008) handling the functions of National Numbering Agencies, i.e., they assign ISINs to stocks and other financial instruments in their countries. The two main international numbering agencies in Europe are Euroclear Bank S.A./N.V. and Clearstream Banking. Therefore, these agencies are authorized to assign ISINs for securities issued in specific European countries and they are obliged to make available the information to all securities market participants.

The structure of an ISIN code is described by norm 6166 of the International Organization for Standardization (ISO). An ISIN code has traditionally three parts: a prefix composed of two letters identifying the issuing country of the security (for instance, FR for a security issued in France, and US for a security issued in the United States), a basic number formed by nine characters (letters and/or digits), and a final single check digit.

For example, BE0003796134 is the Dexia ISIN code where BE is the country code. These two first letters indicate that the country of the issuer is Belgium. The following characters, 000379613, formed the original CUSIP (Committee on Uniform Securities Identification Procedures) number, and the last character, 4, is the check digit. The CUSIP number can be itself decomposed in three parts: The first part is a four-character code identifying the issuer, the second part is a three-character code identifying the type of asset, and the third part (two characters) identifies the security issuance. Note that the SEDOL (which is a seven-character code) is also a part of the security's ISIN and is used for securities issued in the United Kingdom.

The check digit is computed using the following algorithm. We first convert each letter to numbers (A = 10, B = 11, C = 12 …, Y = 34 and Z = 35) and we exclude the check digit, which is what we are computing. Therefore, we obtain for our example of Dexia [11][14] 000379613. We add up (going from right to left) the individual digit numbers doubling one time over two the digit number considered. We begin doubling the first digit, i.e., the first number beginning from the right. We have therefore the following sum: [6] + [1] + [1+2] + [9] + [1+4] + [3] + [0] + [0] + [0] + [4] + [2] + [1] + [2] = 36. We take the 10s modulo ("*a mod b*" is the remainder of the division of "*a*" by "*b*") of this sum, the result of this operation is 6. We subtract this result from 10, this subtraction is equal to 4. We finally compute the 10s modulo of this final result (in case the result from the first modulo computed is equal to zero). We obtain the digit 4 that is the right final number of the Dexia ISIN code. To avoid programming this algorithm, there are many applications on the Web that compute the check digit for a given ISIN code.

ISIN codes are not the only codes used to identify financial securities. Indeed, it is not always easy for practitioners to remember a series of nine-digit numbers. For this reason, most financial intermediaries or exchange places have other coding systems used by the practitioners. The other codes commonly used are the following: the Tradable Instrument Display Mnemonic (TIDM), the Stock Exchange Daily Official List (SEDOL), the CUSIP, the Reuters, and the Bloomberg codes. Nevertheless, orders expressed in another way are generally converted into ISIN codes.

International Training

In today's competitive global business environment, international human resources management (HRM) systems are of significant importance for developing global managers. International training may be defined as any procedure intended to increase an individual's ability to cope and work in a foreign environment. The importance of training in preparing an individual for an intercultural work assignment has become increasingly apparent. International and intercultural work has become the norm for most large organizations. Managers are spending shorter periods in any single country, and they often are moved from one location to another. Because their managers must often operate across borders in teams of internationally diverse units, many organizations express the need for managers who quickly adjust to multiple cultures and work well in multinational teams. This makes the challenge of international training increasingly difficult because conventional methods that rely on country specific knowledge often prove inadequate.

Adjusting to an international assignment can provoke feelings of helplessness in an unprepared manager, who may have difficulty sorting out appropriate from inappropriate behavior. Learning to manage in and cope with a foreign environment involves such a profound personal transformation that it has an analog in the process of human development throughout the life span. Expatriate managers are removed from the comfortable environment of their parental culture and placed in a less familiar culture. A management style that works at home may fail to produce the desired response abroad, or it may be even counterproductive.

A growing consensus in the field of international training is that appropriate pedagogy of any program must begin with a thorough and suitable assessment of managers' strengths and weaknesses. Methods for individual assessment range from paper-and-pencil inventories to elaborate role-playing exercises to behavioral assessment centers. Once managers are assessed and selected for training programs, the key question becomes what design optimizes their training and development. Organizations can improve the quality of managers by providing comprehensive training and development activities after assessment and selection. Considerable evidence suggests that investments in training produce beneficial individual and organizational outcomes.

International competence training and a sensible repatriation plan help buffer the stressors encoun-

Expatriate managers directing locals, such as these oil company workers in Benin, need culture-specific training.

tered abroad. The willingness and courage to undergo the profound personal transformation associated with an international assignment are essential for a healthy expatriate adjustment, even after the expatriate's return. International training can partly remedy cross-cultural insensitivity, but international competence involves more than a series of country statistics and cultural gimmicks learned in a short, pre-departure training session. Making executives aware that they will face different business and social customs is not sufficient, because awareness does not necessarily bring competence in the host culture.

Many organizations are becoming aware of the need to provide continued hands-on training rather than just pre-departure awareness training. In contrast to pre-departure training, post-arrival training gives global managers a chance to evaluate their stressors after they have encountered them. Documentary and interpersonal training methods have additive benefits in preparing managers for intercultural work assignments.

Most international training programs emphasize increasing a manager's cultural competence in dealing with others from different cultural backgrounds by enhancing their cognitive awareness and knowledge of the proposed host culture. The training format is mainly project based, with participants spending much of their time in their respective business areas. At regular intervals they are brought together to discuss their experiences under the guidance of facilitators. So, cultural differences are addressed when they surface in the context of working together. Experiential training formats also provide an opportunity to react to cultural stressors and receive feedback about the adequacy of one's coping responses (i.e., cultural assimilator).

Employees need to actively support the adjustment process of their expatriate managers. International competence–oriented training should be provided before, during, and after the assignment. In addition, the parent firm should be sensitive to the delicate balance between the interests of the parent and the host firm that executives need to maintain, listening and working with them to define and achieve common goals. Training for the global manager should include metacognitive, motivational, and behavioral components.

The effectiveness of global managers will be limited if they are not motivated to perform their jobs. The form and structure of an organization's HRM system can affect employee motivation levels in several ways. Continuous training, job rotation, employment security, performance appraisal, and compensation systems can motivate managers to engage in effective discretionary decision making and behavior in response to a variety of environmental contingencies.

Internet Domain Names

An internet domain name is a unique name that identifies an Internet Protocol (IP) address on the internet. Computers identify each other via numerical IP addresses over the internet. People use domain names to give these IP addresses easily remembered names. Any time someone uses the internet to search for information, buy products, or send e-mail, they are using a domain name to identify themselves or the businesses whose information or products they are seeking. The choice of domain name has potential to make or break an online business. For this reason, a lucrative secondary market has developed for domain names.

Every computer has a unique IP address. The domain name system (DNS) is a network of domain name servers that convert domain names into IP addresses so that computers, and thus individuals, can communicate over the internet. When an individual creates and orders a domain name from a registrar, the name is put into the global registry by the registrar for the registrant. The registry, maintained and overseen by the Internet Corporation for Assigned Names and Numbers (ICANN), is the central directory of the domain name system. Accredited "registrars" are the only agents that can legally submit domain names to the registry. ICANN regulates these agents and keeps a list of accredited registrars. Having one central registry for all domain names assures that those names send internet users to the right IP addresses.

A domain name consists of two essential parts: the top-level domain (TLD) and the second-level domain. The TLD is the rightmost portion of the domain name. Current generic (unreserved) TLDs include .com, .net, .info, .org, and .biz. Typically, businesses anywhere in the world can request one of these common TLDs. Two-letter country-code TLDs (ccTLDs) exist for each country such as .us, .uk, .de, and .au for organizations that wish to be identified by country. TLDs for more specific (reserved) purposes also exist. Examples include .tv (entertainment), .gov (government), .mobi (mobile phone access), .edu (education), .museum (museums), .name (personal names), .int (international organizations established by intergovernmental agreements), .coop (cooperatives), .aero (aviation), .mil (military), .travel (travel), and .jobs (job search). As the internet grows, so does the list of TLDs. TLDs must be approved by ICANN.

The second-level domain (SLD) identifies the organization or host. It is the rightmost portion of the domain name that is to the left of the dot (or "."). For example, in www.google.com, the SLD is "google" and the TLD is ".com." The "www" portion of the name is actually a third-level domain (3LD). The 3LD is left of the SLD. A single domain name can have up to 127 levels. Levels left of the SLD are subdomains. The "www" used in many domain names is just a very common subdomain and it is not an essential part of a domain name. There must be a unique SLD for every TLD; however, SLDs can be duplicated across TLDs. For example, there can only be one encyclopedia.com for a particular IP address, but there can be an encyclopedia.com, encyclopedia.net, encyclopedia.org, etc.

The ability to create and register virtually any domain name has led to a lucrative secondary market for domain names and subsequently a need for a system of dispute resolution. According to marketing researcher Zetetic, as of 2007, 36 domain names had fetched over $1 million on the secondary market, with sex.com being the highest at around $12 million. Speculators in the domain name market, known as "domainers," buy and resell domains. Some speculators, known as "cybersquatters," attempt to profit by buying domain names of celebrities, well-known companies, and trademarks. A kind of cybersquatter, known as a "typosquatter," attempts to profit from common misspellings of popular domain names. Due to the frequency of cybersquatting, many companies now buy domain names defensively by buying their SLDs across TLDs and by buying common misspellings.

If a company feels that it is a victim of cybersquatting, it may file for dispute resolution through ICANN's Uniform Domain Name Dispute Resolution Policy (UDRP) or sue in court via the Anticybersquatting Consumer Protection Act (ACPA, also known as Truth in Domain Names Act) of 1999. An individual can dispute a domain name under UDRP if they feel that a domain name has been registered in bad faith or in violation of their trademark. If the outcome of the proceedings is that the defendant is in violation of UDRP, ICANN can suspend or transfer ownership of the domain name to the plaintiff. If the plaintiff is seeking damages or is unhappy with the UDRP outcome, they can sue under the ACPA. One famous case of cybersquatting was *Electronics Boutique Holdings Corp. v. Zuccarini*, October 2000, which resulted in the defendant being charged with more than $500,000 in damages and attorneys' fees for using five common misspellings to divert business away from the plaintiff.

Intra-Firm Transfer

The price at which multinational enterprises sell their products to their own subsidiaries and affiliates is known as the intra-firm transfer price. In addition to products, the foreign subsidiary may be using techniques, machinery, or processes, owned, patented, and/or licensed by the multinational parent to whom the subsidiary must pay royalties or license fees. Theoretically these prices and fees are equivalent to market prices and fees, but it is often impossible to find such a product, machine, or process on the open market, as they may be unique to the multinational. Many multinational firms also spread overhead and management expenses incurred at the parent over their foreign affiliates and subsidiaries based on percentage of use. The result may be an intra-firm transfer price, fee, or overhead contribution that reduces the profitability of the subsidiary, exacerbated by the tax on gross revenue imposed on subsidiaries and affiliates by host country governments.

Intra-firm trade within the operating networks of multinational enterprises has become increasingly important in international trade. Haishun Sun argues that more than one-third of international trade in goods and services consists of intra-firm transfer and a further one-third consists of exports from transnational corporations.

The parent-subsidiary flow of resources is captured in the internalization theory of multinational enterprise. Internalization argues that multinational enterprises possess a bundle of proprietary firm-specific (ownership) advantages that enabled them to undertake foreign direct investment (FDI). Multinational enterprises were seen as transferring these proprietary advantages to subsidiaries and affiliates via the firm's internal market compared to transfer via the market for final and intermediate products. Ownership advantages were thought to be in such things as proprietary product and process technologies, brand names, access to or ownership of channels of distribution, management, and capital.

The currently dominant resource-based view holds that a necessary, but not sufficient, condition for foreign direct investment is that the subsidiary abroad possesses the resources to compete with other firms in the host country industry. The subsidiary may come to possess these resources via intra-firm transfer from its parent, or from a joint venture partner (or partners) based in the host country or in another source country, or, if the foreign investment is by acquisition, from the subsidiary itself. Hence, the flow of resources may be subsidiary to parent or subsidiary to subsidiary.

The management of cash flows in a large multinational firm, one with possibly 10 or 20 subsidiaries, is obviously complex and critical to the success of the multinational business. Coordination between units requires planning and budgeting of intra-firm cash flows so that flows are "netted" between each subsidiary and the parent, and between the subsidiaries themselves, to reduce payments and currency exchange charges where multiple currencies are involved. Multinationals might economize by establishing a single large pool to negotiate better financial service rates with banking institutions, and flexible timing of payments between units, allowing the firm not only to position cash flows where they are needed most but also to help manage currency risk. A foreign subsidiary that is expecting its local currency to fall in value relative to the U.S. dollar may try to speed up or lead its payments to the parent; similarly, if the local currency is expected to rise versus the dollar, the subsidiary may want to wait, or lag, payments until exchange rates are more favorable.

Multinational firms with a variety of manufacturing and distribution subsidiaries scattered over a number of countries within a region may find it more economical to have one office or subsidiary taking ownership of all invoices and payments between units. Finally, some multinational firms have found that their financial resources and needs are becoming either too large or too sophisticated for the financial services that are available in many of their local subsidiary markets. One solution to this has been the establishment of an internal bank within the firm to buy and sell payables and receivables from the various units.

Intra-firm transfer is further complicated when the relevant knowledge is tacit, rather than codified, making both the transfer and the price difficult to predict or estimate because one or other (or both) of the parties to the transfer has to make a considerable investment to make the knowledge understandable to the transferee. In fact, James Love has argued that the costs of transferring tacit knowledge could be sufficient to prevent market transfer even if the contracting parties trusted each other completely, and therefore never felt constrained by opportunistic hazard or transaction cost expense.

Inventory

Inventory is the stock of any item or resource used in an organization. This implies that all organizations carry some inventory or stock of goods at any time. Inventories range from items such as stationery to machinery parts or raw materials. Generally, organizations with activities centered on products or manufacturing processes have more inventory and need to develop more controls and systems than organizations where the service/product mix is oriented more to the service end of the service/product continuum. It has been estimated that a typical firm has about 30 percent of its current assets and perhaps as much as 90 percent of its working capital invested in inventory. Apart from the cost of inventory, the use of excessive inventory can lead to other issues such as the disruption of work flow and hiding problems related to product quality and equipment breakdown. To address these issues and therefore help management keep the cost down while still meeting production and customer service requirements, an efficient inventory system is needed.

Based on an efficient inventory system, inventory is expected to serve several functions that in turn can add flexibility to a firm's operations. Among the most important are the following: to meet anticipated customer demand, to smooth production requirements, to de-couple operations, to protect against stock-outs, to take advantage of order cycles, to hedge against price increases, and to take advantage of quantity discounts.

To accommodate the functions of inventory, firms maintain different types of inventories. Inventory can be classified by location and type. Based on the location, inventory can include raw material inventory, work-in-process inventory, maintenance/repair/operating supply (MRO) inventory, and finished-goods inventory. Inventory classification by type provides a method of identifying why inventory is being held and so suggests policies for reducing its level. Inventory types include buffer/safety, cycle, de-coupling, anticipation, and pipeline/movement.

In making any decision that affects the size of different types of inventory, four basic costs need to be taken into account: holding or carrying costs, setup or production change costs, ordering costs, and shortage costs. Holding costs relate to physically having items in storage. They include the costs for storage, handling, insurance, pilferage, spoilage, breakage, obsolescence, depreciation, taxes, and the opportunity cost of capital. Obviously, high holding costs tend to favor low inventory levels and frequent replenishment. Typical annual holding costs range from 20 percent to 40 percent of the value of an item. Holding costs are stated in either of two ways: as a percentage of unit price or as a dollar amount per unit. Setup costs are the costs to prepare a machine or process for manufacturing an order or changing from one product to another. That is, to make each different product, it is necessary to obtain the required materials, arrange specific equipment setups, fill out the required papers, and move out the previous stock of material. Ordering costs refer to the managerial and clerical costs to prepare the purchase or production order. Finally, shortage costs are the costs resulting from stock-out or when demand exceeds the supply of inventory on hand. For instance, lost profits, the effects of lost customers, or late penalties are examples of shortage costs.

Having discussed the nature, functions, types, and costs associated with inventory, it is of paramount importance for a firm to know how much inventory to keep in stock or to order. In order to answer this question, it is assumed that demand for an item is either independent of or dependent on the demand for other items. In dependent demand, the need for any one item is the direct result of the need for some other item, usually a higher-level item of which it is part. In independent demand, the demands for various items are unrelated to each other. Dependent demand is a relatively straightforward computational problem. That is, needed quantities of a dependent-demand item are simply computed, based on the number needed in each higher-level item in which it is used. For example, if an automobile company plans on producing 100 cars per day, then obviously it will need 400 wheels and tires (plus spares). The number of wheels and tires needed is dependent on the production levels and it is not derived separately. The

The average firm may have as much as 90 percent of its working capital invested in inventory, such as this yarn in a textile mill.

demand for cars, on the other hand, is independent and unrelated to the demand for other products. Here firms usually turn to their sales and market research departments and other various internal and external sources. Because independent demand is uncertain, extra units must be carried in inventory.

To determine how many units need to be ordered, and how many extra units should be carried to reduce the risk of stocking out, several classes of models can be used: economic order quantity (EOQ)/economic production quantity (EPQ)/quantity discount, reorder point (ROP), fixed-order-interval, and single-period models. The question of how much to order is determined by using EOQ/EPQ or the quantity discount model. The question of when to order is answered by ROP when the quantity on hand of an item drops to a predetermined amount. Fixed-order-interval is used when orders must be placed at fixed time intervals (weekly, twice a month, etc.). Finally, the single-period model is used to handle ordering of perishables (e.g., fresh fruits, vegetables, seafood, cut flowers) and items that have a limited useful life (e.g., newspapers, magazines).

In short, inventories are a vital part of business. Not only they are necessary for operations, but also they contribute to customer satisfaction. The overall objective of inventory management is therefore to achieve satisfactory levels of customer service while keeping inventory costs within reasonable bounds. In doing so, management has two basic functions concerning inventory: to establish a system of keeping track of items in inventory, and to make decisions about how much and when to order. More specifically, to be effective, management must have the following: a system to keep track of the inventory on hand and on order (i.e., inventory counting systems that are periodic and perpetual), a reliable forecast of demand that includes an indication of possible forecast error (i.e., use of point-of sale or POS systems), a knowledge of lead times and lead time variability, reasonable estimates of various inventory costs, and a classification system for inventory items (i.e., use of A-B-C approach that identifies inventory items according to some measures of importance and then allocates control efforts accordingly).

Investment Banks

Unlike consumer banks, investment banks offer services that primarily deal with the restructuring of business ownership, including initial public offerings, mergers and acquisitions, leveraged buyouts, securitization, and private placements. In the sense that most people think of it, an investment bank is not a bank at all—insofar as it does not act as a lender or depository, but rather as a middleman and consultant. Most of an investment bank's income comes from fees.

As a business becomes more successful, it is usually to its benefit to become a corporation (having originated as a partnership or proprietorship, most of the time). Most of the corporation's stock is owned by the core of the company—its founders and various key employees—but a fast-growing company will need to expand beyond the funding capacity of those stockholders. Usually the first source of outside funds is obtained through private placements. These are stock issues that are extremely restricted and cannot be resold by their initial purchasers, and therefore do not have to be registered with the Securities and Exchange Commission (SEC). Nonregistered private placements are limited to 35 nonaccredited purchasers and an unlimited number of accredited investors, including the officers of the company, wealthy individuals, and institutional investors like banks, corporations, pension funds, and so on.

The next step in funding is to seek support from a venture capital fund, a private limited partnership that pools money from a group of (usually) institutional investors. The venture capitalists managing these funds are usually very knowledgeable in a particular industry, and limit their activity to that sector—the transportation industry, for instance, or food and beverages, or dotcoms.

IPOs

An initial public offering (IPO) of stock, which can then be traded on the secondary markets, may follow the venture capital stage. This is the principal activity of investment banks: helping companies go public. Investment bankers act as intermediaries to sell stock to their clients (a similar mix to the sort of investors interested in private placements), and help to determine the stock's initial offering price, based on various factors and comparisons to similar companies and the performance of their IPOs. Once the stock has been sold, the investment bank assigns an analyst to maintain investors' interest in it, regularly issuing reports on the stock's prospects.

During an IPO, an investment bank can underwrite the issue or work on a best-efforts basis. When underwriting the issue, the bank purchases all of the offered stock and resells it itself, to guarantee that the company raises the money it seeks. This is usually the case. In a best-efforts sale, the bank makes no guarantees, only agrees to do what it can. From time to time, an underwriting investment bank misjudges the initial offering price, and is stuck with stock it cannot sell; it must pay the business within four days, while other investors have 10 days to pay for their stock. That is the risk the investment bank takes, and encourages them to thoroughly investigate the business going public—which, in turn, acts as a filter to encourage healthy business and healthy stock.

Since the New Deal created the Securities and Exchange Commission in 1933, investment banking services have been subject to significant regulation. All interstate public offerings over $1.5 million fall under SEC jurisdiction, and state agencies generally have relevant regulations of their own. Newly issued securities must be registered 20 days before their IPO, providing critical information to the government. After registration, representatives of the company and the investment bank go on a "road show," making presentations to institutional investors to explain the merits of their company. The investment bankers will gauge investors' interest in the stock at various prices, as part of the process of determining the initial offering price; if there are more interested investors than shares to go around, the price will usually be increased before the IPO. From time to time, the road show may lead to withdrawing the registration altogether, if there is too little interest in the company. During this period, nothing can be disclosed that is not already in the SEC's registration forms, a situation that invites a lot of spin. This quiet period lasts until 25 days after the IPO.

Mergers and Other Activities

Another area in which investment banks are involved is in mergers—when two or more businesses combine into one business with management drawn from all the constituent businesses, more or less equally—and acquisitions, when one business assumes control of or absorbs another. Stockholders can respond to these situations in various ways, depending on the specifics; if a company becomes too diversified through the results of a merger or acquisition, there is typically a fear that it is no longer strong enough in its field, no longer specialized—a jack of all trades and master of none, when what stockholders want to invest in is mastery. (Stockholders love diversity, but in their portfolios, not the individual companies they invest in.) Ideally, what stockholders want to see from a merger or acquisition is synergy: when the whole becomes greater than the sum of its parts, because of economies of scale, tax benefits, financial benefits, increased efficiency, and increased market power. The Justice Department's antitrust division regulates mergers and acquisitions to protect consumers, and keeps an especially close eye on them when the involved businesses are large or dominant in their industries.

Another investment bank activity is the leveraged buyout, in which a publicly held company is purchased in whole by an allied group of investors—which generally includes the company's senior management, and may include outside investors who provide the necessary capital—and is then taken private. Leveraged buyouts may be motivated by the desire to take the company in directions that stockholders would consider too risky or otherwise undesirable, or as a way to remove current management. They are less common when the stock market is healthy (making a leveraged buyout more expensive).

Lastly, securitization is the transformation of a debt instrument into a publicly traded financial instrument, making it more liquid because of its ability to be bought and sold in open market. Home mortgages can be pooled, for instance, and used as collateral to issue bonds. Investment banks help to securitize debt instrument assets ranging from mortgages to automobile loans, credit card balances, and student loans.

History

Investment banking has a long history in the United States, originally involving the exchange of government- and railroad-issued bonds. By the time of the Civil War, the American securities market had become more sophisticated, in response to the large amount of money changing hands thanks to the successes and changes of the Industrial Revolution, the so-called robber barons, and the various tycoons of industry like Andrew Carnegie. The Union funded its side of the war with the first mass-marketed securities (war bonds), and investment banks continued the practice after the war's end. J. P. Morgan opened a banking house in New York principally to deal in gold, foreign currency, and securities, and later organized a syndicate to replenish the country's gold reserve by issuing government bonds.

Before the Great Depression, most commercial banks offered some investment-banking services, but banking mismanagement was blamed as one of the several causes of the Depression. New Deal banking reforms required banks that participate in the Federal Reserve System to abandon the securities market by 1934, and prohibited certain members of securities firms from acting as officers of commercial banks. Many banks thus broke their investment banking services off into separate companies.

Once the Depression had been weathered, banking stayed stable until the 1970s, when inflation led to a series of bank failures and lengthy deregulation of many commercial bank activities. The 1999 Financial Services Modernization (FSM) Act allowed for the mergers of commercial banks, securities firms, and insurance companies, more or less repealing the earlier New Deal legislation, which soon led to the creation of companies like Citigroup (via a merger of Citicorp with Traveler's Insurance, which itself owned Salomon Smith Barney, an investment bank). The Citigroup merger actually took place a year before the FSM Act, which was passed in time that Citigroup was not required to get rid of any of its services (there would have otherwise been a grace period in order to avoid radical overnight restructuring).

In 2008 the U.S. government intervened to prevent Bear Stearns from filing for bankruptcy. Later, it declined to bail out Lehman Brothers, which filed for Chapter 11 bankruptcy protection. Like other financial institutions then, Lehman Brothers had souring real estate investments and confronted tight credit markets.

Investor Protection

Investors have certain rights that are generally protected through the enforcement of rules, regulations, and laws. Many of these rights include disclosure and accounting rules that provide investors with the information they need to exercise other rights. Other protected investor rights include things such as participating in shareholders' meetings, receiving dividends on pro-rata terms, voting for directors, subscribing to new issues of securities on the same terms as insiders, being informed about the risks, obligations, and costs of an investment, and having orders executed promptly at the best available price.

In addition, as we saw with companies such as Enron, Adelphia, Tyco, and WorldCom, among others, investors need protection from financial scandals. Quite often scandals involve insiders using their discretion to mislead investors and other outsiders through their financial reporting. Investors have the right to receive clear and timely information that allows them to make informed decisions.

Through the use of earnings management (deliberately manipulating a company's earnings so that the figures match a predetermined target) or impression management (presenting a company's performance in the best light possible, potentially resulting in selective financial communication), companies can structure their disclosures in ways that are potentially misleading or unclear. Such earnings opacity can take the form of earnings aggressiveness (results from the tendency to increase reported earnings), loss avoidance (results from the tendency to avoid reporting negative earnings), and earnings smoothing (results from reporting artificially stabilized earnings). These three practices undeniably weaken the link between accounting performance and the true economic performance of a company. In addition, this obfuscation of financial disclosures can make it difficult for investors to make accurate informed decisions; therefore, investor protection is needed.

Often, investor protection through legal action is highlighted as the key factor affecting the quality of earnings reported. This is because insiders enjoy fewer private control benefits and hence have lower incentives to conceal firm performance from outside investors.

In the aftermath of the stock market crash of 1929, the U.S. Congress created the Securities and Exchange Commission (SEC) as part of the Securities Exchange Act of 1934. This was intended to restore investor confidence in our capital markets. Still, today, the mission of the SEC is to protect investors, maintain fair, orderly, and efficient markets, and facilitate capital formation.

Sixty-eight years after the SEC was created, Congress passed the Sarbanes-Oxley Act (SOX). SOX (also known as Public Company Accounting Reform and Investor Protection Act) was signed into law by President George W. Bush on July 30, 2002. It has had a major impact on the way that all U.S. publicly traded companies conduct and document their businesses. Essentially, SOX was created to reverse the public's declining trust in the accounting and financial reporting process by providing a level of investor protection through regulation. To accomplish this, the Public Company Accounting Oversight Board (a private-sector, nonprofit corporation) was created to oversee the financial reporting of public companies. SOX requires companies to, among other things, have their chief executives sign off on their financial statements; strengthen auditor independence; and have an internal audit function that is examined by external auditors. More than five years after its passage there can be little doubt that SOX has strengthened corporate accountability, thus successfully providing a level of investor protection.

To deal with conflicts of interest, the SEC requires brokerage houses and analysts to provide full disclosure and prohibits analyst compensation based on investment banking business. Another risk to investors is the bankruptcy of brokerage firms, and the Securities Investor Protection Corporation (a private-sector, nonprofit corporation) was created by a U.S. act of the same name to restore funds to investors in such situations.

Outside the United States, rules protecting investors often come from different sources. No matter what the source, their enforcement is as crucial as their content. In most countries, laws and regulations are enforced by market regulators, courts, and/or by market participants themselves. In many countries, such enforcement cannot be taken for granted. At times, courts are slow, subject to political pressures, and even corrupt.

Invisible Trade Balance

Invisible trade balance (ITB) refers to the net monetary value resulting from a country's international trade in invisibles during a given period of time, and it forms an important component of the country's balance of payments (BOP). ITB can be defined as the difference between the total monetary value of invisible exports (exports of intangibles) and invisible imports (imports of intangibles) of a country during a specified period of time, in general, a year or a quarter for which the country's BOP records are prepared.

In general practice, ITB is calculated as the total monetary value of invisible exports minus the total monetary value of invisible imports. As a result, for a period in which the total value of invisible exports exceeds the total value of invisible imports, ITB records a positive value indicating a surplus. When the total value of invisible imports exceeds the total value of invisible exports, ITB results in a negative value indicating a deficit for that period. Thus, ITB indicates the surplus or deficit resulting from a country's international trade flows in invisibles during a given period of time. The international trade involving invisibles (or intangibles) is most often referred to as the international trade in services. Therefore, ITB is also most often referred to as the services balance (or services trade balance) in BOP. However, invisible trade and invisible trade balance are the popular terms still used in the United Kingdom and some of its former colonies.

ITB constitutes an integral part of a country's BOP. BOP is a comprehensive record of a country's international transactions with the rest of the world during a given period of time and is comprised of two main accounts, namely, the current account and the capital account. The transactions resulting in capital inflows and outflows are recorded in the capital account. The current account is comprised mainly of the accounts dealing with visible trade (merchandise trade), invisible trade (services trade), and transfers. Some countries, such as the United Kingdom, include receipts and payments of transfers also among the invisibles, while many other countries, like the United States, include transfers as a separate item in the current account. Following the principle of double-entry accounting, the international transactions resulting in receipts from nonresidents are recorded as credit (+) entries and the international transactions resulting in payments to nonresidents are recorded as debit (–) entries in BOP. According to the same principle, the exports are recorded as credit (+) entries and the imports are recorded as debit (–) entries. ITB can therefore be simply defined as the sum total of invisible exports and imports during a specified time period.

The main components of trade in services that are recorded in BOP include transportation, travel, communication services, construction services, insurance, financial services, computer and information services, royalties and license fees, personal, cultural and recreational services, other business services, and government services. Relative to international trade flows in visible goods, the definition and measurement of international trade flows in invisibles are more difficult. Invisibles are also inherently less tradable than visible goods. International trade in visible goods is characterized by the cross-border movements of physical objects. However, the international trade in invisibles is not always characterized by such physical cross-border movements. There are at least four modes in which the trade in services can take place: cross-border supply (the service is traded by the supplier in one country to a consumer in another country without either one of them moving to the country of the other), consumption abroad (the consumer moves to the country of the supplier to consume the service), foreign presence (suppliers in one country supply their services through their affiliates in other countries), and the presence of natural persons (an individual moves to the country of the consumer to supply the service on his or her own behalf or on his or her employer's behalf).

The importance of services-producing sectors, which are collectively known as the tertiary sector, and their export has increased over time both in developed and developing countries. As a result, ITB in many developed countries recorded increasing surpluses in the recent past, and these surpluses helped offset deficits in merchandise trade in some of those countries. At present, the OECD countries, which are net exporters of services as a group, account for about three-quarters of world exports of services. The categories of services that recorded a faster growth during the period from 2000 to 2005 include the following: computer and information services, financial and insurance services, communication services, and other business services. Some developing countries such as India also had similar experiences. However, the deficits in invisible trade balance in a large number of developing countries have been directly related to their growing problems of international indebtedness.

IPC

The IPC (Indice de Precios y Cotizaciones) is an index of stocks that trade on the Bolsa Mexicana de Valores (BMV), which is Mexico's only stock exchange. The IPC is the main indicator of the BMV. It measures the performance of the Mexican stock market, and it is representative of all shares listed on the stock exchange. This indicator was implemented in its current structure in 1978.

The BMV is headquartered on Paseo de la Reforma in central Mexico City. BMV is a private limited company, with the exchange's shareholders consisting exclusively of authorized brokerage firms, each of which owns a single share. The exchange trades debt instruments including federal Treasury certificates (CETES), federal government development bonds (BONDES), investment unit bonds, bankers' acceptances, promissory notes with yield payable at maturity, commercial paper, and development bank bonds. In addition, it also trades stocks, debentures, mutual fund shares, and warrants. Trading is conducted electronically through the BMV-SENTRA Equities System.

The mission of the BMV is to

> contribute to domestic savings, productive investment and stock brokerage in the country, meeting the needs of companies, issuers and governments, as well as of domestic and foreign investors. Provide services to enable access to the Stock Exchange infrastructure, in order to facilitate listing and trading of securities, information dissemination and the operation of the organized capital and debt market and other financial assets.

Investors go to stock exchanges worldwide as an option to protect and increase their monetary savings, supplying monetary resources that in turn allow corporations and governments to finance productive and development projects that in turn generate jobs and wealth. The stock exchanges are organized markets that contribute to this financial channeling in a free, efficient, competitive, equal, and transparent way, holding up previously agreed rules for all participant parties.

The BMV is the physical place where the trades made by the brokerage firms are executed and registered. Investors buy and sell stocks and debt securities through intermediaries, called brokerage firms. Note that the BMV does not buy or sell securities directly. The investors send their orders through an account executive employed by a brokerage firm. These account executives are registered specialists who have received training and are authorized by the CNBV. The buy and sell orders are transmitted from the brokerage firms to the market through a sophisticated Negotiation, Transaction, Registry and Assignation Electronic System (BMV–SENTRA Capitales) where they wait to find an equal but opposite order and thus perfect the operation. Once shares or debt securities have been acquired, performance can be monitored in specialized newspapers and the electronic information system of the BMV.

The BMV is where Mexico's organized securities market transactions are held, and its main objective is to facilitate the securities transaction process as well as market development, fostering its expansion and competitiveness through the following functions:

1. Establish the facilities and mechanisms as an aid in the relationship of the securities supply and demand, credit certificates, and other documents registered at the National Securities Registry (RNV), as well as provide the necessary services for underwriting, offering and the exchange of the aforementioned securities.
2. Publish, provide, maintain, and make available to the general public the pertinent information about the securities listed at the BMV and at the International Quotations System (SIC), about its issuers as well as of the executed transactions.
3. Establish the necessary means to ensure that the transactions held at the BMV by the brokerage firms comply with the applicable legislation.
4. Issue regulations that set standards and operative guidelines as well as conduct norms to promote fair and equitable market practices at the securities market; guard their observation and impose disciplinary and corrective measures, in case of lack of fulfillment, that are mandatory for brokerage firms and the issuers with listed securities at the BMV.

Some important milestones in the history of the BMV are outlined below:

1982—President Miguel de la Madrid allowed the establishment of private brokerage houses with wide latitude to conduct financial transactions in domestic capital markets.

October 1987—U.S. stock market crash. The BMV recovered slowly in 1988.

1991—The index of traded stocks rose 128 percent in new peso terms and 118 percent in U.S. dollar terms. In November 1991, the government eliminated all exchange controls, thereby unifying the various peso exchange rates.

1992—199 companies were listed as trading on the stock exchange. A total of 11 trillion new pesos were traded, and the exchange had a total capitalization of US$139 billion and a price-to-earnings ratio of more than 13.

1993—Mexican investors held about 75 percent of the equities traded.

1994—The market was buffeted by a series of political shocks—including two high-profile political assassinations, revelations of high-level corruption in President Carlos Salinas's entourage, and continued unrest in Chiapas—that contributed to its high volatility throughout the rest of the year.

1995—The stock market collapsed, causing the stock index to fall to less than 1,500 points in February of that year. The main stock index gradually recovered to just under 3,000 points by the end of 1995 and reached 3,300.

September 1996—Mexican stocks gained 24 percent in dollar terms during the first eight months of 1996. A slow recovery would follow in the next years.

2008—The world financial crisis that began in 2008 affected Mexican stocks negatively. The falling peso was a precipitating factor.

Iran

Iran is one of the oldest nations in the world, and currently has a young and educated population. Iran was a key U.S. ally in central Asia until the Islamic Revolution in 1979 transformed the country into a clerical regime. Iran is a member of the Organization of Petroleum Exporting Countries (OPEC), and its oil-related activities are the backbone of the Iranian economy. In recent years, the Iranian nuclear program has been a controversial subject in the international community.

Most Iranians profess Shi'ism, a brand of Islam. It was brought to ancient Persia during the Arab invasion of the 7th century. Some Sunni Muslim fanatics such as Osama bin Laden consider it to be a form of apostasy and do not consider shi'ites to be truly formed Muslims. An endogenous attempt to realize an Iranian democracy took place after World War II when Iranians supported a visionary leader, Mohammad Mosaddeq. Mosaddeq decided to nationalize the country's oil industry, which had been controlled by a British monopoly, the Anglo-Iranian Oil Company. That action made him a national hero, but it also led to his downfall. In 1953 the British were outraged by the nationalization and, working closely with the U.S. Central Intelligence Agency, arranged to overthrow Mosaddeq. Thus, they opened a new era in Iranian history, one dominated by Mohammed Reza Shah Pahlavi. A close ally of the United States, he ruled with increasing repression until he was himself overthrown by the Islamic Revolution of 1979.

The new regime brought a theocratic government into power, which proved to be hostile to the United States. The Islamic regime allowed radical students to take 66 U.S. citizens hostage in the U.S. embassy in Tehran for more than 14 months. That act helped to undermine Jimmy Carter's presidency and turned Washington and Tehran into bitter enemies. Since then, the United States has used various strategies to weaken Iran. It has encouraged Iranian counterrevolutionary groups, imposed economic sanctions, and worked intensely to prevent Iran from building pipelines that could carry its oil and gas to nearby countries. The United States financially supported Saddam Hussein's regime during the Iran-Iraq war (1980–88).

This pressure intensified after President George W. Bush took office in 2001. Bush famously listed Iran, along with Iraq and North Korea, as part of the World's "axis of evil" and claimed in his State of the Union address in 2002 that Iran had become the world's primary state sponsor of terror. Although it is uncertain whether Iran's Islamic regime is still supporting terrorist groups, it clearly did so in the 1990s.

Iran contains about 125 billion barrels of proven oil reserves—roughly one-tenth of the world's total. As a result, the extraction and processing of petroleum are Iran's fundamental economic activities and

Eighty percent of Iran's export earnings come from oil. It has one-tenth of the world's oil and platforms, such as this one.

the most valuable in terms of revenue. Natural gas production is increasingly important. Oil exports account for about 80 percent of Iran's total export earnings and provide revenue for some 40 to 50 percent of the government's budget. This abundance of mineral resources is a cause of suspicion over the Iranian nuclear program. Although the official position of the Iranian government is that the program has only peaceful purposes, this claim is still controversial. Seen from the Iranian perspective, there is a real interest in having the nuclear deterrence: the fear of a possible U.S. invasion. In fact, the United States has troops on both Iran's western border (Iraq) and its eastern border (Afghanistan). Moreover, Israel, India, and Pakistan have nuclear arsenals. Therefore, the Iranian control of a nuclear deterrence is based both on military consideration and on the search for prestige for the theocracy. In this context, the United Nations Security Council issued several resolutions demanding Iran to suspend uranium enrichment.

The misuse of information over the Iraqi program of weapons of mass destruction made the U.S. intelligence community cautious about how findings are used. That may be why it felt right to admit in a National Security Estimate in December 2007 that Iran halted any clandestine work on nuclear energy in 2003. However, there is no evidence that shows the level reached by the program. The danger is that a nuclear-armed Iran could set off a chain reaction that turns Saudi Arabia, Egypt, and Syria rapidly into nuclear powers, too. Thus, the multiplication of nuclear rivalries would increase the consequences of escalation in central Asia and in the Middle East. Falling oil prices negatively affected the economy of Iran in the world economic tumult that began in 2008.

Ireland

For generations, the name *Ireland* has been almost synonymous with *emigration*, but in recent decades that image has drastically changed. From the 17th century onward, religious intolerance and economic conditions combined to disperse people from Ireland across five of the world's continents. The first major exodus consisted of Northern Irish Protestants seeking opportunities in the new British colonies in North America. The greatest Irish mass emigration occurred toward the middle of the 19th century when successive failures of the potato crop created famine throughout rural Ireland, which was overwhelmingly Roman Catholic in religion. A quarter of the population of eight million was lost either to death by starvation or to emigration. In the United States in 1850, the census estimated that nearly a million of the country's latest immigrants came from Ireland.

During World War II, the Irish Republic maintained a policy of neutrality, which made its integration into the postwar international economy problematic. The Irish government pursued a policy of protectionism that resulted in mass unemployment. Taking advantage of a long-standing policy of free movement of labor between Ireland and Britain, thousands of workers crossed the Irish Sea in response to the demand for cheap labor to help reconstruct the bombed metropolitan areas of England, Wales, and Scotland, and to build the social housing that was promised by the first postwar British governments, both Labor (socialist) and Conservative.

The Celtic Tiger Economy

Right up to the early 1990s, a visitor to the Republic of Ireland observing career guidance being given to a typical group of those leaving school would have noticed that "how to emigrate" was at the top of the agenda, with young Irish people being advised on destinations like London or Boston where they could find low-skilled work in sectors such as the construction industry or the hotel trade. Then, from the mid-1990s, the country went through a rapid transformation, gaining a reputation for itself as the "Celtic Tiger."

The economic boom of the late 1990s came from two main sources: inward investment and house-building, so that by the start of the 21st century, the housing sector was accounting for approximately 15 percent of gross domestic product, approximately twice the average of most other European Union (EU) countries. Some critics of this phenomenon were describing the country as "a building site with a national anthem," but such comments cut little ice with Irish policy makers and business leaders, who for generations had seen their country regarded as the "joke" economy of western Europe.

Until the Celtic Tiger economy emerged, the Irish Republic was still a net exporter of people, as it had been since the 18th century. The 30 million people worldwide who claimed Irish origin were often called the "Fifth Province" of Ireland. The intelligent use of this diaspora became one of the key elements in the Irish drive to attract inward investment. Irish American business executives were specifically targeted by the Irish government's development agencies and assured that if they were seeking a foothold within the geographical boundaries of the European Union (which Ireland had joined at the same time as the United Kingdom in 1973), they could do no better than to choose a location which was English-speaking, committed to a business-friendly corporate taxation regime, and relatively enthusiastic toward the Single European Market and the euro single currency.

At the same time, Ireland made full use of regional development grants available under the EU's structural funding programs to provide economic infrastructure, such as new transport links and business parks; and it also committed itself to investment in human capital through the modernization of its education system, especially in the university sector. The result was that national income per capita surged upward, and tens of thousands of immigrant workers flocked to Ireland, especially from poorer east European countries such as Poland and Romania.

Toward the end of the first decade of the 21st century, the future prospects of the Celtic Tiger economy began to look more mixed. The worldwide credit crunch arising from problems in the American subprime money-lending markets resulted in large hikes in Irish interest rates, with the result being a major slump in the housing sector. Irish enterprises such as Ryanair kept attracting often-envious attention from larger but less dynamic competitors.

This small country, which as a sovereign nation-state with full fiscal autonomy and a seat at the European Central Bank, has a population similar to areas of Britain, Spain, or Germany such as Scotland, Andalucía, or Bavaria, which operate merely as "regions" as opposed to "states." Ireland still punches above its weight in the corridors of power in the EU and other influential international organizations. However, unless there is a new economic upturn, the signs are that Ireland is moving toward a position of net emigration once again. To begin with, this is likely to involve eastern Europeans returning to their homeland, rather than the traditional exodus of the Irish themselves to places such as England, the United States, and Australia. However, if or when large numbers of Irish begin seeking work overseas once again, the genreation involved is much more likely to be highly skilled, better qualified, and far less ready to enter low-paid occupations than many of their ancestors.

ISE National 100 Index

The Istanbul Stock Exchange (ISE) National 100 Index tracks the movement of 100 stocks on the ISE. The ISE is the only securities market in Turkey, established in 1986 to provide a market for equities, bonds, real estate certificates, and foreign and international securities. Three hundred twenty Turkish companies are traded on the ISE, which operates from 9:30 A.M. to noon and 2 to 4:30 P.M. every weekday. In addition to the ISE National 100, other indices are the ISE National All Shares, the ISE National 30, the ISE National 50, the ISE Investment Trusts, the ISE New Economy Market, and specific sector and sub-sector indices.

The earliest securities market in the region, the Dersaadet Securities Exchange, was founded in 1866, during the time of the Ottoman Empire. The DSE acted to attract foreign investors through the end of the 19th century and the early years of the 20th, and upon the creation of the Turkish Republic that superseded the Ottoman Empire, the markets were reorganized into the Istanbul Securities and Foreign Exchange Bourse in 1929—just in time for the Great Depression and other events to impact securities and capital markets worldwide. The 1980s brought an improvement to the Turkish economy, as it did to many economies of the region, and regulatory bodies were established to oversee and modernize the Turkish securities market. After several years of regulatory acts preparing for it, the ISE was established.

The list of companies on the ISE National 100 is recalculated quarterly. As of summer 2008, the list is Adana Cimento, Advansa Sasa, Afyon Cimento, Ak Enerji (50), Akbank (30), Akcansa, Aksa, Aksigorta (30), Alarko Holding (50), Albaraka Turk (50), Alkim Kimya, Anadolu Efes (50), Anadolu Hayet Emek, Anadolu Sigorta (50), Anel Telekom, Arcelik (30), Aselsan, Asya Katilim Bankasi (30), Atakule Gmyo, Aygaz (50), Bagfas (50), Banvit, Bim Magazalar, Bossa, Boyner Magazacilik, Coca Cola Icecek, Cimsa, Dogan Gazetecilik, Dogan Holding (30), Dogan Yayin Holding (30), Dogus Otomotiv, Dyo Boya, Eczaciba Si Ilac (50), Eczaciba Si Yapi, Eczaciba Si Yatirim, Ege Seramik, Enka Insaat (50), Eregli Demir Celik (30), Ford Otosan, Fortis Bank, Garanti Bankasi (30), Global Yat. Holding (50), Goldas Kuyumculuk, Grundig Elektronik, GSD Holding (30), Gubre Fabrik (50), Gunes Sigorta, Hurriyet Gzt. (30), Ihlas Ev Aletleri, Ihlas Holding (30), Is Bankasi (30), Is Fin. Kir, Is Gmyo (30), Is Y. Men. Deg, Izmir Demir Celik, Kardemir (30), Karsan Otomotiv (50), Kartonsan, Koç Holding (30), Koza Madencilik, Marti Otel, Merko Gida, Migros (30), Net Holding (50), Net Turizm, Otokar, Park Elek. Madencilik, Pera Gmyo, Petkim (30), Petrol Ofisi (30), Reysas

Lojistik, Sabanci Holding (30), Selcuk Ecza Deposu, Sinpas Gmyo, Sekerbank (30), Sise Cam (30), T. Halk Bankasi (30), T. Ekonomi Bank (50), T.S.K.B. (30), Tat Konserve, Tav Havalimanlari (50), Tek-Art Turizm, Tekfen Holding (30), Tekstil Bank, Tesco Kipa, Tofas Oto. Fab (50), Trakya Cam (50), Turcas Petrol, Turkcell (30), Tupras (30), Turk Hava Yollari (30), Turk Telekom (30), Ulker Biskuvi (50), Vakiflar Bankasi (30), Vestel (50), Vestel Beyaz Esya (50), Yapi Kredi Sigorta, Yapi Ve Kredi Bank (30), Yazicilar Holding, and Zorlu Enerji.

Parenthetical numbers indicate that the company is also on the ISE National 30 or 50.

Israel

Israel is a world leader in technologically advanced products and services. Growth has been impressive in recent years, and macroeconomic policy has been well managed. However, significant structural problems need to be addressed in order for Israel to reach its full economic potential. Israel is a highly open, developed economy with gross domestic product (GDP) of $162.75 billion, or $22,500 per capita (unless otherwise noted, figures are from 2007, and are taken from the Central Bureau of Statistics [CBS] or Bank of Israel [BOI]). According to the Organisation for Economic Co-operation and Development (OECD), Israel's per capita purchasing power adjusted GDP, an indicator of living standards, is 21st in the world, at 88 percent of the OECD average and 63 percent of the U.S. level (using a different methodology, the International Monetary Fund ranks Israel 18th). Israel has been invited to join the OECD.

Israel's population is 7.282 million—75.5 percent Jewish, 20.1 percent Arab, and 4.4 percent others (May 2008). From 1998–2008, annual population growth averaged 2.1 percent; during 1989–2000, over one million people immigrated from the former Soviet Union. Israel has a small land area and high population density. It is poor in natural resources, except minerals. The leading population and business center is the Tel Aviv metropolitan area; other population centers are Jerusalem, Haifa, and Beersheba. Life expectancy is slightly above the European average, but infant mortality is high. Health expenditures are 8.7 percent of GDP (2006). Basic health is 70 percent publicly funded. Although hospitals are overcrowded, medical care is generally excellent. Israel has a high rate of homeownership and an underdeveloped rental market. Land is 93 percent government owned.

Water is very scarce. The world's largest desalination plant opened in Israel in 2005; another plant was added in 2007. Agriculture is technologically advanced, capital intensive, and highly productive, but also highly protected and subsidized. Major exports are produce, flowers, and wine.

Defense expenditures average 8.5 percent of GDP (1998–2007). Since 2002, Palestinian suicide bombings and the associated economic costs have declined sharply. The economy was robust to the Second Lebanon War of 2006; the direct cost in lost GDP was just 0.5 percent. In 2008 Israel received $2.4 billion in U.S. military aid; civilian aid has been phased out.

Economy

In 2001–03, Israel experienced a major recession, caused mainly by Palestinian violence. During 2004–07, real GDP grew steadily at 5.2 percent per year. Israel has free trade agreements with the United States, Canada, and the European Union (EU). Exports are 45 percent of GDP, and are divided approximately equally between the United States, the EU, and others. Leading export sectors are high- and medium-high-tech industry, including pharmaceuticals (36 percent of exports), general services (19 percent), diamonds (15 percent), and high-tech services (11 percent). Exports grew 8.6 percent annually (in nominal terms) over 2004–07, led by information and communications technology (ICT). The weight of ICT in total business product is the highest in the world (2006).

In balance of payments, the current account/GDP ratio rose from minus 5 percent to 6 percent over 1997–2006, falling to 3.1 percent in 2007. The capital account has been liberalized since 1991. Israel is among the frontrunners in receiving foreign direct investment (FDI); FDI is concentrated in the ICT sector.

Israel ranks first in the world in availability of scientists and engineers and in research and development (R&D) expenditures as a percentage of GDP. Israel ranks third in patents per capita. R&D is concentrated in ICT. IBM, Intel, and other multinational corporations conduct R&D in Israel. There is limited government support for R&D.

Israeli venture capital funds raised $10.6 billion from 1998–2007. Over 2004–07, Israel's country risk premium was halved to 30 basis points; Israel's sovereign debt ratings have improved steadily. The financial system has become more competitive, efficient and stable, but further improvement is necessary. The Tel Aviv Stock Exchange maintains ties with NASDAQ and the London Stock Exchange (LSE). NASDAQ lists 75 Israeli companies; LSE lists 50.

Banking is dominated by two large banks. Many analysts see consumer banking as a cartel; corporate banking includes foreign players and is more competitive. A corporate bond market has developed; the banks' traditional dominance of credit markets is being gradually eroded. In 2005, the banks were forced to sell off their provident funds; many funds were purchased by insurance companies. From 2008, pensions are mandatory by law.

Over 2003–07 the deficit/GDP and debt/GDP ratios have declined from 6.2 percent to 1 percent, and from almost 102 percent to 80.6 percent. Government spending/GDP declined from 50.8 percent to 44.9 percent, while taxes stayed near 37 percent. Privatization has contributed to the reduction in debt/GDP.

Historically, the tax burden fell disproportionately on middle-class workers; financial income was untaxed. Since 2003, financial income has been taxed, while income taxes have been reduced. VAT and corporate taxes have also been reduced; current tax rates are 15.5 percent and 27 percent, respectively.

Monetary policy has succeeded in achieving price stability; currently, the inflation target is 1–3 percent. Stanley Fischer, a world renowned economist, has served as BOI governor since 2005. In 2007, the Bank of Israel's interest rate was below the U.S. Federal Funds Rate, a historically unprecedented situation.

Exchange rates are flexible. Over 2006–early 2008, the shekel appreciated by over 20 percent against the U.S. dollar, leading the BOI to intervene in currency markets for the first time since 1997. Israel joined the Continuous Linked Settlement (CLS) system in May 2008, making the shekel fully convertible worldwide.

Business firms have invested in quality improvement; ISO 9000 certification is widespread. Some Israeli companies have attained world-class quality, but traditional industry and construction lag behind.

Education and Employment

Primary and secondary education are plagued by inadequate infrastructure, poor discipline, and low teacher salaries. Internationally standardized test scores are low, despite large expenditures. Student achievement is highly stratified by socioeconomic status. Israel's research universities are excellent but public funding (traditionally 70 percent of university budgets) has stagnated. Access to higher education has been expanded dramatically through the opening of teaching-oriented colleges (public and private). The "brain drain" of academics and physicians (especially to the United States) is an acute problem.

Public administration suffers from severe structural problems. Coalition governments average two years in office, public services are limited, and dissatisfaction with bureaucracy is widespread. Construction planning is centralized, rigid, and slow. Law enforcement has serious weaknesses. Israel ranks 30th in corruption perceptions, second-worst among Western nations. A significant deterioration occurred over 2002–06. Many local authorities suffer from corruption, mismanagement, and inefficiency.

Inequality is high, and has risen since 2000, in part due to reductions in real transfer payments. The poverty rate is 23.7 percent overall, 34.9 percent among children (2006/7). (Because the poverty line is defined in relative terms, it actually measures inequality.) Poverty is concentrated in the Arab and Ultra-Orthodox sectors, which have poverty rates near 60 percent.

In the final quarter of 2007, unemployment was 6.7 percent, versus 10.7 percent (average) in 2003. The private sector labor market is highly flexible, and resembles U.S. and UK labor markets. The public sector is less flexible, and resembles the European model. Unionization has declined, especially in the private sector.

Long term growth of per capita GDP has been slow; Total Factor Productivity (TFP) growth has been disappointing, especially in trade and services, construction, and low-tech industry. Labor productivity is close to the OECD average (2006); the BOI cites foreign workers as an important cause of slow TFP growth. Israel suffers from low labor force participation among prime-aged males. High unemployment and low labor market participation are strongly correlated with low education levels. Arab women and Ultra-Orthodox Jewish men have the lowest participation rates. The general participation rate has improved somewhat since 2004. The government spends little on active labor market policies.

Non-Israeli workers (79 percent foreign, 21 percent Palestinian) comprise 8 percent of the labor force; many are employed illegally. Foreign workers are concentrated in agriculture, construction, hotels, and restaurants, and elder care. "Contract employees" compromise 5–10 percent of the civilian labor force. They are employed through manpower agencies ("contractors") at low wages and with few or no benefits, often against the law. They are concentrated in the service sector; surprisingly, the government is a major employer. Public sector strikes are a chronic problem, affecting essential services and education on all levels; many analysts blame Israel's unusual labor laws. Public monopolies (e.g., ports, utilities) pay abnormally high salaries.

Historically, the government has underinvested in roads and rails. However, road congestion has declined somewhat since 2000; intercity rail is gradually being expanded, and light rail projects are under way in Tel Aviv and Jerusalem. The Cross Israel Highway, Israel's first toll road, opened in 2002. Israel lags behind Western nations in traffic safety. Ports are inefficient and domestic shipping costs are very high. Air transport is uncompetitive; regulations strongly favor domestic carriers.

Italy

Italy is a country of southern Europe comprising 20 regions. It is one of the largest economies in Europe, and in the world. Its growth rates are consistently among the highest in the European Community. Italy's economic growth has been characterized, since the political unification in 1861, by the following factors: the divergence between an industrialized north and a prevalently agricultural south; the interventionism of the state; the predominance of family capitalism; and the large number of small and medium-sized firms. More recently, the Italian economy has been affected by political instability and international competition.

The Italian economy is characterized by a rather marked division between an industrialized north, where the great majority of industrial and manufacturing activities are located, and a less developed south. The dichotomy between the northern and southern parts of the country has been a major problem for the implementation of equal economic policies. The northern regions of the Italian peninsula, especially Lombardy, Piedmont, Veneto, and Liguria, see the greatest concentration of industrial activities. By contrast, the southern part of the country has never experienced industrial development comparable to that of the northern regions. In the 1960s, when Italy went through an economic boom, the divergence between the north and the south heightened, and many people migrated from the south to the north in search of better-paid jobs. Although in recent decades new opportunities for the economic development of the southern region have arisen, thanks also to the financial aid of the European Community, the north-south dichotomy and its social and political implications continue to be a current issue.

Since the origin of Italy as an independent and unified country in the mid-19th century, the Italian state has been markedly interventionist, entering the country's economic life in many ways, especially by subsidizing several industrial sectors. Along with Japan and Germany, Italy has been considered one of the most interventionist states. Italian industries and banks have benefited, over time, from large state subsidies. For example, Sofindit (financial company of the Banca Commerciale Italiana), Ansaldo, Terni, and in recent times even Fiat have received frequent subsidies from the state. The reasons behind the interventionism of the Italian state are several and complex; they are closely linked on the one hand, to the atypicality of the Italian political and economic unification, and on the other to the specificity of the Italian economic growth that witnessed a rather peculiar combination of private and public capitalism.

Family ties have been extremely important for the growth of modern Italian business, and Italy owes much to "familial capitalism," as the remarkably impressive persistence over time of family-run firms in the Italian economy evinces. Although the notion of family business has had for a long time a negative connotation that suggests economic backwardness and commercial weakness, the excellent performances of Italian family-run companies and industries in the past decades contradicts such generalized view. Family-run business can be, in practice, highly articulated forms of managing business that displays a remarkable flexibility, ability in negotiation, and noteworthy capacities of quickly responding to market changes. Well-known Italian companies such as Benetton, Missoni, Fiat, and Beretta, have been founded and run by families.

Along with family capitalism, another distinguishing aspect of Italian economic growth has been the pervasive presence of the so-called *piccola impresa* (small business). Since the late 19th century it has represented a vital component of the domestic economy, particularly in northern Italy. In the 20th century the excellent performance of Italian small business, especially in some specific sectors, made it an admired model of "flexible capitalism." The combination of family capitalism and the pervasiveness of small business (the great majority of Italian manufacturing and industrial activities are run by one family and employ less than 50 workers) seems to be the hallmark of the Italian economy.

In spite of its flexibility and competitiveness, the Italian productive system, however, has been able to cope only partially with the upheavals of the last three decades and the challenges of globalization. In spite of an increasing gross domestic product (according to data provided by ISTAT, Italian national product has grown steadily from 1970 to 2007), the Italian economy has been one of the most unstable in Europe in the last two decades. It has continued to have one of the highest growth rates within the European Community, but it has progressively shown a number of structural weaknesses. Italian economic performance has lagged behind that of other EU countries, and the prolonged climate of political instability in the last few years has affected the Italian economy. The introduction of the euro in the 1990s, which replaced the Italian lira, has led to additional difficulty, with consequent price increases and stagnation of production. Fierce international competition in some sectors, such as textiles, has impacted Italian production. A restructuring of the Italian economy has been called for by many parties.

Jakarta Composite Index

The Jakarta Composite Index is the major stock market index for the Jakarta Stock Exchange. The Batavia Effectenbeurs had been established on December 14, 1912, under the Dutch trading in shares of companies involved in rubber, tin, pepper, and the like. It was closed during World War I, reopened in 1925, and continued in operation until 1942, with the start of the Japanese occupation. It remained closed until 1952 when it was reopened under the Capital Market Emergency Regulations, but the only products traded were Indonesian government bonds. By 1956 it had stagnated and it remained closed during the rest of the presidency of Sukarno, Indonesia's first president. It reopened on August 10, 1977, when it was managed by the Badan Pengawas Pasa Modal ("Capital Market Supervisory Agency": Bapepam), under the control of the Ministry of Finance.

During the years that Suharto was president of the country, according to former investment banker and author Kevin O'Rourke, the Jakarta Stock Exchange (JSE) had become a venue for legalized gambling. Part of this was because of the tiny capitalization and hence the small number of shares being traded. This led to Indonesian banks establishing high-yield portfolio accounts and margin-trading instruments that pushed up stock prices. The economy was further deregulated between 1988 and 1990, allowing foreign investors to trade easily in the country. The Securities and Money Trading Organization also oversaw the Pararel Bourse, which consisted of brokers and dealers. On June 16, 1989, the Surabaya Stock Exchange also opened.

To measure how much shares on the stock exchange were rising, the JSE Index was established using a representative group of companies traded in Jakarta. There was a massive bull run in 1990, and large profits were being made. One of the companies involved there was the British firm Barings Bank, but it started registering a loss from trading despite the large rise in prices. In 1991 they sent over a newly-trained banker, Nick Leeson, who discovered some £100 million in share certificates lying around the room the bank was working from in the Hotel Borobudur. Because of his work there, he was later sent to Singapore where, in 1995, he was involved in the collapse of the bank.

The result of the 1990–91 bear market was that the price of shares became heavily inflated; on July 13, 1992, the JSE was privatized and became the Jakarta Exchange Inc., with Bapepam becoming the Capital Market Supervisory Agency, although it was not until 1996 that it had the power to investigate possible violations of stock exchange rules that were handled by the police. To help the growing numbers of stock traders, the Jakarta Stock Exchange, by this time known as the JSX, established a series of automated trading. This continued to encourage investors and gamblers alike, and was measured by the JSX Composite Index.

The Asian financial crisis of 1997 led to a collapse in the share values of many companies on the JSX, which was measured by falls in the JSX Composite Index. Many people lost fortunes, and it took many years for some of the major companies to regain the price levels that they had in the boom years—some companies did not survive. Some people found fault with the JSX, and as a result, some 30 corporate stocks switched to being listed on the Jakarta Islamic Index that was established in 2002. All the companies listed on this rival index had to fulfill the requirements of Islamic sharia law.

In 2005, with further globalization, the JSX Composite Index, along with the indices from the Bursa Malaysia, the Philippine Stock Exchange, the Singapore Exchange, and the Stock Exchange of Thailand, was used to establish an FTSE/ASEAN index to show the rise or fall of stock prices throughout the member states of the Association of Southeast Asian Nations (ASEAN).

Up until September 2007, there had been a separate Surabaya Stock Exchange, operating in the city on the east coast of Java. In that month it merged with the Jakarta Stock Exchange to create the Bursa Efek Indonesia (Indonesian Stock Exchange). On July 13, 2007, the JSX established the Kompas100 Stock Price Index, which started operating from August 10, 2007, to coincide with the 30th anniversary of the reopening of the stock exchange in Jakarta. For this, the Kompas100 Stock Price Index is based on a weighting of some 100 companies chosen because they reflect the frequency of sale, the value of transactions, and also the market capitalization, as well as the fact that they reflect a range of different sectors of the economy.

Japan

With a GDP of $4.417 trillion in 2007, Japan is the second-largest economic power and the second most important consumer market in the world. Japan was an island country completely closed to all Western influences until the 1850s. But after opening itself to the West in 1853, Japan developed from the status of a medieval country to the top of the economic world by the end of the 20th century. During this period, typical Japanese management practices developed that, along with strong cooperation between government and industry, low expenditures for national defense, and a high interest in technology and innovation, led to unprecedented success for the Japanese economy. During the 1980s, at the height of economic success, Japanese management style was seen as a role model and began to influence Western business practices.

From the beginning of the 1990s, however, Japan went through a major recession that led to numerous changes in traditional Japanese management processes. Only at the beginning of the 21st century did Japan seem to have recovered from its economic crisis; it is now trying to keep its role as a major player in the global economy.

Country and People

Japan consists of 6,852 islands occupying 377,887 sq. km. Honshu, Hokkaido, Kyushu, and Shikoku are the biggest and most populated islands, with Honshu serving as the economic, political, and cultural center of Japan. The capital Tokyo and the major cities Osaka and Nagoya are located on Honshu. Tokyo accounts for only 2 percent of the land but hosts more than 40 percent of the total population (127.5 million people in total). About 18.5 percent of the population are older than 65 years. The average life expectancy, 78.32 years for men and 85.23 years for women, is one of the highest in the world.

Over 80 percent of Japanese observe either the Shinto or Buddhist religion or both. The remainder of the population practice other religions, including Christianity.

Japan is the home of the oldest continuous imperial family in the world, the current emperor being the 125th in an unbroken line. He is the official head of the government but has no governing authority. All his acts require the advice and the approval of the Japanese cabinet. Today the emperor is still considered the spiritual head of the nation and is responsible for performing a variety of Shinto rituals. The current emperor, Akihito, succeeded to the throne in 1989, adopting the formal reign title Heisei ("Establishing Peace"), which is also the imperial reign name.

Today, the Japanese cabinet, headed by a prime minister from the majority party, holds executive power. The Japanese parliament, the highest organ of state power, consists of the House of Representatives (with 500 members) and the House of Councilors (with 252 members). The dominant political party in Japan is the LDP (Liberal Democratic Party), which was formed in 1955 and, because of Japan's rising prosperity, remained in sole power for 38 years. After a year and a half in opposition, it again became the single ruling party in 1996.

Economic Development

Japan's economic success and development is a unique phenomenon. Japan was a closed country (*Sakoku*) until 1853. This was originally initiated by the third Shogun Iemitsu, who—in an attempt to create internal peace and stability—closed the island country to foreign commerce and expelled missionaries in 1635. While the seclusion created internal peace and stability, Japan fell behind in terms of technological development and remained a medieval state for the next 200 years. The turning point in Japanese history came in 1853, when Commodore Matthew C. Perry entered Japan with his "Black Ships" (steam boats), which forced Japan to open up to the West and triggered a chain of events. The Shogunate fell and the Imperial Restoration in 1868 ended Japan's seclusion.

The new Meiji government set out to transform Japan from a medieval empire into an industrialized state within 30 years, so that Japan could match Western developments and deal with them on equal terms. These attempts were supported by the fact that Japan was already a well-developed market with its own currency and distribution system even before opening up to the West. Industry was promoted, Western culture was encouraged, and a parliament was established. The slogan of the new government was *fukoku kyôhei* ("Enrich the country, strengthen the military"). Japan also built up sufficient military power to become Asia's major imperialist power in the early 20th century.

Japan's economic success did not start directly after World War II. After the defeat in 1945 Japan faced the Allied occupation, which forced the country to demilitarize and put an end to the long-running *zaibatsu* (the old Japanese combines) control over the economy. They also made changes in the constitution and the educational system, and gave women the right to vote.

At the end of the Allied occupation in 1952, Japan still ranked as a less-developed country. The Korean War was the first impetus to help Japan recover, because the American forces used Japan as a base to fight the North Korean army and received supplies from Japanese suppliers. Japanese companies started to increase their production and had a young and highly motivated workforce to support them.

Japan's economic development was accompanied by the structural development of Japanese industry. Even before World War II, Japan possessed very impressive light industry, with textiles and food production being the most important. Most notable was the increase of heavy industry, such as machinery manufacturing and the chemical industry. These changes were strongly supported by the Japanese government. The Japanese also had an enormous fascination regarding modern technology and traditionally have shown a great openness toward ideas and con-

Shoppers throng an open-air market in Japan. Although personal consumption has decreased with the country's ongoing financial turmoil, Japan is still the second most important consumer market in the world.

cepts introduced from Western countries. This led them to accept Western products and behavior rather quickly compared to other developing countries.

Other factors that influenced the high growth rate of Japan after the war were found in the strong relationships between government and industry. The government promoted long-term investment in future industries and technologies while keeping expenditures on self-defense relatively low compared to other government ministries. More resources were being spent on developing industry.

From 1953 until 1973 the Japanese economy grew at an annual growth rate of 8 to 10 percent, making it the first less-developed country in the postwar period to graduate to developed nation status. During the 1950s the major industries were textiles and light industry. During the 1960s the iron and steel industry and the shipbuilding industry were most dominant. Japan at that time also hosted the Olympic Games, which was the first time it presented itself on an international stage. By the 1970s, the automotive industry rose to prominence. This development was accompanied by strong urbanization that made Tokyo and Osaka the most populated areas in Japan.

Despite the success of its economic rebound, occasionally Japan would suffer from events that would affect its economy. In 1974 the GNP fell 1.4 percent for the first time since 1950 because of the oil crisis. Growth also fell in the 1970s and slowed from 10 percent to 3.6 percent between 1974 and 1979. Despite a weak economy from 1981 to 1983, a strong dollar led to an increase in exports after 1983. By 1985 the surplus in Japan's balance of payments account reached 3.7 percent of the GNP. Exports had increased in the early 1980s, due to a strong U.S. dollar. Japan's economic turn-around was complete. It had emerged as an economic powerhouse, boasting trade surpluses with the United States and the European Union (EU). This was the time when Western managers and researchers developed a deeper interest in the Japanese economy and traditional Japanese management styles.

The Bubble Economy and the Lost Decade

Japan's export-bolstered economic growth first experienced difficulties after the G-5 Plaza Agreement of 1985 and the rapid appreciation of the yen. Interest rates were lowered in order to increase domestic demand, and the expanded supply of domestic capital resulted in an increase of investment in land and stocks. At the same time, land values increased and finance companies increased the number of loans with real estate as security. Capital secured by such loans was used to purchase more real estate; these were later to become "bad debts." In these years, Japanese companies borrowed massively from Japanese banks, which got their funds from the high amount of household savings. An ongoing inflation allowed them to pay back their debts without any problems until 1990, when the bubble finally burst. Properties purchased at high "bubble era" prices were not able to pay for themselves, putting pressure on the businesses that owned them. Consumers also reacted to these changes and personal consumption decreased. Banks were left with bad loans, with many ending in bankruptcy or needing support from the government.

During the 10 years of recession, the Japanese government invested ¥130 trillion on structural reforms. However, there were no visible effects for a long time due to the inflexibility of Japanese organizations and structures. The 1990s, after the bubble burst, are therefore known as the "lost years" in Japanese economic development. There were difficulties in disposing the bad debts, for which interest payments were late, or which were not recoverable because of bankruptcy. This inevitably forced the Japanese economy into low growth for more than a decade until 2000.

The recession and the lost decade significantly damaged Japan's image as an economic powerhouse. It added a layer of skepticism to the already existing difficulties of Japanese corporations coping with globalization, the increasing challenge that China presented for the Japanese economy, and the tariff and non-tariff entry barriers as well as cultural and business differences that are faced by foreign firms attempting to enter the Japanese market.

Japan's internationalization also got a boost in the 1990s. China became its main competition, since Japanese manufacturers realized that they could not compete with their cheap production processes. This led to the internationalization of a high number of Japanese companies, which previously focused mostly on the Japanese market and had not yet exported their manufacturing processes. Today Japan is the most influential foreign investor in China.

Only in 2003 did the Japanese economy start to show subtle signs of recovery. Parts of the economic recovery are based on the weak value of the yen, which boosted export sales, parts of the long-expected effects of structural reforms started in the 1990s. By 2007 Japan's GDP was growing at 1.9 percent, unemployment stood at 4 percent, and inflation was negligible. In the same year, its exports were valued at $665.7 billion, with nearly 23 percent going to the United States.

Japanese Management

Japanese business practices have been strongly influenced by Japan's seclusion and differ from Western approaches in numerous fields. The extraordinary development of the Japanese economy from a less-developed country to a member of the G7-states, as well as the success of Japanese corporations, made Japanese management a focus of Western researchers and managers.

The most notable differences are lifetime employment, seniority-based pay and promotion, and the role of Japanese trade unions. Lifetime employment refers to the preference of Japanese corporations to hire their employees after their graduation from university and then keep them in the company for most of their length of their careers. Lifetime employment is not a legal requirement for Japanese companies, but a custom that developed after World War II. The strict Japanese labor laws, which make it very difficult to lay personnel off, supported the establishment of this system.

Lifetime employment offers great advantages for the economic development of Japanese corporations. Corporations can invest in the training of their employees and support them in building up know-how over a long period of time. Lifetime employment is further thought to improve employee motivation and loyalty. Next to lifetime employment, seniority-based pay and promotion are also well-known features of Japanese management. Traditional Japanese corporations are strongly hierarchical systems in which career opportunities depend on the length of service in the firm. This provides a stable and reliable system for employees, but could decrease motivation for ambitious workers.

The most well-known and influential part of Japanese management is Japanese production management, which is mostly related to the Toyota Production System. This system became a role model for Western car makers and manufacturers of all kinds of products in terms of safety, quality, and cost effectiveness and made Toyota one of the most successful Japanese corporations in the world. Japanese production management incorporated the just-in-time (JIT) style of management. This is a system in which all parts used during the production process are delivered exactly at the right time and used in their proper amounts. Just-in-time management reduces waste and costs and uses methods such as the *kanbans* (small cards that help the coordination of parts used during the manufacturing process) and *heijunka* (continuous control of quality during the production process as well as after the product is manufactured). Japanese production management is further strongly based on the philosophy of *kaizen*, which refers to continuous improvement of all management and manufacturing processes with the overall goal of improving quality and customer value. All these concepts allowed Japanese manufacturers not only to take the lead in quality and in cost but also supported the development of the Japanese economy.

Other interesting features of Japanese management are *nemawashii* or unofficial negotiations and the *ringi* system, a group decision-making process. Nemawashii refers to communication between negotiators in an environment before an official meeting takes place. This allows all participants of a negotiation to present their ideas and circulate them among all participants. In this way, problems can be solved before a final meeting, and harmony and understanding are secured for all participants. Nemawashii is the reason why Japanese meetings often only have an information exchange function and simply finalize the results of the nemawashii process.

The ringi system, on the other hand, is a bottom-up group decision-making process that includes members of all management levels. In a ringi document a new idea is presented and then improved and revised by all managers involved. The document is often circulated a number of times throughout a company. The whole process is finalized once all participants agree on a solution and sign the document. It sometimes can be signed by up to 30 or more people. The ringi system decreases individual responsibility and informs employees of a new strategy or idea. This allows Japanese teams, departments, or companies to set very ambitious goals, but also leads to time-consuming decision-making processes and indecisiveness in times of crisis.

Japanese management has further become famous for its particular way of managing knowledge. Japanese knowledge management focuses on tacit knowledge or knowledge that is located in people and not documented in the form of reports or data. Lifetime employment supports this practice. Japanese companies do not have to be afraid of their employees leaving their companies and can therefore allow them to gain a high degree of company-related know-how. In many Japanese firms knowledge is therefore communicated from person to person and on-the-job training is preferred. Because of this, knowledge also flows freely within a Japanese firm, a fact that supported Japanese advances in new product development.

The 21st Century

Even against the background of strong economic transformations in countries such as India and China and a strong enthusiasm in dealing with these upcoming economies, it should not be forgotten that Japan is still the world's second-largest economy in terms of GDP. However, Japan's economy faces further challenges. Besides the reforms in the 1990s, there are still many unsolved problems such as the tremendous public debt, the fragile banking industry, and the comparatively unproductive domestic sector.

Since 2007 Japan's baby boomers (Japanese who were born from 1949 until 1951) have been gradually retiring. They account for about 10 percent of the Japanese workforce. For companies, this led to high investments in retirement contributions as well as to a drain in tacit knowledge. However, the retirement of the baby boomers opened the way for a new generation of young Japanese who are entering the corporations. A decreasing Japanese population makes this problem even worse. After years of recession, Japan's corporations now fear a labor shortage for the first time.

These challenges and the turbulent developments in the Japanese economy and management over the last several years led to the question of whether Japanese management practices will become more Western or shareholder-oriented or keep with their traditions. Only in the field of production management do Japanese firms manage to defend their world leadership. The main challenge of Japanese corporations will be to internationalize their workforce and to develop more flexible organizational structures. Japanese negotiation and decision-making practices are further seen as management styles that kept Japanese firms inflexible and delayed reform processes during the 1990s. Some Japanese firms such as Toshiba have taken up the challenge and developed a balance between a profit and efficiency-oriented management style and their classic management style. However, it remains to be seen whether a large amount of Japanese corporations will change their ways to adapt to the 21st century or continue with their traditional ways.

Job Enrichment

Job enrichment arises with the inherent need of employees to be satisfied with their jobs and the tasks that need to be accomplished. Mundane and repetitive tasks and routines might lead employees to lose interest in their jobs and subsequently become dissatisfied and lose morale. Similarly, job content and factors such as job scope, lack of complexity and challenge of routine work duties, job stress, lack of intrinsic or internal motivation, lack of job involvement, and lack of managerial motivation and support can lead to the dissatisfaction of employees. This can have an adverse impact on organizational practices as well as on the productivity of the company.

One way of motivating employees to perform better and increase their commitment to the organization is through redesigning and enriching their job descriptions and task specifications. Job enrichment, sometimes also referred to as vertical role integration, offers greater scope for personal achievement and recognition at work. Job enrichment is an attempt to motivate employees by giving them the opportunity to use a wide range of their abilities, knowledge, and skills. It allows employees to perform beyond their predefined duties, feel valuable to the organization, and further contribute to the realization of organizational goals and targets. It provides scope for challenging and responsible work. Job enrichment also offers opportunities for continuous growth and advancement. Job enrichment can take a variety of forms and occur for many reasons, but it normally involves aspects such as having a variety of tasks, autonomy, and the extent to which the job produces an tangible end result.

Job enrichment can take two forms. The first one is to increase responsibility for decisions traditionally made by supervisors. For instance, certain tasks could include scheduling of work and allocation of tasks. This increased responsibility gives employees the autonomy to perform their duties without direct and strict supervision that occasionally can lead to demotivation and increased stress in the workplace. The second form refers to upgrading jobs to include additional skilled tasks that are not elements of supervisory work, like machine maintenance and ordering supplies. This provides employees with a range of tasks and challenges of varying difficulties that will help them engage in their work. Ideally, these two forms of job enrichment should also contain feedback, encouragement, and communication so as to further motivate employees to go beyond their duties and perform better. Getting feedback on their performance means that errors can be detected and corrected so as to improve the productivity and accountability of workers. Therefore, if employees perform their jobs correctly, then satisfaction is greater, performance is improved, and this leads to enhanced motivation and organizational commitment.

Job enrichment includes a number of different workplace practices, such as quality circles, self-directed teams, job rotation, and information sharing. One possible reason for adopting these practices is to motivate workers and to encourage them to participate in improving productivity, safety, and the quality of their products or services. An alternative motivation for adopting job enrichment is to enlarge the jobs by encouraging multitasking and to adopt peer monitoring. This also improves productivity and, in return, job satisfaction. Furthermore, job enrichment can lead to better work methods, attracting and retaining capable employees as well as helping to increase quality and improve decision making at the job level.

Moreover, job enrichment is closely linked to autonomy in the workplace. Employees receive higher levels of flexibility and responsibility in the tasks that they have to perform, allowing for an enriched content and context of their jobs. This means that jobs are delegated and decentralized so as to achieve the highest possible performance, to minimize employers' control, and to reach the organization's aims and objectives more effectively. Also, having flexible job content enables employees to redirect their efforts, focus on their resources and consider new approaches when dealing with problems. This in turn leads to increased satisfaction and enthusiasm.

Overall, the purpose of job enrichment is to make jobs more intrinsically rewarding through the enhancement of responsibility, authority, and accountability. Job enrichment increases employees' sense of belonging as well as engaging them to perform better. This, in turn, leads to higher organizational commitment, job satisfaction, and improved results. This also has a direct positive effect on organizational performance, on the organization's reputation, and on its relationship with customers.

Johnson & Johnson

Johnson & Johnson is a global firm active in the consumer healthcare, pharmaceuticals, and medical devices and diagnostics sectors with a long history dating back to 1886. At that time, the company's founders—Robert Wood Johnson, James Wood

Johnson, and Edward Mead Johnson—developed a product based on a premise that today sounds like common logic: Doctors and nurses should use sterile sutures, dressings, and bandages to treat wounds. In 1886 they started a small medical products company in New Brunswick, New Jersey, that produced and sold the first-ever commercial sterile surgical dressings. Since then, the company has brought the world new ideas and products that have transformed human health and well-being, such as dental floss, the earliest First Aid kits, sanitary napkins for women, baby powders, and more. The firm has been publicly traded on the New York Stock Exchange since 1944.

The international expansion of Johnson & Johnson started in Canada in 1919 and then continued in England in 1924. A continuous internationalization process accelerated further growth of the firm in the pharmaceuticals and medical products sectors. This overseas growth witnessed the expansion of the firm into numerous countries in Europe, Latin America, and Africa until 1946, more in Asia, Central America, and Europe until 1966, and China in 1985. During this wave of international expansion, operating companies of the firm across the world pioneered several important medical advances and the mother firm entered new businesses (e.g., disposable contact lenses) through acquisitions. These modes, along with internally developed businesses, are the dominant tools of growth for Johnson & Johnson, which has secured a leadership position for the firm in a number of health-related sub-sectors.

Of significant importance for Johnson & Johnson are the values that guide its decision making and are spelled out in the firm's credo. The credo was crafted in 1943 by one of its founders; in a few words, it codifies the company's practice with regard to social responsibility and ethics of business activities. The credo can be summed up as putting the needs and well-being of the people Johnson & Johnson serves first. It focuses on the needs of customers and aims to provide a strict set of rules that guide employees' conduct. The output of this behavior should be in line with the firm's main premise: Healthcare is the business of caring for people and the employees' objective should be to deliver products that promote health and well-being. This aim is assisted by investing personal and corporate resources in developing new treatments through research.

The board of directors consists of 11 board members and is responsible for appointing the senior management of the company. However, local managers are in charge of the subsidiaries of the firm across the world. Each of the subsidiaries functions as its own small business, is strongly entrepreneurial in character, and works on anticipating local customers' needs and delivering high-quality solutions. While local management operates in a small-company setting in each country, they also have access to the know-how and resources of a Fortune 50 company. Currently, Johnson & Johnson has more than 250 companies located in 57 countries globally. These companies are organized into several business segments comprised of franchisees and therapeutic categories.

The usual mode of foreign market entry for Johnson & Johnson is the establishment of a fully operating subsidiary. In smaller markets, though, costs of adapting managerial processes through setting up a wholly-owned subsidiary may be high; in such a case, a local representative is preferred. This is the reason why Johnson & Johnson's products can be found in more than 175 countries, more countries than the ones where the mother company owns operating businesses. The firm also strives to attract and keep talented people in each country who will drive product inventions and leverage breakthroughs in human health and well-being. It currently has more than 119,000 employees.

Johnson & Johnson has recently enjoyed more than $62 billion in sales and more than $11 billion in profits. It is a well-respected firm with a long history and aspires to dominate the fields in which it operates.

Joint Venture

Somewhere between the competitiveness or indifference of autonomy and the border erasure of a merger is a joint venture, a business entity created by two or more parties (generally other businesses) that contribute an economic stake. Joint ventures are more than just agreements between cooperating companies; the venture takes the form of a new business. Often this is because, for instance, one company markets chocolate and the other has a stake in confection-quality peanut butter; while continuing to pursue their own concerns, they create a peanut-butter cup company. Or one company may be experienced in the field of magazine publishing, while the other has developed an improved technology for printing high-quality photographs on thin paper; they could benefit from a joint venture in the form of a photo-intensive magazine.

Though those two examples describe synergistic relationships, there are many reasons a joint venture is desirable, and depending on the industry and the purpose for which it is formed, it may be a corporation, an LLC, a partnership—essentially anything but a sole proprietorship, by its nature. A joint venture may be designed to take advantage of economies of scale. It may be the only way one of the participating companies is willing to share access to certain markets, customers, technologies, processes, or other resources. It spreads out the costs and risks of the venture more than if either company engaged in it on its own—in Hollywood, there have been a small number of movies produced as joint ventures between studios unwilling to take on the full financial risk by themselves, and willing to share the potential rewards. Even when the risk is not perceived to be high, the manner in which a joint venture reduces a company's economic stake relative to pursuing the activity on its own keeps the company more liquid and does not require the interest payments of a loan or other funding.

Recent Examples

Joint ventures may be the quickest way to bring a product or service to market, before other competitors in the industry are able to do so. A joint venture may be an alternative to competition, especially in cases where competition offers no obvious benefits. Hulu is a good example of this, one that demonstrates that the avoidance of competition in no way harmed the consumer or resulted in a product of lesser quality. A Web site that allows viewers to watch ad-supported television shows and movies online—primarily new and classic shows from broadcast television, not the "produced for the Web" shows that had been plentiful elsewhere and in low demand when the site launched—Hulu is a joint venture between NBC Universal and News Corporation (the Australian media conglomerate that owns the Fox television network). In addition to shows from those networks and their cable affiliates (Bravo, the SciFi Channel, USA, FX, et cetera), shows from the Sundance Channel, the Disney Channel, PBS, Comedy Central, and others are available. There is no apparent reason why networks, studios, or viewers would benefit from each network or studio having its own online presence—though in fact NBC continues to show streaming television shows on their own Web site rather than redirecting to Hulu. But the joint venture clearly benefits viewers by aggregating content in one place and providing an experience as uniform as television itself. (Though formed as a joint venture in part to avoid competition between NBC and Fox, Hulu is not immune to competitive impulses, and has pulled content from both Boxee and CBS-owned TV.com.)

Another well-known joint venture is Verizon Wireless, 45 percent of which is owned by Vodafone, a British cell phone operator and the operator of the largest cellular telecommunications network in the world. Vodafone's infrastructure and wireless assets were a perfect match for Bell Atlantic, which was looking to launch a large national cellular network. Announced in September 1999 and launched the following April, the joint venture was known as Verizon Wireless, adopting the Verizon brand name two months before Bell Atlantic renamed itself Verizon Communications. The venture combined the best assets of both companies and allowed for a much more rapid launch than would have been possible otherwise.

There is also the CW Television Network, a result of the struggles of the WB and UPN networks, which had failed to find the same long-term success enjoyed by Fox—their spiritual predecessor in breaking the broadcast dominance of the Big Three networks that had persisted since the days of radio. At the time of its dissolution, UPN—founded by Viacom (owners of MTV, Paramount, and other media concerns)—was owned by CBS, which had been bought by Viacom before the company split in 2006. The WB was owned by media company and content provider Warner Brothers. Both networks had had successful shows, but had been unable to sustain their ratings once those shows reached the end of their runs.

Reflecting the conventional wisdom that neither network had offered enough successful content to justify its continued existence, equal partners CBS and the WB formed the CW Television Network to combine the resources of the defunct networks and focus on programming for the WB's ages 18–34 demographic. Despite rumors that the CW name was just a working title to give executives convenient shorthand by which to refer to the joint venture, the network stuck with it, citing polls showing that the name was highly recognizable even before launch, thanks to press coverage of the plans. The CW continued the WB and UPN's plans to compete with the Big Three (plus Fox) by gearing its content for younger audiences, essentially treating their ratings on a "quality, not quantity" basis by targeting the desirable demographic, one that was brand-conscious, loyal to its favorite series, and had ample disposable income. Popular shows like *WWE Smackdown, Gilmore Girls, Supernatural*, and *Veronica Mars* continued their existence from the old networks to the new one, and the network hoped for a "the whole is greater than the sum of its parts" synergy. The ratings, unfortunately, have not reflected this, but the network has produced several shows—*Gossip Girl* and the remake of *90210*—with headline-generating buzz.

Jordan

The Hashemite Kingdom of Jordan is situated in the Middle East (Southwest Asia) and occupies an important strategic position. It shares land and water (Gulf of Aqaba) borders with Israel (including the West Bank) to the west. It borders on Syria to the north, Iraq to the northeast, and Saudi Arabia to the east and southeast. The capital city of Jordan is Amman, situated in the country's northwest region. Other major cities are Irbid, Az Zarqa, Al Karak, and Al Aqabah.

Jordan is a small country (92,300 sq. km) with limited natural resources. It is covered primarily with desert terrain in the east, while some arable highland areas are present in the west. These areas reflect the climate of the country, which is very dry in the east and with a rainy season, from November to March, in the west. Since the majority of the country is 300 m (984 ft.) above sea level and Amman is 756 m (2,480 ft.) above sea level, snow in the capital city is common.

Just over six million people live in Jordan (2008) and the national growth rate is 2.5 percent. The population of Jordan is young with a median age of less than 24. Jordanians are predominately Arabs (95 percent). The non-Arabs belong to small communities of Circassians, Chechens, Armenians, and Kurds. Recent conflicts in Iraq and Lebanon have contributed to a large inflow of Iraqi and Lebanese refugees and displaced persons. The number of Lebanese permanently settled in Jordan due to the 2006 Israel-Lebanon conflict is small. At the same time, according to an independent census in 2007, the number of immigrants coming from Iraq is estimated to be around 700,000.

Independent Jordan is a relatively young country. After the end of World War I and the dissolution of the Ottoman Empire, the League of Nations gave Great Britain a mandate to govern a large part of the Middle East. In 1921 Great Britain gave semi-autonomous control of what was known as Transjordan to the Hashemite family led by Abdullah I. In 1946 the United Nations approved a British request to end the British mandate; Transjordan became an independent country and Abdullah I became king and the first ruler of the Hashemite Kingdom of Jordan (the name "Jordan" was adopted in 1950). King Hussein ruled the country from 1953 until 1999 and was directly involved in the 1967 war with Israel and indirectly involved in the 1973 Arab-Israeli war. Finally, he negotiated the end of hostilities and signed a peace treaty with Israel on July 25, 1994. King Abdullah II, the son of King Hussein, assumed the throne in 1999 and is currently the ruler of Jordan. Jordan is a constitutional monarchy and executive authority is in the hands of the king and his council of appointed ministers. The legal system is based on Islamic law and French codes; Jordan's constitution guarantees the independence of the judicial branch.

Unlike other Middle Eastern countries, Jordan has very limited natural resources. High levels of poverty, inflation, and unemployment are problems that King Abdullah II started addressing when he took power in 1999. Jordan is a member of the World Trade Organization and currently practices careful monetary policy, pursuing privatization of state-owned enterprises and liberalizing trade. Jordan's exports increased after it signed the Free Trade Agreement with the United States. This agreement, which is driving economic growth, specifies that textiles and garments made in Qualifying Industrial Zones can enter the United States tariff and quota free. This agreement will phase out duties on nearly all goods and services by 2010.

Tourism is a very important sector of the Jordanian economy and contributes to around 10 percent of the country's gross domestic product. A long history, political stability, and diverse geography make Jordan an attractive tourist destination. Some of the most famous Jordanian attractions are Petra in Ma'an, Umm Qais, Ajlun, Jerash, Amman, Al Karak, Madaba, the Dead Sea, Wadi Rum, Fuheis, Mahis, and Al-Omwia's Palace.

Although Jordan is an Islamic country, it has consistently followed pro-Western policies illustrated by economic restructuring and political reforms. Besides signing the peace treaty with Israel in 1994 (the Washington Declaration), Jordan has discussed with Israel issues such as security and water-sharing, infrastructure, finance, banking, and trade. Cooperation with Israel has the potential to serve as an example to other Middle Eastern countries and contribute to long lasting stability and progress in the region.

The ancient city of Petra draws international visitors to Jordan, where tourism accounts for 10 percent of GDP.

JPMorgan Chase & Co.

One of the oldest financial firms in the world, JPMorgan Chase and Co. originated as New York Chemical Manufacturing Company, which was established in 1823. The next year, it became involved in banking services and began the Chemical Bank of New York. It functioned as an independent organization from 1851 onward. The company developed significantly through successive mergers with other financial institutions and banks. There were unions with Corn Exchange Bank and Texas Commerce Bank 1954 and 1986, respectively. The Chemical Bank joined with Manufacturer's Hanover Trust Company in 1991 to become the second largest bank in the United States. Another legacy of the Chemical Bank was First Chicago Corporation, which had merged with National Bank of Detroit.

The most significant merger took place in 1996, when the Chemical Bank acquired Chase Manhattan Corporation to form the largest American banking company of that period. After four years, there was further acquisition, when J. P. Morgan and Co. joined to form JPMorgan Chase & Co. The company grew again in July 2004 after a merger with Bank One Corporation. Jamie Dimon became the new president of the company and continued as the chief executive officer (CEO) from January 2006 onward.

With a penchant for acquisitions since its inception, the company took over Collegiate Funding Services, LLC in 2006. Exchanging corporate trust units with the Bank of New York facilitated JPMorgan Chase's expansion with 338 additional branches and 700,000 customers in New York, New Jersey, and Indiana from April 2006. In March 2008, the company obtained the British offsetting company, Climate Care. In 2008, the company acquired a 39.5 percent stake in Bear Stearns, and the banking operations of Washington Mutual for $1.9 billion.

From its corporate headquarters in New York City, JPMorgan Chase operates in 60 countries and has 180,667 employees. Its American consumer services, commercial banking, and retail financial services are headquartered in Chicago. JPMorgan Chase's services include investment banking, financial transaction processing, security and treasury services, private banking, and asset management for individual customers, small business enterprises, corporations, and government institutions. It provides credit card services, housing loans, insurance, automobile finance, and educational loans to its American clients. JPMorgan Chase is the third-largest banking institution in the United States, preceded by Bank of America and Citigroup. Listed on the NYSE as JPM, the company boasted $2.18 trillion in assets of year-end 2008 and for fiscal year 2008, posted net income of $5.6 billion on revenue of $67.3 billion. In the United States, JPMorgan Chase possesses the largest hedge fund with $34 billion in assets. A component of the Dow Jones Industrial Average, its net income in 2007 and first-quarter 2008 were $14.4 billion and $2.4 billion, respectively.

JPMorgan Chase has faced criticism and legal problems in some of its operations. Its dealings with the troubled Bear Stearns investment firm were not above suspicion. In March 2008, it, along with subsidiary J.P. Morgan Securities, Inc., faced a legal suit by the firm Girard Gibbs LLP. It was charged with violating the Securities Exchange Act of 1934 by misleading clients between March 2003 and February 2008 over auction rate securities. The company's stock advisors faced allegations over loss of investments by the University of California and previous Enron employees.

Notwithstanding these aberrations, the company has instituted community partnership, community development, and environmental protection programs. In 2006 it invested $800 billion, stressing small-business lending, mortgages, and development programs among low- and moderate-income communities inside the United States. The company has also assisted business enterprises owned by women and minority groups. JPMorgan Chase has been the winner of many awards, such as Best Investor Service, Best Custodian Corporate Action Services, Best Global Custodian, and Technology Vendor of the Year.

In late 2008 and early 2009, after receiving $25 billion in federal capital from the U.S. Treasury's program to shore up financial institutions and get credit flowing, JPMorgan Chase looked at ways to make payments easier for problem mortgage loan payers who accounted for more than $100 billion in loans.

Kaizen

Kaizen is the Japanese term for continuous improvement and refers to Japanese management practices that aim to lead a company to higher quality and superior performance. The philosophy of *Kaizen* was popularized in the West by Masaaki Imai in his book about Kaizen, which created worldwide interest in the concept. The term itself is not clearly defined, and is often confused with concepts like Kanban system, total quality management (TQM), and just-in-time management (JIT). However, *Kaizen* is neither a single management activity nor a management technique but can be best described as a positive attitude or the philosophy of creating the highest value and quality for the customer. *Kaizen* is performed by making small changes on an everyday basis to improve productivity, safety for all employees, and business process effectiveness while reducing waste. The overall goal is to enhance the quality of products and maximize cost-efficiency and safety of manufacturing processes.

Western corporations started to show an interest in how to implement *Kaizen* in their organizations when Japanese companies were at the height of their economic success during the 1980s. This interest has resulted in *Kaizen* methods being codified in ISO 9000 and Sigma Six initiatives.

Kaizen is a process—not a result-oriented management approach. It is based on two main aspects: First, Kaizen is not restricted to a single management discipline, but rather should be part of every single business process. Second, Kaizen is a continuous process that is supported by all members of a Japanese organization. We can distinguish between two types of *Kaizen*: *Gemba* (actual workplace) *Kaizen* and *Teian* (plan) *Kaizen*. *Gemba Kaizen* is an action-oriented approach; it refers to improvement activities that are performed at the actual workplace, such as on the shop floor or on the manufacturing line. *Teian Kaizen*, on the other hand, represents the theory-based approach and refers to strategic improvements influenced by top management. *Gemba* and *Teian Kaizen* aim at developing higher production and quality standards.

Kaizen is executed in a number of ways. *Gemba Kaizen* methods are quality circles and suggestion systems. In quality circles, a specialized team develops and designs ideas on how to improve the company's performance. Suggestion systems encourage employees to submit suggestions on how to improve work processes and customer satisfaction. Another aspect that is related to *Gemba Kaizen* is the 5S-System: *Seiri* (sort), *Seiton* (setting in order), *Seiso* (clean), *Seiketsu* (systematize), and *Shitsuke* (standardize). *Seiri* refers to discarding items that are unnecessary and keeping only the relevant ones for the production process. *Seiton* describes how all these leftover items are organized. *Seiso* means to clean all these items, as well as the workplace and all other materials used in the manufacturing process. *Seiketsu* refers to making all the cleaning, control, and improvement processes a regular activity at the workplace, and shitsuke means to standardize and sustain the process to support long-term *Kaizen* goals.

The most prominent *Teian Kaizen* methods include total quality control and JIT management. Total quality control is implemented in all phases of the manufacturing or work processes, and is not only result-oriented. JIT management refers to a production system in which all the parts used during the manufacturing process are delivered only when needed at exactly the right time and in the right amount. By doing so, waste is cut and costs can be reduced.

Besides improving quality and safety, another major aim of *Kaizen* is the elimination of *Muda, Mura*, and *Muri*. Muda includes all corporate activities that do not add value to the product or service, such as overproduction, unnecessary movements or worker waiting time, excessive inventory, or unnecessary repairs. *Mura* describes overburdening people or equipment or any other type of irregularity. *Muri* on the other hand refers to unnecessary difficulties during the production process.

Kaizen is not just the task of a special group within a company—employees of all levels, from the CEO down, participate in *Kaizen* activities. However, *Kaizen* can also include outside stakeholders, such as suppliers. When the *Kaizen* philosophy is applied, every single organization member is responsible for the improvement processes.

Kanban

The Kanban system is a version of just-in-time (JIT) inventory management developed by Taiichi Ōno, who initiated his experiments in organizing the flow of production on the shop floor at Toyoda Spinning and Weaving, carrying over his ideas to Toyota Motors. Informing JIT is the supermarket principle. To maximize the economic return, stack wares on shelving; let consumer demand determine what items are stocked. At all costs be flexible—consumers are fickle. Keep inventories to a bare minimum, constantly adjusting your store layout. The pull of actual purchases should be decisive.

As refined by Toyota Motors, the standard model for the Kanban system organizes the flow of production through the pull of final demand for vehicles, the factory working on a short production horizon. To keep inventories at a minimum, produce—or secure from suppliers—components just before they are actually required in assembly. At each component-producing division is a pallet—for instance, outside the room where bolts of various diameters and threading are manufactured—upon which the division places boxes with finished components, upon which empty boxes are placed for it to fill or for another division to fill. Attached to each box is a flag—a *kanban*—indicating what type of part is already in the box—or the type of part to be produced and placed within it—which division has produced the components, and which division requires the components. Facilitating the process whereby the pull of component demand shapes production in each division, small vehicles snake around the shop floor, picking up empty or filled boxes, dropping them off where the parts they will hold are to be manufactured or where these parts already manufactured are to be utilized. Rather than following a rigid schedule for each division within the factory, stockpiling the completed products in warehouses from which they are obtained if and when required, the Kanban system minimizes inventories and potential wastage—of components no longer needed, for instance—letting the pull dictated by the flow of Kanban around the shop floor dictate daily production.

It should be noted that defects are extremely costly in a JIT system like Kanban. If the bolt division produces bolts with the wrong threading, the door assembly division cannot use them, throwing up bottlenecks to the continuous flow of final vehicle assembly. Thus Kanban goes hand-in-hand with building quality directly into each component of vehicles, aiming at achieving a "zero-defect" ideal, a general goal of the post–World War II Japanese automobile industry aiming to sell in both domestic and international markets.

Kanban is more than an engineering system; it is also a human resources management system. Under the logic of JIT, employees monitor each other's performance in the sense that a division receiving poorly produced components from another division knows immediately which group of workers was responsible for the errors, the shoddy output, the misguided machine calibration, and setup.

Kanban is a way to organize production by tying supplies like these auto parts very closely to the pull of actual needs.

Why did this innovative system emerge in the Japan of the 1950s and 1960s? Economic arguments abound. One possible explanation is the small lot sizes characteristic of the industry in the 1950s and early 1960s. A second thesis points to the prevalence of unwritten implicit contracts—between subcontractors and main parent firms—that may stem from the cultural homogeneity for which Japan is famous. Relatively high costs of land in a country in which most of the land area is mountainous—hence expensive warehousing—may have been a factor. A fourth line of reasoning emphasizes the highly internalized nature of large-firm post–World War II Japanese labor markets: Wages being tightly tied to age and seniority—not to occupations or job assignments—binding workers to firms and firms to workers in long-term relationships; unionization being typically organized within enterprises giving both union and management a common interest in improving productivity and expanding market share. In highly internalized labor markets, in which job assignment is largely independent of wages and productivity gains are important to the union, workers embrace flexibility, mastering new skills, practicing rapid machine recalibration in an effort to speed up each division's ability to respond to changing demands placed on it by other units on the shop floor.

Sociologists and anthropologists often point to general features of Japanese society that may have shaped the internalization of labor in postwar Japan: Concepts of Confucianism that stress mutual responsibility and mutual interdependence, and a willingness of individuals to subordinate their own needs to that of groups, especially small work groups and teams.

Kazakhstan

The largest of the central Asian countries, and the ninth-largest country in the world, with a population of over 15.3 million (2008) in a land area of 2,724,900 sq. km, Kazakhstan was a part of the Russian Empire and then the Soviet Union until independence in 1991. It shares borders with Russia, Kyrgyzstan, Turkmenistan, Uzbekistan, and China, and has a significant coastline in the Caspian Sea. During the Middle Ages, the famed Silk Road connecting China with Europe went through Kazakhstan, which was occupied by the Mongols at that time.

During the 19th century the Russian Empire gradually took over the area controlled by the Kazakhs and from the 1890s a significant number of Russians settled in the region, becoming the government and business class. When the Trans-Aral Railway was completed in 1906, there was even more migration from Russia, encouraged by the government. This led to tensions including the Central Asian revolt of 1916. This led to attacks by the Kazakhs on Europeans, and the Tsarist soldiers then took part in a large-scale massacre of Kazakhs, devastating Kazakh society. During the famine that took place in the region from 1921 until 1922, about a million Kazakhs died from complications from malnutrition and from starvation.

The Soviet Union transformed the country, establishing large collective farms and destroying the power of the local elite. From 1926 until 1939, the population of Kazakhs fell by 22 percent. Stalin deported many people, such as the Kalmyks, to Kazakhstan during the 1940s, with the "Virgin Lands" program that saw an enlargement of the agricultural sector. In 1959 the ethnic Russians made up 43 percent of the population, with only 30 percent being Kazakhs. The centrally planned Soviet system led significant investment in the region that was rich in natural resources, particularly oil and natural gas.

With independence in 1991, many companies recognized the great economic potential of Kazakhstan. It had a well-developed industrial sector involved in the production of chemicals, textiles, the processing of food, and metals. Indeed, some geologists claimed that just about every element in the periodic table could be found in the country, with the gold mines there making up 24 tons, or about 7 percent, of the gold production of the former Soviet Union. The mineral sector has been closely controlled by the Kazakh government since independence, and the country remains rich in iron ore, manganese, and also uranium, chrome, nickel, titanium, silver, wolfram, molybdenum, bauxite, and copper. Its coal mines located at Torghay, Qaraghandy, and Ekibastuz produce most of the coal in the country. This has led to a large heavy-manufacturing base. During the 1980s Kazakhstan made up some 11 percent of the military production for the entire Soviet Union, and since independence most of these factories have been transformed to make nonmilitary products.

In 1993 and 1994 the country went through a major economic crisis coming from the separation of their economy from that of the rest of the former Soviet Union. Since then, it has partially recovered. Nowadays, some 30 percent of the workforce is employed in the industrial sector that makes up 40 percent of the nation's gross domestic product (GDP). There are plans to expand this sector with the exploitation of new oil fields that have been found around the country. The existing ones, such as that on the Mangyshlak Peninsula, on the east coast of the Caspian Sea, have already generated great wealth. However, there have been problems over the use of the Russian oil pipeline, which has therefore involved Kazakhstan in the building of a new pipeline to the Black Sea to reduce the dependence of the country on the politicians in Moscow.

In addition to minerals, agriculture has remained a large industry in the country. Agriculture employs about 20 percent of the population, but makes up only 8 percent of Kazakhstan's GDP, well down from 36 percent in 1993. This drop in the agricultural sector has come largely from mismanagement of resources, and also the lack of water. After independence, the government ensured that it kept control of most of the agricultural land, operating it in about 7,000–8,000 collective farms, each being, on average, about 35,000–40,000 hectares in size.

Keiretsu

Keiretsu refers to the Japanese form of corporate organization that involves a grouping or family of affiliated firms that form a tight-knit alliance and work to each other's mutual benefit. They became prevalent after World War II, prior to which the industries were controlled by large family-controlled monopolies called Zaibatsu. The companies were reintegrated after the war through share purchases to form horizontally integrated alliances across many industries. The companies also bought from each other, making the alliances vertically integrated as well.

Keiretsu exist in a wide array of markets, including the capital, primary goods, and components parts markets. The relationships are usually anchored around a bank, and by cross-ownership of equities in companies. The executives of these companies sit on each other's boards, share information, and set prices and overall strategies similar to the operation of cartels. Many have attributed the global successes of Japanese firms in new markets to this system of operation.

Although the divisions have blurred in recent years, the six major industrial groups (and major companies comprising the group) are Mitsubishi (Mitsubishi Electric, Kirin Brewery, Nippon Oil, Nikon, etc.), Mitsui (Fuji Photo Film, Mitsui Real Estate, Mitsukoshi, Suntory, Toshiba, Toyota, etc.), Sumitomo (Asahi Breweries, Hanshin Railway, Mazda, NEC, Sumitomo Real Estate, etc.), Fuyo (Canon, Hitachi, Matsuya, Nissan, Ricoh, etc.), Dai-Ichi-Kangyo (Fujitsu, Hitachi, Isuzu, Itochu, Tokyo Electric Power, etc.), and Sanwa (Hankyu Railway, Kobe Steel, Konica Minolta, Kyocera, Takashimaya, Toho, etc.). Annual revenues for each conglomerate are in the hundreds of billions of dollars.

The major advantage of a Keiretsu system is that the vertically integrated alliances between suppliers and manufacturers are closely integrated, resulting in suppliers receiving long-term contracts. Research has also indicated an optimal balance of supplier and buyer power in these systems and superior discipline down the network. Finally, the use of a just-in-time (Kanban) system also ensures high quality products, a major competitive advantage for most Japanese (particularly the automobile) industries.

The major criticisms of this system include complaints by foreign firms about the collusion of the system with Japanese governmental authorities, who try to protect their local businesses, hence violating antitrust laws. Moreover, the system creates a vertical chain of affective relationships between producers, wholesalers, and retailers that outside firms find difficult to penetrate. Finally, the Japanese channels are longer, more expensive to operate, and complex, thus imposing additional surcharges on the customer because of the inefficiencies—the only reason to continue having them is to exclude foreign competitors.

Even though the Keiretsu system is physically rooted in the Japanese landscape and national character, businesses in other parts of the world like the Tata Group (India) and the Virgin Group (United Kingdom) are described as such, even though these groups exhibit looser equity ownership connections than their Japanese counterparts. Keiretsu in many ways are also similar to Chaebol, or South Korean conglomerates, although current Western conglomerates like General Electric and even pre–World War II Zaibatsu in Japan appear to be more comparable.

Kenya

The Sahara Desert accords the continent of Africa a natural geographical divide into two distinct regions: the northern sub-region and the southern sub-region, also called sub-Saharan Africa. The northern sub-region comprises the North African countries of Morocco, Algeria, Tunisia, Libya, Egypt, Sudan, and Western Sahara. The southern sub-region (sub-Saharan Africa) accommodates 48 countries, of which 42 are mainland countries and six are island countries. These 48 countries are spread across four geographical regions: west Africa, south Africa, east Africa, and central Africa. In west Africa, there are 21 mainland and two island countries; in south Africa, 10 mainland and three island countries; in central Africa, five mainland countries; and in east Africa eight mainland and one island countries.

Kenya is a mainland country in the east African part of sub-Saharan Africa, formerly the British East Africa. Kenya gained independence from the United Kingdom in December 1963. Nzee Jomo Kenyatta was the first president and ruled from the start of independence in 1963 to his death in 1978. In a constitutional succession, Daniel Arap Moi became president in 1978 and reigned for 24 years, stepping down in 2002. During this period, political instability in Kenya grew with ethnically charged, violent, and fraudulent elections in the political process. In fact, Kenya became a one-party state under the ruling Kenya African National Union (KANU), spurring domestic and international political pressure to liberalize the political process. The domestic and international political pressure brought about change and the conduct of free and fair elections that put Mwai Kibaki in power in 2002. However, his reelection bid in 2007 suffered yet another blow characterized by ethnic violence that disrupted economic activity and almost tore the country apart.

Kenya is about twice the size of the U.S. state of Nevada and borders Sudan and Ethiopia to the north, Uganda and Somalia to the west and east, respectively, and Tanzania and the Indian Ocean to the south. Kenya's topography is unique, including highlands comprising the most flourishing farming area in Africa, and Mount Kenya, the second highest peak in Africa. Though the climate is tropical with two major seasons, the dry and the rainy, the interior part is also arid.

The population of Kenya is about 38 million, ranking in seventh position in sub-Saharan Africa. About 55 percent of the population are between the ages of 15 and 64 years, 42 percent are under 14 years, and about 3 percent are 65 years and over. The life expectancy of the total population is about 56 years. Females live slightly longer than their male counterparts do. Infant mortality is higher in males than in females. The literacy level of the population is relatively high, and higher among males than females. However, literacy rate as a measure of human capital has not promoted substantial economic development.

Diversity in Kenya is not as pronounced as diversity in Nigeria, the most populous mainland country in the west of sub-Saharan Africa. While Nigeria has 250 ethnic groups, Kenya has only nine ethnic groups that include Kikuyu, 22 percent; Luhya, 14 percent; Luo, 13 percent; Kalenjin, 12 percent; Kamba, 11 percent; Kisii, 6 percent; Meru, 6 percent; other African, 15 percent; and non-African (Asian, European and Arab), 1 percent. The diversity of the ethnic groups in Kenya has contributed to some dimensions of instability and corruption.

The Kenyan economy is market-based, revolving predominantly around agriculture, services, and private foreign industrial investment. In recent times, agriculture—horticulture and tea—contributed 23 percent and 22 percent, respectively, of the total export earnings. The service sector is dominated by tourism, which contributes 63 percent of gross domestic product (GDP), and the manufacturing sector accounts for only 14 percent of the GDP. The boost in the industrial sector resulted in the inclusion of Kenya in the African Growth and Opportunity Act (AGOA). The AGOA is an American initiative aimed at stimulating trade with African countries.

Economic performance in Kenya has not been steady. From 1963 to 1973, the economy grew significantly, reaching about 7 percent of GDP. However, between 1974 and 2001, economic performance declined overall, showing stagnated, negative, and minimal GDP growth at various points. The inadequate macroeconomic, microeconomic, and institutional policy reforms are responsible for aggravating the decline in GDP. Nevertheless, economic growth improved slightly in 2001. In addition, in 2006 GDP growth reached about 6 percent and 2007 projections about 7 percent, due to reforms instituted by President Mwai Kibaki. However, economic performance in Kenya still faces several growth inhibitors that include dependence of agricultural produce exports on world price fluctuation, unreliable service sector (tourism) due to poor governance and instability promoted by ethnic disunity, industrial export competition, and a continued high rate of corruption. Transparency International ranks Kenya among the most corrupt countries in Africa. These factors influence the Kenyan economic growth negatively, leaving about 50 percent of Kenya's population below the poverty level.

KLSE (Malaysian Stock Index)

The Kuala Lumpur Composite Index (KLCI), recently renamed the Bursa Malaysia, was introduced on the Malaysian Stock Exchange in 1986 to provide a performance indicator for the share prices similar to those that exist on other stock exchanges. Under the British, the colonial power in Malaya (as it was then called), most companies operating in the peninsula were traded on the London Stock Exchange until the establishment of the Malayan Stockbrokers' Association that traded mainly in shares of rubber and tin companies, rubber and tin being the major exports of Malaya. The public trading of shares on the Malayan Stock Exchange started in 1960 when a group of brokers were brought together in Kuala Lumpur, then opened another trading floor in Singapore the following year—the two being connected by telephone and thus being a single market with a single set of prices in both places. In 1964 it became the Stock Exchange of Malaysia, and in the following year (when Singapore became independent), the Stock Exchange of Malaysia and Singapore—remaining as such until 1973 when currency interchangeability ended and the exchange split into the Kuala Lumpur Stock Exchange Bhd. (KLSEB) and the Singapore Stock Exchange.

Prior to the establishment of the KLCI in 1986, the measure of the performance of shares on the KLSEB was shown by the Fraser's Industrial Index. This had its origins in the firm Fraser & Company, a part of the trading group Fraser & Neave, which had been a dominant force in the early days of share-trading in Singapore, and was effectively the stock exchange for Singapore (where shares for British Malaya were also traded) until the establishment of the stock market in Kuala Lumpur in 1960. Because of its history, the Fraser's Industrial Index continued in use for many years.

In 1985, the year before the introduction of the KLCI, the Fraser's Industrial Index for Kuala Lumpur hovered around the 3,000 level as the Malaysian government sought to introduce their New Economic Policy and give members of the Malay ethnic group a greater percentage of shareholdings, with laws stipulating that there needed to be 70 percent local shareholding. In 1987, using the Fraser's Industrial Index, the market fluctuated wildly, running from around 2,800 at the start of the year, up to a peak of 5,500 by the middle of the year, and then back to roughly where it had started by the end of December. This was one of the reasons for the introduction of the KLCI.

Within a couple of years of its introduction, the KLCI was providing a good measure of the performance of the KLSEB, running at levels between 300 and 400. The *Far Eastern Economic Review*, the well-respected Hong Kong–based finance and news magazine, started quoting it regularly, and described it as being "widely watched," largely because it had a far wider base than the Fraser's Industrial Index, noting its movements were in tune with many of those on Wall Street. The magazine in 1989 called the KLSEB the "darling of foreign institutional investors," and also noted that the KLCI was closely following the changes in shares in tin in the country, as well as fluctuations in industrial and commercial stock, far more than shares in companies concerned with property or finance. On August 13, 1989, it reached a peak of 515.09, and was not that much affected by the crash in property stock in August 1990. In 1993 the KLCI reached a peak of 1,275.32, the highest it had reached up to that point.

In 1994 the KLSEB renamed itself the Kuala Lumpur Stock Exchange (KLSE), and in 1995 the KLCI was increased to include 100 companies from the stock exchange's Main Board, which had about 500–650 companies. The 100 were chosen because of their importance in the market, and also because they reflected a range of sectors of the economy. The index is capitalization-weighted; thus, rises or falls in the prices of companies with larger market values have a proportionally greater impact on the movement of the index.

The biggest fall in the KLCI came in 1997 when, during the Asian financial crisis, the index fell more than 500 points in six months. By August 1998, it had fallen to 261.33, the lowest it had ever been. However the underlying economic indicators showed that the country was relatively robust, and it had managed to weather the Asian financial crisis, and by 2000, the KLCI reached 974.38, after a massive surge in share prices through investment opportunities and speculation.

The KLSE was renamed the Bursa Malaysia in 2004, and the KLCI managed to reach 1,000 in November 2006, the highest it had been in six years. Throughout 2007, it rose steadily as the Malaysian economy continued to improve, surpassing its previous record on April 9, 2007, when it closed at what was then its all-time high of 1,298.3. On May 3, 2007, it reached 1,342, rising to 1,386.67 on June 20, and closing at 1,410 on October 29. Since then it fell, including a dramatic 9.5 percent drop after the government faced a major setback in the general election on March 8, 2008—an election that saw its majority in parliament reduced significantly.

Koç Holding

The owner of Koç Holding, Vehbi Koç (1901–96), started his first company in 1926 and later established Koç Holding in 1963 by gathering all his companies together. Employing around 94,000 people and with the largest dealership network in Turkey, Koç Holding currently has operations in automotive and consumer durables (core groups of the holding), financial services, energy, food, retailing, tourism, and information technology industries. Koç Holding was ranked 190th in 2007, 358th in 2006, and 389th in 2005 in the Fortune Global 500 list. Therefore, the company has increased its worldwide performance in recent years.

The current business groups within Koç Holding are as follows. The energy group is very effective and includes many companies. The group holds 51 percent of the public shares of Tupras, the eighth largest oil refinery in Europe; a 50 percent stake in Opet, operating in retail sales, commercial and industrial fuels, lube oil, and shipping; full ownership of Aygaz, the largest liquefied petroleum gas distributor in Turkey; and many other companies including Mogaz, Opet-Aygaz Bulgaria, Entek, Akpa, Demir Export, and Koç Statoil Gaz. The consumer durables group has 15 production facilities in four countries, 16 brands (including the famous Arcelik and Beko), and 39 companies outside Turkey. The group is the market leader with 58 percent share in household appliances, 41 percent share in television sets, and many others in the heating and cooling market. Koç automotive group achieved 45 percent of both total motor vehicle production in Turkey and automotive export in 2006; Ford Otosan (partnership with Ford Motor of the United States), the leading company in the Turkish automotive industry, and Tofas (partnership with Fiat of Italy) are the two key companies of the group.

The finance group is also the leading one in Turkey; it includes Koç Financial Services Group, an equal partner with UniCredit of Italy, Yapi Kredi Bank, the fourth-largest bank of Turkey, Yapi Kredi Leasing, Factoring, Insurance, Koç Allianz Sigorta (insurance company), and Koçfinans. The food and retailing segment includes Migros-Tansas (retail chains), Koçtaş (an equal partnership with B&Q, the largest home improvement retailer in Europe), and Tat (the market leader in tomato paste, ketchup, and tomato products).

History

In the second half of the 1920s, construction activities began in Turkey after years of wars (World War I, 1914–18, and the Turkish Independence War, 1919–22); Vehbi Koç expanded his business toward building supplies and hardware (a strategic and visionary move). Koç decided to institutionalize the company as he believed that one-person companies could not develop much further. In 1938 he established Koç Trade Incorporated by organizing his businesses under one roof. He traveled abroad a lot and saw industrialized countries, which helped enlarge his vision and business abilities and made him understand the importance of partnership with foreign companies such as General Electric, Ford, Fiat, Allianz, Siemens, Yamaha, LG Electronics, and UniCredit Group. These partnerships provided know-how transfers through licensing.

In the 1950s, the corporation undertook its local manufacturing investments to replace imported goods and then produced the first of many locally produced goods in Turkey: light bulbs, cars, tractors, trucks, refrigerators, washing machines, and more. In the 1960s the corporation expanded its product range; such high growth and diversification of the corporation necessitated a new organizational structure. Thus, Koç Holding was established in 1963 and now serves as the decision-making authority that identifies, controls, and coordinates the firm's activities. The holding began exports during the 1970s and its success continues. Vehbi Koç gave his position in 1984 to his son Rahmi M. Koç, who retired in 2003 and was succeeded by his son Mustafa V. Koç, the current chairman.

Koç Holding is a good example of a successful worldwide company that was established, prospered, and thrived through pioneering strategic investments and partnerships enabled by the vision, leadership, and entrepreneurial abilities of its founder and his descendants. The 2006 acquisitions of Tupras, the biggest company in Turkey and the third-biggest oil refinery in the world, and Yapi Kredi Bank, the fourth-largest bank of Turkey, are two recent examples of these visionary strategic investments; the energy group may soon be another core business group of the holding in addition to the current core business groups of automotive and consumer durables.

Korea, South

South Korea, whose official name is the Republic of Korea (ROK), is economically the fourth-largest in Asia, following Japan, China, and India, and 13th-largest in the world based on 2007 data. It is now an Asia-Pacific Economic Cooperation (APEC) and Organisation for Economic Co-operation and Development (OECD) member, defined as a High Income Nation by the World Bank and an Advanced Economy by the International Monetary Fund (IMF) and CIA.

South Korea's rapid modernization is evident in this view of the 14th-century Sungnyemun gate surrounded by development.

South Korea is located at the crossroads of northeast Asia. It lies between Japan to the east, the Russian Far East to the north, China to the west, and North Korea at the borders. Its total population is 48.5 million (2007) and it uses won (KRW) as a currency. Its capital and the largest city is Seoul (10.1 million population), the second-largest metropolitan city in the world. There are several other big cities in South Korea—Busan (3.5 million), Inchon (2.6 million), Daegu (2.5 million), Dajeon (1.5 million), Gwangju (1.4 million), and Ulsan (1.1 million).

The country's total area is 38,462.49 sq. mi. (99,617.39 sq. km) but only 19 percent is arable because of the mountainous and rocky terrain. Its official language is Korean (written form: Hangeul) and it has four distinct seasons a year, representing a humid continental climate. In Seoul, the average January temperature range is 19 degrees F to 33 degrees F, and the average July temperature range is 71 degrees F to 83 degrees F. As of 2005 approximately 46.5 percent of the South Korean population expresses no religious preference. Of the religious people, 29.3 percent are Christian (8.3 percent Protestants and 10.9 percent Catholics), 22.8 percent are Buddhist, and the rest adhere to various new religious groups.

South Korea was established in 1948 after World War II. With the Cold War, the Korean War began in 1950 and was expanded through the involvement of the

United States and the Soviet Union. South and North Korea were finally divided along the 38th parallel after the armistice signed on July 27, 1953. South Korea has since developed a successful democracy as well as a booming economy. Starting as one of the world's poorest agrarian societies in the 1950s and 1960s, Korea developed rapidly, fueled by high savings and investment rates, and a strong emphasis on education. From 1962 to 2007, Korea's gross domestic product (GDP) increased from US$2.3 billion to US$969.9 billion, with its per capita gross national income (GNI) soaring from $87 to about $20,045. Today, its success story is known as the "Miracle on the Han River," a role model for many developing countries.

The direction of Korea's industrial policy changed significantly every decade. From the 1960s, Korea started to promote exports by enacting relevant laws and regulations and establishing export-oriented development plans. The chemical industry was the center of the nation's industrial policy in the 1970s and there was industrial restructuring in the 1980s, aiming at promoting small and medium-sized enterprises (SMEs). In the 1990s South Korea was known as one of the four Asian Tigers with Hong Kong, Singapore, and Taiwan because they were relatively poor during the 1960s, but maintained high growth rates and rapid industrialization between the early 1960s and 1990s. They were evaluated as successful with the help of educational reform and with a cheap, yet productive workforce.

However, in 1997, an accumulation of corrupt business practices and bad loans led to a series of bankruptcies and a massive devaluation of South Korea's currency. In 1998 the Asian economic crisis bottomed out from South Korea. After the Asian financial crisis hit in 1997, Korea took on reforms to bring about a speedy recovery. Korean businesses took the initiative to increase transparency and meet global standards while policies to facilitate startups were put into place. The nation began rebounding in 1999. The country was able to continue its growth toward becoming a major economic power after a swift recovery. Since 2000, innovation has topped the national agenda. To bring about more innovation in industry, Korea has promoted business-friendly policies as well as policies enhancing cooperation between large companies and SMEs, continuing to focus on technology-intensive activities.

International Trade

Korea's trade volume in 2007 amounted to US$728 billion, in contrast to US$230 million in the end of 1948. Korea's export growth depended mostly on trade with advanced countries such as the United States, Japan, and the European Union (EU). With Korea gradually increasing its trade with developing countries, however, the reliance on trade with advanced countries has steadily declined. Korea has signed free trade agreements (FTAs) with 16 countries, including Chile, Singapore, the European Free Trade Association (EFTA), ASEAN, and the United States. Negotiations with the EU, Canada, and India were under way by the end of 2008.

Major import items include industrial raw materials such as crude oil and natural minerals, while major export items include semiconductors, automobiles, ships, consumer electronics, mobile telecommunication equipment, steel, and chemicals. Korea is the largest in shipbuilding, the third-largest in semiconductors, and the fourth-largest in digital electronics in the world. Korean textiles, steel, and petrochemicals are fifth in terms of volume, and automobiles are also fifth in the world. Korea's shipbuilding sector has been the industry leader since 2005, accounting for 40 percent of the world's total shipbuilding orders. With almost 11 percent of the global market share, Korea's semiconductor sector is at the forefront of the industry, particularly in terms of flash memory and DRAM (Dynamic Random Access Memory). In 2006, Korea's DRAM ranked first in the world, with a 49 percent market share and the flash memory chips took up 63 percent of global markets.

Infrastructure

South Korea has a very advanced and modern infrastructure and is a world leader in information technology such as electronics, semiconductors, LCD displays, computers, and mobile phones, led by Samsung and LG. It is the home of the world's third-largest steel producer, POSCO, and one of the world's top five automobile producers, headed by Hyundai and Kia.

South Korea is also the world's most connected "information society" with one of the top rankings in each for internet use, internet penetration, broadband penetration, mobile phone ownership, 3G mobile telecoms, WiFi hotspots, and WiBro (Mobile WiMax) coverage. The South Korean government has pushed very hard for eGovernment initiatives to provide most government services online. South Korea has strong digital infrastructure to support robust e-commerce with a 73.5 percent broadband penetration rate in 2006. It also boasts a thriving local e-commerce economy, with almost 34 million South Koreans online out of 48.5 million. Moreover, the volume of online spending was about $414 billion in 2006. South Korea was the first country in the world to provide high-speed internet access for every primary, intermediate, and high school. The internet is seen as a major facilitator of shopping in South Korea.

Education

Like other highly developed countries, the service sector has grown to comprise about two-thirds of GDP in South Korea. At the same time, living standards and in particular the educational level in South Korea has risen exponentially. Based on data from the United Nations Human Development Report 2007/08, South Korea is rated "High" with a 0.921 on the Human Development Index (HDI), and ranked 26th out of 177 countries. The index indicates a high level of life expectancy (males 75.7 years, females 82.4 years in 2006), literacy (99.8 percent adult literacy rate), education, and standard of living. Education in South Korea is regarded as crucial to success and thus competition is fierce. South Koreans have invested in education as a means toward economic progress.

According to the 2005 annual publication of comparisons in education systems produced by the OECD, South Korea is in first place in terms of the proportion of younger people who have completed an upper-secondary education in the world, with 97 percent reaching this level. In terms of the proportion of population entering higher education, South Korea had a similar pattern in the younger group, which is third behind Canada and Japan in the world.

South Korea is also working toward a peaceful reunification with North Korea. After the Korean War, North Korea and South Korea signed an agreement in 1953 to pursue peace. In June 2000, as part of South Korean president Kim Dae-jung's Sunshine Policy of engagement, a North-South summit took place in Pyongyang, the capital city of North Korea. On October 4, 2007, Roh Moo-Hyun and North Korean leader Kim Jong-il signed an eight-point agreement on issues of permanent peace. Despite the Sunshine Policy and efforts at reconciliation, progress has been slow.

Kuwait

Although very small in territory, Kuwait occupies an extremely important place in global geopolitical and economic discussions because of its natural resources. Kuwait has the world's fifth-largest proven oil reserves and, as such, is the fourth-richest (in per capita income) country in the world. Its importance has grown with rising worldwide demand for oil connected to the economic expansion of China, India, and other developing nations.

Kuwait is situated in the Middle East (southwest Asia). It lies at the northwest corner of the Persian Gulf and is surrounded by Iraq to the north and northwest, Saudi Arabia to the south and southwest, and the Persian Gulf to the east. The capital of Kuwait City serves as the country's political and economic center.

Other major cities are Ar Rawdatayn, Al Jahra, Ash Shuwaykh, As Salimiyah, Az Zawr, and Al Wafrah.

Kuwait is one of the smallest countries in the world (17,820 sq. km). It is mostly desert, with the exception of salt marshes around Kuwait Bay and coastal dunes in the eastern part of the country. It is the only country in the world without rivers, natural lakes, water reservoirs, or mountains. The warm tropical climate is typical of desert regions: Summer (from May to November) is extremely hot and dry with temperatures exceeding 113 degrees F, while winter (from December to February) is cool with average temperatures around 56 degrees F.

Kuwait's population is estimated to be between 3 and 3.5 million people. Interestingly, Kuwaitis are a minority in their own country since approximately 2 million residents of Kuwait are non-nationals. Although they are in the minority, Kuwaitis control political and business life through a freely elected legislature. Approximately 57 percent of the population are Arab, 39 percent are Asian, and 4 percent are classified Bidoon (stateless Arab residents of Kuwait). The population in Kuwait is relatively young, with a median age of 26 years and a population growth rate of 3.6 percent.

Independent Kuwait is a relatively young country. Although evidence shows that Kuwaiti territory has been used as a trading post for centuries, the modern history of Kuwait begins in the 18th century when Kuwait City was established. Ottoman Turks and other Arab groups threatened Kuwait in the 19th century, so Kuwait's ruling Al-Sabah family requested protection from Great Britain. Great Britain protected Kuwait and oversaw its foreign relations from 1899 until 1961, when on June 19, Kuwait became an independent nation. The Al-Sabah family ruled Kuwait from its inception with the exception of Iraq's invasion of Kuwait in the early 1990s (August 1990 until February 1991). Today, Kuwait is a constitutional emirate ruled by princes (emirs) from the Al-Sabah family.

Kuwait has a small and relatively open economy that is dominated by the oil industry. It is a highly industrialized country with per capita income of $55,300. Due to the escalating prices of oil, Kuwait's gross domestic product (GDP) has been growing at around 6 percent, which makes Kuwait one of the fastest-growing economies in the region.

Petroleum accounts for half of Kuwait's GDP and 95 percent of export revenues. The majority of the petroleum industry is state owned and accounts for 80 percent of government income. Although Kuwait has not been diversifying its sources of income as quickly as some of its neighbors (for example, the United Arab Emirates), it has pursued significant investments in construction, banking and financial services, logistics, and telecommunications.

Kyoto Protocol

The Kyoto Protocol to the United Nations Framework Convention on Climate Change is an agreement signed by a coalition of countries worldwide that are committed to reducing emissions and pollution in an international effort to stop the growing threat of global warming. Ratified in 2002, the legally binding agreement will try to accomplish a 5.2 percent cut in emissions without the participation of one of the leading nations on the planet, the United States.

Global warming is an increase in temperature of the Earth's atmosphere that can lead to changes in global climate. While greenhouse gases are necessary to keep Earth at a livable temperature, global warming prevents the heat from these gases from bouncing off the Earth's surface and back into space. Instead, it keeps the heat bouncing back and forth and thus raises the overall temperature of the planet to unsafe levels. These levels could cause terrible storm systems or disrupt the seasons. In the long term, it could lead to flooding of coastal regions of the world.

Noticing the growing problem, leaders of nations from around the world met in Kyoto, Japan, to address this issue. They developed an accord that required each nation to cut its emissions and gases significantly, depending on its own emission levels. The cuts would be apportioned with 8 percent cuts by Switzerland and most of the European Union, 7 percent by the United States, and 6 percent by Canada, Hungary, Russia, Japan, and Poland. These goals were agreed to be met between 2008 and 2012. This would lead to a 5.2 percent cut in emissions by the entire industrialized world. To be a valid treaty, the accord needed to account for 55 percent of the world's emissions. With Russia signing the accord in November 2004, the treaty was validated.

The United States chose not to sign the treaty on the grounds that "the changes would be too costly to introduce and the agreement is flawed." Many nations expected the United States, as a world leader, to sign the accord, President George W. Bush instead created voluntary incentive-based programs for companies to reduce emissions and has created programs to enhance and further climate technology.

President Bush defended his position against the Kyoto Protocol by explaining that complying with its strict rules would result in a loss of $400 billion to industry and 4.9 million jobs to U.S. citizens. Businesses would be forced to retool their factories or simply shut them down, which would both hurt shareholders and the factory workers who lose their jobs. Also, Bush stated that he would not sign a treaty that required only the United States to make some cuts that would, in the end, give smaller countries more power and raise the cost of living for Americans. Following a Reagan-style government, Bush decided that instead of telling American businesses when and how to cut pollution, he would give them a deadline and a goal. He would let them find their own innovative ways to make their cuts so that they can do it in a way less harmful to the interests of their companies.

While much of the industrialized world is adhering to the Kyoto Protocol, some maintain that the Protocol nevertheless will ultimately fail to achieve its objectives if the United States remains uninvolved. Its predictions for a future following the guidelines of the protocol will not be met. If any international effort is made against climate change post–Kyoto Protocol, it will be fashioned in a way that sustains, if not increases, U.S. power throughout the world. Bush set in motion some research in new technology, and when advancements are made, the information needs to be shared with other less prosperous nations.

Labor Standards

Labor standards are multidimensional and vary from country to country depending on national institutions, economic interests, income level, stages of development, openness to trade, and economic, social, political, and cultural conditions. International labor standards refer to those labor principles, norms, conventions, and recommendations that do not depend on national circumstances, and that are intended to be universally applied. These standards cover issues in the areas of employment, work, social security, human rights, and social policy.

International labor standards are generally considered institutional mechanisms for raising the quality of economic growth in developed and developing countries. For that reason, the issue of international labor standards has been given a high profile in regional and multilateral policy discussions and negotiations. In 1996 the Organisation for Economic Co-operation and Development (OECD) published a policy brief that defined and limited a set of core labor standards: (1) prohibition of forced labor; (2) freedom of association; (3) the right to organize and bargain collectively; (4) elimination of child labor exploitation; and (5) nondiscrimination in employment. In 1998 the International Labour Organization (ILO) adopted the Declaration of Universal Principles and Rights at Work, which consists of (1) freedom of association and the effective recognition of the right to collective bargaining; (2) the elimination of all forms of forced or compulsory labor; (3) the effective abolition of child labor; and (4) the elimination of discrimination in respect to employment and occupation. International frameworks, such as the global corporate citizenship initiative Global Compact have adopted the four principles of the ILO declaration adopted in 1998. The rationale behind the adoption of the ILO international labor standards by the Global Compact initiative is that responsible practices by the business community, such as assuming at least a minimum of universal norms in working conditions, are essential for promoting social justice, peace, and prosperity.

Since creation of the ILO in 1919 more than 190 Recommendations and over 180 Conventions have been adopted by the International Labour Conference. The ILO classifies international labor standards into 22 subjects: (1) freedom of association, collective bargaining, and industrial relations; (2) forced labor; (3) elimination of child labor and protection of children and young persons; (4) equality of opportunity and treatment; (5) tripartite consultation; (6) labor administration and inspection; (7) employment policy and promotion; (8) vocational guidance and training; (9) employment security; (10) wages; (11) working time; (12) occupational safety and health; (13) social security; (14) maternity protection; (15) social policy; (16) migrant workers; (17) seafarers; (18) fishermen; (19) dockworkers; (20) indigenous and tribal people; (21) specific categories of workers; and (22) final articles conventions.

Concerns regarding labor issues at the international level, especially in exporting countries, have generally two dimensions: humanitarian and economic. At the humanitarian level, the arguments are around the promotion of universal moral working and living conditions and the search for fairer trade circumstances that include the development of social, labor, and political provisions. At the economic level, the arguments are based on the premise that countries that do not guarantee and enforce at least minimum international labor standards may have an illegitimate competitive advantage in their exports and may result in a global "race to the bottom" in labor and social standards.

Historical Background

The relationship among trade, development, and labor standards has long been interrelated. Generally, in more advanced countries labor standards are policy articulated and legally enforced. The issue of trade and international labor standards precedes the creation of the ILO in 1919. Indeed, the objective of the ILO was to undertake shared actions at the international level to improve labor conditions worldwide. This objective is reflected in the preamble to the constitution of the ILO, which begins:

> Whereas universal and lasting peace can be established only if it is based upon social justice; and whereas conditions of labour exist involving such injustice, hardship and privation to large numbers of people as to produce unrest so great that the peace and harmony of the world are imperilled.... Whereas also the failure of any nation to adopt humane conditions of labour is an obstacle in the way of other nations which desire to improve the conditions in their own countries.

The pioneer of the idea of international labor legislation and the precursor of the ILO was the French manufacturer Daniel Le Grand (1783–1859). Le Grand repeatedly appealed to several European governments for joint legislation on working life and conditions, which are seen as predecessor of the international labor Conventions of the ILO.

Between 1856 and 1857, the private initiative by industrialists that aimed at the protection of workers known as the International Benevolent Congress adopted the motion in favor of collectively drafting international measures for the regulation of industrial labor, which together with the labor movement were the beginning of the internationalization of labor regulations. In 1889 the Swiss Federal Council called on the support of 13 governments to consider a proposal for a convention to internationally regulate working conditions.

Simultaneously the German government organized an international mine and labor conference, known as the Berlin Conference, that took place for two weeks in March 1890. This conference set the recommendations for the prohibition of child labor, Sunday work, regulation of mine labor, women, and young persons' labor. Although no international assurances were formalized, this Berlin Conference was the first time that multilateral recommendations were discussed collectively by governments regarding labor issues.

In August 1897 delegates from 14 countries sat together in Zurich in the first International Congress of Labour Protection, and passed among others a resolution for the creation of an international labor office. Between 1897 and 1919, other meetings with similar objectives took place in both Europe and America. In 1919 at the Paris Peace Conference, the trade unions demanded appointment of a tripartite Commission on International Labour Legislation. The International Labour Organization was brought in effect by Part XIII of the Treaty of Versailles, and declared that "universal and lasting peace can be established only if it is based upon social justice."

The Labour Charter set in the Treaty of Versailles (1919) consisted of nine principles to guide the policy of member states of the ILO regarding labor issues: (1) labor should not be regarded merely as a commodity or an article of commerce; (2) the right of association; (3) the payment of an adequate wage to maintain a reasonable standard of living; (4) an eight-hour day or a 48-hour week; (5) a weekly rest of at least 24 hours; (6) the abolition of child labor; (7) equal pay for equal work; (8) equitable economic treatment of all workers in country; and (9) an inspection system to ensure the enforcement of the laws for workers' protection.

These nine principles were extended in the Declaration of Philadelphia in 1944, giving particular emphasis to (1) labor is not a commodity; (2) freedom of expression and association are essential to sustained progress; (3) poverty anywhere constitutes a danger to prosperity everywhere; and (4) the war against want must be carried on with unrelenting vigor within each nation, and by continuous and concerted international effort in which the representatives of workers and employers, enjoying equal status with those governments, join with them in free discussion and democratic decisions with a view to the promotion of the common welfare.

The Declaration of Philadelphia asserts what is central criteria for national and international policies and measures: "all human beings irrespective of race, creed or sex, have the right to pursue both their material well-being and their spiritual development in condition of freedom and dignity, of economic security and equal opportunity."

Internationalization of Labor Standards

International organizations, such as the ILO and the OECD, have a critical role in setting international labor standards through social clauses in trade-related agreements. The inclusion of labor standards elements in trade agreements such as the European Union and the United States Generalized Systems of Preferences (GSP) are examples of initiatives at the bilateral level. Moreover, labor standards can also be addressed at the regional level through provisions such as the adoption of the "EU Charter of Fundamental Rights" and the labor "side agreement" of the North American Free Trade Agreement (NAFTA). At the multilateral level, examples of initiatives include the linking of World Trade Organization (WTO) membership to ILO membership. In this case, a country trading with another with better labor protections is required to meet the standards of its trading partner. Violators of this principle are subject to WTO sanctions.

Some authors agree that social clauses involving labor issues are best addressed in regional trade agreements such as NAFTA, the European Union, and Asia Pacific Economic Cooperation (APEC) rather than multilateral trade agreements due to the current limited influence of labor on multilateral organizations such as the WTO.

Skeptical views on labor standards as mechanisms to ensure quality of economic growth argue that the moral and humanitarian arguments behind the introduction of nontrade issues into trade agendas is a form of national protectionism and labor exploitation. The view is built on the argument that international labor standards prevent competition from imports from low-wage economies. Another argument, which rests credibility in the International Labour Standards approach, is that they rely on principles rather than rights, and therefore implementation and enforcement depend on voluntarism, consequently they are unaccountable and unstructured. In order to overcome this, there are suggestions for anchoring these principles on follow-up and monitoring mechanisms committed to both improve workers conditions and ensure legitimate competitiveness.

Landed Cost

According to the Institute of Supply Management, landed cost is "the total accumulation of costs for an imported item, including purchase price plus freight, handling, duties, customs clearance and storage to a designated point of delivery." A firm that focuses on the item's initial purchase price alone may significantly underestimate the real cost of acquiring and bringing that item to its final delivery point. Accordingly, when making purchasing decisions, landed cost should be the basis of comparison between potential suppliers of a given item. Firms that do not consider total landed costs may pay potentially more for imported goods than for domestic goods, despite a less expensive purchase price abroad.

When calculating landed cost, a variety of cost issues should be considered. While their specific application will vary by organization and situation, these costs generally include the following:

1. Purchase Price: Base price of the item. This is the starting point for calculating landed cost.
2. Transportation: Additional costs to ship the item to the final point of delivery. This may involve inland transportation within the country of origin, ocean shipping or air freight, and inland transportation in the destination country. Freight forwarding and other handling charges also may apply. With the increased variability present in long, global supply chains, there may be an increased need for expedited shipments using air freight. An estimate of these costs should be included, as it is possible for one unexpected, expedited shipment to negate months of savings from international sourcing.
3. Insurance: Marine insurance or other insurance to cover loss or damage for the shipment. These costs may be higher for imported items due to the additional risk exposure inherent in international shipments.
4. Export and Import: The country of origin may impose export fees and taxes on the items. Similarly, the destination country may require customs duties that vary depending on the type of item and country of origin. Fees for customs brokers to facilitate customs clearance also may be involved.
5. Financial Transactions: Banking fees typically are higher for international transactions. Also, if payment is to be made in a foreign currency, currency exchange costs may be incurred. Furthermore, the buyer may be exposed to currency exchange risks from fluctuations in exchange rates.
6. Inventory and Warehousing: Because of the longer lead times and increased variability typically present in global supply chains, warehousing and inventory costs will increase for items from a foreign supplier. Each day of increase in transit time means a corresponding increase in inventory-in-transit, and larger inventory safety stocks will be needed to cover the higher risk of delays. The result is a significant increase in inventory carrying costs and a potential need for more warehousing space.
7. Administrative Costs: Various indirect costs may be higher for an imported item. There may be an increase in employee travel and communication expenses for evaluating and monitoring the foreign supplier. Foreign language documents may need translation. Additional information technology or software may be necessary for managing a more complex supply chain. Also, because international shipments are subject to increasingly strict security measures, the costs to comply with these measures also should be considered (e.g., the United States's advance manifest rule, and the Customs-Trade Partnership Against Terrorism [C-TPAT] program).
8. Impact on Competitiveness: Though difficult to quantify and include in landed cost calculations, there may be further impacts from working with a foreign supplier that the firm should recognize. The longer lead times from a foreign supplier may result in reduced responsiveness and flexibility in the supply chain. As a consequence, customers demanding fast, responsive service may choose to go elsewhere if their needs are not met by the firm.

Familiarity with International Commercial Terms (Incoterms) is useful for understanding and determining total landed cost. Incoterms are internationally recognized terms of sale that specify what is included in the supplier's quoted price. From this, the buyer is able to determine clearly which additional expenses, such as transportation or customs duties, must be incurred by the buyer in order to bring the item to a designated delivery point. In addition, many software applications are available to help a firm determine the landed cost for an item. Landed cost calculator is a common name for such software applications.

Late Mover

Also called a late follower or a later market entrant, a late mover is a firm that enters a market some time after both the market pioneer(s) and after early follower firms. While there are no set guidelines in terms of the passage of chronological time that clearly differentiate late movers from early movers, it is generally acknowledged that late-mover firms enter markets characterized by significant numbers of existing competitors and, as such, the markets are often relatively mature in terms of growth rate. Kodak, for example, was labeled a very late mover in the inkjet printer market when the company decided to enter this market with its own brand of inkjet printer many years after numerous other firms had established strong footholds in the market. Similarly, the Coca-Cola Company, with its Dasani brand of bottled water, entered the bottled water market quite late in terms of its earlier high growth but nevertheless has found such a timing strategy to be profitable for the firm and a valuable complement to the firm's portfolio of beverage products.

Given that market timing is an important element in firms' marketing strategies—since firms seek to make the most of their limited resources in relation to perceived market opportunities—late movers must often be concerned with being "too late" to market, which can reduce the opportunity available to the firm, as opposed to being "too early" to market, which can waste a firm's resources. The firm that either implicitly or explicitly pursues this particular type of market-follower strategy (where the other type of follower strategy is to be an early follower—entering the market soon after the market pioneer or pioneers) ultimately seeks opportunities to pursue and exploit some form of follower advantage. Specifically, this is typically where the firm's entry strategy enables it to obtain greater economic or behavioral benefits in comparison to those achievable by pioneering firms and earlier follower firms, such as lower-cost product development (as a result of evaluations of the pioneer's new product) or more-effective product positioning (as a result of learning from the pioneer's marketing mistakes).

At the same time, however, late movers must be sensitive to order-of-entry effects, where there are effects on marketing performance that are directly attributable to the sequence of entry of a firm into a market relative to that of competitors. For example, research on frequently purchased consumer goods has found that, as a firm's order-of-entry increases (e.g., the later it enters in relation to competitors), market share, probability of consumer trial, and probability of repeat purchase by the consumer are all observed to decrease.

Given the pros and cons of late following, it is not surprising then that research on follower firms indicates there are both late-mover success stories and stories of failure. Where late movers have been successful, characteristics of the market have often included that the market demand "explodes" around the same time as the late mover enters the market—suggesting that earlier firms, including the pioneers, were ultimately too early to market and/or that there is a technological change or development in the market that enables the late mover to capitalize on the change and introduce an innovative product rather than a me-too or imitation product.

On the other hand, where late movers have failed, there may have been any number of circumstances faced by such firms, such as being up against strong incumbents who, individually or collectively, have depleted the potential market to a point where it is not economically viable for a new entrant to enter. Alternatively, there may be psychological factors at work, such as where the market pioneer has become synonymous with the product category. Still other reasons include that one or more incumbent firms may have found ways to lock in existing customers to such an extent as to make the economic switching costs sufficiently high that they discourage customers from considering switching to the product of a new entrant.

The implication of such findings for late movers is that there are a great many risks associated with later market entry. There may or may not be profitable opportunities to enter a market depending on the characteristics of the market and the firms seeking to exploit them and, as such, it is critical that firms considering such a timing strategy evaluate the circumstances on an ongoing basis. For firms already in the market, there are also implications; such firms should be vigilant for openings in the market that may be profitably exploited by late movers who, by choice or circumstance, ultimately enter markets when such entries may be least expected.

Latin America

While broadly defined by many, Latin America commonly is the region of the world in the Americas where Spanish or Portuguese are the primary language(s). This includes the countries of Mexico, most of Central and South America, Cuba, the Dominican Republic, and Puerto Rico. Often in the United States (and worldwide) Latin America is generically applied to all of the Americas south of the United States.

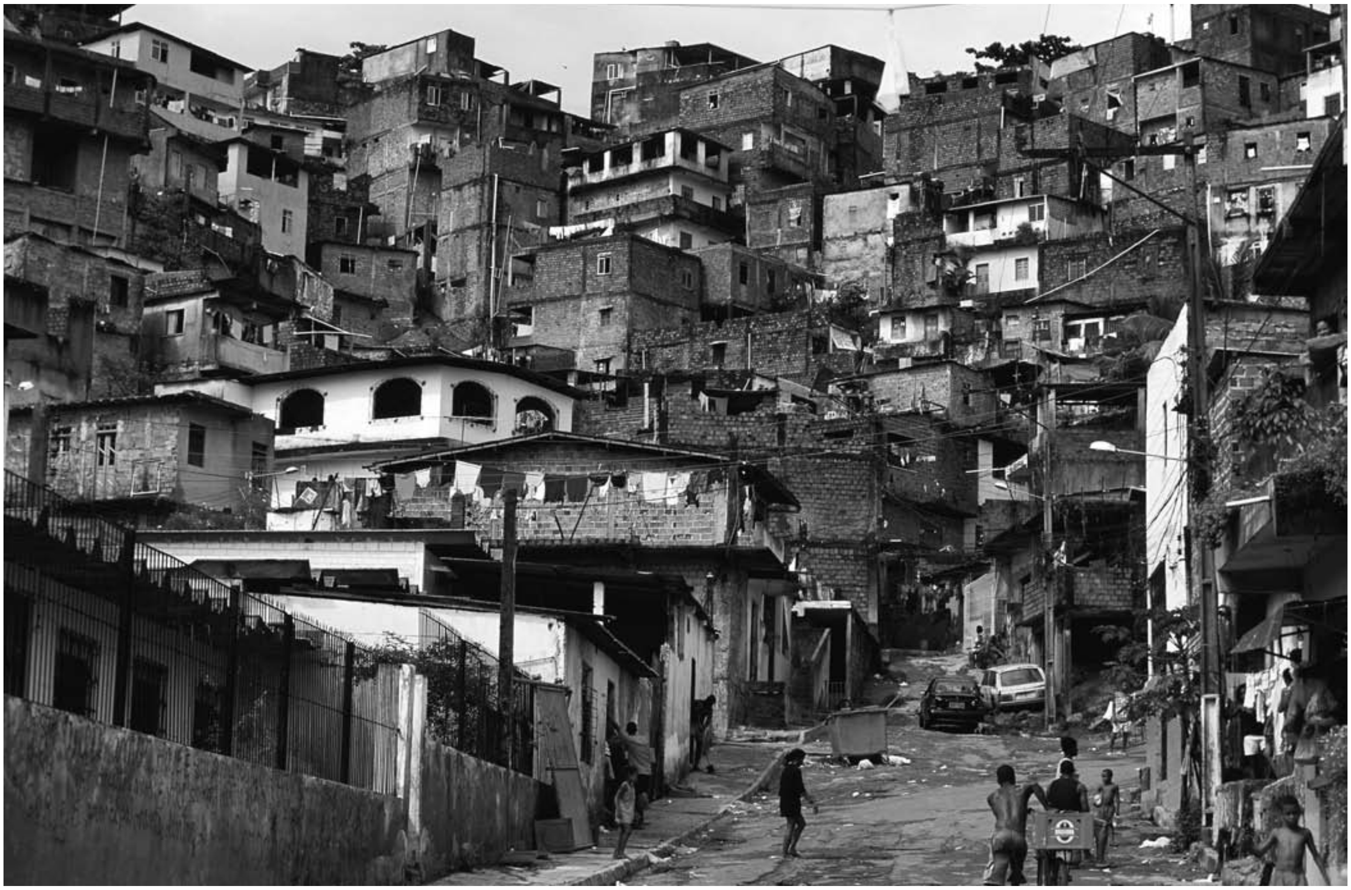
The economies of Latin American countries vary greatly; yet this mostly underdeveloped market is attractive to many multinational corporations. The Gross Domestic Product (GDP) of Latin America is approximately $3.33 trillion with a purchasing power of approximately $5.62 trillion. Marked by explosive growth, Latin America was projected to have an economic growth rate of 5.3 percent in 2006, which was the fourth consecutive year of growth greater than 4 percent.

While Spanish and Portuguese dominate the languages spoken in Latin America, Quechua and Aymara (languages traced to the Incas), Nahuatl and Mayan (languages traced to the Mayans), Guarani (an official language of Paraguay), English, French, Haitian Creole, Spanish Creole, and Dutch are also spoken. Most business transactions take place in Spanish, the most dominant language of the region.

Although official borders of the region are somewhat amorphous, it is commonly assumed that 21 countries and 10 dependencies make up the region. These countries are Argentina, Belize, Bolivia, Brazil, Chile, Colombia, Costa Rica, Cuba, the Dominican Republic, Ecuador, El Salvador, Guatemala, Haiti, Honduras, Mexico, Nicaragua, Panama, Paraguay, Peru, Uruguay, and Venezuela.

French dependencies include French Guiana, Guadeloupe, Martinique, Saint Barthelemy, Saint Martin, Saint Pierre, and Miquelon. Netherlands dependencies are Aruba and Netherlands Antilles. The U.S. dependency is Puerto Rico.

Designed to improve the economic outlook in Latin America, ECLAC (United Nations Economic Commission for Latin America and the Caribbean) was established in 1948 and has its headquarters in Santiago, Chile. This is one of five regional associations created by the United Nations to encourage trade and mutually beneficial relationships among its members.



This favela *(slum) outside Salvador de Bahia, Brazil, is indicative of continuing struggles with extreme inequality even in the most rapidly growing economies of Latin America, which has been called the world's most economically unequal region.*

Several trade blocs also exist within the region. These include Mercosur/Mercosul (regional trade agreement among Argentina, Brazil, Paraguay, and Uruguay founded in 1991) and the Andean Community of Nations (CAN—comprised of Bolivia, Colombia, Ecuador, and Peru founded in 1969). The Caribbean Community, or Caricom, is a customs union for 15 Caribbean countries that provides for free trade in goods between member countries and a common external tariff against nonmember countries.

The Dominican Republic–Central America Free Trade agreement (DR-CAFTA) encompasses free trade among Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua, the Dominican Republic, and the United States. DR-CAFTA and NAFTA (North American Free Trade Agreement) are bilateral free trade agreements that have varying levels of success and have come under some scrutiny in recent years. Although the level of effectiveness of these agreements has come into question, the reciprocal relationships with the United States continue to be fruitful for many multinational corporations.

Although these agreements are in place in an effort to improve the economies of the countries, the United Nations has marked the extreme inequality and poverty that exists in the region. ECLAC notes that this is the most economically unequal region on earth. This report notes that while industries such as technology and information systems have been booming in the region, much of the population does not have access to basic infrastructure and services such as food, water, and sanitation.

Finally, Latin America has been chastised by many for its environmental controls. While some unscrupulous multinational corporations choose to place their facilities in these countries to avoid environmental protection policies and high labor costs in other areas of the globe, there have been efforts in recent years to improve environmental standards. In fact, Uruguay (ranked 3), Argentina (9), Brazil (11), Peru (16), Paraguay (17), Costa Rica (18), Bolivia (20), Colombia (23), Panama (28), and Chile (42) all rank above the United States (45) in the 2005 Environmental Sustainability Index (ESI, developed and published by Yale's Center for Environmental Law and Policy), which tracks elements of environment sustainability including natural resources, pollution levels, and societal capacity to improve environmental performance over time. In 2006 the ESI was replaced by the EPI (Environmental Performance Index). The 2008 rankings show Colombia (ranked 9), Ecuador (22), and Chile (30) in the top 30. By comparison, the United States does not appear in the top 30.

The Latin American economy is incredibly fruitful, bearing $715 billion in 2007. The economy is marked primarily by its heavy focus on manufacturing (where it competes heavily with China) and has experienced rapid growth over the past decade. This period of prosperity is projected to continue through the next several decades.

While growing, the overall performance of the Latin American economy has not reached its potential. Mexico constitutes a huge percentage of the industrial activity attributed to the region. Exports are chiefly agricultural, though some countries (i.e., El Salvador, Costa Rica, Brazil, Mexico) export medium-to-high-technology manufactured products.

Studies on the sustainability of the Latin American economy are mixed. While it has firmly been established that the economies of these countries are growing as a bloc, there remain outside threats (i.e., China's manufacturing prowess) and internal weaknesses (i.e., retention of talent and development of employees) facing the region.

Latvia

Originally founded in 1918, the Republic of Latvia possessed one of Europe's most modern economies and highest standards of living prior to World War II. Upon regaining independence in 1991, Latvia underwent a rapid transition from the centrally planned economy of the Soviet era to a highly modern, free-market, Western-style economy. Developments in the Latvian economy include rapid growth of all economic sectors, particularly the service sector that has become dominant, increased trade and market orientation toward the West, increased foreign investment, and a privatization program that is largely completed.

Latvia became a member of the World Trade Organization in 1999 and a member of both the North Atlantic Treaty Organization and the European Union (EU) in 2004, granting Latvia access to some of the largest markets in the world. Even prior to EU accession in 2004, Latvia had experienced rapid economic growth. Facilitated by stable internal processes and expanding trade, Latvia has led the EU with an average annual growth rate of 8.1 percent since accession. Rapid growth has led to inflation, but increases in income, including minimum salary requirements, and price/interest stabilization have allowed significant growth in standard of living and consumer spending. Approximately 75 percent of Latvia's foreign trade is with other EU members and the importance of EU trade has been consistently expanding. Significant trade also exists with Russia and the United States. Trade between Latvia and its Baltic neighbors Estonia and Lithuania has increased exponentially since entering the EU.

Latvian exports in 2007 exceeded $8.1 billion and consisted primarily of wood products, machinery/equipment, metals, textiles, and agricultural products. Latvia's most important export partners are Lithuania (14 percent), Estonia (12 percent), Russia (12 percent), Germany (10 percent), and Britain (8 percent). Industrial output has been expanding consistently in Latvia, averaging increases of 7.6 percent each year between 2001 and 2005. Important industrial products include vehicles, railroad cars, agricultural machinery, synthetic fibers, appliances, electronics, pharmaceuticals, and processed foods. Leading agricultural products include grain, beets, potatoes, vegetables, meat, dairy products, and fish. The Latvian government is striving to increase exports, a goal that is being realized in part through EU assistance.

Imports in 2007 exceeded $14.8 billion with leading imports including machinery, chemicals, fuel, and vehicles. Principal import partners include Germany (16 percent), Lithuania (13 percent), Russia (8 percent), Estonia (8 percent), and Poland (7 percent). With few natural resources, Latvia is typical of most European countries in its dependency on imports for energy and raw materials. To reduce dependency on energy imports, Latvia has been supportive of exploring alternative energy options including the possible construction of a new regional nuclear power plant in the Baltic States. A negative balance of trade is one of the most pressing issues facing the Latvian economy, but demand for imports including consumer goods is likely to remain high as the discretionary income of Latvians continues to rapidly increase.

Latvia was recently ranked as having the fifth-highest travel and tourism growth rate in the world and the country's transport infrastructure has undergone significant modernization and expansion to better facilitate trade and tourism. Reflecting Latvia's importance as a trade entrepot and break-of-bulk point, the country has three major ports—Ventspils, Riga, and Liepaja—each of which is also a special economic zone offering incentives including lowered taxes and free customs regimes. Ventspils Free Port is one of the busiest in the Baltic Sea region and is among Europe's leading ports in cargo turnover. Latvia is also an increasingly important airline hub with Ryanair, state-owned AirBaltic, and other airlines opening new air routes to an ever-increasing number of major cities globally. Direct flights between Riga International Airport, the leading airport in the Baltic States, and the United States are being planned pending the establishment of visa-free travel between the two countries.

Latvia enjoys many economic strengths. The World Bank ranks Latvia as one of the best countries in the world in which to do business. It is the hub for banking and finance within the Baltic region. Its currency, the lats (LVL), has proven to be one of the most stable in the world since its inception in 1993 (Latvia plans to adopt the euro). The Latvian government has among the lowest levels of general debt within the EU. Volume of foreign investment, mainly from other EU countries, in all sectors of the Latvian economy is increasing, accounting for around 34 percent of annual GDP volume at the end of 2006. Perceived as a stable and hospitable atmosphere for business and as a gateway between Europe and Russia, the Latvian economy is poised for continued growth.

Leadership

Leadership is the process whereby an individual influences a group of individuals to achieve a common goal. Leadership may be defined as a person embodying the will of a group; as a combination of special traits or characteristics that individuals possess enabling them to induce others to accomplish tasks; or as the things leaders do to bring about change in a group. The leadership process involves leaders, those who engage in leadership, and followers, those toward whom leadership is directed.

It is difficult to find one overall definition of leadership, but most definitions of leadership contain the elements found in Ralph M. Stogdill's classic definition of leadership as the process (act) of influencing the activities of an organized group in its efforts toward goal setting and goal achievement. Leadership is a process involving three key elements: influencing others to behave in a certain way; working with people in a group context; and influencing group members in the direction of goal accomplishment. More recent discussion of the notion of leadership tends to highlight the leader as a manager of meaning, focusing on how leaders engage in "sense-making" in the organization. In both cases leadership is seen as a process whereby the leader identifies what is important in the organizational context.

Leadership is in many ways similar to management. Leadership and management both involve influence, entail working with people, and are concerned with goal accomplishment. Nevertheless, the functions of leadership may also be seen as quite different from management. While management produces order and consistency, leadership produces change and movement. In this perspective the primary functions of management are concerned with planning, organizing, staffing, and controlling. The primary functions of leadership are concerned with establishing direction, aligning, motivating, and inspiring people.

Throughout history, several different approaches to leadership have been proposed. An early systematic attempt to study leadership was the trait approach that dominated the scene up to the late 1940s. The trait approach seeks to determine the personal qualities and characteristics of leaders and suggests that leaders are born with special traits that make them great leaders. Among the many traits contributing to leadership identified in this tradition are intelligence, self-confidence, determination, integrity, and sociability.

In contrast to the trait approach, the skills approach emphasizes the competencies needed for effective leadership. While the trait approach implies a belief that leaders are born rather than made, the skills approach implies that leadership competences could be learned. An early work in this tradition is the three-skills approach, distinguishing between three basic personal skills: technical, human, and conceptual. It is important for leaders to have all three skills, but at different levels of the management structure, some skills are more important than others. The important skills for top management are human and conceptual skills, for middle management all three skills are important, and for supervisory management technical and human skills are important. Later models point furthermore to the importance of problem-solving skills, social judgment skills, and knowledge.

A change of focus from the personal characteristics of leaders to their behavior as leaders led to the development of the style approach that was important during the late 1950s and 1960s. In the early work on leadership behavior by a group of researchers from Ohio State University, the empirical studies showed that responses clustered around two general types of leader behavior: initiating structure and consideration. Initiating structure behaviors include organizing work, defining role responsibilities, and scheduling work activities. Consideration behaviors are relationship-oriented behaviors and include building respect, trust, and liking between leaders and followers.

Generally the style approach suggests that leaders engage in two primary types of behaviors: task behaviors, such as facilitating goal accomplishments, helping a group get organized, and giving directions, and relationship behaviors, including taking an interest in workers as human beings and recognizing accomplishments. These two types of behavior may be combined differently by leaders.

Instead of focusing on the leader, the contingency approach shifts the focus toward how situational factors affect leadership. Typically researchers in this tradition will seek to specify the situational variables that will moderate different leadership approaches. Following this perspective, effective leadership is contingent on matching a leader's style to the right setting.

A more recent perspective on leadership can be summarized under the label "new leadership approach," referring to a number of approaches to leadership that emerged in the 1980s that focus on similar themes, although applying slightly different terms to describe the new kinds of leadership with which they are concerned: transformational leadership, charismatic leadership, visionary leadership, or simply leadership. Together these labels reveal a conception of the leader as someone who defines organizational reality through the articulation of a vision, based on a reflection of the organization's mission and the values that will support it. The new leadership approach then depicts leaders as managers of meaning rather than in terms of an influence process.

An important intellectual impetus for the ideas associated with the new leadership approach derives from James M. Burns's distinction between transactional and transformational leadership. Transactional leadership refers to the exchanges that occur between leaders and their followers in which the former offers rewards for compliance with his or her wishes. In Burns's view the effectiveness of such leadership is limited to the implicit contract between leader and followers. The transformational leader raises the aspirations of his or her followers such that the leader's and the followers' aspirations are fused. Transformational leaders are able to engage their followers to achieve something of significance and also to morally uplift them. Charismatic leadership is often described in ways similar to transformational leadership. Charismatic leaders act in unique ways that have specific charismatic effects on their followers. The personal characteristics of a charismatic leader include being dominant, having a strong desire to influence others, being self-confident, and having a strong sense of one's own moral values.

It has been argued that transformational and charismatic leadership were constructs of the late 20th century. The increasingly distributed nature of leadership combined with concerns about the dark sides of charisma has led to attempts to reconceptualize the notion of leadership. Important elements in these post-charismatic and post-transformational leadership models are truly distributed leadership in teams, learning from experience and failure, and leadership practice as more consciously made public and open to challenge and testing.

Lebanon

Lebanon has a liberal economy with free transfer of capital and goods. It is a small and service-based

A technician repairing mobile phones in a shop in Beirut in 2002. Such small businesses are a mainstay of the economy.

economy—services account for approximately 71 percent of its gross domestic product (GDP), which was estimated at $24.6 billion in 2007. The main economic sectors are financial services, tourism, commerce, manufacturing, and agriculture. In particular, agriculture is the main source of employment in rural areas, but it is relatively underdeveloped with inefficient production techniques. As a result, the sector represents only a small portion of the GDP. Main agricultural products include vegetables, potatoes, tobacco, and fruits.

The majority of Lebanese industrial firms are small family-owned entities, concentrated in the capital city of Beirut. Food and beverages are the main industrial subsector, with the highest workforce and number of firms. Other industrial sectors are furniture, textiles, clothing, leather, wood products, and metal goods. Although the industrial sector has significantly recovered since the civil war (1975–90) and regained some of its regional competitiveness, it was badly hit during summer 2006, when a conflict with Israeli forces resulted in the destruction of many factories including dairy, steel, and glass facilities.

As a result of civil war, Lebanon suffered serious physical and infrastructural damage. This led to a boost in the construction sector in the postwar era. One of the major projects was the redevelopment of downtown Beirut. The massive reconstruction program was funded by a substantial amount of external and internal funds, which led to the accumulation of a huge debt. This debt still represents a major drain on public resources. In an effort to reduce the burden of public debt, successive governments sought support from existing creditors and the country's foreign allies. Nevertheless, despite these efforts from the Lebanese government, public debt represents a long-term problem.

Lebanon was regarded as the regional financial hub during the 1960s and early 1970s due to its developed banking sector and particularly its banking secrecy law. However, the sector suffered a slowdown during the civil war, with capital moving outside the country. The sector recovered in the postwar period, with 131 commercial banks operating in the country under license from the central bank (Banque du Liban). These banks are supervised and regulated by the Banking Control Commission. Commercial banks are the main creditors to the Lebanese government, buying high-yield treasury bills and Eurobonds to fund the government reconstruction plan, which makes them highly exposed to public debt. Lebanese commercial banks are expanding regionally in the Middle East and north Africa.

Many investment houses and brokerages were established during the 1990s, offering investment opportunities to wealthy individuals, but they had limited success. The Beirut Stock Exchange, which closed in 1975 due to the outbreak of the civil war, reopened in 1995, and trading started in January 1996. The liquidity is low, and six banks are among the only 11 listed companies. Despite the efforts to regain Beirut's role as a financial center in the region, the process has had limited success due to the growth of many financial centers in the region such as Bahrain and Dubai.

The mild climate of Lebanon and its location on the Mediterranean coast make Lebanon a popular tourist destination, particularly among Arabs from the Gulf region. Tourism, which played a vital role in the Lebanese economy before the civil war, is one of the fastest-growing sectors.

Due to limited agricultural and manufacturing machinery, and lack of mineral resources, Lebanon depends on imported products for economic activities. Main imports include mineral products, machinery, vehicles, chemicals, and oil. According to the Ministry of Economy and Trade, imports were estimated at $11.815 billion in 2007. At the same time, Lebanon's main exports are fresh and processed food, textiles, finished jewelry, paper, and paper products. Exports were $2.816 billion in 2007.

With a reputation for little intervention in economic activities, the Lebanese government always encourages private investment initiatives (local or foreign). In its effort to boost investment in Lebanon, the government created the Investment Development Authority in Lebanon (IDAL) under the Investment Development Law 360. IDAL is entrusted to identify investment opportunities in Lebanon, to assist local and foreign investors in their investment projects, and to provide them with a wide range of investment incentives. Under the Lebanese Commercial Law, companies can be formed either as partnerships or limited liability entities; all Lebanese companies and branches of foreign firms must be registered with the Registry of Commerce. In this respect, Lebanon offers a wide range of investment opportunities across all sectors of the economy, coupled with a moderate corporate tax rate and a multilingual, skilled, and well-educated labor force.

Legal & General Group

Legal & General Group is one of the United Kingdom's leading financial services companies. According to the Fortune Global 500 ranking for 2007, Legal & General Group is the ninth-highest ranked insurance company, although ranked only 162 overall. The company's ordinary shares (stock) appear in the Financial Times Stock Exchange 100 Index (in fact, the company is among the top 50 most traded companies).

The company, with headquarters in London, offers various types of insurance as well as providing pensions. Although British-based, Legal & General has an interest in various European countries as well as in the United States (Metropolitan Life Assurance Company of New York was acquired in the 1930s). It withdrew from Australia in 1998. Nevertheless, approximately 90 percent of Group operating profit (£1,233 million in the last available year) comes from its United Kingdom activities. In addition to its own direct sales through its consultants, the company (as is common in the United Kingdom insurance market) sells its products through its association with numerous banks and building societies. Some interesting statistics regarding the company are that 5.75 million people worldwide rely on Legal & General for their life insurance, pension, investments, or general insurance plans; and almost £250 billion is invested on behalf of investors, policyholders, and institutions.

Personal financial products sold by the company include, on the insurance side, annuities, endowments, and household, auto, health, and life insurance. But the company also offers various types of investments (unit trusts [mutual funds], investment trusts, and investment bonds) and arranges mortgage finance. This last activity is merely one aspect of Legal & General's interest in the property market, since the company also operates one of the largest (110 branches operating nationwide) estate agency/letting franchise businesses in the United Kingdom. Pension interests span pension fund investment management services and group pension bulk purchase annuities.

The company's history is somewhat unusual. Founded in 1836 (the date appears in the corporate logo) by six lawyers in a coffee shop in the City of London (the London Stock Exchange had similar humble beginnings), the business was originally registered as a society, and the fact that its membership was restricted to members of the legal profession was reflected in its chosen name—the New Law Life Assurance Society. When policies became available to the general public (even if membership remained in the same restricted hands as before), the name changed to Legal & General Life Assurance Society, and it became a wholly-owned subsidiary of Legal & General Group plc in the 1970s (following a United Kingdom corporate law initiative aimed at making clearer the distinction between "public" [henceforth a plc] and "private" companies).

In 1999 Legal & General announced an ambitious plan to link up with NatWest (formerly National Westminster) Bank in what would, had it been successful, have been the United Kingdom's first "bank-assurance" company. However, though market reception to the deal was so poor that the initiative had to be abandoned (NatWest was subsequently taken over by the Royal Bank of Scotland), the subsequent acquisition of the Scottish Widows' Life Assurance Society by another United Kingdom High Street bank (this time Lloyds/TSB) indicated there was nothing wrong with the underlying concept per se.

Like many other companies, Legal & General is today anxious to establish its sustainability credentials. It is thus a member of the Dow Jones Sustainability World Index, the FTSE4Good Index, and (since 2006) the Dow Jones Sustainability STOXX Index. The company has also been placed in Business in the Community's Corporate Responsibility Index and was second in its sector in the 2006 Business in the Community Index. Legal & General's marketing paper now exceeds half recycled content (saving over 10,000 trees per year) and the company's corporate social responsibility engagement program now includes social and ethical issues, and supporting guidelines, to influence its key suppliers. More than one in eight employees now contributes to the company's Give As You Earn charity support scheme.

Legal & General has been judged Best Life Assurance Provider (by *Professional Advisor* magazine); Life Assurance Provider of the Year (in the *Financial Advisor* Life & Pensions Awards); and Best Service Provider (the *Lifesearch Protection* Awards). The company attributes its outstanding success to its

> clear and consistent strategy and … a wide range of value-for-money products backed by strong technical skills, excellent administration, multi-channel distribution and a customer service ethic.

Legal Environments

Firms, as societal entities, operate in particular economic, political, and legal environments. The legal environment is a result of legislative intervention by the government (state) and the positive practices that are recognized and sanctioned by the positive law. Historically, the legal environment has usually been nationally defined, although scholars have tried to group legal systems into various groups, based on their similarities and dissimilarities.

A student of this topic would usually argue that there are two basic groups of legal systems, which traditionally have been opposed: the Anglo-Saxon (Anglo-American) model and the continental European law. However, although both main systems of law may have their distinctive features listed, in fact there are far too many convergences in recent times. In the past the common law (Anglo-Saxon) model would be predominantly based on the precedents, and the continental European law would be primarily based on the codifications. But, there is ever-increasing legislative activity in the Anglo-Saxon countries, with a number of codifications taking place as judiciary may uphold the consistency of court practice. In either system, a judge may take a stance to create a precedent, but the sources of precedent would differ significantly.

Anglo-Saxon Versus Continental European Models

Growing empirical literature has attempted to prove the overall superiority of the Anglo-Saxon model. Although it is evident that economies of Anglo-Saxon countries may be doing comparatively better than the others in the long run, it is not empirically corroborated that the growth sustained over a period of time may be directly attributed to the features of the legal system (legal environment). Legal systems, although they may be classified into larger groups, are basically heavily influenced by national colors and experiences of legal development, especially in revolutionary environments (when there is abrupt change in the development).

Scholars studying legal environments would focus more, nowadays, on judiciary independence from the state and the politicians. It is believed that if the judiciary protects consistently property rights, even from the state, the results of development will be better, and in the case-law system, judges historically have been more prone to uphold the sanctity of private property rights. Ex post judging is far better in responding to local information, rather than the application of abstract law, regulating the principles.

However, increasingly the common law countries are resorting to promulgating laws and codices, in order to better capture different areas of law. In the United States, the Uniform Commercial Code (UCC) is probably the best example. The growth in legislative activity may also be seen as a sign of upcoming struggle between judiciary and legislative power for predominant societal influence. Most recently the discussion on "political delegation" would suggest that it is necessary to subsume, at least formally, all institutions of the state to the highest democratically elected body in the country (assembly, parliament, etc.), although that body is controlled exclusively by the politicians. The literature has also defined a common law system as one in which judges exercise discretion to decide cases in independent and/or adaptive lawmaking ways, while in continental European countries the state would control judicial outcomes and the content of law as well.

The basic premise of change between the two wider legal groups has been the perception as to what extent the judicial practice may influence the future legal decision taken by the court. It is a fact that in Anglo-Saxon countries precedents are a source of law and they have to be regarded in the future when the act is required in a similar situation. However, although in the continental European legal system judiciary practice is not a formal source of law, judges take into consideration the prior practice in order to ensure consistency in acting in the court and the country.

In comparative law, the literature is quite often focused on a set of five parameters, like (1) judicial incentives; (2) exogenous legal human capital; (3) the processing of litigant information into judicial error–reducing legal human capital; (4) the cost of producing evidence and legal arguments; and (5) the penalties (damages) levied in adjudication.

Judicial incentives may be influenced by the way their independence is defined. Often in the analysis judicial independence features highly, especially as it is believed to be an important feature of the Anglo-Saxon model, which contributed to its better results. In the U.S. model, over 80 percent of serving judges are subject to some kind of election, reelection, or recall voting. But even in the United States the upper echelons of judiciary are dependent on politicians who decide on their promotion to the highest offices. Similarly, in the continental European countries, the government may have a strong say in appointment of judges, especially in the case of higher courts. However, the very path of professional progression differs between European (especially French) and U.S. judges. In Europe, judges are often career civil servants, who have opted for the judiciary profession almost immediately upon graduation from the university; in the United States, judges are appointed from among practicing lawyers who have had more than 10 years of professional experience.

Comparative analysis of independence has shown more than a puzzle—judges should be independent, but the question is from whom? And, if one is independent, does it mean that he or she is also unbiased (objective)? Often it is assumed that judges, if not appointed by the government directly, will be critical of the government and look at the breaking of law made by the government in an unbiased manner. However, empirical research does not corroborate this claim. Some judges are more independent and unbiased in the way they operate than others, but it cannot be generalized as to what contributes to that.

Another important feature is the relationship between precedents and statutes. Anglo-Saxon law is believed to be based on a set of more or less harmonious precedents (*stare decisis*), while the continental European legal practices are based on the interpretation of law and the application of the abstract legal (statutory) rule to a concrete situation. However, even in the latter case there is a high level of consistency in judiciary practices, as the higher courts have the right of cassation and therefore for the performance of judges it is important that their decisions not be annulled and/or modified by the higher court. Therefore, even in the continental European legal systems, court practices are consistent, that is, *jurisprudence constante*.

At the far end, the issue is primarily behavioral—whether the judges will be expansive or rather conservative (narrow) in their apprehension of laws. Some recent empirical research has clearly shown consistency of judicial behavior across various systems. However, de jure legal practice is not a formal source of law in continental European legal systems, but, as already pointed out, will be seriously considered in the process of application of law. In both systems the vast majority of judges will opt not to rock the boat.

Career Paths

Another important feature of these two main groups of legal systems that has already been mentioned is the career path in either of the systems. In the continental European system the judges follow the clear career path from a judicial trainee in lower courts to the position in the higher courts, including the Supreme Court. Although there are mid-career entrants from the legal profession, it is fairly rare to have those transfers. However, transfers from the judge's chair to the bench are more frequent, especially in the situations where there is a public distrust in the judicial system or endemic economic crisis. There are attempts in both systems to objectivize the appointment of judges and base their direct promotion on merit. In France, a complex panel decides on the appointments of judges, and the panel is chaired by the president and consists of the corresponding ministers and others, mainly appointments from the judiciary.

In contrast, in both the United States and Canada, judges are appointed only after a somewhat long and distinguished professional career, usually as a practicing lawyer. In either system the politicians are still in a position to influence the appointment of new judges/justices, with more or less interference, However, it seems that the principles of political delegation are gaining good soil, and it is to expect that judges will be more often appointed by "independent" panels, and their promotion will be based upon their performance results and personal zeal to succeed. One feature certainly remains to be noted. In the Anglo-Saxon practice there is a well-established process where judges are exposed to collegial referee procedures (peer review).

Courts

In various jurisdictions the courts are organized in their own way—for instance, in France, specialization for particular court cases (administrative court, family court, etc.), while generalization is more specific for the United States, although the situation is changing. Nevertheless, there are opportunities to reconcile these two factions. In the United States, it is believed that appellate specialization has, in fact, led to a somewhat biased position of the court, especially in patent cases, where this specialization in the Federal Circuit has led to an overly pro-patent orientation. More generalized courts may be more active in the competition for cases, that is, attracting jurisdiction and therefore ensuring more effective and efficient behavior under the outside influence.

Further on, the systems differ in how they handle court-released information. It is possible to have an environment in which all the interested parties disclose much information or simply feed the judge with the information he or she may need. A judge who is more under (immediate) public scrutiny may behave in a manner that he or she will carefully weigh the need for changes in the existent practices before committing to the change in the practice and new precedent being deliberated. In contrast, the judge or a Supreme Court justice who is not known to the broader public may be more enticed to make a decision that would depart from the current practice, especially if the welfare loss or gain is a zero-sum game.

Procedural elements are also very important in contrasting legal regimes. Namely, procedural elements do influence judicial incentives and direct engagement in the procedure before the court. An Anglo-Saxon, i.e., Anglo-American, model of adversarial justice requires a judge to be an unbiased referee as both sides present the facts and try to establish the truth. The judge in turn is not expected to actively look for other evidence. In contrast, the continental European model requires a judge to be an active participant in the procedure and to actively seek truth, and may require the presentation of facts in order to establish proof.

Similarly, the use of jurors differs between the systems, although in principle jurors are used almost exclusively in criminal cases. In the Anglo-Saxon model the jury decides guilt, while the judge as a professional does the sentencing, usually well after the case before the jury has been completed. In the continental European model, jurors often sit with the presiding judge as a member of the panel and decide on the major issues by majority vote. Even the concept of the jury has changed over time. In the past jurors were chosen because they were familiar with the case, and nowadays the court looks for full impartiality of jurors.

Legal environments/legal systems differ from country to country and to a large extent they may have shown some signs of convergence, but in fact they remain largely national, belonging more or less consistently to the legal groups we have outlined here.

Lenovo

Lenovo, originally known as Legend Group, is one of the largest personal computer (PC) manufacturers in the world. It employs more than 25,000 people and has more than 66 overseas branches, operating in more than 166 countries across six continents. Lenovo is the best-known brand in China and Asia, with $164 billion annual turnover in 2007.

Legend was originally established in 1984 by 11 Chinese computer scientists with initial capital outlay of RMB 200,000 (US$25,000), headed by Lenovo’s founding chairman Liu Chuanzhi. In 2003 the company changed its official business name from Legend to Lenovo. As the most respected Chinese technology company, Lenovo offers a range of product categories, including personal computers, networking products, software and peripherals, mobile handsets, and other digital products. Its award-winning Think products (Thinkpad notebooks, Think-Certer desktops, etc.) have been ranked as premium-brand leaders in the global PC industry. As the leading technology company in China’s information technology (IT) industry, Lenovo commands more than one-third of the PC market in China, 7.6 percent of market share in the world. According to Gartner’s marketing report, Lenovo is ranked the fourth PC seller in the world compared to HP, Dell, and Acer, with market shares of 18.3 percent, 14.9 percent, and 9.5 percent, respectively, in 2007.

Lenovo’s development can be divided into three significant stages: initial development (1984–93), domestic growth (1994–2003), and going international (2004–). In the early 1980s, China experienced significant changes both politically and economically. Information systems and technology development became the fastest growth areas in China. With 11 employees, Lenovo began selling foreign computers to Chinese customers. Its initial entrance into the PC market was as a sales agent of IBM. Slowly, the company began to grow by developing and commercializing its own IT products. In 1988 Lenovo launched its own brand of personal computer and established its Hong Kong branch. After nearly 10 years of initial development, Lenovo completed its role change from a sales agent to a computer manufacturer.

Between 1994 and 2003, Lenovo entered its rapid domestic development era. The company realized that the Chinese PC market was not yet captured by major international players, such as IBM, Compaq, or even Acer. Very quickly, Lenovo decided to develop and retail PCs at a low cost to Chinese customers. This strategy made Lenovo a huge success. In 1996 Lenovo became the market share leader in China for the first time and commanded 27 percent share of the PC market in China by 2003. In 1994 Lenovo was listed on the Hong Kong stock exchange and became a constituent stock of the Hang Seng Index in 2000. After 20 years of development, Lenovo successfully became a leading brand in the IT industry and an important player in China and Asia. In 1999 the company was ranked in the Chinese national top 100 electronic enterprises and became the top PC vendor in the Asia-Pacific region. In 2000 it was ranked in the top 10 of the world's best-managed PC vendors.

After holding the leader position in Chinese and Asian markets, Lenovo aims to expand its business internationally to succeed in the long term. Acquiring IBM's Personal Computing Division was a milestone in the history of Lenovo's international expansion that made it China's "go global" star. On December 8, 2004, Lenovo announced acquisition of IBM's PC business with US$650 million in cash and US$600 million common stock. This strategic alliance gave Lenovo's customers preferred access to IBM's world-class customer services and enabled Lenovo to take advantage of IBM's powerful worldwide distribution and sales network. The business transaction with IBM made Lenovo the world's third-largest PC business with approximately US$12 billion annual revenue for 2003.

The success of the company is also highly correlated with its emphasis on technology innovations. Lenovo is the first Chinese company to introduce PCs to households in China and first developed the Legend Chinese Character Card that could be used to translate English operating software into Chinese characters. This pioneering innovation has affected the lives of millions of Chinese and received the highest National Science-Technology Progress Award in China. Additionally, Lenovo's three research centers—China, Japan, and the United States—have produced many world-class advanced PC products. The company now holds more than 2,000 patents and has won hundreds of technology and design awards. Its extraordinary research and development capability has distinguished Lenovo from its competitors.

Leontief Paradox

Wassily W. Leontief (1905–99) was the first scholar to empirically test the predictions of the Heckscher-Ohlin (H-O) theorem, one of four main results of the H-O model (credited to Eli Heckscher and Bertil Ohlin). This theorem establishes a relationship between a country's abundance of factors of production, the intensity with which these factors are used in production, and the country's trade patterns. It builds on the principle of comparative advantage and states that countries will tend to export those goods that use relatively intensively their relatively abundant factors of production. In other words, a country that is relatively abundant in, say capital, will tend to export goods that are relatively capital intensive.

Leontief conducted a test in 1953 of the predictions of the H-O theorem, for which he utilized 1947 input-output data for approximately 200 industries in the United States. A stylized fact about the post–World War II economy, and 1947 in particular, was that the capital-to-labor ratio in the United States was higher than in any other country. According to the H-O theorem then, U.S. exports in 1947 would, on average, be more capital intensive than imports. In order to test this prediction, Leontief aggregated industries into sectors and used the input-output data to similarly aggregate factors of production in these sectors into two general categories: labor and capital. Using these data, he then calculated estimates of the capital and labor requirements for the production of the typical bundle of exports and imports in 1947.

What Leontief found was in contradiction to the trade pattern predicted by the H-O theorem: U.S. export industries were on average less capital intensive than import-competing industries in 1947. This contradiction became known as the Leontief paradox.

Responses

Since the publication of Leontief's paradoxical results in 1953, a voluminous body of both theoretical and empirical literature has emerged on the subject. From this literature, several responses to Leontief's paradox can be useful in interpreting the validity of the H-O theorem. The first of these criticizes the choice of data. The argument is that 1947 was not a normal year because the global economy was still recovering from World War II. Leontief's response to this criticism was to conduct a second investigation in 1956 using 1951 trade data. His paradoxical findings persisted.

A second response to the Leontief paradox is anchored in the classification of factors of production into two broad categories: labor and capital. This criticism has given rise to the generalized factor-endowment model that takes into account many subvarieties of capital, land, and human factors, and recognizes that factor endowments change over time as a result of technological endowments. Specifically, economists have argued that capital needs to be viewed more broadly to include highly skilled labor as a form of (human) capital. This can help to partly explain Leontief's results: exports that were relatively labor intensive can be reinterpreted as relatively human-capital intensive and not necessarily intensive in the use of unskilled labor.

Another response to the Leontief paradox has centered on the role of imperfect competition. The argument here is that trade provides a larger potential market for products, making higher production levels possible (economies of scale), which leads to increased efficiency and competitiveness. This can further help explain Leontief's paradox: even though the United States was capital abundant, imports of capital-intensive goods could have been the result of economies of scale achieved by foreign producers that gave them a comparative advantage even if their nation was actually labor (not capital) abundant.

Finally, the role of demand characteristics has also been identified as a potential response to the Leontief paradox. While the H-O theory does well in predicting trade driven by supply conditions (such as trade in natural resources), it does not do as well in predicting the patterns of trade in manufacturing goods that are influenced by domestic demand conditions. The Linder hypothesis (after Staffan Linder) expanded on the H-O theorem by distinguishing between supply and demand characteristics as determinants of trade. If nations have similar per capita income, then they have similar tastes, i.e., they will have overlapping demand structures.

Linder's hypothesis predicts that nations with similar demand structures are likely to both import and export similar types of manufactured goods. Linder's contribution can further explain the Leontief paradox: U.S. trade with similar-income countries implies trade in similar goods, i.e., capital-intensive goods made in the United States can be traded for capital-intensive goods made in other countries. For example, intra-industry trade describes much of U.S. export and import patterns today.

In conclusion, Leontief's paradoxical conclusion has inspired numerous attempts to replicate his work with data from other periods and countries. Modified forms of Leontief's test continue to be examined today and continue to be a standard method for the analysis of trade. Although the H-O theory has undergone many refinements, empirical tests have generally produced mixed evidence in support of this factor endowment theory (and the H-O theorem in particular). Thus the best way to think about the H-O theory is as one that explains a portion, rather than all, of the determinants of trade.

Less Industrialized Countries

Less industrialized countries are those that are also sometimes called developing countries, and can include emerging economies and failed states. These terms have essentially replaced the older Third World or Global South labels, but there is no strict agreement on the right way to distinguish between the advanced and industrialized nations and the rest of the world. Every framework of vocabulary used for such distinctions presents its own problems, or develops certain connotations that fall out of favor.

The First, Second, and Third World

As the new world order came into focus in the years following World War II, economist Alfred Sauvy coined the term *Third World*—echoing the *Tiers Etat* ("Third Estate"), the French commoners who "had nothing and wanted to be something" in the days leading up to the French Revolution—to refer to those nations that were neither U.S.-allied (the First World) or Soviet-allied (the Second World). As the term came into common usage, it was sometimes criticized for a perceived implication that this "third" world was an afterthought, one less important than the first two—when in fact the use of "third" in the term reflected only Sauvy's desire to compare those countries uninvolved with the Cold War to the politically active peasantry. A French writer writing in a French magazine (the August 14, 1952 issue of *L'Observateur*) for a French audience, he knew his meaning would be understood; as the phrase became adopted and used for decades outside the context of that essay, this "thirdness" came to seem less innocuous.

Though it was true that most of the countries that did not take sides in the Cold War—or at least had not done so in 1952—were less developed and less industrialized, than those of the First and Second World, Sauvy's emphasis was on their political neutrality. In time, that underdevelopedness instead became the key characteristic of anything referred to as "Third World," to such a degree that after the early 1960s, when Americans became aware of the devastating extent to which poverty had taken hold in parts of their own country, it became fashionable and politically expedient to refer to "Third World living conditions" when describing impoverished neighborhoods or social groups. While understandable, the usage further eroded the usefulness of the "Third World" category in discussions of global politics.

Attempts were made to rejigger the term, though. Hungarian-British economist Peter Bauer, wishing to update the term to reflect the conditions of the world around him in the 1980s, just as Sauvy had written of those conditions in 1952, defined the Third World not as a politically neutral segment of the globe or a political remainder, but as that part of the world that sought Western aid—regardless of the country's political sympathies or economic policies.

The North-South Divide

Another schema sometimes used to discuss the world and its groups of industrialized and less industrialized countries is the "North-South divide," which reflects the general tendency during the Cold War of the developed countries—the First World and much of the Second—being located in the Northern Hemisphere, while developing countries were in the Southern Hemisphere. This map only works if you ignore New Zealand and Australia, and the fall of the post-Soviet states has further muddied it, but for all its imperfections it is an interesting way to describe the world. Unlike the First/Second/Third World model,

Women hauling firewood in Bangladesh, where the female literacy rate was only 31.8 percent in 2003. Literacy is one of the factors used by the United Nations to determine a country's Human Development Index rating.

it describes not a political allegiance but a state of development.

It is true, even in the 21st century, that most of the countries with the highest scores on the Human Development Index are in the north; most of those with the lowest are in the south. Willy Brandt, the Chancellor of West Germany in the 1970s, proposed that the line dividing north from south was roughly 30 degrees north latitude, putting Africa and India in the south but dipping in order to include New Zealand and Australia in the north.

Developing Countries and the Human Development Index

The term *developing country* came into use to refer more or less to the same countries as the Third World did, those of the "global south," and is used more or less synonymously with "less industrialized." While "less industrialized" describes a current state, "developing" describes an ongoing process, as well as the implication that developing countries are in the process of becoming developed ones, and that those countries that are already developed represent a sort of goal or role model.

Development entails industrialization, stability, infrastructure, and a reasonable standard of living. Developing countries fall behind the curve in one or more of these areas. The United Nations developed the Human Development Index (HDI) as a way to measure development, by looking at education, gross domestic product per capita, literacy, and life expectancy and converting these into a single figure. The index has been used since 1990, and its prevalence has helped fuel the popularity of the "developed/developing" description of the world's countries. It has been criticized from the start, though, for not really offering much information; it is debatable whether an HDI rating correlates strongly with a high quality of life, and if not, exactly what it reflects.

Least Developed Countries and the Fourth World

The French Revolution etymological origins of Sauvy's *Third World* coinage were completely shorn off when the term *Fourth World* came into currency in the 1970s, though the original usage did stay consistent with his use of *Third World*. As originally coined, the Fourth World consists of stateless nations: those nations, peoples, and ethnic groups that have no autonomy but exist under the thumb of other nations. Native Americans were the notable example in the 1970s, a time when the success of the civil rights movement had led to activism for improved rights and living conditions for the Indian reservations in the United States, and other reforms in the government's dealings with native tribes. Indigenous and aboriginal peoples in other countries may also be included, as well as the Palestinians displaced by the creation of Israel, and the Roma.

In time, the Fourth World usage was extended by some to include the Least Developed Countries, a United Nations designation for those countries that suffer from significantly low income ($900 per capita), profound economic vulnerability in the form of instability or other problems, and weak human resources as indicated by poor average health, nutrition, and education. Only two countries classified as Least Developed have ever graduated from the list—Botswana in 1994 and Cape Verde in 2007—a testament to the difficulty of escaping pronounced poverty with insufficient resources. A decision on the graduation of Samoa has, as of 2009, been pending for several years.

The Least Developed Countries often have some special vulnerability that has been holding them back and prevents or slows what those in developed countries would consider the normal pace of development. Political corruption can have extensive consequences in this area, for instance, and easily becomes an institution that the "man on the street" is so accustomed to that he no longer objects to it to a degree proportionate with the real harm it causes. The type of government may be hostile to development, particularly in the case of dictatorships or rule by warlords, a condition that still persists in much of sub-Saharan Africa. Unresolved civil wars and prolonged ethnic fighting are similarly destabilizing. Often many of these conditions are simultaneously true, in addition to extreme poverty, special challenges because of the physical conditions of the country, and a poverty of natural resources.

Currently the 49 Least Developed Countries are: Afghanistan, Angola, Bangladesh, Benin, Bhutan, Burkina Faso, Burundi, Cambodia, the Central African Republic, Chad, Comoros, the Democratic Republic of the Congo, Djibouti, Equatorial Guinea, Eritrea, Ethiopia, Gambia, Guinea, Guinea-Bissau, Haiti, Kiribati, the Lao People's Democratic Republic, Lesotho, Liberia, Madagascar, Malawi, Maldives, Mali, Mauritania, Mozambique, Myanmar, Nepal, Niger, Rwanda, Samoa, São Tomé and Príncipe, Senegal, Sierra Leone, the Solomon Islands, Somalia, the Sudan, Tanzania, Timor-Leste, Togo, Tuvalu, Uganda, Vanuatu, Yemen, and Zambia.

Landlocked Developing Countries and Small Island Developing States

The United Nations recognizes two special categories of less industrialized countries, classes of countries that face special challenges: the Landlocked Developing Countries (LLDCs) and Small Island Developing States (SIDS). Because of their lack of access to the sea, the high cost of transportation, and their resulting isolation from the world, LLDCs are more constrained in their options than other developing countries. They must move their goods through other countries just to reach a port—still a critical trading concern even in the age of the airplane and the automobile. Sixteen of the 30 LLDCs, just over half, are also on the Least Developed Countries list. In many cases, the route to the sea is perilous and unreliable, for reasons of terrain, banditry, or both. LLDCs spend twice as much of their export revenues on transport as other developing countries (on average), and three times as much as developed countries. It does not help that most LLDCs—as opposed to the landlocked countries of Europe—are surrounded by other developing countries, and thus the transportation infrastructure in use to reach the sea is resource-intensive and inefficient.

SIDS face the opposite problem. As islands, their access to resources is narrow, and their transportation costs extremely high, putting the benefits of economies of scale out of reach and making import goods prohibitively expensive while simultaneously making it difficult to offer competitive prices on export goods. Because of import costs, it is especially difficult for SIDS to export manufactured goods that require nondomestic components. The cost of energy and basic infrastructure is also high, and most islands are especially vulnerable to natural disasters. SIDS tend to experience more economic growth volatility than other countries, and are highly reliant on the public sector.

The UN's list of LLDCs is: Afghanistan, Armenia, Azerbaijan, Bhutan, Bolivia, Botswana, Burkina Faso, Burundi, the Central African Republic, Chad, Ethiopia, Kazakhstan, Kyrgystan, the Lao People's Democratic Republic, Lesotho, Macedonia, Malawi, Mali, Moldova, Mongolia, Nepal, Niger, Paraguay, Rwanda, Swaziland, Tajikistan, Turkmenistan, Uganda, Uzbekistan, Zambia, and Zimbabwe. Until the graduation of Botswana, Swaziland was the only African LLDC which was not also a Least Developed Country. The list of SIDS is American Samoa, Anguilla, Antigua and Barbuda, Aruba, the Bahamas, Bahrain, Barbados, Belize, the British Virgin Islands, Cape Verde, the Commonwealth of Northern Marianas, Comoros, the Cook Islands, Cuba, Dominica, the Dominican Republic, Fiji, French Polynesia, Grenada, Guam, Guinea-Bissau, Guyana, Haiti, Jamaica, Kiribati, Maldives, the Marshall Islands, Micronesia, Mauritius, Montserrat, Nauru, the Netherlands Antilles, New Caledonia, Niue, Palau, Papua New Guinea, Puerto Rico, Samoa, São Tomé and Príncipe, Singapore, St. Kitts and Nevis, St. Lucia, St. Vincent and the Grenadines, Seychelles, the Solomon Islands, Suriname, Timor-Leste, Tonga, Trinidad and Tobago, Tuvalu, the U.S. Virgin Islands, and Vanuatu.

Heavily Indebted Poor Countries

The International Monetary Fund and the World Bank have since 1996 maintained a Heavily Indebted Poor Countries program that makes low-interest loans available to countries with unsustainable levels of external debt. To be eligible for the program, a country must be in a situation of unsustainable external debt and have an established track record of poverty reform.

As of 2009, the program recognizes 41 countries as "potentially eligible" based on their debt situation. Of those, 23 are at the completion point: Benin, Bolivia, Burkina Faso, Cameroon, Ethiopia, Gambia, Ghana, Guyana, Honduras, Madagascar, Malawi, Mali, Mauritania, Mozambique, Nicaragua, Niger, Rwanda, São Tomé and Príncipe, Senegal, Sierra Leone, Tanzania, Uganda, and Zambia. Eleven are at the decision point: Afghanistan, Burundi, the Central African Republic, Chad, the Democratic Republic of Congo, the Republic of Congo, Guinea, Guinea-Bissau, Haiti, Liberia, and Togo. Seven are pre-decision point: Comoros, Eritrea, the Ivory Coast, the Kyrgyz Republic, Nepal, Somalia, and the Sudan. These "points" refer to the stages the program takes a country through. Pre-decision point countries are not yet ready to enter the program but have the potential to become eligible if they initiate a system of legal, economic, and financial reforms. Decision point countries receive debt relief funding while carrying out those reforms, which they must do satisfactorily while maintaining economic stability, in order to reach the completion point, at which point benefits extended to the countries become permanent.

The program has been criticized for adopting too arbitrary a definition of "unsustainable"—at inception, it was defined as debt which exceeded 200 percent the amount of the country's exports or 280 percent of the government's revenues (later changed to 150 percent and 250 percent respectively). Originally intended as a six-year program of two three-year phases, it quickly became clear that not enough time had been allotted to get these countries back on track. The international organizations' expectations may have been too heavily informed by the administrators' own experiences as citizens of wealthier, healthier nations. Impoverished countries, like impoverished people, do not easily spring back from debt, especially when the conditions that necessitated the debt persist.

Further, even low-interest loans can continue to contribute to the "poverty trap." As discussed at length by Columbia University economist Jeffrey Sachs, the poverty trap occurs when an entity reaches a certain level of poverty at which sustainable economic growth is impossible. Though potentially true of people, it is especially useful to describe the condition of significantly impoverished countries, in which sustainable economic growth is impossible both within that country—the poor remain poor, because no programs

The landlocked country of Mali in west Africa ranks among the world's 49 least developed countries. In 2008 the American company Hallmark placed one of Mali's largest handicraft export orders ever, employing this man and 220 other Malians.

exist to improve their station in a meaningful way or such programs are too corrupt or inefficient—and for the country as a whole. Such countries are unable to effectively provide health care, education, or basic social services, and typically have economies that are unfavorable to foreign investment.

Because the population increases so quickly, a country that is significantly impoverished will experience a decline of per-capita resources with each successive generation; debt relief and other foreign aid that is insufficient to counterbalance this has little long-term effect on a country's poverty and external indebtedness, and the lack of apparent improvement resulting from such aid can discourage organizations from extending further aid, since they can feel they are throwing money down a well. While charities rightly say that "every little bit helps," on a macroeconomic level, countries in need of aid that receive only a "little bit" will simply have their poverty prolonged rather than repaired. Citizens of wealthy nations tend to be intuitively unaware of this, in part because the poor of their own countries have access to significantly greater resources and there is more opportunity for economic mobility.

Sachs's solution to this is to make sure foreign aid is spent in specific, sustainability-focused, ways: on public health and nutrition, education, infrastructure (sanitation, water and power, roads), and "institutional capital" (to fight corruption in the government, judicial system, and law enforcement administrations). The HIPC program admits that it cannot guarantee sustainability and avoid the poverty trap, and puts the burden of doing so on the countries the program serves.

Failed States

A special type of developing country, the failed state is one which has ceased to develop or has significantly retarded development because of some critical failure of responsibility on the part of its government. Often this means an inability to participate as a member of the international community, either because of the distractions of internal strife or a simple unwillingness. Basic public services may not be provided by the government, or it may have become unable to make or enforce collective decisions. It may have lost control of its territory to paramilitary groups, civil war, bandits or warlords, or other forces.

At the end of 2008, the list of failed states maintained by the American think tank the Fund for Peace included 177 countries in some state of failure or at risk of failure. The twenty worst (in increasing order of severity of failure) were Sri Lanka, Nigeria, Lebanon, Ethiopia, Uganda, North Korea, Haiti, Myanmar, Bangladesh, Guinea, the Central African Republic, Pakistan, the Ivory Coast, Afghanistan, the Democratic Republic of Congo, Iraq, Chad, Zimbabwe, the Sudan, and Somalia. All of these except Sri Lanka and Lebanon had been in the 20 worst the previous year, and in most cases had been at the top of the list since its inception in 2005.

Millennium Development Goals

In 2001, the United Nations adopted eight goals of international development (with specific targets) which had been established at the Millennium Summit the previous year:

1. To eradicate extreme poverty and hunger, halving between 1990 and 2015 the number of people who earn less than a dollar a day or who suffer from hunger; and achieving full employment levels for all.
2. To achieve universal primary education by 2015.
3. To promote gender equality, and eliminate gender disparity at all levels of education by 2015.
4. To reduce child mortality, reducing mortality by two-thirds between 1990 and 2015 among children under 5 (such mortality in many parts of the world stemming from malnutrition and treatable illnesses).
5. To improve maternal health, by ensuring universal access to reproductive health care by 2015 and reducing by three quarters between 1990 and 2015 the number of women who die in childbirth or while pregnant.
6. To combat HIV, malaria, and other major diseases, by halting their spread by 2015.
7. To ensure environmental sustainability.
8. To develop a global partnership for development, a goal that should inform the design of the worldwide trade and financial system, and which should result in special assistance for the least developed countries.

192 United Nations member states and a score of international organizations made the pledge to pursue these goals.

Letter of Credit

A letter of credit (LC) or documentary credit is a means of payment in a trade transaction that commits the issuer, usually a commercial bank, on behalf of its customer, a buyer, to pay a seller contingent on documentary evidence that the seller has met the terms and conditions of the letter of credit. A letter of credit is commonly used in international trade. A seller (exporter) who does not wish to risk nonpayment by a buyer (importer) may require the issuance of a letter of credit by the buyer's bank as a condition of the sale. In a letter-of-credit transaction, the issuing bank's credit risk is substituted for the credit risk of the buyer that is otherwise assumed by the seller whenever transactions are conducted on open account terms. The letter of credit serves as a method of payment when informational asymmetries exist about the buyer's capacity to pay.

Process

A commercial letter-of-credit transaction involves six steps: (1) after a sales contract has been negotiated that requires a letter of credit, the buyer or applicant applies to its bank to issue the letter of credit, committing the bank to pay the seller or beneficiary upon the receipt of specified documents, such as a bill of lading and a draft drawn by the seller demanding payment, before the expiration of the letter of credit; (2) the issuing bank then requests a correspondent bank in the seller's vicinity to advise the seller that a letter of credit has been issued in its behalf; (3) and (4) upon this advice from the advising bank, the seller arranges to ship the goods and then submits the required documents called for in the letter of credit to a local bank that serves as the negotiating bank, receiving and examining the documents for compliance with the terms and conditions of the letter of credit and then forwarding them to the issuing bank; (5) the issuing bank also examines the documents for compliance and then honors its commitment to pay once it is satisfied that the terms and conditions of the letter of credit have been met; and (6) the issuing bank arranges for repayment from its customer, the buyer, in return for the documents that allow the buyer to take possession of the merchandise. In practice, the negotiating bank may pay the seller immediately after confirming that the documents comply and either debit the issuing bank's account immediately or await its repayment.

The documents that a letter of credit requires the seller to deliver vary but commonly include a transport document, such as an ocean or marine bill of lading, issued by the shipping company to the seller. The billing of lading serves as a receipt for the goods and also conveys title to them. Another is a draft or bill of exchange that is drawn by the seller on the buyer or buyer's bank, demanding payment of the amount specified in the letter of credit. Other documents that may be required in a letter-of-credit transaction include a commercial invoice, certificate of origin, packing list, inspection certificate, and insurance documents.

Virtually all letters of credit are irrevocable; once issued, they cannot be changed or canceled without the agreement of the buyer and seller. Letter-of-credit payment terms vary according to the negotiated sales contract and are reflected in the draft drawn by the seller. A sight draft calls for immediate payment while a time draft defers payment into the future but rarely beyond 90 days. Additionally, the seller may wish to have added assurance of payment by requesting its local negotiating bank to commit to making the payment in the event the issuing bank does not by adding its confirmation to the letter of credit.

Governance

The use of letters of credit, which is estimated to account for 15 percent of the world's trade transactions, is governed by the Uniform Customs and Practice for Documentary Credits (UCP), established in 1933 by the International Chamber of Commerce to harmonize practices across member countries. The latest revision, UCP 600, effective in July 2007, was intended to simplify and clarify the practices governing the use of letters of credit, which continues to be critical to facilitate trade when informational asymmetries about the creditworthiness of customers persist.

LG

LG is a leading family-owned business conglomerate, called a *chaebol*, in South Korea. It was the first chaebol to adopt a holding company structure in 2001. The member companies carry out varied businesses including electronics, chemicals, and telecommunications. LG Electronics is the central company, placing special emphasis on overseas markets, and has established a global network of production and marketing.

LG is the fourth-largest chaebol, with 36 member companies and assets of 57.1 trillion Korean wons (some $57.1 billion) as of April 2008. Since its inception in 1947, LG has been controlled by the Koo and Huh families, and, from 1995, governed by Bon-Moo Koo, the third-generation owner and group chairman. The member companies numbered 50–63 in 1987–95, but they have gradually decreased since 2005, to less than 40. This was because, in the process of LG's transformation into a holding company in 2001–05, many member companies constituted two separate chaebols, called GS and LS, which were controlled by, respectively, the Huh family and part of the Koo family.

At the top of the new LG is LG Corporation, the holding company that was created to take over the shareholding function from LG Chemicals in 2001. In December 2007, LG Corporation had 14 "son" companies, including three main companies—LG Electronics, LG Chemicals, and LG Telecom—which, in turn, had 16 "grandson" companies. The holding company supervises its subsidiaries regarding performance, investments, long-term strategies, and other key managerial decisions, and has the ownership of the "LG" brand, which replaced "Lucky-Goldstar" in 1995. The company is fully controlled by Bon-Moo Koo, who is the dominant shareholder, a representative board member, and the chief executive officer.

Subsidiaries

The member companies of LG invested worldwide to establish a total of 176 subsidiaries for manufacture and sale in 49 countries by 2007. There are 89 subsidiaries in 15 Asian countries (including 49 in China; five each in India and Taiwan; four each in Indonesia, Japan, and Singapore), 48 in 20 European countries (12 in Netherlands; six in Poland; four each in Germany, Russia, and the United Kingdom), 34 in 10 American countries (18 in the United States; five in Mexico; four in Brazil), and five in four African countries. Sales generated in 2007 by 150 domestic and foreign affiliated companies of LG totaled some $76.3 billion, 52 percent of which was foreign sales.

The flagship company in LG is LG Electronics. Its sales for 2007 amounted to some $23.5 billion, which was more than double that by LG Chemicals and more than five times that by LG Telecom. LG Electronics earned 37 percent of the sales from mobile phones alone, among more than 25 products, and 24

LG's leading company, LG Electronics, had 2007 sales of $23.5 billion, of which 72 percent was in exports.

percent from three others—television (10 percent), air conditioners (8 percent), and refrigerators (6 percent). The majority (72 percent) of the total sales was by export, and 85 percent of mobile phones and 42–57 percent of the other three products were sold in foreign countries.

International Sales

LG Electronics has increasingly become interested in world markets and, by 2007, created 74 subsidiaries in 42 countries, which accounted for 42 percent of all the group's member companies. Among them are one holding company in the Netherlands, 34 subsidiaries for manufacture or research in 13 countries (13 in China; three each in Thailand, Vietnam, Mexico; two each in India, Indonesia, Brazil; six in France, Kazakhstan, Poland, Turkey, Egypt, Morocco), and 39 subsidiaries for sales or service in 34 countries (three in the United States; two each in China, the Netherlands, and Ukraine; 15 in Europe; seven in the Americas; six in Asia; and two in Africa). The company also has 28 offices or centers for sales, service, or research in 21 countries.

Sales generated in 2007 by LG Electronics and its 112 domestic and foreign affiliated companies amounted to some $53.4 billion, 81 percent of which was foreign sales. LG Electronics has put emphasis on new technology and, recently, design, and increasingly spent money on research and development (R&D): 4–4.2 percent of sales in 2002–03; 5–5.4 percent in 2004–05; 4.2 percent in 2006; and 6.6 percent (some $1.6 billion) in 2007. For R&D, the company operates 17 centers in Korea and 18 organizations in 10 countries (four each in China, United States; two each in Japan, Russia; six in India, Israel, France, Germany, UK, Brazil).

LIBOR

LIBOR, or London Interbank Offered Rate, is the interest rate at which banks in London will lend large-denomination Eurocurrency deposits to other banks for specific maturities. LIBOR is the ask price in a bid/ask spread interest rate quotation. The bid price is LIBID, or London Interbank Bid Rate. LIBOR can refer to any interbank lending rate offered on short-term Eurocurrency deposits but generally the term refers to the reference rate established by the British Bankers' Association (BBA).

Since January 1986 the BBA has set a daily reference LIBOR or BBA LIBOR. Each London business day, interbank offered rates from eight to 16 reference banks, as determined by the BBA, are assembled for 10 major currencies. To calculate BBA LIBOR, the middle two quartiles of the compiled quotations lending rates for a specific currency and maturity are averaged. The averaged rates are then distributed each morning to market participants through such business news services as Reuters and Bloomberg.

For the various maturities LIBOR is quoted on the basis of a 360-day year except for quotations for British pounds, which use an actual 365-day year. Currently the BBA distributes 150 daily rates each day reflecting 15 maturities that range from overnight to one year in the 10 currencies. BBA LIBOR serves as a benchmark or base rate for the pricing of an estimated $350 trillion in loans, derivatives, and other financial products around the world, including interest rate swaps, floating rate notes, syndicated loans, and adjustable rate mortgages.

Origins and Development

As a rate on Eurocurrency or offshore deposits, LIBOR originated with the Eurodollar market in the post–World War II era. Avoidance of U.S. government regulation that then prohibited the payment of interest on short-term dollar deposits and placed ceilings on interest paid on longer-term deposits is credited with spurring the development of the Eurodollar market. Subsequent restrictions on capital outflow from the United States in the 1960s led to its further growth.

The oil shocks in the 1970s and the resulting increase in offshore dollars are also cited as important contributors to the emergence of the Eurodollar market. Because the interbank market for Eurodollars became centered in London, the world's leading financial center second only to New York, the term LIBOR arose for quotations in this market. Subsequently similar terms have arisen for interbank offered rates in other international financial centers, such as SIBOR in Singapore and BIBOR in Bahrain.

One explanation for the growth of the Eurocurrency market is greater efficiency in that market because of less regulation and lower deposit intermediation costs as well as significant economies of scale in operations. As a result, LIBOR is a competitive funding rate or cost of funds for banks. Arbitrage, profit-seeking through the simultaneous buying and selling of (near) equivalent financial instruments to exploit price discrepancies across markets, ensures that LIBOR on U.S. dollars tracks such close equivalents as the overnight U.S. federal funds rate and U.S. certificates of deposit. However, these rates are not complete equivalents. Lower LIBOR costs due to greater operational efficiency in the Eurocurrency markets may be offset by the risks inherent in an unregulated banking market without a lender of last resort or deposit insurance.

The Treasury-Eurodollar Spread

U.S. dollar LIBOR has also been found to have a long-term equilibrium relationship with rates on U.S. Treasury bills (T-bills) for equivalent maturities with LIBOR exceeding T-bill rates by a relatively stable spread due to the existence of greater risk on LIBOR borrowings. This difference between LIBOR and T-bill rates, specifically 90-day rates, is a financial market indicator known as the TED (Treasury-Eurodollar) spread that is used to measure financial market liquidity and credit risk. Historically the TED spread tends to average below 0.5 percent or 50 basis points, with greater spreads seen as indicators of a lessening of confidence in banks and the financial system.

In 2007–08 during the subprime financial crisis, the accuracy of BBA LIBOR as a benchmark rate was called into question. There were reports that reference banks had been understating their LIBOR rates in order to appear more liquid than they were in reality. The BBA agreed to investigate and subsequently announced measures to better ensure the reliability of BBA LIBOR.

Libya

After two decades of isolation, Libya has reemerged as an extremely fertile investment opportunity for several reasons. First, Libya has historically been Europe's gateway to Africa and an ideal steppingstone to enter emerging markets on the African continent. Second, after years of isolation, Libya is making investments in its infrastructure an attractive scheme for foreign investors. Third, Libya has great potential to become a leading tourist destination, with the longest coast on the Mediterranean (1,700 km), a great historical heritage, and a very attractive climate. Finally, Libya holds the largest oil reserves in Africa and the ninth-largest oil reserves in the world. This is essential in the context of geopolitical and economic discussions occurring around the world since the demand for oil is high.

Libya is officially known as the Great Socialist People's Libyan Arab Jamahiriya and is situated in north Africa. It lies south of the Mediterranean Sea, between Egypt to the east, Sudan to the southeast, Chad and Niger to the south, and Algeria and Tunisia to the west. The capital city of Libya is Tripoli on the coast of the Mediterranean Sea. Other major cities are Banghazi, Surt, Zawarah, Ghadamis, Sabha, Tobruk, and Al Jawf.

Libya is the fourth-largest country in Africa with almost 700,000 sq. mi. (1.8 million sq. km). Ninety percent of Libyan territory is desert with a dry and hot climate. Climate along the Mediterranean coast is warm during the summers and rainy during the winters.

Libya is one of the least densely populated countries of the world, where 90 percent of the population lives in less than 10 percent of the area. Most inhabited areas are along the coast and urban centers, with more than 50 percent of the population residing in Tripoli and Benghazi. Approximately 6 million people—indigenous Berbers and Arabs—live in Libya. The population in Libya is young with a median age of 23 years and more than 50 percent of population younger than 15. Population growth rate is 2.2 percent.

Independence

Until fairly recently the peoples of Libya have been subjected to the control of foreign powers. Phoenicians, Greeks, Romans, and Ottomans left their imprint on the history and landscape of Libya. During the first half of the 20th century (1911–43) Libya was controlled by Italy. After Italy was defeated in World War II, Libya was put under the protectorate of the United Nations. Libya declared independence on December 24, 1951.

In 1969 a small group of military officers led by Muammar Al-Qaddafi overthrew King Idris, abolished the monarchy, and proclaimed the new Libyan Arab Republic. Al-Qaddafi emerged as the chief of state, a political role he still occupies today. Libya's confrontational foreign policies and support of terrorism in the 1980s led to increased tensions and consequent sanctions by the West. In 1999 Libya surrendered two suspects in the 1988 Pan Am 103 bombing and in 2003 publicly announced its wish to stop producing and storing weapons of mass destruction. These two events contributed to lifting the sanctions against Libya, with the West once again seeing it as a potential political partner and a recipient of future foreign investments.

Economy and Liberalization

The discovery of large oil reserves in 1959 enabled Libya to transition from one of the world's poorest countries to one of the wealthiest in Africa (per capita gross domestic product [GDP] is $13,100 [PPP]). Today the Libyan economy depends almost exclusively on revenue from the oil sector. Oil sector revenues contribute around 95 percent of export earnings, 60 percent of public sector wages, and 25 percent of GDP.

Libya is on a path to liberalize its command economy and transition to a market economy by applying for World Trade Organization (WTO) membership, reducing subsidies, and starting a privatization process. However, the liberalization process is not without obstacles. Despite efforts to encourage private sector participation, extensive controls of prices, credit, and trade constrain growth in Libya. Access to food and water are additional problems. Currently Libya imports 75 percent of all food and only around 30 percent of the population have access to safe drinking water. Despite these obstacles, Libya's potential is immense. It is home to a welcoming and well-educated population, valuable natural resources, and natural beauty that could assure growth in years to come.

Licensing

Licensing is generally considered a contractual arrangement or transaction in which one organization, called the licensor, permits the use of its intellectual property by another organization, called the licensee, in return for a fee or royalty payment. To grant a license is to permit the use of intellectual property. The term *license* also refers to the legal document detailing the grant and usage of the license. The British term for license is spelled differently: *licence*.

The exchange process in licensing involves the sharing of intellectual property. The World Intellectual Property Organization defines intellectual property as the creations of the mind: inventions, literary and artistic works, and symbols, names, images, and designs used in commerce. Intellectual property has two categories: industrial property and copyright. Industrial property includes inventions that are patented, trademarks, industrial designs, etc. Copyright relates to literary and artistic works such as novels, films, music, or architectural designs. Generally, intellectual property includes copyrights, patents, and trademarks but could also refer to specialized creations of the mind such as circuit layout or plant breeding.

Copyrights, patents, and trademarks are actually three different types of creations, each having its own legal framework. Intellectual property is a generalized term commonly used to denote all of these by lumping them together, but care should be taken to differentiate among them as they have separate legal frameworks, connotations, and implications.

Intellectual property draws its legal implications from physical property. Just like physical property can be owned legally and the owner can derive benefit by using that property, intellectual property can also be owned and the owner can derive benefit from his or her effort. When an individual, group, or agency invests in the creation of something new that could have commercial implications, they have a right to exploit the advantages of their efforts. Licensing provides the legal framework for letting the creator of intellectual property possess the exclusive legal right to derive benefit from his efforts and for the user of that intellectual property to pay for its usage. Thus licensing becomes the legal instrument to enable the creator and user of intellectual property to enter into a mutually beneficial arrangement. When anyone uses somebody else's intellectual property without having a license to use it, then it is illegal because that infringes upon the rights of the creator. However, critics of the concept of intellectual property argue against granting exclusive rights to creators, suggesting that it results in intellectual monopoly and intellectual protectionism leading to harming of public interest at the expense of individual rights. Further, the critics cast doubt on the claim that protection of intellectual rights really benefits the creators.

Licensing becomes especially important in the case of high-technology industries such as information technology, telecommunications, pharmaceuticals, or power generation. There are several reasons for this importance: high technology accounts for a substantial share of economic activity, many low-technology industries such as agriculture turn into high-technology businesses as technology advances, and high-technology products are entering into a wide range of businesses. Ownership of technical standards in high-technology industries becomes a source of competitive advantage for companies in those industries. Battles to set and control technical standards in high-technology industries are known as format wars.

Companies hope to gain competitive advantage against their rivals by having the ability to develop high-technology products and processes. This can happen only if they have exclusive rights over the high-technology products and processes they create. Licensing provides the legal means of ownership of the intellectual property that goes into creating those high-technology products and processes. By possessing the legal rights of ownership over standards and formats, companies can license them to other companies. The company that helped to pioneer those standards and formats stands to gain economically through the license fees that flow back to it. An example of the use of licensing in high-technology industries is that of Dolby, which used its ownership of the technological standards in noise-reduction technology for the music and film industries. It charged a small licensing fee for letting recording companies use its technology and foregoing such fees on media recorded using Dolby technology. This helped the company keep out rivals who could have developed their own, possibly superior, technology.

Licensing is of special importance to organizations that operate internationally. International licensing is a contractual arrangement in which a foreign organization, the licensee in this case, purchases the rights to utilize another organization's (the licensor in this case) intellectual property for a negotiated fee or royalty payment. If the intellectual property in this case is the product design, then the licensee can buy the rights to produce that product in its own country. The royalty payment can be negotiated on the basis of the number of products sold in that country.

Organizations contemplating implementation of international strategies think of an option to enter a foreign market. These options are the several modes of entry such as exporting, franchising, joint ventures, strategic alliances, and wholly-owned subsidiaries. Licensing is also considered among the significant modes of international entry and is an important element of the strategies of many international companies.

When used as a mode of entry into foreign markets, licensing involves little cost. This is so because an organization that has already invested in the creation of intellectual property only has to look for more opportunities outside one's own country to utilize it. If it can license that intellectual property to some other organization and earn revenue, then it is additional income at practically no extra investment. By licensing, an organization extends the usage of its intellectual property without any significant risks.

There are four basic issues in international licensing: (1) specifying the agreement boundaries; (2) determining compensation; (3) establishing rights, privileges, and constraints; and (4) specifying the duration of agreement. When entering into the licensing agreement, the detailed contract should specify these four issues unambiguously. The parties to the contractual agreement should both be clear on the limitations imposed upon them, detailing what they can and cannot do. For instance, if the agreement limits the rights of either the licensee or licensor or both, then they should remain within such limits. The compensation to the licensee under licensing agreements is generally in the form of royalty payments. The royalty is paid in the form of a flat fee, a fixed amount per unit sold, or as a percentage of the sales of the licensed product or service. The licensor and the licensee must be clear about their rights and responsibilities toward the contractual arrangement. This prevents disputes over the terms and conditions of licensing arising later. The time period for which the licensing arrangement is entered into must be specified clearly. This period can be anywhere between a short-term arrangement, say, of one year to a long-term arrangement of even 100 years. The period depends on the time that the licensee thinks is appropriate to amortize its investments and the licensor perceives to be enough for it to learn the technology involved or the perceived benefits to accrue.

Risks and Benefits

There are several benefits of licensing to both the parties involved. The licensee benefits in terms of added revenue streams with relatively little additional investment. They get the opportunity to make and sell products based on their intellectual property in markets that they themselves are unwilling or unable to enter. The licensor does not have to bear the development costs and risks associated with creation of intellectual property and gets to use a tried and tested technology or product. For organizations that lack the technological ability, licensing offers a convenient, less risky way to utilize the intellectual property created by other more capable organizations.

At the same time, there are some drawbacks to licensing. Both parties forego opportunities that they could have used if they were not part of a mutually binding agreement. For instance, if the licensing agreement prevents one company from entering a foreign market so long as it is in an arrangement with some local company, it cannot do so. Similarly, the local company is constrained to use the technology provided and cannot use some other technology or sell some other products of another company at the same time if the agreement prohibits them to do so. Another problem with licensing is that it is based on a written contract. However carefully it may have been drafted, there is always scope for disagreement, especially if there is lack of mutual trust between the licensor and licensee. Often, disagreements may result in costly litigation. To an organization that offers technology through licensing, there is the risk of losing that technology to unscrupulous parties who may not honor the agreement and pass on that technology to others. An opportunistic licensor may also learn the technology and access the confidential information associated with it, and then could terminate the contract to deprive the licensee of further royalty payments. From the strategic viewpoint, a licensee who grants a license to the licensor may not have full control over how the intellectual property is ultimately used. For instance, if the licensee uses inferior quality materials to make products based on the licensor's technology to augment its profits, then the impact may be felt on the licensor's reputation and image.

Despite the drawbacks, licensing offers a good way for entry into foreign markets provided steps are taken to reduce the risks of some of the drawbacks. For example, the parties involved in the licensing agreement could enter into a two-way rather than a one-way arrangement. Transfer of technology from the licensor to the licensee can be reciprocated by reverse transfer of technology that is the intellectual property of the licensee, making it a cross-licensing arrangement. This binds both the parties to respect each others' rights and reduces the risks of facing the drawbacks described above.

Related Terms and Other Uses

There are some terms related to licensing that also need to be understood. Franchising, like licensing, is another mode of entry into foreign markets. Franchising has many similarities to licensing and is often considered a special form of licensing. Franchising involves not only sharing intellectual property but also brand name, business model, and operating system along with support services such as advertising, training, and quality control. The party that grants the franchise is called the franchisor while the party that accepts or solicits it is the franchisee. Franchising is also generally a longer-term commitment compared to licensing. The application of licensing is usually in the transfer of technology for manufacturing industries, while franchising is generally used for a package of facilities and information for service industries. International franchising, quite similar to international licensing, is a popular form of international business activity. There are similar arrangement like legal contracts and royalty payments.

Licensing is used in several different contexts apart from its application to organizations and international business. A very familiar document is the driving license that is legal permission to drive a vehicle. Character and entertainment licensing constitutes the biggest segment of licensing, generating billions of dollars in revenue every year. Popular characters like Mickey Mouse are licensed to users by movie studios and broadcasting services such as Walt Disney. Designer names such as those of apparel manufacturers are licensed in the form of fashion licensing. Professional sports licensing is another fast-growing area where sports events such as the Olympic Games, professional organizations such as the National Basketball Association, and teams market their brand names for usage by businesses. Art licensing is a niche area where licensed artwork and artist-brand properties are licensed, bringing much-needed revenue to museums and artists.

Lifestyle Research

Lifestyle research stands at the boundary between a number of traditional academic disciplines, developing expertise from sociology and the social sciences in areas as distinct as business, retailing, marketing,

A new area of lifestyle research uses information about internet use patterns and consumption.

understanding of consumers, and health and social care. The very diversity of fields and disciplines with an interest in lifestyle research creates complexity in an already dynamic and fast-changing area of research. Multifaceted approaches are used, alongside a variety of academic and business conventions, but typically, lifestyle research focuses on subgroups within the general population defined by age, occupation, religion, sexuality, medical conditions, or behaviors.

In terms of business research, this market segmentation of the consumer market is a key use for lifestyle research. As the importance of the consumer in determining the success of business operations has become increasingly clear to businesses, so the importance of lifestyle-based market segmentation has increased and the importance of ongoing cultural change has been recognized. Ongoing social and cultural change, both in purchasing dynamics, in related group behavior, and in lifestyle decision making are illuminated by lifestyle research but also act as a key source of information for strategic planning within business and for the ongoing development of successful corporate strategy. The links between lifestyle research and the development of successful marketing strategies are currently being discussed within the academic literature, both from a management perspective and from a social science perspective. The development of an increasing understanding of the diverse research that contributes to this area of study is key to the ongoing development of successful and strategic business development.

Typically, research in this area is grounded first in the concept of lifestyle and relates this to various aspects of an individual or group lifestyle. Key themes that may influence lifestyle include activities/behavior, values and attitudes, individuals versus groups, group interaction, coherence, recognizability, and choice. Within this definition, lifestyle research may focus either upon the implications of belonging to a certain group or upon the implications of certain lifestyles, including areas such as the role of lifestyle in the management of clinical conditions or the impact of a voluntarily adopted lifestyle on other areas of an individual's life. In business terms, lifestyle research is used both to classify consumers in terms of patterns of behavior, purchasing, etc., and as a way of looking at lifestyle as a key factor in the generation of new products, services, etc.

One important distinction lies between research that attempts to identify causal relationships between a lifestyle and the development of certain patterns of health and behavior and an alternative pattern of lifestyle research that evaluates the impact of lifestyle changes. Both have considerable implications for business, being directly linked to the development and promotion of goods and services. The lifestyles assessed may be proscriptive—and much of the research in this area lies in health—or broader changes that reflect the development of society, the economy, and the workplace. Business research generally focuses upon this latter scenario, where the intertwining of cause, effect, and incremental change provides fruitful ground for research.

One useful example of this intertwining is the relationship between the availability of processed ready-meals and the lack of availability of time for cooking. Does a lack of time trigger the demand for ready-meals? Or does the availability of ready-meals facilitate broader changes in lifestyle that tend to mitigate against the "ring fencing" of time to devote to cooking? The answer to such questions is unlikely to be simple—and in this example the ongoing development of skills within the consumer group would play a contributing role—but this example illustrates the complexity of cause, effect, and contributing factors within lifestyle research.

Lifestyle retailing is an additional important area of study, where the promotion of a "lifestyle package" linked to a brand, a group of products, or a service forms part of the marketing strategy for many companies. The creation of aspirational brands within a consumer economy—be they products or services—is a key driver for many businesses. Typically, however, this builds upon initial market-segmentation work, and successful lifestyle retailing strategies tend to indicate a very well-researched and clearly identified market-segmentation strategy.

Building upon this, so-called subcultures of consumption have been a focus for some additional study focusing around ideas and theoretical frameworks from general consumption literature and applying these in a variety of servicescapes. A more recent approach to segmentation, for example, has included Web-based-related lifestyle research, where access, enthusiasm, and propensity to use internet resources formed a key defining a part of an individual or group lifestyle and hence the basis for recent research.

Linder Hypothesis

The Linder hypothesis states that countries with similar per capita incomes tend to trade more intensively with each other. The claim originated in 1961 with Swedish economist Staffan Linder, who observed that countries with similar incomes also tend to have similar preferences. Domestic manufacturers that primarily produce for the domestic market will seek out export markets in countries whose citizens have similar incomes and preferences. Thus, high-income countries will specialize in different versions of high-quality goods for trade among themselves. As a result, trade in similarly capital-intensive goods flourishes among countries with similar capital-labor ratios (e.g., automobile trade between the United States, Europe, and Japan). Though considerable anecdotal evidence of the Linder hypothesis exists, systematic research on the subject has yielded mixed results.

The Linder hypothesis is one attempt to reconcile the Heckscher-Ohlin model of international trade theory with empirical evidence on trade flows. In the Heckscher-Ohlin model, comparative advantage is a result of differences in factor endowments. Countries with more capital per worker should, according to the theory, export goods that use capital more intensively than they use labor and import goods that use labor more intensively. If trade flows follow the predictions of the Heckscher-Ohlin model, one would expect to find that the developed (capital-rich) countries such as the United States export capital-intensive goods and import labor-intensive goods.

However, empirical studies have not always confirmed the Heckscher-Ohlin predictions. Using input-output data for the United States for 1947, economist Wassily Leontief showed that the capital/labor ratio in imports was higher than the capital/labor ratio in exports. This is the opposite of what the Heckscher-Ohlin model predicts and became known as the Leontief paradox. The Linder hypothesis, which can be an equilibrium in theoretical models if capital intensity is related to income elasticity of demand, can partially explain this paradox by producing the requisite amount of trade in capital-intensive goods between similarly developed countries. This could explain the higher capital/labor ratio present in imports for some developed countries. While the Linder hypothesis and the Leontief paradox are related in this way, the

Linder hypothesis is not a complete resolution of the paradox, nor is it a necessary component of any proposed solution to the paradox.

Indeed, as Edward Leamer points out, the Leontief paradox can be resolved in an extension of the Heckscher-Ohlin model to more than two goods (the Heckscher-Ohlin-Vanek model). In the same way, if confirmation of the Linder hypothesis is to be found, it will be in the context of a multigood model of trade. This is fundamentally a consequence of the fact that the Linder hypothesis is directly linked to intraindustry trade—that is, trade in similar goods or goods with subtle differences in variety or quality. A model explaining this feature of trade must have more than two goods.

The empirical validity of the Linder hypothesis itself has been at issue since its first exposition. Studies that use highly aggregated categories of goods have not always found statistical evidence of the hypothesis. Disaggregated studies have had more success as the hypothesis may hold better for individual subsets of goods whereas the effect is harder to detect on average, a situation known as aggregation bias.

In general, explaining the high level of intraindustry trade is a challenge for basic models such as the Heckscher-Ohlin model. Confirmation of the Linder hypothesis and explanation of intraindustry trade both require a further level of detail capable of allowing a connection between trade patterns and domestic consumer preferences.

Liquidity (or Market Liquidity)

Liquidity (or market liquidity) is the ease with which financial market participants can quickly execute large trades without significantly impacting prices. An investor buys a financial instrument in a liquid market with confidence that there will be a ready prospect for its sale in the future. In the absence of market liquidity, an investor faces liquidity risk or the financial risk that an asset cannot easily be sold. A financial instrument that trades in a highly liquid market carries less liquidity risk, which both encourages greater investment and reduces the funding costs of the issuer.

Another benefit of market liquidity is rapid price discovery. New information is an important driver of market trading. Dispersed beliefs of traders on an asset's equilibrium price as a result of any new information may converge toward a consensus more quickly in a more liquid market. Alternatively, on liquid stock exchanges characterized by the participation of many uninformed liquidity or noise traders, informed speculators may be able to trade more profitably on private information, which, in turn, increases both the returns to monitoring management and the informational content on management performance in a stock's price.

The benefits of market liquidity may also be seen as a public good that may justify a role for government in its maintenance. The significance of sound financial markets for stable economic growth and the reliance on them to guide and transmit monetary policy have also led to increased concern for the maintenance of market liquidity. Illiquidity in financial markets may have serious consequences for overall economic activity. With responsibility for the safety and soundness of financial systems and in their role as lender of last resort, central banks are critical to the provision of liquidity to illiquid markets.

There is no one universally accepted measure of market liquidity. The degree of liquidity found in any market is most commonly assessed in terms of tightness, depth, and resiliency. Tightness refers to the relative divergence of trade prices from mean prices reflected in bid-ask spreads or the market's capacity to align supply and demand at minimal cost. Depth reflects the number of trades or the size of trades that can be completed without impacting current prices. Alternatively, depth may be reflected in the turnover or trading volume in a market, which is a commonly used measure of liquidity. It is generally assumed that tightness and depth are positively correlated with narrower spreads found in more actively traded markets. A third common measure of market liquidity is resiliency or the speed at which prices and order volume return to their equilibrium values subsequent to a large trade.

The determinants of market liquidity in any one market can result from the interaction of various factors including financial instrument design, market microstructure, and the behavior of market participants. The design of financial instruments determines their substitutability, which, if high, may result in higher concentration and measured liquidity in one among the alternatives. Such preferences would then induce investors preferring greater liquidity to also invest in that one financial product. Alternatively, substitutability may lead to greater liquidity for all as one substitutable product may more easily serve as a hedge for another.

Market microstructure can also significantly influence market liquidity. One distinction is between trade execution systems: auction-agency or order-driven markets, such as most organized stock exchanges, and quote-driven or dealer markets, such as the foreign exchange market. Price discovery is believed to be enhanced by the former while the latter allows faster execution of trades but reserves for the dealer a monopoly on information about order flow. Such systems vary around the world and are not necessarily determined by the particular financial instrument traded. They are often the result of historical or institutional legacy. In general, market liquidity is enhanced by the existence of competitive trading structures for market makers and participants. For example, the ability to trade a stock on both an organized exchange and over-the-counter (OTC) or on more than one exchange increases the market liquidity for the stock. Competition between exchanges and markets can increase liquidity by increasing trading efficiency. Other microstructure elements can also affect market liquidity. For example, lower transaction costs and the standardization of trading and settlement practices appear to increase market liquidity. Finally, market participant behavior and composition are other factors affecting market liquidity. An increase in investors' risk aversion reduces it as does the loss of confidence in their forecasts of future prices. Greater heterogeneity of financial market participants, including cross-border participants, increases liquidity through the enhanced prospect of matching buyers and sellers in the market.

Although greater market liquidity is generally considered a public and private good, there is also the possibility of excess liquidity. Financial crises often follow the collapse of asset price bubbles that are generally believed to be created by excess liquidity resulting from the expansion of credit in one or more markets. Following the collapse of a bubble, credit tightens as the value of bank assets falls and liquidity may evaporate in markets throughout the financial system. Ultimately, the liquidity of financial instruments in a market depends upon the confidence of market participants in their ability to assess their value and trade them at will. Excessive confidence can lead to excess liquidity and asset bubbles. The loss of investor confidence can lead to illiquidity and the collapse of markets. In such cases financial markets look to central banks to restore liquidity.

Lithuania

The southernmost of the Baltic States, in medieval times Lithuania was a powerful kingdom in eastern Europe, and as part of the Polish-Lithuanian Federation, was one of the largest and most powerful entities during the 16th century. It became a part of the Russian Empire in the 18th century (mainly with the Third Partition of Poland in 1795), and gained its independence in 1918. However, it was invaded by the Soviet Union in 1940, by Nazi Germany in 1941, and then reoccupied by the Red Army in 1944. It remained a part of the Soviet Union until independence in 1991.

Traditionally the Lithuanian economy was heavily dependent on agriculture, although the traders from the Hanseatic ports also were interested in minerals such as iron ore and coal sourced from near Memel (Klaipeda). Napoleon gained many of his supplies from the region before his invasion of Russia in 1812, and from independence until World War II, the republic's main products were rye, wheat, barley, oats, and potatoes. Its exports included bacon, dairy products, cellulose, timber, flax, and also livestock, with the major imports being herring, coal, cement, metals, textiles, and machinery. Although most of the trade was with Poland, Germany, Latvia, and Scandinavia, there was also trade farther afield.

In 1939 when war broke out, Benjamin Kagan, a Lithuanian textile manufacturer, was in England on a Lithuanian-government buying mission. His son, Joseph Kagan (1915–95), was later to move to Britain himself, where he set up a textile business and developed Gannex, which was used in the Gannex coats that were much favored by statesmen and politicians around the world. This was one of many economic successes of Lithuanians overseas, with Joseph Kagan being named a Lord prior to his disgrace.

During the Soviet and then the German occupation of the country, Lithuania was devastated. From 1944, the entire economic life of the country was placed under state control, and Lithuania became a part of the Soviet Union with all major decisions being made from Moscow, and the vast majority of people in the country working for state-owned enterprises or on collective farms. During this period the infrastructure of Lithuania, much of which had been destroyed in World War II, was rebuilt, and the economy was integrated with the rest of the Soviet Union. As a result, after independence in 1991, Lithuania struggled economically. It introduced rapid privatization of the economy and of land ownership, but did suffer from rampant inflation of 225 percent in 1991, rising to 1,100 percent in the following year, 409 percent in 1993, and then dropping to 45 percent in 1994. In February 2002, the local currency, the litas, was pegged to the U.S. dollar, and inflation now stands at 3.6 percent.

Lithuania now shares borders with Latvia, Belarus, Poland, and the Russian Federation; it maintains a large number of export industries, and also imports much from overseas. Machinery and equipment make up 22 percent of the country's exports, and 18 percent of Lithuania's imports. Other exports include mineral products, chemicals, textiles, clothing, and foodstuffs, with imports also including mineral products, chemicals, textiles, clothing, and foodstuffs, as well as transportation equipment. There is now a sizable tourist sector with many people, including Germans and also Jews whose families lived there before World War II, visiting Lithuania.

Because of its history, Lithuania was keen to engage with western Europe, partly as a guarantee against future invasion. This led to Lithuania joining the North Atlantic Treaty Organization (NATO) on March 29, 2004, and negotiating for membership in the European Union, which was granted in May 1, 2004.

Lloyds TSB Group

The Lloyds TSB Group came from a merger of Lloyds Bank and the Trustee Savings Bank. Lloyds Bank itself was one of the oldest banks in the United Kingdom and was established as a company in 1765—at that stage providing a private banking service—called Taylors and Lloyds in Dale End, Birmingham, in central England, taking its name from its founders John Taylor, a button maker, and Sampson Lloyd II, an iron manufacturer and dealer. Two sons of the original partners established Barnetts Hoares Hanbury and Lloyd in Lombard Street in London. It was not until 1864 that the bank opened its first public bank branch in Oldbury, then six miles west of Birmingham (but now a suburb of Greater Birmingham).

Gradually Lloyds Bank grew, started taking over other businesses, and formed Lloyds Bank (France) in 1911 from Armstrong and Co., which they had just bought out. In 1914 they took control of the Wilts and Dorset Bank, and four years later bought the Capital and Counties Bank. They also took over Fox, Fowler and Company of Wellington, Somerset, the last private firm in Britain to issue its own banknotes (which it did for the last time in 1921). Lloyds Bank had deposits of £1,094 million in 1951, and £1,654 million in 1966.

In 1918 Lloyds Bank expanded into South America with the purchase of the London and River Plate Bank, which was later merged with the London and Brazilian Bank to form the Bank of London and South America, which in 1986 was fully merged into Lloyds Bank. This saw Lloyds Bank have a heavy financial interest in Argentina as well, being largely used by its British community that controlled many of the businesses, at least until the 1940s. Lloyds Bank, through the National Bank of New Zealand, and the Rural Bank, which it took over in 1994, also had an important role in New Zealand. By this time it had already established its life assurance company, Lloyds Abbey Life, and in 1995 it bought the Cheltenham and Gloucester Building Society, making it a major lender in the British mortgage market. From 1930 until 1987, the *Lloyds Bank Review* provided generations of high school and university students with information on banking and economic reform proposals.

By contrast, the Trustee Savings Banks had been established from 1810 as part of the framework encouraged in Britain during the Napoleonic Wars to promote thrift. However, in the early 19th century many banks were not stable, and investors were worried about their funds. As a result, the Trustee Savings Banks established a system of independent trustees to guarantee the management of the bank, which was how it had achieved its name. In 1919 the banks had £100 million in deposits, which rose to £162 million by 1929, and £292 million by 1939. After World War II, plans were introduced to help unify the system. With changes being made in the inter–savings bank clearing in 1955, by 1973 there were 73 different savings banks with 1,549 branch offices. Finally merger arrangements were made, and in 1975 the network was whittled down to 19 independent banks, which in 1985 were finally merged to form the TSB Bank plc.

In 1995 the Trustee Savings Bank merged with Lloyds Bank and they formed Lloyds TSB. It still uses the black horse set in a green frame that has been the symbol of the bank for many years. It currently employs 74,000 people and has a revenue of £16,874 million (2007), with net income of £3,321 million (2007), making it the fifth-largest banking group in the United Kingdom. As well as banking through Lloyds TSB Bank in England and Wales, and Lloyds TSB Scotland in Scotland, and through Cheltenham and Gloucester Building Society, it also runs the Scottish Widows Bank. In insurance and investments, it runs its own Lloyds TSB Insurance Services Ltd. and Scottish Widows; and in wholesale and international banking, it runs the Lloyds TSB Corporate Markets, Lloyds TSB Commercial Finance, Blackhorse, and an offshore banking arm. Involved in sponsorship of many events and charities, Lloyds TSB was appointed the first Official Partner for the 2012 Olympic Games to be held in London. In late 2008 Lloyds TSB looked forward to its merger with HBOS, which was to create Britain's biggest High Street bank called Lloyds Banking Group.

Lobbying

Lobbying refers to attempts to influence policy decisions made by elected officials. The term originated in the political systems of the United States and United Kingdom during the 19th century when efforts to influence the votes of lawmakers were conducted in the entrance hall (or "lobby") of parliamentary chambers. In business, lobbying is an example of a nonmarket strategy. While market strategies involve decisions such as product positioning and pricing, nonmarket strategies are actions taken by individuals, firms, or special interest groups to influence the political, regulatory, and social environments in which they operate. Some companies and industries have found that lobbying is a crucial aspect of their business, and recent studies have shown that lobbying can effectively influence policy outcomes.

Different Types of Lobbyists

Different kinds of business actors lobby political decision makers. Individual businessmen and women, for example, can be important contacts for elected officials. In France, leading business and political figures commonly make informal contacts with each other during their studies at elite graduate schools. Later in life, business leaders can use these contacts to voice their policy preferences to government and administrative representatives.

Individual firms—especially large ones—can also participate in lobbying and public policy advocacy. Google provides a case in point: with a staff of 12 lobbyists including former communications directors, speechwriters, and policy advisers of the Clinton administration, Google has built a substantial presence in Washington.

If managers lack the time, resources, or contacts to influence public policy decisions themselves, they may delegate the task to an outside lobbyist. For instance, when it made its controversial bid to take over the U.S. petroleum company Unocal in 2005, the China National Offshore Company hired the services of the Washington-based lobbying firm Akin Gump Strauss Hauer & Feld to establish relationships and set up meetings with lawmakers.

In some cases, individual companies may feel they have a better chance to influence policy if they lobby as part of a wider group: In this instance, they may join professional associations. Germany, for example, has a dense network of special interest groups that are organized around specific industrial sectors (such as the German Association of the Automotive Industry), products (including the Association of Cigarette Manufacturers), or markets (such as the Federal Association of Exporting Companies). These groups maintain political offices in Berlin, establish strong connections with officials in the powerful Economics Ministry, and use these to influence policy so that it meets their members' specific requirements.

When attempting to influence general laws, trade associations and individual companies may form nationwide employers' associations. One such example is the U.S. Chamber of Commerce, whose 300 policy experts, lawyers, and communicators represent the interests of over three million businesses of all sizes and sectors, hundreds of trade associations, thousands of local Chambers, and more than a hundred American

Chambers of Commerce around the world. In the UK, the Confederation of British Industry (CBI) promotes the general interests of British business by contributing to debates on over 80 policy issues.

As business has become increasingly globalized, supranational associations have emerged to represent the interests of the business community above the nation-state level. For example, with the increasing number of economic directives introduced by the European Commission, it is estimated that 15,000 business lobbyists are now active in Brussels. Some, such as BusinessEurope and the European Roundtable of Industrialists, represent private employers at the interprofessional level. Others, including the European Federation of Pharmaceutical Industries and Associations (EFPIA) and the Committee of Professional Agricultural Organisations (COPA), represent the interests of specific industries.

Companies, organizations, and private citizens can lobby policy makers in numerous ways. More than one method is frequently used concurrently. Lobbyists and policy makers may meet informally. In the United States, lobbyists can legally invite policy makers out for dinner, to concerts and sporting events, and even on trips. For example, when Starbucks began lobbying in Washington, it flew members of Congress to its Seattle headquarters to introduce them to the company and educate them on its strategy and the coffee industry.

Another way of lobbying is to participate in formal meetings with policy makers. In some countries, governments establish advisory committees to gain private-sector input on policy issues. France, for example, has developed an extensive network of consultative organs, including the Economic and Social Council, designed to elicit advice and acquiescence from trade associations.

Companies often also use written communications to convey a particular point of view. In this way, Microsoft found letter-writing campaigns to be a useful form of advocacy when several states sued it for anticompetitive behavior. Lobbyists are now more than ever using the media to articulate their interests and influence public opinion so that it is sympathetic with their causes. The internet also provides lobby groups with a powerful tool for attracting the attention of specific target audiences and increasing the visibility of their specific concerns.

The Influence of Lobby Groups

Not all lobby groups have the same influence over policy makers; their ability to shape policy outcomes depends on both internal and external factors. Internally, lobby-group influence depends on financial resources, knowledge, and membership structures. In essence, groups are better placed to influence policy makers if they have large financial resources to fund their lobbying activities, if they possess the often highly technical expertise required by government officials to make policy, and if they possess a homogenous membership whose similar interests make it easier to reach common policy positions.

A major external factor affecting the influence of lobby groups is the structure of the political system in which they operate. In so-called corporatist systems (such as Austria, Germany, and Sweden), interest groups are guaranteed a voice in systems of institutionalized policy making: the representatives of employer and employee organizations are invited to participate in negotiations with state officials to reach agreements on policy issues and gain responsibilities for securing compliance with decisions.

Other countries (such as the United States or the United Kingdom) do not have such institutionalized lobbying practices. In these pluralist systems, power is more widely distributed among many autonomous lobby groups, each representing the social and economic forces in the wider society. These groups compete against each other to gain the attention of policy makers. The greater the organized opposition to a lobby group's policy demands, the weaker its ability to shape policy outcomes to the advantage of its members.

The acceptance of lobbying varies across countries. In the United States and the United Kingdom, lobbying has long tended to be considered as a legitimate aspect of the political process. In continental European countries, however, seeking to influence policy makers tends to generate largely negative connotations: Lobbying is seen as an opaque practice, giving an unfair advantage to those who can afford to carry it out. In response to these concerns, the European Commission launched an initiative in 2005 to make lobbying in Brussels more transparent.

Local Adaptation

All firms that operate in a single, domestic context have to design and implement product, pricing, promotional, and distribution strategies to compete effectively in their respective markets. On the other hand, firms that operate on an international scale face an additional challenge that must be tackled before they cross borders. The main dilemma for the marketing strategy of such multinational entities is the decision to either follow the same marketing program across all foreign markets or employ a different approach that corresponds to each foreign market's idiosyncrasies. This dilemma is the backbone of the global commercial policy of multinational corporations, and in the business literature it is called "standardization versus adaptation" of international marketing strategy.

In particular, local adaptation is the act of employing a marketing strategy that is unique for the market under scrutiny and thus different from the marketing strategy used in other countries. Such a difference denotes modifications in the marketing mix with the purpose of adapting to the cultural diversity of international markets. Local adaptation includes modifications on marketing elements such as the following: (1) the product's tangible elements such as size, taste, packaging, or ingredients used; (2) the product's intangible elements such as brand name and brand positioning; (3) the promotional message and promotional media; (4) pricing toward middlemen and final consumers; and (5) number and type of middlemen.

Locally adapted activities such as the use of different brand names or the use of different promotional efforts within retailing outlets across countries are numerous and have led firms to both success stories and major marketing blunders. For example, the ice cream unit of a giant firm like Unilever is called by different names (either Eskimo or Ola or Algida) in countries such as Sweden, the United Kingdom, Greece, or Spain. Additionally, large U.S. retailers have realized that successful types of promotional activities in the United States (such as "buy two extra-large sizes and get one free") have no equal appeal among consumers in a country like Germany, and so they have adapted their in-store promotional strategy.

The main purported advantage of an adapted strategy is that such local responsiveness meets local customers' needs more efficiently than a standardized strategy that employs a common marketing program for all countries and thus ignores local markets' specificities. On the other hand, though, local adaptation bears a major disadvantage compared to standardization. It is a very expensive task to undertake, since modifications for each country in which a firm operates increase costs enormously. As a result, the effect of such a strategy on typical performance measures such as profitability is debated. However, there are suggestions in the literature that firms that locally adapt their marketing strategy perform better in other measures such as total sales or market share due to their closer look at local markets' needs.

Thus, the decision as to whether firms should eventually employ a marketing program that is partly or wholly adapted to local idiosyncrasies is not an easy one and involves many considerations. These considerations influence the degree to which the firm will eventually adapt its marketing elements and include factors that have to do with both the intra- and extrafirm environment such as the delegation of decision making within the multinational enterprise and the market size, respectively. A synoptic categorization of factors, internal and external to the firm, distinguishes among influences that are either mandatory or discretionary and have to do with (1) characteristics of each market in which the firm operates (e.g., weather conditions, local ethical rules, and legal guidelines); (2) the synthesis of the consumer base the multinational firm addresses (e.g., demographic/psychographic characteristics of consumers and their attitudes toward foreign products); (3) the nature (price versus nonprice) and intensity (high or low) of competition; (4) the nature of the product (e.g., consumer versus industrial goods, luxury versus nonluxury products, culture versus noculture-bound products); and (5) organizational and managerial characteristics (e.g., openness of the firm toward international operations or international experience of business executives).

For example, legal restrictions in several countries necessitate a locally adapted promotional strategy on behalf of tobacco firms, which cannot advertise their brands on TV and thus must employ alternative means of advertising. Additionally, many multinational firms face increased competition by their local counterparts and may need to adapt their pricing strategies in order to become more attractive to local consumers. An example of an intrafirm influence is the polycentric orientation of the mother firm, which "forces" local subsidiaries to employ their own, locally adapted product policies that match local consumers' preferences.

Summarizing, it must be noted that the decision whether to adapt or not is not necessarily antithetical to the decision to standardize. A firm usually employs diverse reasoning before actual strategic decision making, and adapted elements may coexist with standardized elements in the same marketing strategy. It is therefore more appropriate to talk about the general degree of adaptation and not in terms of a dichotomy between adaptation and standardization.

Local Competitors

The standard economic textbook treatment of competition gives the impression that production and consumption take place on the head of a pin, as if space did not matter. In reality, of course, space does matter, in ways that constrain the boundaries of competitive domains and the intensity of competition in those domains. The resources for which firms compete are not evenly distributed in space, but are geographically clustered, often independent of political-administrative boundaries. Agglomerations such as the wine industry in Southern California, the financial district of the City of London, the Indian film cluster in Mumbai, the surgical instruments cluster in southern Germany, or the boat building cluster in northern New Zealand all conjure images of highly localized business activities, supported by locally specific institutions and social structures.

Local competition may be understood from two perspectives, with different predictions for the nature of business transactions. Standard economic theory suggests that within a given locale barriers to entry are lower than elsewhere to the extent that labor skills, material and financial assets, information, and other inputs are more readily available locally. The presence of a large number of firms in the region is predicted to increase business entry rates into the region because potential business founders will view a large local business population as an indicator of market and investment opportunities. By contrast, the ecological approach to competition highlights the crowding effects of business populations. A large population of firms, which all draw on the same or similar resources, is predicted to depress firm entry rates. The more firms' market domains overlap, the more strongly they compete. The addition of a firm to an existing population has stronger competitive effects on firms in the same domain than on firms in more distant domains, reducing founding rates and increasing failure rates.

One way to reconcile these theoretical predictions is to consider the definition of competition that they assume. Economic theory views rivalry more as a form of competition among a narrowly defined population of firms, focusing on the social and cognitive aspects of competition. Local competitors, from this perspective, tend to orient their activities toward those firms they perceive as rivals. The ecological perspective, by contrast, subscribes to a less-social definition of competition. It highlights the more diffuse and indirect interdependence between firms that may or may not be directly aware of each other. Of course, economic rivalry and ecological competition may operate jointly in a given setting. For example, firms may compete globally in product markets, but locally in factor-input markets.

Research

Our understanding of local competition draws on substantial academic research that typically falls in one of three categories. One line of research focuses on the geographic distribution of resources. A second body of literature studies the flow of information across space. And a third body of research focuses on the level at which economic aggregates can develop competitive advantage. While each of these literatures has a distinct focus, they share the argument that the optimal location of a firm depends on the locations chosen by the firms with which it interacts. Local competitive processes reflect the resource interdependence of firms.

Research on the geographic distribution of resources suggests that the local availability of resources influences the location decision of firms, evident, for example, in the spatial concentration of new business foundings. Many of the resources that firms require to compete effectively are considered, from the perspective of the individual firm, more or less fixed in space. They include human capital, special-purpose equipment, and a range of specialized infrastructure services that are very difficult to transfer across large distances. The market is thus said to require local coordination and control of economic activities and a division of labor between independent but interlinked producers. Localized production systems are evident particularly in those industries that face significant uncertainty, such as software, design, fashion, and high-technology manufacturing. The negotiations involved in production and exchange in such industries are less easily carried out at a distance. Many firms, therefore, remain local, and they depend strongly on their immediate competitive and institutional environments for economic resources, public support, and customer demand. The intensity of competition among firms is a function of the similarity in resource requirements.

Interestingly, the location of a firm relative to its competitors can increase both the intensity of competition and the likelihood of cooperative behavior. The possibility of and need for collaboration with local competitors is the focus of analysis of a second body of research, which investigates flows of information across firms and related organizations. Geographic colocation of competitors makes it easier to observe and monitor competitors. Managers are generally more sensitive to the strategies and actions of local competitors because of their limited capacity to collect information on nonlocal competitors and the ambiguity of interpreting information from a distance. This suggests that managers focus on the actions and capabilities of competitors located in close vicinity.

Research shows that business networks tend to be localized because reliable information is usually best conveyed through direct, personal contacts. For this reason, information and knowledge tend to diffuse slowly through space away from the point of origin. This process can affect the spread of new strategies and products, the adoption of innovations, and the diffusion of organizational models. When combined with dependence on a common resource base and recruitment from a common labor pool, frequent business interactions tend to increase the level of information exchange among local managers, thus improving the awareness of the capabilities of local competitors.

A third line of research is concerned with the extent and form of local competition (and cooperation) as a source of competitive advantage, not for individual firms but for the business population in which they are located. Competitors outside the local production system do not have equal access to the cost advantages of local populations, and they struggle to maintain competitive parity with the clustered competitors. The central argument is that the sustained competitive advantage of local populations of firms is based on knowledge that limits the spread of such knowledge to other populations and regions. Such knowledge is often referred to as architectural knowledge, because it relates to the complex and intangible understanding of how the entire production system works. Such knowledge tends to develop as an inseparable part of the local production complex and is, therefore, not easily transferable to other locales.

In sum, research on local competition suggests that geographic distance continues to play an important role in economic life. While technological advances in communication have reduced the costs of economic transactions and cross-border trade agreements have led to the gradual softening of trade barriers, the transfer of outputs, labor, and information has not become instantaneous or frictionless. Local transactions are increasing in many regions around the world even more rapidly than global transactions. The increased sophistication and differentiation of goods and services in many industries requires an increasing number of transactions and creates local interdependencies that are nontradable. This explains why there will continue to be regional disparities in economic development.

Localization

Localization is an international strategy that some companies pursue in their international business operations. Companies pursuing localization try to modify their products and services so that products have local features demanded by local consumers and are suitable to laws and standards. The modifications needed to localize products can be as simple as translating the labels to the local language or can be as complex as changing and adding many features to the product. In short, a localized product has local features and looks. Localization is sometimes used interchangeably with adaptation, local adaptation, and local responsiveness. The opposite of localization is internationalization or global integration that refers to the efforts of companies to standardize their operations to capitalize on similarities across foreign markets. Therefore, localization is important for global business as it is one major strategy used in international operations.

Localization is a part of the integration–local responsiveness debate. The integration or global integration strategy is based on achieving efficiency and synergy by coordinating, integrating, and standardizing operations and products across foreign markets. Therefore, companies pursuing the global integration strategy expect to increase their performance capitalizing on coordination and integration. However, the local responsiveness or localization strategy (also called multidomestic or multilocal strategy) argues that markets differ and products should be localized rather than standardized to better serve local consumers and meet the local demand.

Localization or multilocal strategy has various advantages. Localized products may better serve local consumers. The headquarters will not be busy thinking about what needs to be done in individual foreign markets. In case of lack of experience in foreign markets, local managers can make better decisions. As well, localization is an opportunity to analyze the foreign market through different ways of producing and marketing products. Successful products developed and produced for foreign markets can also have potential in the domestic market as new products. Despite these advantages, localization has various disadvantages as well. Conflicts may arise when local divisions formulate their own vision, culture,

This Wal-Mart store in Mexico City was selling a variety of locally adapted and nonadapted products in 2007.

and way of doing business that may not be suitable to headquarters. The localization approach also lacks coordination and synergy among individual markets as affiliates are not much encouraged to share their knowledge and experience. This situation may cause duplication of activities and reductions in economies of scale. For example, affiliates can have the same production system for the same tasks, causing increases in production costs. Lack of coordination may also prevent knowledge transfer and may even cause competition among affiliates. In sum, although localization provides opportunities to better meet the local demand, it can cause inefficient manufacturing, duplication of resources, and thus cost increases.

Why do companies localize their offerings? Environmental, structural, and organizational factors can affect localization decisions. When the local business environment and culture is complex and different, localization is needed. For example, there may be differences in terms of payments, price sensitivity, marketing practices, and distribution. Therefore, foreign companies need to modify their practices to suit these local practices. In addition, structural factors, for example, competition and demand characteristics, may also necessitate localization. Last, companies have different goals, policies, and orientations toward doing business. Some companies can have a long-term orientation toward the foreign markets whereas others have short term. Long-term orientation requires a better understanding of and offering to the local market; localization is a good strategy to achieve this.

Some products are more suitable to localization than to standardization. However, even standardized products such as medicine are somewhat localized. For example, the same medicine to cure heartburn is sold for US$185 in the United States, whereas it is around US$40 in Mexico and Turkey. However, the medicine is sold as capsules in the United States but as tablets in Mexico and Turkey. This is an example of localization with respect to price and form of the product. Some other examples of localization are as follows: Wal-Mart in Mexico localized their operations by adjusting working hours, human resource management policy, product breadth, and marketing programs to better serve Mexican consumers. Products like food and clothing are very suitable for localization, as modifications are highly needed in such products. Electronics and other high-tech products tend to be standardized. Nevertheless, we also see localizations in such products. Refrigerators, for example, are highly localized to meet different market needs. In Spain, meat capacity is important, whereas in France vegetable and fruit capacity is important; in the United States, refrigerators are generally larger since consumers generally shop weekly for groceries rather than daily as done, for example, in Turkey.

In conclusion, localization is an international business strategy whose argument is that companies should localize or modify their offerings according to local tastes, preferences, and needs because markets are different in terms of consumer behavior characteristics, laws and regulations, socioeconomic conditions, economic, institutional, and competitive environments.

Local/National

Local nationals (or locals) are the citizens that reside in a multinational corporation's host country. When an organization decides to venture out into global markets, it may elect to send some of its current employees to start the business with the intent of integrating local nationals into the process. However, the management team will have to address political, economic, and cultural issues that may arise in the designated country. In order to address the different types of inequities that may arise, those in the international business arena must develop policies and procedures that address these issues and create a sense of fairness for everyone involved. Many believe that that there should be standards for social responsibility and ethics in order to make sure that developing countries are not exploited. Having a formal global approach to these types of challenges can ensure a sense of fairness for everyone involved in the process.

Organizations need to decide if it is best to establish the international business function internally or externally. It is important for organizations to assess their current workforce to determine if they will need to rely on expatriates to establish a presence in the host company or whether it is more feasible to hire employees from the host country in order to minimize cultural and language barriers.

If the organization elects to start internally, it may assign a team to set the budget, ship products, and develop the international marketing plan. However, this can become expensive, so the organization may evaluate two other options. One option is to hire employees from the host countries. Many organizations elect this option in order to minimize cultural and language barriers and secure labor that is cheaper than its current workforce. If the organization elects to hire employees from the host country, it is important that it assimilates these new hires into its corporate culture so that they will have an understanding of what the organization values and how it operates.

Representational Approaches

In 2007 Farzad Khan introduced a conceptual framework that identified four representational approaches to understanding how social inequities surface in developing countries as they attempt to venture into international business. When the model was created, it was established that there are many parties involved in the process. Since representation ranged from local workers to international mass-media organizations, each party was defined in terms of geography. The two categories introduced are locals and foreigners. Locals were defined as individuals or entities that are primarily located in the developing countries. Locals are very diverse and have different perspectives and interests. Individuals falling into the "foreign" category are those that do not fit into the "local" category. Significant players in the foreign group would include international businesses that are directly involved in specific situations and their critics.

Both of these groups are considered to be "representers" as they work to resolve issues that arise. Each situation is analyzed and evaluated on the representers' role in the situation and the worldview of the situation. The approaches attempt to conceptualize the representation of the ethical issues involving international business in the developing world. The four different approaches are:

- Approach 1 (No-speak): Foreigners are the representers and the issue is expressed from a foreign world viewpoint. The local residents have no voice and they have no input into the worldview. Local worldviews have no place in the development of issues and the local experience is not considered relevant in social equity issues. Most of the international business research follows this approach (i.e., Hofstede's Culture's Consequence).
- Approach 2 (Us-speak): The commonality between this approach and the first approach is that the foreigners are the representers. However,

the difference is that the worldview incorporates the local experience. This approach attempts to represent local realities (local view) in a way that the local inhabitants understand the situation. In many instances, the representer places himself in the locals' position and attempts to articulate the viewpoint based on the locals' perspective.

- Approach 3 (Same-speak): The locals are the representers and the worldview is the same as the foreigner's perception. Locals represent themselves based on one or more worldviews that originate from the West (i.e., modernism, post-structuralism, secular nationalism). Many of the most influential representations of ethical issues that affect international business in developing countries are based on this approach.
- Approach 4 (Other-speak): Locals are the representers, and international business issues are explained in the context of local viewpoints. When evaluating this approach, representation is being explained by locals using local concepts.

The approaches provide an explanation as to how foreigners and locals perceive the severity of social issues, which is important to the interactions in the business community. Multinational corporations have to understand the culture and values of the countries where they do business. Otherwise, the corporation may suffer as a result of conflict on social and business ethics issues. There has to be some sense of social responsibility on the part of the multinational corporation.

Cultural Issues

George England and the Meaning of Working (MOW) International Research Team conducted a study that explored what work meant to people all over the world. Participants came from countries such as Japan, Yugoslavia, Israel, the United States, Belgium, the Netherlands, Britain, and Germany. The meaning of work was evaluated on three core concepts, which were work centrality, societal norms about working, and work goals. Work centrality measured the importance and value of work as it related to the individual's life. Societal norms about working addressed beliefs and expectations regarding special privileges and duties associated with work. Work goals explored the work-related outcomes that were preferred by the participants across the span of their career. The researchers discovered that the higher the mean work centrality score, the more motivated and committed the workers are in society. Looking from a global human resource planning initiative, the results of the study provide organizations information about why employees value work and what they need in order to be satisfied with their jobs.

However, management teams have to be cautious with these results and explore other research that deals with global workforces. One will need to assess the importance of work as it relates to having a quality of work life. For example, Americans are known to work the longest hours in a year and value job duties over family responsibilities. However, that practice is not the norm in all cultures. Therefore, organizations will have to determine what is important to the local nationals in each country that they desire to enter.

Staffing

There are different levels of international employees around the world. An expatriate is an employee who is sent by a company in one country to manage the operations of the same company in another country. There are three types of expatriates: parent country nationals (PCNs), host country nationals (HCNs), and third country nationals (TCNs).

Parent country nationals (PCNs) are employees who are born and live in the parent country. These employees tend to be responsible for starting up operations at locations in another country. A hiring manager is responsible for staffing these operations with employees who can adapt to the new environment and be self-motivated. Some of the highly desired characteristics of a candidate include work experience with other cultures, knowledge of multiple foreign languages, and extensive overseas travel. However, some multinationals are concerned about hiring too many PCNs given the additional expenses that are incurred by the company. For example, the multinational will have to consider costs such as relocation expenses, cultural training, housing assistance, taxation allowances, incentives and rewards, and family issues.

Host country nationals (HCNs) are employees who are born and raised in the host country. Multinationals have found that hiring managers from the host country is an opportunity to build good public relations with the natives of that country. This approach shows an economic commitment on the part of the multinational by providing locals with the opportunity to gain employment and fueling the local economy. Another incentive is that hiring an HCN is not as costly as hiring a PCN.

Third country nationals (TCNs) are employees who were not born or raised in either the host or parent country, but work in the host country. These candidates tend to be sought when there are jobs that require a certain level of expertise and skills to perform certain jobs.

Different countries will utilize different combinations of these employees to staff their international operations. Four of the major approaches utilized include the following:

1. Ethnocentric staffing approach: The staffing plan is dictated by the multinational's values, attitudes, practices, and priorities. The corporate office is responsible for establishing human resource policies and practices as well as selecting candidates who are equipped to provide leadership to the subsidiaries in other countries.
2. Polycentric staffing approach: Although the corporate office may make all of the hiring decisions, there is consideration for the needs of the local subsidiaries. In addition, the policies and practices are developed at the local level to meet the needs of the locals filling the jobs. Although locals are selected for managerial positions, it is rare for these individuals to be promoted to the corporate office. These employees tend to be promoted to positions at the local level only.
3. Regiocentric staffing approach: Human resource policies and practices are dictated by the needs of the region. The approach utilized is similar to what occurs in the polycentric staffing approach. However, there is a broader territory—it is regional versus local. Therefore, there are opportunities to hire and promote workers to regional levels.
4. Geocentric or global staffing approach: The multinational's focus is to look at the "big picture" and develop a plan that provides optimal utilization of all resources, not just human resources. Local and regional concerns are not given priority; rather, they are given equal weight as some other factors in the decision-making process. Staffing practices are developed at the corporate level and the selection process is based on a global pool without regard to a person's country of origin or cultural background.

When considering these approaches, the organization must consider issues such as the following:

- National concerns: Multinationals are expected to work within the legal parameters of the host country. Therefore, it is essential to be aware of the local employment law policies and practices.
- Economic concerns: The multinational has to consider cost of living expenses (i.e., housing, food, incentives, and rewards).
- Technological concerns: Given the increased use of technology in business operations, multinationals need to determine if the host country's workforce has a skilled pool of potential candidates.
- Organizational concerns: The multinational's level of internationalization as well as the product life cycle are two important factors evaluated when determining staffing needs.
- Cultural concerns: It is imperative that the corporate office considers the differences between the corporate and subsidiary cultures when making staffing decisions and policies.

Compensation

Localization has different meanings depending on the audience. Some view the concept to mean the removal of expatriate allowances but retention of the home-country base salary and long-term benefits, whereas others believe that it means to remove expatriate allowances as well as shift the employee's base salary to the host-country levels while the long-term benefits remain the same as the home country's plan. When creating a compensation system for international employees, one must take four basic components into consideration: base salary, indirect monetary compensation (benefits), equalization benefits, and incentives.

The base salary is the foundation of an international compensation system because it represents the minimum rate at which a candidate will work for your company. Some organizations have elected to develop an international compensation system based on the policies and procedures of the parent company's country, whereas others have created an international compensation program based on the host country. Regardless of which practice is utilized, it is important for the compensation professional to consider what happens to the employee's pay once they leave that assignment. On average, the typical international assignment usually lasts from three to five years.

Indirect monetary compensation means benefits. Although most benefits packages are the same as what is offered in the home country, organizations must consider how to address situations where a host country may require certain benefits that are not offered in the home country. It may be in the organization's best interest to consider offering such benefits in order to keep employees motivated and maintain positive attitudes.

Equalization benefits are those benefits offered in an effort to minimize any financial hardships that an employee may experience as a result of considering an international assignment. Some of these benefits include housing allowances, educational allowances, language and culture training, employment opportunities for spouses, and emergency leave.

Some organizations have found that it is beneficial to offer incentives to expatriates. Some of these incentives include an assignment completion bonus, cash bonuses, stock options, and performance-based bonuses.

One of the most popular theories addressing the compensation field is equity theory. Equity theory implies that individuals evaluate whether or not they are being treated fairly by comparing their situation to others. In this scenario, it is common for an employee to compare his/her pay to the pay of other employees, especially those coworkers performing the same duties. Many researchers and practitioners in the field strongly believe that work attitudes and perceptions are based on whether or not an employee believes he/she is being fairly compensated in comparison to the perception of what other employees are being paid. This theory applies to both internal and external structures.

Organizations tend to address these concerns via market pay surveys (external equity) and job evaluations (internal equity). In order to ensure that external equity and internal equity issues are addressed, human resource professionals should consider the following tools when preparing an international compensation package: (1) an international compensation management grading system that is comparable to the domestic grading system; (2) a base salary delivery process that is integrated into the home country's base pay system but that also takes local country laws into consideration; (3) an incentive and reward system that motivates employees worldwide; and (4) a performance management system that rewards employees regardless of their geographic location.

Locational Advantages

Locational or location-specific advantages refer to various business opportunities present in individual foreign markets so that companies are encouraged to invest in such markets. Companies invest in a particular foreign market as long as this market has something to offer to the company so that investment in this particular market can be profitable for the company. For example, among other things, China and India offer location-specific advantages to apparel firms because labor cost in these countries is low and apparel is a labor-intensive product. So, apparel firms benefit from the cheap-labor opportunity that the Chinese market offers. Similarly, the Middle Eastern countries offer locational advantages to oil companies because they have large oil reserves; companies in search of oil can benefit from the locational advantages of large oil reserves by investing in these countries. Highly populated countries, assuming other conditions are also appropriate, can also be an example of locational advantages. Their high population may be an indication of a locational advantage (i.e., large market) for some firms. In sum, locational advantages are very important for global business because they explain to a certain extent why companies invest in a particular country rather than in others.

After companies have decided to internationalize their operations, a very important question is which foreign market(s) to invest in. Investment decisions in a particular foreign market (location) are made after careful and thorough analyses have been done. Companies analyze politics, laws and regulations, economy, geography, climate, taxation, market characteristics, and many other factors in a market, and unless a particular market offers some sort of advantage to foreign companies, this market will not be chosen as an investment location.

Companies generally internationalize their operations to get resources, to seek a market, to seek a strategic asset, and to increase the efficiency of their operations. Locational advantages also mainly refer to these four factors (resource, market, strategic asset, and efficiency). When companies lack resources (raw materials and intermediary materials, labor, know-how, and others) in their domestic markets, a logical option is to seek them in foreign markets that have appropriate resources. When the domestic market is saturated, meaning that there is not much possibility of further increasing demand in the domestic market, companies try to find markets in which there is still demand. When companies want to further strengthen and protect their ownership advantages or diminish those of their rivals, they seek appropriate strategic assets in foreign countries. Therefore, these four locational advantages play important roles for companies in deciding an appropriate location in their internationalization process.

Ownership Advantages

The term *ownership advantages* (also called competitive or monopolistic advantages) is closely related to locational advantages in the internationalization process. Ownership advantages mean that companies possess something valuable and/or unique that gives the company a competitive edge over its rivals; this may be a unique product, brand name, technological expertise, resources, and managerial and marketing skills. Locational advantages alone may not mean much unless ownership advantages are also present. That means that a particular country can offer some sort of locational advantage; however, it will be costly for a foreign firm to come to this foreign country and establish its operations rather than operating in its domestic market.

How, then, is it possible for a foreign firm to invest in a foreign country and be more successful than already-established domestic companies, given that it has additional costs of establishing operations, facilities, and factories when compared to domestic companies? The answer is related to ownership advantages; the foreign firm should have ownership advantages that will provide higher returns than domestic companies. For example, a company can have a well-known brand name, but it may lack a resource in its domestic market to produce the product, or the domestic market may be saturated. By investing in a foreign market that has the resource used in the production of the product and yet is saturated, the company can effectively produce the product and get a benefit from its well-known brand and the large size of the foreign market.

Examples

Some examples of locational advantages are as follows: Alcoa, the U.S.-based aluminum company, invested in Brazil because Brazil has large reserves of bauxite, the most important aluminum ore. Nike, the U.S.-based shoe company, relocated its production to low-wage Asian countries that offer low-labor-cost advantage. Many computer companies in the 1990s invested in the Philippines, which offered low-cost and well-educated and trained labor advantages. Some companies exporting to the United States relocated their operations in Mexico and export their products across the border. The reason for such production relocations is related to locational advantages that Mexico offers; companies that relocated their production to Mexico first benefited from cheap labor costs, and in addition, they benefited from duty-free export since goods manufactured and assembled in Mexico can be shipped to the United States without paying duty according to the North American Free Trade Agreement (NAFTA). Therefore, Mexico provided cheap labor and duty-free export locational advantages to foreign firms.

Locational advantages can include anything that individual markets or countries have and that companies utilize to increase their performance. Availability, quality, quantity, and efficiency of factors of production differ in countries. Companies in search of increased performance, new markets, new resources, and appropriate labor can relocate their operations toward locations having appropriate advantages.

Lockheed Martin

Lockheed Martin is a multinational company established in 1995 through the merger of the Lockheed Corporation with Martin-Marietta. The Lockheed Corporation and the Martin Company were originally incorporated in California in 1912. Martin-Marietta was founded in 1961 through the merger of the Martin Company with the American-Marietta Corporation.

Lockheed Martin, along with its subsidiaries, is a leading aerospace and defense company and has held the number one position as the world's largest defense contractor by revenue since 1995. More than half of Lockheed Martin's revenue since 1998 was earned through contracts with the United States Department of Defense and other U.S. federal government agencies. The company operates in four principal segments: Aeronautics, Electronic Systems, Information Systems and Global Services, and Space Systems.

The Aeronautics segment provides military aircraft, air mobility, global communications, and surveillance systems. Some products of this segment include the F-2 defense fighter created primarily for the Japan Air Self-Defense Force (JASDF); the F-35 joint strike fighter; the F-16 multirole fighter that is currently operated by nations such as the United Arab Emirates, Pakistan, Bahrain, Venezuela, Belgium, Denmark, the Netherlands, Norway, Israel, Egypt, Korea, Turkey, Greece, Jordan, Italy, Chile, Oman, and Thailand; the F-22 for intelligence gathering, surveillance, and reconnaissance missions; P-3 maritime patrol aircraft for submarine detection; U-2 high-altitude reconnaissance aircraft; C-130J Super Hercules tactical transport aircraft; and the T-50 advanced military jet trainer. The aeronautics segment also provides transport management solutions for air, sea, and land traffic in the United States and internationally. This includes air traffic control, airport management, aviation management, navigation, and vessel traffic management.

Lockheed Martin's Electronic Systems division offers missiles and missile defense systems that include weapon fire control systems; air-air missiles, antiarmor missiles, fire support, precision strike, and strategic systems integration.

The company's Information Systems and Global Services segment provides services mainly to the federal government. There are six critical areas in which services are provided: Business Process Management; E-Government; Enterprise Architecture; Homeland Security; Information Assurance; and Systems Development and Integration. Although a major military

This structural engineer from the Lockheed Space Operations Company was working with the precision laser docking systems of the space shuttle Endeavor *in 1993. Lockheed Martin will build the next space shuttle,* Orion*, to replace the current shuttles in 2014.*

contractor, Lockheed Martin also provides civil government agencies such as the U.S. Postal Service with automated sorting systems that enable the efficient handling and delivery of mail to over 134 million addresses across the United States. Lockheed Martin is also the largest U.S.-based material handling systems company.

Lockheed Martin's Space Systems segment capabilities include ground systems; launch systems; space operations; space payloads; spacecraft, which include government and commercial satellites; and training and services that include astronaut and mission control training and premission testing.

Controversy

Unfortunately, Lockheed Martin has also been the subject of several controversies. In 2007 a jury in Albuquerque, New Mexico, awarded a security analyst approximately $5 million after he had been wrongfully dismissed from the company. In 2000 the company agreed to pay $13 million to the U.S. government after it was discovered that Lockheed Martin had passed top-secret technology to a Hong Kong–based company, AsiaSat (Asia Satellite Telecommunications Company Limited), in which the Chinese government is a major shareholder. Another disappointing moment for Lockheed Martin came when NASA lost its $250-million Mars climate-orbiter in September 2003. The Lockheed Martin–built spacecraft was reportedly incorrectly programmed with Imperial units instead of SI units. The company accepted partial blame for contributing to the fundamental cause of the crash.

In spite of these turbulent moments the company has generally reported a profit since the merger in 1995 with the exception of 2001 and 2002, when losses were approximately $520 million and $1.05 billion, respectively. However, since its merger in 1995, the company has been among the first 100 of the Fortune 500 companies in the United States and has recorded a profit of $2.53 billion in 2007, with a rank of 57 on the Fortune 500 companies listing. In 2005 the company owned over 2,300 patents, and in August 2006, Lockheed Martin won a multibillion-dollar contract to build the space shuttle *Orion*, which will replace NASA's space shuttles. This new space shuttle is expected to make its inaugural flight by 2014.

Lombard Rate

The Lombard rate used to be a key interest rate in Germany, although such rate existed in France, Belgium, and Switzerland as well. The Lombard rate was the interest rate charged by the German central bank, the Bundesbank, for very short-term loans made to commercial banks against collateral securities that were marketable and easily convertible into cash. The loan helped commercial banks to deal with temporary shortage of funds. With the introduction of the euro in Germany, the Lombard rate has lost much of its importance and has since been replaced by the European Central Bank's marginal lending rate.

In effect, the Bundesbank had two rates at which it could make loans to banks—the discount rate and the Lombard rate, with the latter being higher than the former. For this reason, banks would first borrow at the discount rate. However, the extent of borrowing at the discount rate was limited by borrowing quotas. Hence, for additional financing, the banks would borrow at the Lombard rate.

In the past, the Lombard rate was a major instrument in Bundesbank's monetary policy. For example, following the era of German reconstruction after World War II, the Bundesbank increased the Lombard rate in the mid-1960s to curb inflationary pressures. Similarly, to curtail excessive currency speculation under the Bretton Woods system, the Bundesbank increased the Lombard rate in the early to mid-1970s to make it more expensive to borrow the German mark, the currency of Germany prior to 2002. However, in the mid- to late 1970s, the rate was cut appreciably to counter recession. During the 1992–93 exchange rate mechanism (ERM) crisis, the Bundesbank lowered the Lombard rate repeatedly to mitigate the effects of the crisis. Starting 1999, the Bundesbank does not report the Lombard rate.

Prior to the introduction of the euro, the Bundesbank was regarded as an important one in the European Community (EC), now the European Union (EU). Hence, changes in the Lombard rate would make headline news across Europe, and speculation about changes in the rate prior to Bundesbank meetings was rife. Changes in the Lombard rate would also affect stock prices and the German mark exchange rate. However, in the late 1990s and with the euro replacing the German mark in 2002, the significance of changes to the Lombard rate decreased considerably as the Bundesbank used other mechanisms to control the money supply, for example, using the security repurchase agreements. The frequency of changes to the Lombard rate declined in the 1990s, just like the implications of the changes. The changes were interpreted as being technical rather than nontechnical, i.e., the change did not convey information about the Bundesbank's stance on monetary policy, but served as a mere realignment, for example, to match the increase in the repo rate. With the advent of the euro, monetary policy powers were transferred from the Bundesbank to the European Central Bank (ECB). As a result, the ECB's marginal lending rate assumed the role of the Lombard rate. Accordingly, changes to the Lombard rate have not been set since 1999.

Lowe's

Lowe's (Lowe's Companies, Inc.) is the world's second-largest home improvement retailer (after The Home Depot, Inc.). It focuses on retail customers and commercial business customers. Lowe's offers a complete line of products and services for home decorating, maintenance, repair, remodeling, and the maintenance of commercial buildings. Lowe's is a North Carolina–based company, incorporated in 1952, and now employs around 160,000 people (as of January 1, 2008). Its headquarters is located at Mooresville, North Carolina. Lowe's is quoted on the New York Stock Exchange with the ticker symbol of LOW. It has approximately 32,000 shareholders (as of January 1, 2008).

Lowe's and its subsidiaries (Lowe's HIW, Inc., and Lowe's Home Centers, Inc.) operate as home improvement retailers in the United States and Canada. It is doing business in 1,534 stores throughout the United States and Canada in two different types of stores: a 117,000-square-foot store for bigger markets and a 94,000-square-foot store for smaller markets. The company's stores stock hundreds of thousands of items such as paint, lighting, flooring, doors, windows, and tools, and all are available through its special order sales system.

Lowe's targets three different types of customers: retail do-it-yourself customers (i.e., homeowners and rental customers), do-it-for-me customers (these require installation assistance), and commercial business customers (i.e., repair and remodeling contractors, electricians, landscapers, painters, plumbers). Lowe's owns and operates 11 regional distribution centers located in North Carolina, Georgia, Indiana, Pennsylvania, Texas, California, Ohio, Florida, Connecticut, and Wyoming. Each center serves 126 stores on average. Lowe's sources products from around 7,000 merchandise vendors worldwide, with no single vendor accounting for more than 5 percent of the total.

Lowe's was founded in 1946 as a typical, small-town hardware store. It was incorporated in 1952 as Lowe's North Wilkesboro Hardware, Inc. The company adopted its present name in 1961. It began trading on the New York Stock Exchange in 1979. Lowe's major business consisted of sales to professional homebuilders. However, the company changed its strategy to serve do-it-yourself consumers in 1980 when housing markets started to decline. Since then, Lowe's has become regarded as one of the industry leaders.

Lowe's executives include Robert A. Niblock (chairman, chief executive officer), Larry D. Stone (president, chief operating officer), Robert F. Hull, Jr. (chief financial officer), Gregory M. Bridgeford (executive vice president), Michael K. Brown (executive vice president), Charles W. Canter, Jr. (executive vice president), Joseph M. Mabry, Jr. (executive vice president), Matthew V. Hollifield (chief accounting officer), and Gaither Keener, Jr. (secretary, general counsel). Lowe's board of directors includes Leonard L. Berry, Peter C. Browning, Paul Fulton, Dawn E. Hudson, Robert A. Ingram, Robert L. Johnson, Marshall O. Larsen, Richard K. Lochridge, Robert A. Niblock, Stephen F. Page, and O. Temple Sloan, Jr.

One of Lowe's strengths is being independent of any single product. The company balances its product portfolio with various brands. Also, Lowe's has

With its 1,534 stores all located in the United States or Canada, Lowe's may suffer from overdependence on its U.S. operations.

a good customer service reputation, which makes it well known in the industry. Another reason for Lowe's success is its focus on the needs of its diversified customers. By offering its special order sales system, Lowe's provides its customers a choice from a wider collection of product options beyond what the store stocks.

The most important weakness of Lowe's is probably its U.S.-dominated presence. Lowe's is concentrated almost entirely in the United States. Although it has some stores in Canada and has announced plans to enter into Mexico, Lowe's is dependent on its U.S. operations. Lowe's is not utilizing the opportunities in other markets. For example, the Chinese market is massive, and contrary to the U.S. market, is expected to expand; Lowe's rival The Home Depot acquired The Home Way, a Chinese home improvement retailer, in 2006. Lowe's is still losing out on opportunities, and thus reducing its competitiveness against its rivals.

Another disadvantage of Lowe's is its limited control on the quality of the products. The company has recalled some of its products for quality reasons. This most likely occurs because of Lowe's many different worldwide vendors. This diversity results in fewer quality checks and some defective products. Such incidents affect operations and its brand image and consumer perception, in which Lowe's is investing heavily.

Low Wage Production

Low wage production is one of the most controversial issues in business analysis. Low wages can be found in both advanced and poor economies. Conventional economic theory suggests that there is no problem so long as factors of production, including labor, are paid their marginal product. If wages are low, this is because there are large numbers of unskilled and low-productivity workers competing for jobs. Moreover, customers benefit from low prices for goods and services. Artificially increasing wages only subsidizes the few and increases the level of unemployment. Critics complain that low wages reflect the exploitation of workers in general and disadvantaged groups in particular. They boost the profits of companies and undermine conditions for everyone.

There is no objective definition of low wages. Wage levels can be measured in absolute terms or in relation to a national average. If wage dispersion increases, there is a greater chance of more workers falling into a low wage trap. Simple marginal productivity theory has difficulties explaining the scale of wage differences, whether at the top where quite extraordinary pay increases have been made or at the bottom. It is often argued instead that low wages are a product of labor market segmentation. Women, migrants, and ethnic groups get caught in secondary labor markets where employment relationships are more casual and wages lower. Such labor market segmentation builds on and reinforces discrimination.

Labor market institutionalists argue that employers also have a choice of strategies, and some choose to emphasize low wage production and pursue policies to sustain this, including opposition to worker organization and state regulation. In many developing countries, this argument can be extended to incorporate the informal sector. Less-regulated labor markets in these countries also encourage the use of child labor, which pulls the overall wage rate. Poor countries have often been seen as labor surplus economies where production is effectively based on unlimited supplies of cheap labor that can migrate in from the countryside.

Two main means have been used to improve the condition of low wage workers. Workers themselves have organized to form trade unions, but since their bargaining position is not always strong, governments have also been pressured to pass minimum wage laws and antidiscrimination laws. Despite prophecies of doom from some economists, both trade unions and legislation can be argued to have a positive effect on the situation of low wage workers and the economy as a whole by reducing abuses and exploitation and forcing employers to look for more efficient forms of production. Many countries now have a minimum wage law to provide a floor to low wages. Ironically, some of the longest lived of these are to be found in the different states of the United States. The value of such laws has also been evidenced when the removal of protection for the low paid has not led to the positive effects claimed by neoclassical economists. Under the auspices of the International Labour Organization (ILO), there has also been an attempt to set minimum labor standards embodied in the 1998 Declaration of Fundamental Rights at Work.

In recent decades globalization has been argued to have created a greater space for low wage production. It has dramatically increased the size of the world working class and brought workers into closer competition with one another through deregulation and falling transport costs. This enables footloose capital to choose where it locates and who works for it. Governments reduce labor protection in favor of "deregulatory beauty contests" to attract this capital. This has weakened the bargaining power of labor as a whole and led to a shift in returns to capital and labor across the world and increased inequality between skilled and unskilled workers who are trapped in low wage production.

The alleged threat from intensified low wage competition manifests itself in the advanced world in increased immigration and competition from imported low wage goods. Outsourcing enables multinationals to engage in "social dumping" by moving production abroad to less-regulated areas. Export processing zones with unregulated or less-regulated conditions have become common. Antisweatshop campaigners have also evoked the plight of low wage workers in the developing world. This leads to claims that labor is being forced into a "race to the bottom." But it is arguable that a greater threat exists in competition of the low wage producers within and between poor countries. The threat of cheap Chinese production is perhaps more evident in Mexico than in the United States or western Europe.

However, these pessimistic arguments need to be subject to cautious assessment. Free market economists, for example, see low wage production as a stepping-stone to more sophisticated forms of production. Empirically, while there is no doubt that labor's position in advanced countries has been weakened, it is not clear that migration and trade with poor countries are large enough factors to account for it. Other accounts focus on the internal relations in the advanced world and policy choices to weaken labor. No less in the low wage producers, it is not always that case that those at the bottom of the supply chain have no bargaining power.

Arguments about low wage production are often presented as if there is an inevitable conflict of interest between workers in advanced and poor countries, the skilled and the unskilled. But what has been called "the high cost of low wages" can be argued to link together the interests of low wage workers in poor countries, low wage workers in advanced countries, and higher paid workers who not only often face the same employers but also are forced to subsidize low wage companies that fail to pay their workers a living economic and social wage. This is sometimes called "the Wal-Mart effect" after the U.S.-based multinational that prides itself on low prices but is accused of not only benefiting from low wage production but failing to provide the mass of its workers with health insurance, etc., which then has to be paid for out of state funds.

Loyalty

Loyalty, or customer loyalty, means that customers exhibit a commitment to, or a relationship with, an organization such as a retailer, a leisure service provider, a bank, or an airline. Loyal customers mean that the organization has a higher level of customer retention and thereby a more stable customer base. The longer a customer "stays" with an organization, the greater their experience of, and engagement with, the organization. For the organization, this leads to lower customer price sensitivity, reduced expenditure on attracting new customers, and improved organizational profitability. A loyalty business model is a strategic approach in which resources are deployed with the aim of increasing the loyalty of customers.

Customers may exhibit behavioral or attitudinal loyalty. Behavioral loyalty is exhibited by staying with a provider and/or by increases in the number or frequency of their purchases or both, leading to increased customer spending. Attitudinal loyalty is associated with a positive identification with the organization, which may lead to customers acting as advocates for the organization and thereby influencing the decisions of others. Both types of loyalty can be exhibited in relation to a brand, a retailer or their organization, or to a specific service or retail outlet.

Scholars have proposed four different segmentations of loyalty orientation that can be used as a basis for segmentation: (1) loyalty, associated with high relative attitude and high repeat patronage; (2) latent loyalty, associated with high relative attitude, but low repeat patronage; (3) spurious loyalty, associated with low relative attitude, but with high repeat patronage; and (4) no loyalty, associated with low relative attitude, and with low repeat patronage. J. Rowley develops this segmentation recognizing that some staying behavior is based on inertia rather than positive engagement with an organization, and suggests the following loyalty categories: captive, convenience-seeker, contented, and committed.

Loyalty schemes are one of the ways by which organizations seek to enhance customer spending and advocacy. Members give basic demographic details when they register as members. In exchange, they receive a plastic loyalty card, rewards card, point card, club card, or discount card. This card is then used as a form of identification when purchases are made so that rewards or points can be registered to the member's account or discount granted. While these rewards are intended to incentivize members to exhibit behavioral loyalty, some organizations also capitalize on the opportunity to link purchase behavior to demographic data, which allows them to segment their customer base and thereby to better target their offers. Loyalty schemes have become a widespread feature of the retail and service landscape. Major categories are in retail and operated by single retailers (e.g., Boots Advantage Card, Tesco Clubcard, Priceline Club Card); travel, which reward travelers with discounts or enhanced service (e.g., AAdvantage Program, Hyatt Gold Passport); and financial services, typically associated with store or credit or debit cards (e.g., American Express Membership Rewards, HSBC Premier). Coalition schemes are where a managing agent operates a scheme on behalf of a number of retail and service sector partners (e.g., AirMiles, Nectar).

Tesco Clubcard, managed by DunnHumby, is a particularly sophisticated loyalty scheme that builds brand awareness and engagement with the Tesco brand. Tesco regards Clubcard as a "thank you card," which has an underlying contract and promise that if members join the Clubcard, they become a long-term stakeholder in the brand. The reward design is multidimensional and targets both behavioral and attitudinal loyalty. The quarterly mail-out with reward points is used as an opportunity to communicate with customers and to create a positive event with impact. Rewards, available through Tesco Freetime, include experiences delivered by a range of other organizations/brands. Tesco has invested considerable effort in developing data-mining algorithms that allow them to mine the data in order to improve both the offer to the customer and to inform strategic decisions associated with entry into online retailing and financial services.

Some have suggested that the term *loyalty scheme* is a misnomer, since such schemes do not generate loyalty, but rather simply offer low-level discounts. Some organizations have withdrawn schemes, but other schemes have been long established, lending credence to the belief that as with many other business strategies, success lies in implementation that aligns with business objectives and context.

LUKOIL

LUKOIL (LSE: LKOD; NASDAQ: LUKOY; RTS: LKOH) is a Russian leader and significant global player in exploration and production of oil and natural gas. In 2007 the company accounted for 18.6 percent of Russian oil production and 18.1 percent of Russian oil refining. Globally, the company reported having 1.3 percent of the world's oil reserves and 2.3 percent of the world's oil production. LUKOIL's proven hydrocarbon reserves make up 20.4 billion barrels of oil equivalent (BOE). This makes the company the second in the world (after ExxonMobil) among publicly owned oil and gas companies in terms of reserves. LUKOIL's daily production of hydrocarbons reaches 2.2 million BOE. In 2007 net profit was $15,388 million (an increase of 25.1 percent compared to 2006).

The ambition of LUKOIL is to become and remain a global energy company. The company declares that it aims to support long-term economic growth, social stability, prosperity, and progress in the regions where it operates, as well as to care for the environment and to ensure sustainable use of natural resources.

Although the major oil exploration region for LUKOIL is western Siberia, the company is also involved in exploration and production projects in Central Asia, Africa, the Middle East, and South America. In addition, LUKOIL owns four refineries in Russia, as well as refineries in Ukraine, Bulgaria, and Romania. The company also has an extended retail network in 19 countries. It controls about 200 tank-farm facilities and close to 6,000 gas filling stations in Russia, the Baltic States, eastern Europe, Cyprus, Turkey, and the United States. In 2005 LUKOIL put in operation the Nakhodkinskoye gas field that started its gas program targeting rapid growth of gas production. The key regions for development of LUKOIL gas production are the Bolshekhetskaya Depression, the northern Caspian, and Tsentralno-Astrakhanskoye field in Russia as well as the Kandym-Khauzak-Shady project in Uzbekistan and the Shakh Deniz project in Azerbaijan.

The company was established in 1991 as a state concern named LangepasUraiKogalymneft (hence the current name LUKOIL). At the time of writing, over 50 percent of LUKOIL's stock were free-floated shares both in the Russian stock market and in the London Stock Exchange. LUKOIL proudly declares itself to be the only public Russian oil company whose share capital is dominated by minority stakeholders. LUKOIL's strategic partner is ConocoPhillips, an American oil and gas company that owns 20 percent of LUKOIL's stock. LUKOIL has a number of partnership agreements and joint projects in upstream, gas processing, and downstream projects with Gazprom.

Since 1993, LUKOIL has been headed by its president Vagit Alekperov. In the last years of the Soviet Union's existence, Alekperov held the positions of deputy and first deputy of the Ministry of Oil and Gas. Long-term experience in the oil and gas field as well as a powerful network of relationships in the industry maintained since Soviet times contributed to Alekperov's success in turning LUKOIL into an industry leader in Russia.

In 2008 the company employed about 150,000 people in 60 regions of Russia and 30 countries on four continents. LUKOIL, like most other Russian oil and gas companies, is one of the most attractive employers in the country. However, like many Russian companies in the natural extraction field, LUKOIL has an image as a secretive and tightly controlled organization. Visitors to the impressive LUKOIL headquarters in Moscow meet uniformed bodyguards, and both employees and visitors are subject to security checks and their belongings are x-rayed.

LUKOIL is known as a major sponsor of Russian sports teams, such as Spartak soccer club in Moscow, professional water polo club Spartak, LUKOIL motor-racing team, the national ski-racing team, and others. In 2007 the company provided financial support to the fund "Application Committee Sochi–2014," aimed at nominating Sochi to host the XXII Winter Olympic Games in 2014.

Luxembourg

A landlocked country in Western Europe, Luxembourg (998 sq. mi., population 480,222, gross domestic product [GDP] $38 billion in 2007) is a hub of its economic and political activity. Once a part of the Low Countries that produced so much of the fine art and music of the late Middle Ages and Early Modern period, Luxembourg has a history dating back to the construction of Luxembourg Castle in 983, named for the House of Luxembourg whose dynasty presided over the country until 1477, when Luxembourg and the Netherlands became part of the Habsburg Empire. The modern state formally dates from 1867, after France and Prussia nearly engaged in war over control of the small country. Despite its independence, the king of the Netherlands remained the ruler of Luxembourg until 1890, when William III died and passed control of the Netherlands and Luxembourg to separate heirs.

Modern-day Luxembourg is a trilingual country, with German, French, and Luxembourgish as its official languages. Luxembourgish, spoken by some 300,000 people worldwide, is a Moselle Franconian language: a High German dialect developed among the German immigrants in France, Belgium, and Romania during the 12th and 13th centuries.

Luxembourg is a parliamentary democracy with a constitution ratified in 1868, a year after the second Treaty of London. The legislature is unicameral, consisting only of the Chamber of Deputies, the 60 members of which are directly elected from four regions every five years. The Council of State, 21 nonpoliticians appointed by the Grand Duke, advises the Chamber during the drafting of legislation. The Grand Duke, currently Henri I, is the hereditary monarch and head of state, while the prime minister is the head of government and serves on the Council of Government with the other ministers of the executive branch.

Since 1958, Luxembourg was part of the Benelux economic union with Belgium and the Netherlands—its fellow former Low Countries—the name of the union derived from the first letters of each country's name. Most of Benelux's concerns and duties have since been subsumed into the European Union, of which the Benelux countries were founding members.

Luxembourg is one of the wealthiest nations in the world, and the second-largest investment fund center (after the United States). The GDP per capita is the highest in the world—$87,995 in 2006—but in recent years the government has run at a budget deficit for the first time in recent history, a casualty of the 21st century's slowing economic growth. Inflation and unemployment have historically been low, and the GDP high, thanks to a history of industrialization and banking excellence. The industrial sector has included significant export levels of steel, chemicals, and rubber, and as industry declined, the financial sector has soared. The country has actively courted the interest of internet companies, and both Skype and eBay have opened headquarters in Luxembourg as a result.

Maastricht Treaty

The Maastricht Treaty is the supranational agreement that created the European Union (EU) and moved member states closer to economic and political unity. Also known as the Treaty on European Union, it derives its name from the Dutch city Maastricht in which it was signed on February 7, 1992, following a prolonged period of often fractious and politically charged negotiations. After eventually being ratified by all members, the Maastricht Treaty took effect on November 1 of the following year, superseding the Treaty of Rome and the European Economic Community (EEC) and marking the greatest degree of multinational cooperation achieved to date among European member states. The treaty can be regarded as the continuation of a decades-long trend wherein many European nations have been progressively moving toward economic and political unity.

At the time the Maastricht Treaty brought the EU into existence, it contained 12 original member countries, with Austria, Finland, and Sweden later joining as additional signatories in 1995. In 2004 and again in 2007, the treaty was amended to permit the inclusion of 12 additional states (10 in 2004, two in 2007) into the EU. Presently three countries are candidates for EU membership, and the treaty is expected to be expanded again with the anticipated accession of Croatia, Macedonia, and Turkey into the EU, although as of 2008 no admission date had been agreed upon. However, in the wake of the rapid expansion of the EU in the first years of the 21st century, many citizens of current member states advocate a slower rate of expansion.

Subsequent external protocols associated with the Maastricht Treaty facilitated the adoption of new policies related to political and economic unity, including the establishment of EU citizenship, giving citizens of states holding full EU membership the right to live and work in any EU state and the right to vote in elections in that state. Many aspects of EU law and the Maastricht Treaty regulate matters unrelated to trade or economic affairs, such as television broadcast standards, exhaust regulations for automobiles, public health guidelines, and the elimination of capital punishment.

While many dimensions of the Maastricht Treaty also address social and political issues, arguably its primary function is to strengthen its members economically. Specifically, cultivation of closer economic linkages between member states improves the ability of the community as a whole to compete in the arena of global trade. By eliminating or reducing tariffs and by simplifying the movement of goods and labor across borders, the community as a whole was foreseen as becoming more economically efficient and competitive. The Maastricht

Treaty delineated policies and distinct phases of Economic and Monetary Union (EMU) that eventually led to the introduction of the euro in 1999 and established it as the common currency of most EU member states. The treaty also established the economic criteria that EU states must fulfill as members.

Additionally, the treaty created a body of institutions that have become collectively known as the "Three Pillars of the EU": the European Communities (EC) pillar that had existed in previous form within the European Community (EC) organization, the Common Foreign and Security Policy (CFSP) pillar, and the Police and Judicial Cooperation in Criminal Matters (PJCC) pillar. The first pillar, or EC Pillar, is concerned principally with economic, environmental, and social policies and addresses matters such as agriculture, customs, economic/monetary union, healthcare, and immigration and citizenship policies. The second, or CFSP Pillar, addresses foreign policy and military matters such as deployment of peacekeepers. The third, or PJCC Pillar, promotes cooperation in combating smuggling, terrorism, and other forms of crime. The pillar structure of organizing laws and regulations is slated to be abolished by merging into a single, consolidated European Union authority in 2009 pending the ratification of the Treaty of Lisbon.

Support for the Maastricht Treaty has not been universal, and its ratification was contested heavily in several nations including Britain, Denmark, and France. Elements within both the British government and the general public were opposed to certain social provisions proposed by Maastricht, and Britain was initially granted exemptions from the social chapter of the treaty such as those regulating workers' pay and benefits. After a change in government, Britain eventually did adopt Maastricht's social protocols, but together with Denmark and Sweden has declined to adopt the euro as its currency. After initially voting against the treaty by a narrow margin, Danish voters later narrowly voted to ratify Maastricht after Denmark was permitted to opt out of certain of the treaty's sociopolitical provisions. Maastricht was only narrowly approved by French voters in a 1993 referendum. More recently, in 2005, Maastricht's constitution was to be ratified, facilitating a greater merging of sovereignty among members, but opposition was voiced in many countries and voters in both France and the Netherlands rejected the EU constitution via referendum.

Macroeconomics

Macroeconomics is a part of economic analysis that focuses on the understanding of economic issues at the aggregated level. It is related to microeconomic analysis, which pursues the study of the individual economic behavior of economic agents such as households, firms, and governments and deals with the issue of the functioning of markets with an emphasis on welfare. Macroeconomics in contrast aims at the understanding of the economy as a whole. The study is concerned with the economic aggregates such as total demand for goods and services by households and firms, the total investment in the economy, the value of exports and the spending by the state sector. At the same time it endeavors to understand the relationship between national income and consumption as well as taxation, savings, and imports. The key issues of the analysis are national output and economic growth, unemployment, and the development of the price level in the form of inflation.

Macroeconomic analysis can take the form of a partial analysis in which relevant aspects are identified as the object of analysis within the general economic process. This follows an isolation of particular behavioral cause-effect relationships on the basis of assumptions, which leads to a construction of models. The ceteris paribus analysis examines how a change of a variable affects another dependent variable within the model and assumes that all other variables remain unchanged. This form of partial analysis is applied in the interest rate–investment relationship, for example. Here we assume that all other variables remain constant but that a change in the money supply will have an effect on the interest rate, which in turn will change investment in the economy.

Macroeconomics can also pursue a general analysis that analyzes the interdependence of all economic variables. Here the effect of a change in demand for a particular good X will be analyzed with regard to its effect on all other goods, prices, and production factors as well as on the general goods and factor markets. In particular, does the general analysis focus on the effect of a change of the price level in the goods market on other partial markets such as the money market and the factor market, in particular the labor market. The analysis can be ex-ante or ex-post. The ex-ante analysis incorporates the plans and expectations of economic agents and aggregates (e.g., construction of an equilibrium on the basis of the consumption and investment plans on the goods markets), whereby the ex-post analysis explains economic situations that have already taken place (e.g., national income accounting, circular flow of income, gross domestic product, etc.). Macroeconomics can take a static or a dynamic form, when it is assumed that no economic agent has any need to readjust their economic plans.

The analysis, however, blurs individual results due to the aggregation; this leads to macroeconomic analysis being less definite depending on the size and heterogeneity of the selected groups of aggregates. Keeping this in mind, the value of the macroeconomic insight is necessary for the identification of economic policy options and their respective efficacy. Macroeconomics plays an important role in growth theory, labor market theory, monetary theory, and international and development economics. The input-output analysis aims to disaggregate some of the macroeconomic variables to gain a more detailed insight into economic processes.

Some of the main issues in macroeconomic analysis are inflation, unemployment, and output and growth. The inflation rate is the annual increase in the average price of goods and services. The price index measures the average level of prices; the common price index is the Consumer Price Index (CPI). The CPI measures the cost of purchasing a standard basket of goods at different points in time: the prices are weighted according to the economic importance of each individual good or service included in the basket. The CPI is the most widely used measure of inflation and is also used as the basis for many governmental inflation targets. Other important indices used are the Retail Price Index (RPI), the GDP deflator, and the Producer Price Index (PPI).

Unemployment measures the number of people who are registered as actively looking for work. The unemployment rate is based on the labor force, which accounts for the total number of people in paid employment and those who are registered as looking for work. The unemployment rate is calculated as the number of people who are looking for work as a percentage share of the total labor force. Output and growth are commonly measured on the basis of the gross domestic product (GDP), which measures the total value of goods and services produced within an economy over a particular period of time (data can be quarterly or annual). The gross national income (GNI) measures the total income that is generated within an economy. Economic growth indicates a positive change in those figures. Macroeconomic theory assumes cyclical changes in the form of recessions and booms that have impact on the general price level in the economy (recessionary gap, inflationary gap) as well as the rate of employment.

Macroeconomic Policy

Macroeconomic policy is divided into two main policy options that aim to stabilize the economy and smooth out any cyclical fluctuations. These policies are fiscal policy and monetary policy. Fiscal policy uses a variation of taxation and government expenditure to affect the injections into and the withdrawals from the economy. Monetary policy focuses on a variation of the money supply and the setting of the interest rate as a cost of borrowing from the central bank by commercial banks and thereby affecting the overall lending rate within the economy. The government can also use the exchange rate to influence its trade volume and trade direction with other economies (open economy macroeconomics).

Keynesian Economics

The history of macroeconomic thought is determined by the development from classical economics where a natural adjustment toward full employment is assumed to Keynesian beliefs. John Maynard Keynes revolutionized economics by suggesting in his General Theory of Employment, Interest, and Money that this automatic adjustment does not take place and that supply does not create its own demand. He emphasized a refocus on an adjustment of the demand side within the economy to achieve an equilibrium. The General Theory reiterates many behavioral assumptions of the classical theory, in particular, the objectives of profit and utility maximization, marginal values, perfect competition on goods markets, the static form of analysis that assumes technology as given; furthermore, the analysis ignores the dynamic impact on economic growth of any of such factors as population and production factors. Keynes accepted the capitalist form of the economic structure, which enabled an incorporation of his theory into a neoclassical synthesis.

The Keynesian emphasis lies in the construction of the equilibrium level of national income from a short-term perspective, while allowing the capital stock to remain unchanged. This can result in an equilibrium situation below the level of full employment, which would then necessitate governmental intervention in the form of fiscal or monetary policy. The impact of any changes in consumption demand is highlighted by the multiplicator-accelerator process, which describes the size of the effect that a change in any of the autonomous demand aggregates (i.e., not dependent on national income, here nonconsumption demand) have on national income. This analysis assumes both a constant marginal propensity to consume and a constant marginal propensity to withdraw.

In the case of a national income level below full employment, any change in the autonomous demand aggregates will lead to an increase in national income over a number of periods in the form of the multiplier process, whereas any change in the autonomous demand aggregates (investment, government expenditure, exports) in a situation of full employment will lead to inflationary tendencies as demand will outweigh the potential of supply due to the scarcity of resources. One such autonomous demand aggregate is investment demand, and this aggregate is dependent on the interest rate and the marginal rate of capital productivity. As long as the marginal factor productivity is greater than the market rate of interest, investment will be positive, with the constraint of the constant marginal productivity investment being negatively related to the interest rate.

On the monetary side of the economy, Keynes assumes three motives for holding money, which have macroeconomic implications. These motives are transaction, precaution, and speculation. He derives the liquidity preference curve as the money demand curve, which shows a negative relationship between money demand and the interest rate. In the case of a strong fall of the market rate of interest, the speculation demand of money becomes infinite, which might lead to a liquidity trap. The Keynesian theory had a major influence in the formation of the relationship between inflation and unemployment. The Phillips Curve represents a growing rate of unemployment going alongside a fall in the inflation rate, thus suggesting a trade-off between inflation and unemployment. The trade-off was later refuted by Friedman and Phelps and their suggestion of the nonaccelerating inflation rate of unemployment (NAIRU). This NAIRU is the natural rate of unemployment at which the inflation rate remains constant. Monetarists believe that governmental policies can only achieve a reduction of this rate in the short term, as in the long term any of such policies will be purely inflationary.

A widely used form of analysis is the IS-LM model that describes a simultaneous derivation of an equilibrium on the goods market and the money market. Here the IS curve is derived from the goods market, which represents different equilibrium situations for various combinations of interest rate and national income. Within a closed economy with no state, the goods market is assumed in a state of equilibrium when $Y = C(Y) + I(r)$ or when $Y = C(Y) + S(Y)$, whereby Y denotes national income, $C(Y)$ consumption demand dependent on national income, $I(r)$ investment dependent on the market rate of interest, and $S(Y)$, savings dependent on national income and it holds that $C = Y - S$. The LM curve represents the money market equilibrium, where the demand for money (L) has to equal the exogenously determined (by the central bank) supply of money (M). The demand for money depends on the market rate of interest as well as on the national income level (motives for holding money), for the equilibrium M = L (r,Y) must hold. Within this analysis the variables Y, C, I, S, and L are considered ex-ante variables—they are planned. In the IS-LM diagram we can identify the interest rate–national income combination at which both goods and money market are in equilibrium.

A situation of disequilibrium leads in Keynesian analysis to output adjustments rather than price changes in the short run. This has repercussions on the labor market, hence also affecting national income, which in turn affects the consumption demand and hence impacts back onto the goods market. Such a cumulative effect of contraction of output and reduction in demand can result in a situation of depression with excess supply of products and labor. In this sense macroeconomic outcomes can be led back to microeconomic behavioral forms of economic agents in situations of disequilibrium that are also dependent on their expectations of future economic situations and outcomes. According to Leijonhufvud and Clover, Keynes highlighted the notion that prices do not always effectively signal shortages and excesses and hence do not always act to coordinate the plans of economic agents. Furthermore, it is doubtable whether the market rate of interest responds coherently to disequilibria between savings and investment demand within the economy, in particular when assuming international capital markets and recent developments in financial markets in the form of securitization.

Keynesian economics found its main impact until the 1970s, when a sustained phase of stagnation in many developed nations led to a monetarist counterargument. This movement led to a refocus of governmental policies onto monetary policies rather than fiscal ones. Keynesian theory had a strong impact on functional finance whereby a contractionary economic policy was meant to tackle an inflationary situation whereby the expansionary economic policy aimed at a deflationary gap in the form of economic fine tuning under the belief of cyclical changes. These cyclical fluctuations could vary from Kontradieff-cycles (50–60 years), Juglar-cycles (9.5 years), to Kitchin-cycles (3.5 years).

Madrid General Index

The Índice General de la Bolsa de Madrid (IGBM), or Madrid General Index, represents the most relevant set of indices in Spain besides the IBEX 35. The Madrid General Index is comprised of a changing number of stocks (currently more than 100) that are traded in the Bolsa de Madrid. The IGBM is made up of two sets of indices: based on price and profitability measures. It has been published since the end of the 1940s. From 1986, the IGBM, both for prices and yields, has not changed its base, and the calculations are linked to the current series with the December 31, 1985, base = 100. The base value of the new sectorial and subsectorial indices has been 1,000 since the closing of the market on December 31, 2004.

The IGBM indices are divided into two series: the first corresponds to all the series of price indices and the second to performance indices. Composition and weightings are the same for both. The unified sectorial and subsectorial classification for Spanish Exchanges (BME) established on January 1, 2005, applies to all IGBM companies. IGBM's sectors are as follows:

1. Oil and energy
2. Basic materials, industry, and construction
3. Consumer goods
4. Consumer services
5. Financial and real estate services
6. Technology and telecommunications

The management of the IGBM is the responsibility of the management committee, which is supervised and appointed by the board of directors of the governing body of the Bolsa de Madrid. The management committee responsible for the IGBM indices is comprised of five members and a general coordinator (responsible for calling ordinary and extraordinary meetings) whose functions are (1) ensuring that the indices are calculated in accordance with prevailing technical rules; (2) holding half-yearly meetings to decide on the composition of the IGBM for the following six months, as well as extraordinary meetings, whenever necessary; and (3) drawing up a report, which must be approved by the board of the governing body if it is necessary to change the technical rules for calculating the IGBM indices.

IGBM is not made up of a fixed number of companies. During each six-monthly meeting, all those companies that fulfill all the requirements are admitted and those that no longer do so are excluded. The criteria to join the IGBM are based on the following liquidity features: (1) trading volume of more than €3 million; (2) turnover velocity of more than 10 percent of capitalization on an annual basis, taking into consideration only the equity capital in free float; and (3) trading frequency of more than 50 percent.

At the extraordinary meetings, those companies who, in the committee's view, are likely to meet the requirements can join the IGBM before the next six-monthly definition. The management committee makes decisions on admission or exclusion of companies when it deems convenient and under special circumstances that are not mentioned in the prior specifications.

The weighting of each company is calculated on the basis of the market capitalization on the last day of the preceding six-month period. The following adjustments are taken into account: capitalization adjustment of Spanish companies in the IGBM, weightings of sectors and subsectors, and adjustments for foreign companies. In order to calculate the IGBM on a daily basis, the daily indices of each IGBM-listed company are used. The Index Value, with 100 as the base, is the quotient between the daily price and the so-called reference price, that is, the price at the close of the day prior to the change in the composition of the IGBM. In relation to daily adjustments for operations that affect IGBM-listed companies, capital increases, or mergers and acquisitions between two IGBM companies belonging to the same subsector, or splits, are taken into account for the daily calculation of the index, although dividends paid by companies are not.

Make-or-Buy Decision

The term *make-or-buy decision* represents the decision of firms to organize their goods and services internally or externally. This decision is so central to the functioning of businesses that it has attracted scholars from multiple disciplines such as supply chains, vertical integration, technology, flexibility, allocation of resources, large versus small organization, and core competencies, among others. Further, factors that have been documented as being central to the make-or-buy decision include total acquisition cost, complexity of the product, technological factors, costs, and skills. Others have discussed factors that include environment characteristics, lifetime costs, and opportunity costs. Although these factors are important, what is missing is the role of market orientation and production costs in the make-or-buy decision-making process.

Given that market orientation leads to superior performance, and that production costs depend on the costs of transportation, which in turn depend on the cost of fuel, it is imperative that managers understand the circumstances under which a making or buying decision is most desirable.

The Make-or-Buy Model

Market orientation refers to the extent to which a firm is able to meet customers' needs. John Narver and Stanley Slater (1990) view market orientation as a combination of three behavioral components—customer orientation, competitor orientation, and interfunctional coordination—whereas Ajay Kohli and Bernard Jaworski's (1990) view of market orientation relates to information generation, dissemination, and responsiveness relating to customers. Clearly, the fundamental benefit of being market oriented is the creation of superior customer value and continuous superior performance for the business. Empirical research supports this assertion. However, market orientation is the function of costs; e.g., if a product is expensive, customers may be unwilling to buy, and thus a lack of market orientation on the part of firms.

Further, the significant increase in the geographical scale of production and distribution has necessitated that firms compare production costs. For the purpose of this study, production costs is defined as the total costs incurred by a firm through the purchase of input goods, its transportation to a plant, and its production. Prior research addresses the elements of time in transportation, such as order time, timing, punctuality, and frequency, and evaluates the differences between adjacent trading partners, nearby trading partners, and distant trading partners. However, there is little reference to the heart of the transportation costs, such as the cost of fuel. Clearly, an alternative to geographical proximity is that suppliers that are located far from plants should coordinate their transportation systems, leading to considerable reduction in transportation time and costs. Or, firms should make the product in-house, leading to savings in transportation time and costs.

Research indicates that a "make" decision is desirable when strong competition exists between firms and their vulnerable core competencies. By contrast, a "buy" decision allows firms to respond flexibly to changes that can occur in technology, demand, and costs, and hence avoid inefficiencies. This makes the argument for the need for inclusion of market orientation and costs in the make-or-buy decision-making model in order to create superior value for customers and superior performance for businesses.

The model suggests that although a firm's decision to make gives rise to market orientation, its initial cost of production increases up to a point, beyond which the production cost decreases, and thus enables a firm to be more cost competitive and market oriented. By contrast, a firm's decision to buy has a constant cost. While one scenario may suggest that the production cost exceeds the benefit being market orientation, another scenario suggests that the benefit of market orientation outweighs the cost of production. A third scenario indicates that buying is more desirable than making because buying is always cheaper than making. Clearly, the first scenario is desirable for managers engaged in service industries, whereas the second scenario is applicable to manufacturing. The third scenario is advisable for managers who need to maintain a stable market orientation and thus keep production cost low; however, firms that are equipped to handle only stable markets will not be effective because real markets are often complex and unpredictable.

Although the model depicts how costs can be minimized, sometimes volatile changes in the price of fuel should be factored into the production costs. Indeed, rising fuel costs have been identified as an emergency that affects all supply managers. In sum, the implication for managers is that they should recognize the need for preserving market orientation by keeping costs low through the make-or-buy decision.

Malaysia

Malaysia is located in southeastern Asia on a peninsula bordering Thailand to the north, the northern one-third of the island of Borneo bordering Indonesia, Brunei, and the South China Sea, south of Vietnam. The country is slightly larger than New Mexico. The capitol of Malaysia is Kuala Lumpur.

Great Britain established colonies and protectorates in the area of current Malaysia during the late 18th and 19th centuries. During World War II Malaysia was occupied by Japan from 1942 to 1945. In 1948, the Federation of Malaya was formed on the Malay peninsula, which became independent in 1957. Malaysia joined the United Nations on September 17 of that year. The present day Federation of Malaysia was formed with the merger of the former British colonies of the East Malaysian states of Sabah and Sarawak on the northern coast of Borneo; Singapore joined Malaya in 1963. The first years of Malaysia were volatile; there was a communist insurgency, a confrontation from Indonesia, Filipino claims to Sabah, and Singapore's expulsion from the federation in 1965. From 1981 until 2003, under the longest-serving prime minister, Mahathir bin Mohamad, Malaysia successfully diversified its economy by reducing its dependence on exports of raw materials and expanding into manufacturing, services, and tourism.

Some of Malaysia's natural resources include tin, petroleum, timber, copper, iron ore, natural gas, and bauxite. Its estimated population in 2008 was approximately 27 million. The dominant religion is Islam, followed by Buddhism and Hinduism. The country's official language is Bahasa Malaysia.

Government

The government of Malaysia is a constitutional monarchy, and the heads of the states are either hereditary sultans or appointed governors. The constitution was ratified on August 31, 1957, and has been amended many times since. The most recent amendment to the constitution was in 2007. The position of the king is largely ceremonial; the current king is Sultan Mizan Zainal Abidin, who has acted in that capacity since December 13, 2006.

The cabinet is appointed by the prime minister from among the members of Parliament with consent of the king. Kings are elected for five-year terms by and from the hereditary rulers of nine of the states. The last election was held on November, 3 2006 and the next will be held in 2011. The prime minister is selected from the house of representatives. When the legislative elections have concluded, the leader who commands the support of the majority of members in the house becomes prime minister. It has been tradition since independence that the leader of the UMNO party becomes prime minister.

The bicameral Parliament or Parlimen consists of the house of representatives, known as Dewan Rakyat, and the senate, which is known as Dewan Negara. This upper house contains 70 seats, with 44 appointed by the king and 26 elected by 13 state legislatures. These senators serve three-year terms with a limit of two terms. The house of representatives or Dewan Rakyat is made up of 222 seats. The members are elected by popular vote to serve five-year maxi-

Malaysia is rich in natural resources, such as this lumber being prepared for export. The country has thrived through export-oriented industrialization and a series of pragmatic economic policies.

mum terms. Elections for the house of representatives were held on March 8, 2008, and are also scheduled for June 2013. Citizens must be 21 years of age or older in order to vote.

There are a variety of sharia and civil courts in Malaysia. Civil courts include the federal court, court of appeal, high court of Malaya on peninsular Malaysia, and the high court of Sabah and Sarawak in the states of Borneo (judges appointed by the king on the advice of the prime minister). Sharia courts include sharia appeal court, sharia high court, and sharia subordinate courts at the state level, and deal with religious and family matters such as custody, divorce, and inheritance, but only for Muslims. Decisions of sharia courts cannot be appealed to civil courts.

Economy

Malaysia today is an emerging multi-sector economy. However, in the 1970s it was a producer of raw materials. When Prime Minister Abdullah Badawi came into office in 2003, he tried to shift the Malaysian economy farther up the value-added production chain in several ways. Foremost, he attracted investments in high-technology industries, medical technology, and pharmaceuticals, which has largely contributed to the nation's successful diversification strategy. Electronics exports remain a significant driver of the economy, but the government is continuing efforts to boost domestic demand to wean the economy off of its dependence on exports. Malaysia profited from the higher world energy prices of 2008 since it is an oil and gas exporter. However, the rising cost of domestic gasoline and diesel fuel forced Kuala Lumpur to reduce government subsidies.

The country was hit hard by the Asian Currency Crisis in 1996–97 but recovered by 2000. Inflationary pressures began to build in 2007 and in 2008 inflation stood at nearly 6 percent, even though Malaysia "unpegged" the ringgit from the US dollar in 2005 and the currency appreciated 6 percent per year against the dollar 2006–08. This has helped to hold down the price of imports.

The government presented its five-year national development agenda in April 2006 through the Ninth Malaysia Plan, which outlined the national budget for 2006–10. Prime Minister Abdullah unveiled a series of development plans for several regions of Malaysia that have faced the challenge of attracting business investment. Under Prime Minister Abdullah's leadership real gross domestic product (GDP) growth has averaged about 6 percent per year, but regions outside of Kuala Lumpur and the manufacturing hub of Penang have not seen such gains.

The Malaysian central bank has maintained healthy foreign exchange reserves and the regulatory regime has limited Malaysia's exposure to riskier financial instruments and the global financial crises. So while these steps may spare Malaysia some of the brunt of the economic financial crisis that began in 2008, decreasing worldwide demand for consumer goods is expected to hurt economic growth.

Malaysia's estimated Purchasing Power Parity per capita for 2008 was $15,700. Purchasing Power Parity in general for 2008 was $397.5 billion (estimated). The GDP composition by sectors is as follows: agriculture, 9.7 percent; industry, 44.6 percent; services, 45.7 percent. The estimated unemployment rate for 2008 was 3.7 percent, but that rate was expected to rise as demand for consumer goods decreases. Estimated public debt for 2008 was about 43 percent and the federal budget had a deficit of approximately $10 billion.

In terms of agriculture products, peninsular Malaysia primarily produces rubber, palm oil, cocoa, and rice. The Sabah region primarily produces subsistence crops, rubber, timber, coconuts, and rice and the Sarawak area produces rubber, pepper, and timber.

In terms of industries, peninsular Malaysia hosts rubber and palm oil processing and manufacturing, light manufacturing, electronics, tin mining and smelting, logging, and timber processing. Sabah hosts logging and petroleum production and Sarawak hosts agriculture processing, petroleum production, and refining, and logging.

Sabah and Sarawak are located in the Eastern portion of Malaysia. Some major ports and terminals are Bintulu, Johor Bahru, Kuantan, Labuan, George Town (Penang), Port Kelang, Tanjung and Pelepas.

The Strait of Malacca and South China Sea are the principal bodies of water surrounding Malaysia and are high-risk areas for piracy and armed robbery of ships. There have been numerous reports of commercial vessels that have been attacked and hijacked both at anchor and while underway. The vessels that are hijacked are often disguised and their cargo is diverted to ports in east Asia. Their crews are usually murdered or cast adrift.

Regional Issues

Malaysia is one of several nations that have asserted sovereignty over the Spratly Islands. China, the Philippines, Taiwan, and Vietnam have also asserted sovereignty over these islands in question. In 2002 the "Declaration on the Conduct of Parties in the South China Sea" eased tensions between the nations over the Spratly Islands, but it is not legally binding. In March 2005 a joint accord among the national oil companies of China, the Philippines, and Vietnam was established regarding marine seismic activities in the Spratly Islands. However, Malaysia was not a party to the accord.

Other disputes continue over deliveries of fresh water to Singapore and Singapore's land reclamation, bridge construction, and maritime boundaries in the Johor and Singapore Straits. The International Court of Justice has even gotten involved and held public hearings in 2007 in response to the Memorials and Countermemorials filed by the parties in 2003 and 2005 over sovereignty of Pedra Branca Island/Pulau Batu Puteh, Middle Rocks, and South Ledge. The Court awarded Ligitan and Sipadan Islands, also claimed by Indonesia and the Philippines, to Malaysia but left maritime boundary and sovereignty of Unarang rock in the hydrocarbon-rich Celebes Sea in dispute. In September 2008 Brunei and Malaysia agreed to resolve their offshore and deepwater seabed dispute, resume hydrocarbon exploration, and renounce any territorial claims on land.

Malaysia is a major center in human trafficking of women and children for the purpose of commercial sexual exploitation, and men, women, and children for forced labor. Those who migrate willingly from south and southeast Asia to work usually go to Malaysia, and some are essentially involuntary servants of Malaysian employers in the domestic, agricultural, construction, plantation, and industrial sectors. Malaysia enacted antitrafficking legislation to combat this problem in July 2007, but it did not take action against exploitative employers or labor traffickers. Additionally, the government had not ratified the 2000 UN Trafficking in Persons (TIP) Protocol as of 2008.

Managed Float Regime

The current worldwide financial environment is called a managed (or dirty) float regime. With national and regional economies increasingly intertwined, currencies are almost universally managed by central authorities: While exchange rates fluctuate daily, central banks or other institutions buy and sell currencies in order to influence their value. This intervention works, in part, to slow down the damage that can be done by economic crises in the international economy.

The *managed* modifier is used to highlight the difference between this circumstance and a "pure" floating exchange rate, one in which those fluctuations are governed by market forces. The dirty float regime is one in which currencies are allowed to fluctuate—they are not pegged to fixed values as in fixed exchange rate systems—but intervention manipulates those fluctuations, like the paddle in a boat at sea, still bobbing with the waves rather than being affixed to a pylon, but (ideally) never capsizing or pulled too far in one direction or another.

The foreign exchange market, currency speculators, and arbitrageurs all amplify the size and frequency of currency fluctuations, and central bank intervention is meant to counteract that. More than three quarters of the activity on the foreign exchange market is speculative, purchases made with no intention of "spending" that currency. This has been increasingly true since the late 1990s, when currency speculation started to become more and more intense, more and more aggressive. When speculators short huge amounts of a country's currency, the government can buy it back in order to stabilize prices and prevent a plummet—essentially acting as a force to countermand the already artificial nature and very real effects of currency speculation and the treatment of money as a commodity good.

Compared to private entities, central banks have tremendous foreign exchange reserves, and use various strategies to try to stabilize the market, influence inflation or interest rates, and constrict or enlarge the money supply. There is often a target rate for their currency—not as fixed as a pegged rate, but a range to shoot for. Economist Milton Friedman has advocated applying the buy low/sell high strategy to the managed float: Central banks should buy up their currencies when they are exchanging at too low a rate, and sell them when the rate is too high, thus not only stabilizing the currency market but making a profit. To date, central banks' activities have been more reactive than this, and so there is too little real-world data to evaluate the effectiveness of Friedman's strategy.

Typically, intervention occurs not with every jot and jostle of the market, but a few times a year in order to right the course. It is not always enough, but the severity of currency-related crises like the Asian financial crisis of the late 1990s is enough to demonstrate the need for action of some kind.

Management

Management is the process that organizations use to reach their goals utilizing people and other resources. Organizations and the environments that they are located in are changing quickly and significantly. Traditional hierarchical command and structured organizations are proving too slow and costly for the 21st century. Rather than working with a boss and subordinates, an increasingly typical situation is one driven by teamwork that integrates different types of know-how to foster creative solutions. Information technology is offering new and richer ways for people to collaborate, even when they are located in different parts of the world. Networking is increasingly an important factor. On one level organizations are partnering with other organizations to combine their expertise and strengths to take advantage of opportunities otherwise unavailable to them—for example through joint ventures. On another level individuals are increasingly creating and joining networks in their companies, professions, and very large global ones.

The Evolution of Management Thought

The roots of management are in ancient military organizations. Sun Tzu's *The Art of War* (4th century B.C.E.) is an example that discusses many strategic, structural, and interpersonal management issues. Adam Smith in *The Wealth of Nations* (1776) had the insight that having each person perform a narrow task well might result in greater agility and quality in production. This notion is called job specialization or the division of labor.

In the early 20th century, Frederick W. Taylor put forth an approach called "scientific management." This involved doing time-and-motion studies and otherwise collecting data to try to determine the best ways to do each task and movement that constituted a job. Henri Fayol, a French mining executive, in his book *General and Industrial Management* (1916), developed a functional taxonomy of management comprised of organizing, command, coordination, and control. Max Weber, a German academic, in *The Theory of Social and Economic Organization* (1922), distinguished traditional nepotistic family-run businesses from ones with more fairness and objectivity in hiring, promoting, and decision making. He called such "rational" organizations "bureaucracies," emphasizing that they ran on the basis of set rules and policies rather than the whims and power of individuals. Chester Barnard's *The Functions of the Executive* (1938) viewed organizations as cooperative systems, which need to obtain the voluntary cooperation of their members.

In the mid-20th century, Herbert Simon suggested that managers do not search indefinitely for the best alternative but rather often decide upon a decision choice that will work, although not necessarily optimally. He called this "satisficing." In the 1960s organizations were viewed as systems analogous to biological organisms. Under "systems theory," organizations first took in inputs, such as financial material and human resources, which went through a transformation process, involving technologies and managerial actions, within the organization; next they sent out outputs, including goods and services.

In the 1980s and 1990s, "quality management," sometimes called "Japanese management," became a leading approach. Key features included the continuous improvement of products and services, of the level of customer satisfaction with them, and Just-in-Time (JIT) inventory, where the company purchases of materials would be limited to those needed for the particular day or week. In the 21st century, managing for sustainability, or "green management," is increasing its influence as companies grapple with the ethical and legal need to make their operations and products support, rather than hurt, our natural environment.

Culture, Environments, and Ethics

Just as different nationalities have cultures, so do organizations. The internal environment of an organization includes a corporate culture that is comprised of the key values, beliefs, understandings, and norms generally shared by members of the organization. The fundamental values that characterize an organization's culture are communicated through symbols, stories, slogans, and ceremonies.

Contemporary business is often conducted by multinational companies (MNCs) operating around the world. More and more markets are becoming worldwide ones, and organizations must recruit people who are adept at intercultural relations and communications. One important trend has been outsourcing of jobs from high-wage countries to low-cost ones.

The publicity of a series of large corporate scandals involving Enron, Arthur Andersen, WorldCom, Tyco, poison-painted Chinese toys, and Bernard Madoff provided an impetus for higher expectations of managers. The Sarbanes-Oxley law reflects this trend. A key way companies can be ethical is through devising strategies whereby they help to alleviate poverty, improve health, or introduce environmental sustainability through business activities that are profitable. So rather than rue the need to spend money on the research and development of environmentally helpful and conscientious parts of a product or service, a company might relish the prospect of aligning with the requirements of society before they are legally mandated so that if that does occur, they will be in the best competitive position.

Functions

The management process is comprised of planning, organizing, leading, and controlling activities. Planning involves setting goals and objectives and determining what actions should be taken to move toward accomplishing them. Organizing is the process of assigning tasks, allocating resources, and coordinating the people and groups of the organization in the implementation of plans. Leading is the process of encouraging others to commit themselves to working well and supporting goals. Controlling is the process of evaluating actual work performance against planned results and directing any adjustments that might be needed to improve performance.

One of the important choices in decision making is whether a decision is best made by a manager or a larger group. Group decision making must occur with a sensitivity to avoid the tendency toward groupthink, or premature agreement on a decision. Some companies institute a devil's advocate position to ensure that the potential downsides of proposals are accurately considered. Problem solving can be improved through such creativity-stimulating procedures as brainstorming, where initially all ideas that come to mind are put on the table and then evaluated. Increasingly, teams are highly diverse and global. Also, working over the internet in virtual teams is an important trend.

Beyond tactical or short-term plans, organizations develop long-term strategies. Sometimes these are premised on competitive advantages exceeding those of competitors for providing superior value. Sometimes firms articulate the fundamental purposes of their organization in mission statements. The strategic management process involves environmental analysis of demographic and cultural aspects of societies in which the organizations exist, the technological product and processes available, the force of the economy, and legal and political forces (both local and international). When developing strategy, an organization must also analyze its internal capabilities, including its operations, logistical activities, marketing and sales, service procurement, technology development, human resource management, firm infrastructure, and resource management. Often firms focus on their core competence associated with things they do best. Generic strategies for obtaining competitive advantage include striving to be the lowest-cost producer of a product or provider of a service and making their product or service different in ways valued by customers. Firms must monitor and evaluate how their strategies are implemented and attempt to adjust them in line with the implications of such information.

Organizational Structure

Organizational structure refers to how the people, departments, technologies, and locations of a company are connected. Different ways of structuring an organization are appropriate for different situations. When units or people are interdependent and require each other to complete their work well, an integrated structure that fosters interaction, coordination, and cooperation might be appropriate. Organizations that have a formal structure are often specified by organizational charts showing how people and units are connected with each other as far as who reports to whom and who has authority over whom.

The current tendency is to move away from hierarchical multilevel organizations and rather institute flatter ones where employees are empowered and enabled by technology to make decisions themselves rather than seeking the approval of higher-ups as much. Traditional organizations were centralized, where top management had to approve most things. Contemporary organizations are more typically decentralized. Some organizations are organized around certain products or services; others are organized around categories of customers; and yet others have geographic structures. Organizations in which people have two bosses are called matrix structures. For example, a person might report to a functional department head (e.g., finance) and also to the head of a project they are in, such as the solar energy project.

Managing in a Networked World

Information systems were initially used for data storage. The ability to provide numerical summaries and calculations involving data was called "data processing." As computer technology developed, management information transcending mere data agglomeration was provided by these technologies. Initially a company's information was centralized in one large computer, access to which was through specialized programmers. Then the microcomputer revolution of the 1980s fostered the dispersion of the collection and analysis of information and companies to many small computers in departments, offices, and even on individual desks. This fragmentation was reversed to an amazing extent in the 1990s and early 21st century by the development of organizational networks (or intranets) and the internet and World Wide Web.

At the onset of the second decade of the 21st century, more sophisticated collaborative social and professional networking technologies are changing many managerial functions. For example, LinkedIn.com is a worldwide social and professional network with more than 30 million members. LinkedIn allows a manager in, for example, the pharmaceutical industry in New Jersey to find experts in new media in places such as Finland or India to collaborate on fulfilling needs, perhaps developing Web-based training.

An incipient trend that may develop into an important venue for conducting business is the use of three-dimensional augmented virtual interfaces, such as virtual worlds. For example, the Second Life virtual world provides people in business with a virtual representation of themselves (called an "avatar") that can attend meetings and share and discuss documents and PowerPoint presentations, while making nonverbal gestures and expressions. So a publisher in London might have a meeting in Second Life with production people in Mumbai, editors in San Francisco, and marketing people in Pretoria without the time delay, cost, neglect of their jobs, and exhaustion of contemporary travel. Certainly the benefits for global sustainability of such a structure are stark.

Management Development

Management development is the organized approach to prepare individuals to better achieve career and collective goals by working with and through human and nonhuman resources in order to continually add value to the world and its stakeholders. Managers who do things fast and rapidly achieve career and organizational goals demonstrate effectiveness; those who achieve their goals by controlling their human and nonhuman resources without exhausting or wasting them demonstrate efficiency. Managers who do things first and continually add value to enterprises demonstrate creativity; those who do things together and collaboratively address the needs of the world and its stakeholders demonstrate responsiveness. Managers who develop the motives and attitudes, capabilities, and behavior patterns to be consistently effective, efficient, creative, and responsive contributors to enterprises enhance individual career and organizational global performance at the supervisory, middle management, and executive levels.

Successful global businesses integrate management development with organization development initiatives to ensure alignment between management development activities and business strategy. Management development teaching techniques that are often used to advance global business are either formal on-the-job or off-the-job approaches. Among the former are the internal coaching or guided experience method; the internal job rotation method; and the internal performance committee method. Among the latter are the accreditation by independent bodies approach; the market-led MBA degree approach; and the national competency approach.

Although domestic star performers have been selected for global business assignments and undergo an informal "sink or swim" international on-the-job test, formal on-the-job approaches are more likely to produce better global business results. The internal coaching method is a form of guided global experience conducted either by an experienced in-house superior or an external consultant providing initial talent diagnoses, assigning meaningful in-house tasks, evaluating performance, and supportively counseling management development candidates about future global business performance improvements. The internal job rotation method moves managers on a regular schedule from job to job in the company to develop an individual with an appreciation of the whole company, broadened contacts, and proven adaptability.

The internal performance committee method is a way for managers to gain exposure to and participate in group decision making in order to develop a sense of collective responsibility for global business policies. The internal on-the-job methods, however, while providing relevant company-specific experience, offer no guarantees that the lessons learned are correct, timely, or desirable for the professional development of individual managers, since companies may perpetuate a tradition of organizationally well-adapted but professionally underdeveloped global business managers. To address that management development risk, organizations supplement their on-the-job approaches with formal off-the-job ones.

The accreditation by independent bodies approach attempts to certify institutions and management development programs that meet an external set of standards for professional management development. For example, the European Foundation for Management Development (EFMD), a global organization devoted to the continuous improvement of management development, launched the European Quality Improvement System (EQUIS), which has become a leading international system of accreditation for higher education institutions in management and business administration. Management graduates from EQUIS-accredited institutions are certified to have met general external standards of management development, not limited to those from any one organization.

The market-led MBA degree approach is primarily an American-British qualification of management development expertise that prescribes a course of instruction lasting one to two years, focused on business management functional skills demanded by domestic and global markets. Some of the market-led MBA degree programs are also accredited by independent nongovernmental bodies, such as the Association to Advance Collegiate Schools of Business (AACSB) International, which ensure that accredited MBA degree programs advance management development knowledge through sustained faculty scholarship, provide high-caliber teaching of quality and current curricula, and produce management development graduates who have achieved specified professional learning goals. In addition, there are market-led nondegree programs that purport to enhance management development but exhibit a wide range of effectiveness.

Finally, the national competency approach toward management development focuses on a government-led identification of needed individual, organizational, and national functional and performance competencies, along with support for institutions and programs that produce those competencies, such as the Management Standards Centre (MSC) in the United Kingdom (UK) responsible for setting National Occupational Standards (NOS) for management development in all domestic sectors to identify and address national managerial skill gaps to improve UK global competitiveness.

Competitive management development for global business requires both formal on-the-job and off-the-job training techniques to sustain individual talent and organizational learning capable of successfully handling international business challenges. Responsible global business leaders need to institutionalize an appropriate blend of both formal approaches, and avoid provincial methods, to develop world-class managers ready, willing, and able to capitalize on current and future global business opportunities.

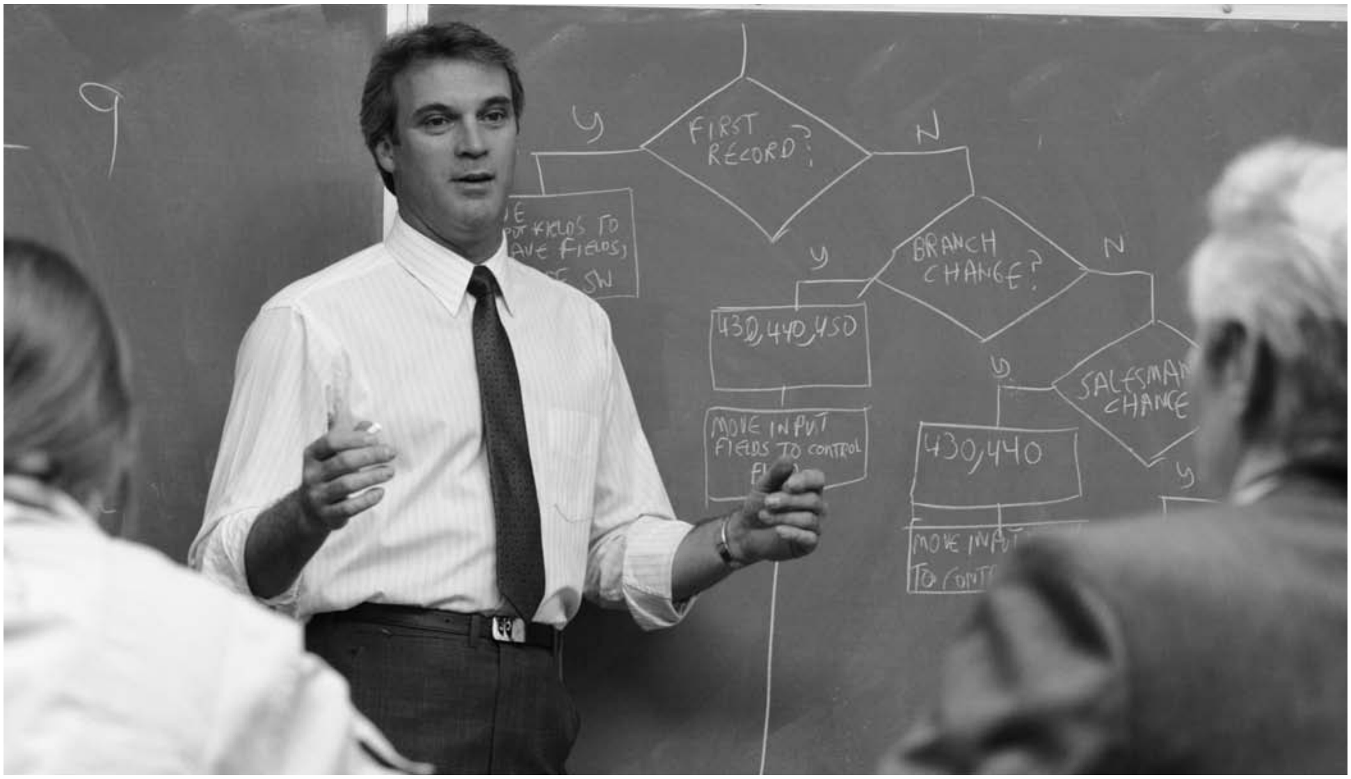
Management Education

As organizations have grown in size and scale over time, so too has the need for the systematic training and development of managers. To fill that void, there has been an increasing creation and utilization of programs in which knowledge about the distinct functions of organizations could be transferred to the people who direct them. Today, all manner of organizations and institutions have begun to teach this class of individuals through numberless learning systems, curricula, and processes generally known as management education.

Although management education has existed in some form since ancient times, the advent of modern management education is a more recent phenomenon. It appeared almost in step with the basic structures of modern management, which is a practice that gained awareness as a distinct discipline in the years around World War II. Prior to then, management had not been commonly perceived as a central factor in any economy.

It was not until the late 18th to mid-19th centuries that a handful of figures across business, government, society, and the academy began to emphasize particular roles of management and structures of modern organization. And only by the outset of the 19th century, in the Scottish mill community at New Lanark, did Robert Owen effectively become the first manager, when he began to concern himself with specific issues related to work and worker. But while Owen espoused education as a necessary factor in forming the complete human, it was not until the late 19th century that the Japanese government-official-turned-businessman, Shibusawa Eiichi, began to strongly encourage higher education opportunities throughout the business community as a way to improve society. His focus on formal business education has been identified as the conception of the first professional manager.

Also by the late 19th century and into the first few decades of the 20th, the emergence of new organizational structures demanded substantive management and formal education for the people performing it. There had in the interim been a proliferation of study and thought on management and organization, especially as "Big Business" took shape in the years around World Wars I and II. By then, academic institutions, mainly in the Western part of the world, had for some



Besides the relatively new management education programs that got their start in the mid-20th century, many managers can benefit from informal continuing education.

time been teaching in disparate areas and classifications of management; for instance, Harvard offered a program of study in business administration and the Massachusetts Institute of Technology offered courses in engineering administration. But in the new order following World War II, and notably with the establishment of the GI Bill in the United States, there came a growing demand for business-related courses. As a result, colleges and universities began to offer more graduate and undergraduate courses in areas such as marketing, finance and accounting, and organizational operation.

But it was not until the 1949–50 academic year, when Peter Drucker joined the faculty of the Graduate Business School at New York University, that the world would be introduced to the first appointment of a professor of management. Through a combination of teaching and consulting work, Drucker observed and formulated the basic principles of modern management. Among his consistent, overarching themes was that it is the responsibility of management to develop people to perform productively and autonomously, and that the highly-skilled worker is the most valuable resource in any organization. These seemingly simple insights had vital implications as Drucker detected a broad social and economic shift from manual work to knowledge work. For it would become increasingly and continuously necessary for managers to learn about, understand, and integrate the principles and practices of good management.

In the coming years, and well before the end of the 20th century, management education programs became a fixture in organizations and institutions across the business, government, and social sectors. Today, a good many managers are likely to have acquired a master of business administration (MBA) or related graduate degree following their undergraduate studies—and may do so even after having obtained an undergraduate degree from one of the burgeoning programs in management, business administration, or specialized areas of both. Yet much as these programs encourage students and businesspeople to communicate with each other on practical problems as a method of learning, there remains a tension within management education as primarily an applied discipline versus an academic pursuit. Among the popular concerns is that the MBA course of study is effectively irrelevant for students who lack adequate managerial experience, and that the concept of management is being distorted by excitement over the perceived glamour of subjects such as leadership and entrepreneurship.

Nevertheless, high executives and upper-level decision makers, middle managers, and other individuals with conceivable potential for management positions have considerable access to a range of continuous learning opportunities. These include numberless combinations of formal or informal instruction delivered by personnel within the organization, external outfits such as management consultants, or specially-designed programs that draw people to faculty on a college or university campus. It also happens that an outgrowth of this focus on education is an enormous industry that produces books and magazines on all areas of management—even those outside business.

In all, the effective education of managers remains a consistent need in developed society and especially in the modern era of globalization.

Management Information Systems

The field of management information systems (MIS) is concerned with a special class of information systems, used to evaluate other information systems in use in the operations of an organization, and to automate, support, and supplement human decision making processes involved in those operations. Like other information systems, the 21st century's management information systems are dependent on and an outgrowth of the rapid sophistication of computer technology at the end of the 20th century and the availability of cheap computing power and an enormous software industry prepared to produce specialized software for business operations.

Management information systems is not simply the study and implementation of the software and other information technology that can be used in the workplace, or of management techniques in operating a business. It is not even the combination or intersection of the two. MIS examines the relationship between the two, and the emergent phenomena associated with that relationship. While accounting information systems, essentially a subset of MIS, focuses on the financial and record-keeping aspects of the business's operations, MIS looks largely at what organizational theory calls "internal control."

Internal control is the way in which a business's resources are allocated and recorded, and is thus implicated in the business's security—its protection from fraud, infringement, negligence, theft, and mismanagement. The concerns of internal control are efficiency, reliability, clarity of reports and records, and compliance with standards and objectives. It prizes consistency, deriving both fairness and efficiency from the practice of handling any given situation in the same way every time, whether it is a crisis or an everyday business transaction.

In the interest of preventing fraudulent financial reporting, the Committee of Sponsoring Organizations of the Treadway Commission (COSO), founded by the United States's major accounting associations, encourages the use of its Internal Control–Integrated Framework. Under this framework, internal control is discussed in terms of five components: the control environment, the foundation for internal control; risk assessment, the discovery and analysis of the risks involved in the attempt to achieve the organization's objectives; information and communication, the systems involved in information processing; control activities, the processes designed to carry out management's directives; and monitoring, the self-evaluation of the system. Clear objectives and budgets must be set before any of this framework can be in place; a surprising amount of poor management comes simply from the lack of explicit objectives, without which neither success nor progress toward it can be recognized.

MIS often involves decision support systems (DSS), a class of information systems that augment decision-making processes with software by making the relevant data easy to access both in raw form and organized in various categories and databases. Purchasing decisions are informed by inventory and sales data, for instance, while decisions about an employee's contract are easier to make when his contributions are easy to identify and collate, instead of relying on general impressions that can be affected more by personal relationships and chemistry than objective business sense. Decision support systems can be communication-driven, facilitating the decision-making processes involving multiple people; data-driven, as in the purchasing example; document-driven, when the relevant data is "unstructured" (in the form of customer letters, for instance, as opposed to manipulable numbers in a spreadsheet); knowledge-driven, when procedures or problem solving are involved; or model-driven, when the current situation can be compared to others.

Executive information systems are a subtype of decision support systems and are specifically designed for executive-level decision making affecting the whole of the company, and focused on the overall goals of the company more than the day-to-day transactional operations. The needs of these systems vary by the company's industry, but will include significant data about and evaluations of the other parties the company works with—buyers, vendors, contractors, regulatory agencies, and so on—and relevant industry-wide information.

Expert systems, instead of supplementing the human decision process, attempt to reproduce human expertise in a specific domain. Far more than simple databases of facts, these systems are based on the discipline of knowledge engineering, which integrates and formalizes knowledge into computer systems using sophisticated mathematical knowledge and a thorough understanding of cognitive science.

Management Research

Management research reflects the broad, eclectic, interdisciplinary character of both the academic field of management and management practice. Research within management can range widely from highly quantitative, positivist, and functionalist studies to qualitative, postmodernist, and critical approaches, and to transdisciplinary work that transcends traditional boundaries between different philosophies and methodologies.

Frederick W. Taylor (1856–1915) is generally seen as the founding father of the "scientific" strand of management research, epitomizing the classical, functionalist (i.e., where the aim is to improve the effectiveness of the functions of management) approach. Taylor used detailed time studies (in which he would break a particular job into individual components and measure each to the hundredth of a minute) in a bid to optimize shop floor work and improve efficiency and worker productivity at his employer Bethlehem Steel. His "scientific management" became highly popular in the first two decades of the 20th century, spearheading the efficiency movement in America.

The Taylorist belief that all people are primarily rational economic agents and that quantitative scientific methods offer the best way to address management problems continued to underpin the subsequently developed quantitative or "rational" management research philosophies and methodologies. For example, statistical methods of analysis, network analysis, simulation techniques, and theories of linear and dynamic programming associated in particular with operations research, management science, accounting, and finance began to gain prominence in the 1960s as part of the rise of Systems Rationalism, which drew heavily on Taylorist principles. Like Taylorites, systems rationalists relied on science in search for universal tenets that managers could use to plan, forecast, and boost effectiveness in their work. Quantitative management research methods (including those left behind by Systems Rationalism) are still informed by similar goals.

In contrast to scientific management and Systems Rationalism, the Human Relations movement (1925–55) gave rise to the management research focus on social or "normative" issues in employee behavior and management. Elton Mayo (1880–1949) is normally heralded as the founder of the Human Relations approach. Mayo was involved in the observational and experimental studies of worker productivity at Western Electric's Hawthorne plant and drew on clinical psychology, sociology, and anthropology to make sense of the shop floor dynamics. He emphasised the need to research employees' needs for social belonging (which he saw as more important than monetary incentives or physical working conditions), so that managers could provide appropriate leadership and generate commitment as a means of improving productivity.

Similarly to the principles of Taylorism in relation to the subsequent "scientific'" approaches to management, these research goals of the Human Relations school continued to inform many of the later qualitative, social sciences–oriented research philosophies and methodologies. For instance, the growing concern in practitioner and consultant literature with organizational culture and quality (from 1980s onward) has drawn inspiration from Japanese corporations, the specific "culture" of which became seen as the key to instilling employee commitment and loyalty and thus improving business performance and quality.

This concern became translated into attempts to analyze corporate cultures in order to enable managers to shape them by creating and instilling particular value systems in their organizations. This research agenda has produced and still underpins today a diverse range of organizational culture-related research objects and management tools—from teamwork, Total Quality Management, empowerment, and self-actualization to emotional intelligence, organizational storytelling, and organizational spirituality. It typically relies on qualitative or mixed methods of analysis.

One approach to management research voguish particularly in Europe is that called Critical Management Studies. This Marxist-inspired perspective views management suspiciously as devising dehumanizing methods for controlling workers. Another recent development in management research is the growing interest in transdisciplinary work, whereby ideas and methods traditionally associated with one research area are adopted by researchers in other areas. As a result, management research can now transcend the boundaries between different philosophies, specialisms, and methodologies as well as be located within them.

Management Science

Management science (also known as operational, or operations, research) is an interdisciplinary field that assists decision making through the design and provision of quantitative and qualitative models of problematic situations.

More than any other war before it, World War II challenged the opposing armies with problems concerning logistics, equipment evaluation, and search tactics. Interdisciplinary teams of scientists tackled such problems, resulting in a set of applied mathematical methods that were used successfully to support decision making. Following the war, these methods were quickly appreciated as applicable to the challenges facing management and industry. The crowning achievement was the generic applicability of one particular mathematical algorithm known as the simplex method. This algorithm could find an optimum solution for the attainment of an objective based upon a set of mathematically structured constraints. Its relevance to problems concerning distribution, transportation, location, inventory, and scheduling provided management with a powerful method for controlling costs and maximizing revenues. The 1950s saw a host of new applied mathematical developments (such as the modeling of queues, multistage planning, and feedback modeling), serving to consolidate management science as the field that could provide much-needed support for making decisions in an increasingly competitive world.

The basic approach of management science begins by defining the problem of interest. Data is collected and fed into the structured mathematical model relevant to the particular situation. The model is developed, verified, and validated, and an optimum solution is generated. Since a problematic situation is liable to the perturbations of its contextual environment, an optimum solution is usually accompanied by a set of results that show how it changes with external circumstances—what is known as sensitivity analysis. The model, its results, and recommendations are then communicated to management in order to assist decision making.

Aside from the utility of finding optimum solutions, the logical thinking demanded by mathematical modeling facilitates learning about the situation of interest. Indeed, for many management scientists, finding an optimum solution is secondary to the knowledge gained through the process of modeling a problem. The reason is that although the model might find an optimum result, this result is based only upon what was inputted in the model. A wide array of extraneous variables, not easily amenable to mathematical modeling, will ultimately affect the implementation of the model's recommendations in ways that the model cannot show. As such, what is optimum in a model should actually be interpreted as a good approximation of what will happen in a real-world implementation.

The challenge of accounting for extraneous variables, and the perceived value of learning about situations, has led management science to develop approaches for dealing with unquantifiable uncertainty, intimidating complexity, and requisite negotiation. Known as Problem Structuring Methods, their roots lie in psychology, choice theory, game theory, and systems thinking. They rely less on applied mathematics and more on an effective integration of qualitative and quantitative analyses. A good example of this integration can be found in Strategic Options Development and Analysis (SODA). This is a particular cognitive mapping approach, inspired by the psychological theory of personal constructs, whereby the model design renders the qualitative input amenable to the analytical tools of graph theory. Another leading method is Soft Systems Methodology (SSM). This promotes a particularly rigorous learning process that helps decision makers plan for the future systemically, that is to say, in a holistic manner. An effective qualitative substitute for probabilistic decision theory can be found in a method known as the Strategic Choice Approach (SCA).

Contrary to the purely quantitative models for which management science is famous, problem structuring methods have developed especially for dealing with situations whose structure is not readily manipulated within the bounds of mathematics. Problems and opportunities in such situations are more the product of human perception than of hard data. For this reason, the methods rely less on algebra, probabilities, and data collection, and more on diagrammatic representation, scenario development, and the clarification of managerial perceptions. Not unlike the challenges of strategic planning—as opposed to the resolution of operational problems—the methods require the active involvement of decision makers in a joint modeling effort with the structuring expert(s) or facilitator(s). For this reason, the process and content of the methods are more readily transparent than the abstract symbolism of mathematical models.

Managerial Accounting

Many definitions of accounting exist, although a popular one is that formulated by the American Accounting Association: "the process of identifying, measuring and communicating economic information to permit informed judgments and decisions by users of the information."

It is important to note, however, that all the information so provided does not have to be financial in nature, and qualitative as well as quantitative data might well help in the process of assisting management to make more informed decisions.

Managerial (the more normal United Kingdom expression is *management*) accounting is one of only several different facets of the accounting discipline. The normal distinction made is between financial accounting on the one hand and managerial accounting on the other. In this strict dichotomy, financial accounting is concerned with the preparation largely of documents that relate to past performance (hence the income statement ["profit and loss account"], statement of financial position ["balance sheet"], and cash or funds flow statement). Clearly, however, the projection of such documents to a future time period/date is also possible. In all developed nations it is mandatory to produce the specified documents on a regular basis (annually would be the norm), although for internal control purposes it is likely that any organization of a reasonable size would generate them far more frequently than this. But one of the most interesting aspects of the financial accounts is that the annual documents, at least in summary form, invariably must by law be made available to external constituencies ("external" meaning other than the incumbent management). Thus owners and government (because of the corporate tax implications) have an inalienable right in this regard; and employees and their representatives, investment analysts, the local community, etc., all might well be perceived also to have a vested interest in corporate performance as evidenced by the statements produced.

The structure and composition of the organization's financial accounts is constrained by legislation, the requirements of both the object country's accounting profession (perhaps collectively representing several bodies) and its stock exchange. In the United States, the Financial Accounting Standards Board has established Generally Accepted Accounting Principles (GAAPs) that are deemed to underpin the preparation of a business's financial statements. The world is increasingly moving toward the adoption of International Financial Reporting Standards because of the need to compare the performance of businesses on a global scale, particularly given the move toward multiple stock exchange quotations for multinational corporations (MNCs).

The situation described above should be compared with that of managerial accounting, which is largely concerned with the provision of information to people solely within the organization in order to assist their better decision making. Such information is not intended to be released to external constituencies—indeed, much of it is highly sensitive and the very last sort of thing one would want one's competitors to get hold of. Such information relates to the costs and relative profitability of different products or product lines; the basis on which capital expenditure decisions are made; budgets for both the impending (in detail) and subsequent (in rather less detail) financial periods; and the identification of alternative uses for the company's resources, including such things as whether a product or service should be produced internally or "bought in" from outside (when the economist's concept of "opportunity cost" becomes an important consideration). Unlike the organization's financial accounting reports, its managerial accounting activities are unrestrained by GAAPs (since policing and enforcing them would be impossible), although one would nevertheless hope for some level of internal consistency in the provision of managerial accounting information.

However, it is important to recognize that the accounting function is not restricted merely to the two subdisciplines identified. Thus a further "arm" that can easily be identified is that of financial management, concerned with the management of all the cash resources available to the business. It therefore incorporates the aspects of working capital management (i.e., the management of accounts payable [creditors] and accounts receivable [debtors]); what should be done to take maximum benefit from surplus cash resources; and, should it be necessary to arrange additional financing, what form should this take (debt versus equity, for example), and if debt is to be raised, should this be domestically or internationally (when a lower annual interest cost might well eventually be outweighed by an adverse exchange rate movement in the interim).

Treasury accounting, internal auditing, the post-completion auditing of capital projects, and financial services accounting are all additional examples of the variety of the accounting function in the typical organization.

Origins and Development

It is generally accepted that the origins of today's managerial accounting (even if then termed cost accounting) can be traced back to the Industrial Revolution, having its genesis in the United Kingdom in the 18th century, and with substantial progress in cost accounting procedures having accelerated during World War I. However, as H. Thomas Johnson and Robert S. Kaplan argue, thereafter progress ossified, such that over the 60-year period post 1925, there was little progress recorded in the managerial accounting domain. This they attribute to the requirement that information relating to product costs was more in order to feed the organization's (external) financial accounting reports, with the separation of the ownership and management of organizations (in the United Kingdom this followed immediately upon the Joint Stock Act of 1844), than it had any regard to management's desire for information that would assist in its decision-making processes.

Thus, in order to assist in the generation of financial statements that would summarize the financial position of the company (principally for the benefit of its owners and creditors), cost accounting emerged to meet the requirement to allocate costs between the cost of creating the goods that had been sold, on the one hand, and those costs that remained embedded in unsold inventories, on the other. So while simple procedures developed to enable this apportionment to occur (i.e., an allocation of cost between the two competing objectives that was both simple and verifiable), the result was that the generation of sufficiently accurate information such as to enable the distinction to be made between profitable and unprofitable products and/or services simply did not occur.

Thankfully, since the work of Johnson and Kaplan (and probably largely because of it), the managerial accounting "discipline" has moved on apace. Thus the informational deficiencies that had erstwhile been in evidence have been largely addressed via an increasing number of initiatives (of which activity-based costing is but one of many), and while overriding standards might still remain to be applied (and it is probably beneficial that they should be held in abeyance at least in the short term), the movement for revamping the subdiscipline to increase its credibility in the global environment of the 21st century gathers momentum.

Manufacturing

The word *manufacturing* has its roots in three ancient Latin words: *manu,* meaning by hand; *facere,* meaning to make; and *faber,* or maker. Recent definitions have expanded this definition into "to make from raw materials by hand or machinery." The Department of Trade and Industry of the British government has defined manufacturing more broadly as "manufacturing firms transform ideas into products and services," incorporating a range of activities from research to recycling of products. Over the past thousands of years, manufacturing has evolved from a craft practiced by individuals to an organizational activity performed by firms to an intraorganizational activity coordinated and controlled by sophisticated networks of firms transforming raw material into finished products. The equipment used to support manufacturing has undergone a similar evolution from simple tools to systems employing complex technology combinations.

In the years before the Industrial Revolution, manufacturing was an artisan activity. Craftsmen produced customized items and services for clients using hand tools. Production was heavily reliant on the judgment of the craftsman who implemented his own idea of standards and quality. Components could not be substituted from one producer to another and replacement parts had to be made by the original craftsman. To identify their work, some craftsmen would place a distinctive sign or "brand" on items.

The Industrial Revolution

All of this changed in the Industrial Revolution that occurred between 1770 to 1820 in England. Several factors combined to create the Industrial Revolution: a critical mass of people, improved market access, political stability, technology, and financial innovation. The critical mass of people was as a result of improvements in living conditions, increasing the local population. This created a market for manufactured products as well as labor for factories. Expansion of European powers in the previous 200 years provided large global markets for manufactured products. Political stability in England provided a low-risk environment for investments in large-scale production and distribution. Mass production required improved equipment, and the invention of the steam engine provided motive power for these new tools to produce items on a large scale. To support these production innovations required large amounts of financial capital that was available at the time from local banks.

Manufacturing in England and in the United States developed along different paths. English manufacturers focused on integrating skilled labor with machinery while the United States incorporated the use of unskilled labor. The machine tool industry began with Henry Maudsley, who created the first powered lathe, a machine to turn and cut metal. In the hands of skilled craftsmen, the ability to accurately produce metal components with a round profile such as screws accelerated the development of other machines supporting innovations in iron and textile production. The colonies in America initially imported all of their requirements for manufactured products. However, the conflict for independence encouraged Americans to develop their own sources of manufactured products. Development was initially slow because England prohibited the export of production tools or emigration of skilled labor. This changed when an English immigrant, Samuel Slater, brought British textile technology to America.

Technological improvements developed machine tools further, improving their accuracy and providing a basis for an increased range of metal processing industries. During this period, the manufacturing techniques of standardization and interchangeability began to be adopted into industry, beginning with the production of weapons in the United States. Simeon North, who developed a milling machine, and Eli Whitney applied these ideas in the manufacture of guns for the U.S. Army. Unlike the previously handcrafted items, these muskets were composed of standardized, uniform subcomponents, enabling any combination of them to be assembled into finished items. Another advantage of standard components was that relatively unskilled labor could be involved in manufacturing, enabling rapid expansion of production.

Scientific Management

Parallel developments in machinery and production techniques continuously improved manufacturing. A key advance in production technique was the Scientific Management paradigm created by Frederick Taylor that had the following principles: (1) the optimal methods of working should be identified and implemented across the organization; (2) workers should be selected and trained to perform the tasks of the organization; and (3) management of the organization should focus on planning and analysis while workers executed manual tasks.

In practice, manual tasks were analyzed and decomposed into subtasks, which were then optimized to improve efficiency. Mass production, which was implemented by Henry Ford in the manufacture of automobiles, was the combination of standardized, interchangeable component production with the management techniques of Taylor.

Postwar Developments

U.S. manufacturing firms began growing rapidly, with further gains in efficiency occurring during the two world wars. The years after World War II saw the dominance of U.S. firms as they improved their processing and organizational abilities using techniques learned from weapons production. Wartime improvements in electronics enabled better control of machine tools resulting in Numerical Control systems, developed by MIT for the U.S. military. Rising incomes also meant that there were ready markets for finished products.

Even though U.S. manufacturers dominated world markets in 1970 and were refining their advantage with the development of computer-controlled tools, new techniques were being refined in Japan that would result in major changes by 1980. By focusing on efficiency and quality, Japanese manufacturers lowered production costs dramatically. Toyota, for example, achieved production efficiencies and quality levels that were several times better than its U.S. competitors' using a system called Just-in-Time manufacturing or JIT. These production techniques were a logical extension of the mass production approach and followed these principles: (1) elimination of waste by elimination of inventory and by improved quality; (2) shifting workers from individual, low-skill tasks to high-skill, shared tasks; and (3) continuous refining and improvement.

Additional techniques employed by these firms included Concurrent Engineering, in which design and development was done simultaneously, and Total Quality Management, where quality was viewed as an organizational rather than a departmental function. By the end of the 1980s, Japanese firms dominated the manufacture of consumer items and occupied a sizable share of automobile manufacturing. Global financial liberalization and opening of world markets enabled manufacturers to invest in markets that were previously unavailable. Simultaneous improvements in information and communication technology enabled control of these organizations, linking them into production networks. The 1990s saw movement of manufacturing capacity from developed to developing countries with Mexico, then China benefiting from investments by U.S. manufacturers.

Current Methods

Present-day manufacturing is driven by the changes in production created by new technology, work methods, and the economic environment and changes in demand caused by new market requirements. Unlike the environment faced by firms 50 years ago, customers demand higher levels of customization, resulting in fragmented markets. In response, organizations are increasing their pursuit of a cross-functional approach to coordinate complex flows of materials and information in manufacturing networks. Instead of breaking tasks into subunits to be optimized, firms are developing integrated approaches to all manufacturing activities.

In the 1990s manufacturing capacity increasingly moved from developed to developing countries such as Mexico and China, with other countries with low labor costs not far behind. Above, a television factory in Tajikistan in central Asia.

One approach to serving the new, fragmented market is Mass Customization, the ability to provide customized products or services using flexible process at an acceptable cost. Under the mass production paradigm, individual customization would be prohibitively expensive, out of the reach of all but a few consumers. However, improvements in manufacturing technology and supporting services have made the concept of Mass Customization increasingly feasible. Dell Computers has leveraged standardized computer components and its supply chain to provide millions of computer configurations to customers. Smaller manufacturers have used advanced technologies to provide a range of customized items from clothing to toys.

Manufacturing currently revolves around six major activities: research, design and development, production, logistics and distribution, sales and marketing, and services. Research is conducted into new technologies and techniques for manufacturing. Many established aspects of present-day manufacturing technology began as research ideas at universities. Computer-Aided Manufacturing, for example, had its roots in research conducted at MIT, and manufacturing techniques have been refined using industry and university research. Design activities translate ideas into detailed specifications for production. Products, services as well as the processes that create them, can be designed, and design is seen as a way of differentiating products in the marketplace. Customers have been found to pay a premium for products with superior aesthetics, such as those produced by Apple.

Production activities convert inputs into outputs according to the design specifications provided. Material processing activities, for example, convert metals, plastics, and ceramics into finished items using techniques ranging from cutting, joining, deformation, and melting. Traditionally, manufacturing processes have been subtractive or formative. In subtractive processes, material is removed from a block larger than the size of the finished product. Examples include machine tools such as lathes, drills, and milling machines. Formative processes apply transforming forces, heat or force, to material, creating a final shape. Examples of formative processes include forging, casting, or bending equipment.

Advances in materials science and process control have created a new class of processing technologies known as additive processes. In additive processes, material is manipulated to form a finished product in successive layers. Examples of additive processes, sometimes called rapid prototyping or rapid manufacturing processes, include stereolithography, selective laser sintering, 3D printing, and laminated object manufacturing. Initially, these technologies only formed specialized plastics into prototypes, but recent refinements have enabled them to process metal components. These technologies enable organizations to engage in mass customization strategies, providing individualized products to customers.

Logistics can be defined as the management of material flow and information both within and across facilities. Within facilities, logistics is required to ensure that material is available where and when it is needed. Across facilities, logistics coordinates the movement of components and finished products for further processing or final sale. Sales and marketing activities interface with the final customer, earning revenue and providing valuable information on market developments. Coordination of marketing and production activities is important to manufacturers because improperly managed customer demand can lead to additional cost or lost revenue.

Finally, services have increased in importance from support functions such as advice and repair to business drivers in their own right. Manufacturers have pursued "servitization" strategies, in which the sale of industrial products is replaced by the provision of industrial services. The engineering firm Rolls-Royce offers a program for integrated provision of equipment and support on a lease basis, enabling customers to reduce up-front capital costs. Global concerns about the environment have placed increasing pressures on manufacturers from a range of public and private stakeholders. Manufacturers are being called to account for the impact of their products across the entire life cycle from raw material to disposal. Some organizations have taken a proactive approach, launching initiatives to reduce material and energy usage by changes in design and production.

The future of manufacturing is likely to see an increasing range of technology and techniques to convert concepts into finished products and services. In this context, firms may exhibit a range of models to serve customers, from the traditional sale of products to service-led models. Manufacturing has come full circle, from individual artisans creating customized products to mass manufacturers and now to small and large organizations providing customized products to individuals.

Manufacturing Strategy

A manufacturing strategy can be defined as the pattern of organizational decisions that determine the ability of a manufacturing firm to deliver its product and service requirements to customers. Successful implementation of manufacturing strategies requires the coordination of physical assets, production capabilities, and relationships as manufacturing firms move from individual facilities to business networks. The importance of manufacturing strategy has increased in the last 30 years due to increasing global competition, and a firm's manufacturing ability is now seen as key to competitive advantage.

While the field of manufacturing has had a long history, strategies specific to manufacturing firms have emerged fairly recently. From the mass production era in the 1900s until the 1960s, organizations viewed manufacturing solely in terms of equipment to convert raw materials into finished products and production arrangements such as plant layouts. Long-term organizational strategy was formulated by finance and marketing departments with manufacturing's role limited to the production of the varieties, quantities, and quality specified by these functions. Decisions were primarily about plant, equipment, and personnel with little effort allocated to examining the potential of manufacturing beyond that of a support function.

Initial ideas regarding manufacturing strategy emerged in the late 1960s, as researchers and organizations realized that manufacturing firms were responsible for a large proportion of a firm's physical and human assets. Arguments were made for manufacturing to become more central in formulating strategy, rather than the tactical position it occupied at the time. Few organizations paid attention to the arguments, and the 1980s brought increasing competition from Japanese firms, particularly in automobiles and consumer products. These relative newcomers provided a combination of lower prices and higher quality, something that was not thought possible at the time. Incumbent organizations at the time viewed cost and quality as linked, with higher quality only being achieved at a higher cost. As a result, Japanese firms began taking market share from U.S. and European manufacturers, with many organizations forced to close or sell their businesses.

Since these organizations viewed manufacturing as plant and equipment, the first response was to invest heavily in new production facilities with automated machinery. However, while some organizations experienced success, the costs of these investments took a heavy toll on others, most notably General Motors, whose $60-billion investment in automation generated little return. Organizations realized that there was a need for better management of manufacturing and a greater understanding of how manufacturing could contribute to organizational competitiveness.

Significant research effort was allocated to manufacturing strategy and researchers have created a range of frameworks of increasing sophistication to aid organizations. Initially, frameworks examined equipment, personnel, and management systems required for manufacturing at a single facility. More recent research has expanded the decision areas to include the coordination of manufacturing networks. Increasingly, firms shift the production of items that they cannot produce competitively to other locations, and manufacturing organizations can be viewed as a network of coordinated business relationships. As such, manufacturing strategy decision areas now incorporate decisions on whether an organization will make an item in-house or buy it from another firm. While they examine a range of organizational characteristics, these frameworks can be divided into five perspectives: top-down, bottom-up, market requirements, internal capabilities, and best practice.

Top-Down, Bottom-Up

The top-down perspective positions manufacturing as part of corporate strategy. Senior management examine the requirements of the marketplace and the capabilities of the organization and choose a path of action best suited to the firm. Each functional division such as marketing, finance, and manufacturing creates individual strategies that are designed to support the organization's achievement of its overall objectives. In this perspective, manufacturing adopts a supportive role within overall organizational strategy. A bottom-up or emergent perspective takes the opposite view of manufacturing strategy. In this view, knowledge is created as part of ongoing manufacturing operations. Strategic ideas may emerge from the experience of lower-level staff that may alter the direction or competitive positioning of the firm. These ideas can be adopted at the lower level, with senior management's role changing from originator of strategy to provision of resources to support these emergent ideas.

Market Requirements

The market requirements perspective attempts to explicitly link manufacturing with the demands of customers. Organizations assess the market to determine the areas of manufacturing performance desired by customers. This information is then used to improve the organization's performance in these areas. There is a general agreement among researchers on these performance areas as detailed below.

1. Flexibility: Flexibility is defined as the ability to change manufacturing operations to provide new products, and to incorporate new processes or new delivery options. Improved flexibility can aid organizations in recovering quickly from disruptions and increase sales by providing new options to customers.
2. Dependability: Dependability is defined as the ability to provide required items in the time they were expected. Dependability ensures that manufacturing operations are stable and provides assurance to customers.
3. Delivery Lead Time: Delivery lead time is defined as the time customers are required to wait in order to receive their products or services. Improved speed of delivery can reduce costs to an organization by reducing internal inventory and provide items more quickly to customers.
4. Quality: Quality is defined as the ability to produce items that conform to specifications and meet customer requirements. Within the organization, a high quality level reduces costs and improves dependability of the organization. Outside the organization, a high quality level improves customer satisfaction and can help differentiate the firm's products from those of competitors.
5. Cost: Manufacturing organizations also attempt to minimize the cost of producing products and services. Within the organization, costs are linked to the other abilities as higher quality and dependability can minimize waste, reducing costs. Outside the organization, lower costs can be used to win market share from competitors by providing lower prices to customers or to increase profitability by maintaining the same prices as competitors.

A commonly used framework to determine the relative importance of performance areas is the order winning and order qualifications framework. Order winning factors are the performance areas that contribute to winning business or customer orders and are determinants of market success. Order qualifiers are the areas that the organization needs to provide a minimum level of performance in order to maintain its market presence. If the organization does not provide that level of performance, it will not be considered by customers, but improvement beyond a minimum level will not win additional business.

Internal Capabilities

The internal capabilities perspective takes the opposite view to the market approach as it focuses on an organization's manufacturing resources as critical to its success. This perspective is built on the resource-based view of organizations in which firms are seen as a collection of resources coordinated to provide organizational capabilities. Resources can be tangible (for example, equipment) or intangible (for example, employee skills). The focus is therefore on identifying and understanding which resources are valuable in order to build strategies that maximize their potential.

Best Practice

Best practice approaches focus on the adoption of operational practices that enable superior performance. This paradigm has its root in the benchmarking approach, which is a method of improving organizational performance by comparing company practices with those of other organizations. Best practice approaches to manufacturing strategy were initially stimulated by a need to understand the superior performance of Japanese firms but have been extended to incorporate practices from manufacturers worldwide. Researchers identified the practices that support these performance levels, adapting them for adoption by other firms. The assumption was that in adopting these practices, other firms can achieve a similar level of performance. As manufacturing practices are continually evolving as technologies and customer requirements change, this identification-adaptation-adoption process is continuous or a firm may risk losing its competitive edge. The highest level of best practice is known as world-class manufacturing, defined as the practices required delivering the highest level of performance in quality, design, efficiency, and delivery when compared to other firms internationally.

Individually, none of these paradigms will be sufficient for formulating and implementing a manufacturing strategy. In practice, these paradigms are linked by organizations when formulating and implementing a manufacturing strategy. Generally, a company will formulate a strategic vision, incorporating the views of top management and ideas from manufacturing practice. The internal resources and capabilities of the organization are then assessed against the needs of the marketplace. Based on this assessment, the organization will make choices about which areas it will develop in order to build or maintain its competitive advantage. The organization will then seek to identify or develop best practices to achieve superior manufacturing performance.

Manufacturing Yield

The yield of a manufacturing process or of any production line is of paramount importance to manufacturers as it is directly related to corporate profitability. For many manufacturing companies, the only alternative to remain competitive is to improve yield. Manufacturing yield is generally considered to be a measure of manufacturing success, and it is defined as the ratio of the number of usable devices after the completion of a production process to the number of devices at the beginning of the process. Yield also refers to how much salable product can be produced. So, a higher yield means that more items can be produced for the same overhead cost, which permits unit cost and unit sale price to decrease. This may contribute toward making the company competitive and profitable.

Manufacturers are generally preoccupied with eradicating the factors or failure mechanisms, which affect the yield of a product. However, before doing so, the manufacturer must understand how each stage of the manufacturing process affects yield. Since the definition of yield indicates that it is a statistical parameter, the various stages of product manufacture can be represented as probability functions, which are multiplied in order to attain the overall yield. These probability functions include failure probabilities for various defect types. Yield can be effectively controlled if these failure probabilities can be reasonably determined. This further indicates that there is some relationship between yield and reliability as reliability is simply the failure probability subtracted from one. Reliability is also defined as the probability that a device will perform its intended function for a specified time under the stated environmental condition.

There are two types of reliability problems: intrinsic failures, which are inherent to the manufactured device; and extrinsic failures, which are due to manufacturing defects. Extrinsic factors include poor design, improper manufacturing operations, contaminated environments, defective raw materials, poor incoming inspection, or inadequate shipping and handling.

An example of how yield can be affected by reliability problems can be understood by looking at the manufacture of integrated circuits (IC). There is a trend in the microelectronics industry to produce smaller integrated circuit chips that are capable of more sophisticated functions. Fabrication of advanced integrated circuits usually involves 300 to 400 process steps. However, the fabrication of ICs can be simplified into two major stages known as the front-end and the back-end. In the front-end, the components of the integrated circuits are manufactured, whereas in the back-end, metal is added to connect the components of the chip. Each stage consists of several hundred steps, and it is easy to envisage defects being introduced during any step. For instance, the first step in the front-end stage involves the construction plan and circuit diagrams of the chip. Poor plan design may lead to chips that do not function as intended, thereby diminishing yield. Another instance in which defects can be introduced is in the back-end stage where layers of wires are added to connect the various components. Improper connection sequence or poor connections can also lead to defective chips, thereby leading to poor yield.

Improving Yield

Using proven technology makes it easier to keep yields higher, but old technology soon becomes expensive to maintain, which ultimately leads to increased overhead and reduced profit margins. At first, it may be difficult to achieve high yields with new technology because large amounts of items may be discarded during the learning phase. Nevertheless, overhead cost should eventually become lower and the benefits of the new technology will be realized as the new technology is grasped. However, there is a great snare that many companies fall into. Particularly, small companies with smaller budgets tend to learn as they go along, which can lead to poor revenues and terrible backlogs that eventually cripple production schedules. It may be worth the cost to hire engineers to optimize the new technology as early as possible.

Manufacturing yield can also be improved by implementing simple corrective actions, which include correcting process defects before they occur. This can be done by thoroughly characterizing all machinery whereby the parameters that affect the performance of the machine are clearly understood and documented. Other corrective measures involve real-time control and monitoring of process variation; alert systems to indicate when a process is moving out of control; sufficient training to enable operators to take immediate corrective action; and advanced statistical analysis to identify the root causes of defects.

Another technique that can be applied to improve manufacturing yield is known as design for manufacturability or design for manufacture (DFM). The essence of this technique is to encourage manufacturers to use simplified designs for their products. Simplified designs through a process of standardization result in fewer parts, which minimizes the opportunity for a defective part or an assembly error. This reduces production cost, improves quality, and contributes to increased yield. Design for manufacturability is built on several product design guidelines, which are summarized in its definition.

In the article by David Anderson on "Design for Manufacturability and Concurrent Engineering," DFM is defined as the process of proactively designing products to (1) optimize all the manufacturing functions: fabrication, assembly, test, procurement, shipping, delivery, service, and repair, and (2) assure the best cost, quality, reliability, regulatory compliance, safety, time-to-market, and customer satisfaction. An article on design for manufacturability by Kenneth Crow states that research has indicated that decisions made through the design period account for approximately 70 percent of product cost. If this is accurate, it is easy to visualize how poor product design can adversely affect manufacturing yield.

It is therefore imperative that manufacturers strive to attain better and better yield levels for their products. In order to achieve this objective, manufacturers must implement the necessary measures to mitigate or even eliminate the introduction of defects into their products. Failure to do so will lead to poor yields, ultimate loss of competitiveness, and possible extinction of the business.

Maquiladora

Maquiladoras are plants devoted to producing or assembling intermediate goods required by other companies in their productive processes, so they are part of productive chains for activities of international subcontracting. They operate under a special tax system that allows them to import inputs and components free of tariffs for assembling products destined for the international market.

Maquiladoras rose in the 1960s. They expanded as part of the processes of internationalization of production, the establishment of free trade agreements, and economic globalization. They are considered an alternative to increasing international competitiveness by taking advantage of the conditions offered by the host countries: abundant and cheap labor, flexibility in the use of the workforce, a corporative system that favors trade unionism control and discipline in the factory, and loose regulations in protecting the environment. To encourage their establishment, governments offer tax benefits and other economic incentives, creation of infrastructure, labor deregulation, and containment of wages.

Maquiladoras initially developed in border areas and were considered a proper means to solving problems of unemployment and migration. They reached significant development during the 1980s and 1990s along the border of Mexico and the United States and in countries of southeast Asia such as Korea, Taiwan, Hong Kong, and Singapore. However, the internationalization of production through maquiladoras should be regarded as a phenomenon of global industrial redesign. They have constituted export-processing zones involving an asymmetrical industrial articulation between developed and peripheral countries based on a new regime of international division of labor, which benefits contracting corporations without encouraging industrial development in the host country.

Initially, maquiladoras emerged as small plants of low investment, characterized by intensive use of unqualified workforce under a very fragmented and routine assembly work process. They have been called "sweatshops" owing to low wages, piecework payment, extended hours of work, poor working conditions that damage the health of workers, abuse and gender inequity, unjustified dismissal, and illegal employment of child labor. They operate traditionally with female labor, especially with single mothers and teenagers who accept the conditions of work and compensation because they need the employment to survive. These precarious job conditions explain their high levels of turnover.

In addition to this traditional model of maquiladoras, a segment of them has evolved toward manufacture under forms of lean production and flexible specialization. They are factories with sophisticated technology that enables increased automation of the work process that requires higher levels of skills in the workforce; there was an increasing incorporation of specialized technicians and engineers. In these plants, the traditional advantage of cheaper labor lost its importance. In its place, competitiveness rested on greater flexibility based on polyvalent work and the use of Japanese manufacturing techniques such as Just-in-Time production and Total Quality Control.

Also, a smaller segment of maquiladoras corresponds to highly capital-intensive companies based on research and development processes. They require increased investment and advanced technology to facilitate innovation and design. They increasingly participate in integrated international business networks operating under diverse collaborative and exchange frameworks.

Trade liberalization trends and economic regionalization and globalization have pushed many countries to accept the establishment of maquiladoras as part of their strategies to boost economic development and facilitate their incorporation into the international economy. However, primarily large transnational corporations control this process. They impel off-shoring production to increase their competitive capabilities in the global markets, which rarely attend the development requirements of the host country. One of the great problems is related to the so-called runaway shops, the footloose industry and the fly-by-night enterprises: The maquiladoras simply move to distinct geographic zones when they find greater competitive advantages. This process creates what it wanted to avoid, i.e., unemployment, migration, and the emergence of ghost towns that have no alternative economic activities for the people. Therefore, governments are increasingly forced to establish better regulations to guarantee more equitable treatment and a different incorporation of the maquiladoras considering the economic and social needs of the country. The design of national development strategies tends to encourage a better integration of national manufacturing, a greater economic development, and an advantageous incorporation to the flow of international trade and production.

Marathon Oil

Marathon Oil (Marathon Oil Corp.) is one of the largest integrated oil companies in the United States. It is engaged in exploration and production of crude oil and natural gas. It was incorporated in 1965, and now employs about 30,000 people (as of January 1, 2008). The company is headquartered in Houston, Texas, and it has exploration and production activities in the United States, Angola, Equatorial Guinea, Gabon, Indonesia, Ireland, Libya, Norway, Ukraine, and the United Kingdom (UK). Marathon Oil is quoted in the New York Stock Exchange with the ticker symbol MRO. Marathon Oil has approximately 60,000 shareholders (as of January 1, 2008).

The United States is the company's largest geographic market (92 percent of the revenues in 2006). Marathon Oil generates revenues through three major business divisions: refining, marketing, and transportation division (86 percent of the revenues in 2006); exploration and production division (14 percent of the revenues in 2006); and integrated gas division (less than 1 percent of the revenues in 2006).

Specifically, Marathon Oil is engaged in worldwide exploration and production of crude oil and natural gas and domestic refining, marketing, and transportation of crude oil and petroleum products. The company's principal operating subsidiaries are Marathon Oil Company and Marathon Ashland Petroleum, LLC. The company has exploration and development activities in the following countries: United States, Norway, Equatorial Guinea, Angola, and Canada (principal exploration activities); United States, UK, Ireland, Norway, Equatorial Guinea, Gabon, and Russia (principal development activities).

Marathon Oil also operates other businesses that market and transport its own and third-party natural gas, crude oil, and other products manufactured from natural gas primarily in the United States, Europe, and west Africa. Marathon Oil's key products include crude oil, natural gas, condensed and natural gas liquids, propane, heavy fuel oil, asphalt, sulfur gasoline, graphite electrodes, aromatics, aliphatic hydrocarbons, liquid hydrocarbons, cumene, base lube oil, polymer-grade propylene, slack wax, refined products, merchandise, and transportation. The company also offers service stations.

The company was formed in 1887 under the name Ohio Oil Company in northwestern Ohio, which was the leading center for crude oil production at that time. Then it was known as USX Corporation. In 1962 the company changed its name to Marathon Oil Company. In 1998 Marathon Oil and Ashland, Inc., formed Marathon Ashland Petroleum, LLC to refine, market, and transport crude oil and petroleum products. Marathon Oil now owns 100 percent of Ashland's shares. The company changed its name to Marathon

Oil Corporation in 2001. The company formed a joint venture with Pilot Corporation in 2001—Pilot Travel Centers LLC, which operates travel centers that offer diesel fuel and gasoline as well as various services, including on-premises brand-name restaurants. Marathon Oil grows with various acquisitions. In 2002 the company acquired GlobexEnergy, Inc., and acquired Western Oil Sands, Inc., in 2007.

In 2008 the executive team of Marathon Oil included Thomas J. Usher (chairman), Clarence P. Cazalot, Jr. (president, chief executive officer), Gary R. Heminger (executive vice president), Janet Clark (chief financial officer), William F. Schwind, Jr. (secretary, general counsel), Michael K. Stewart (controller), Paul C. Reinbolt (treasurer), and Jerry Howard, Philip G. Behrman, Steven B. Hinchman, David E. Roberts, Jr., and Janet Clark (senior vice presidents). The company's board of directors included Charles F. Bolden, Jr.; Clarence P. Cazalot, Jr.; David A. Daberko; William L. Davis; Shirley Ann Jackson; Philip Lader; Charles R. Lee; Dennis H. Reilley; Seth E. Schofield; John W. Snow; Thomas J. Usher; and Douglas C. Yearley.

There are many reasons why Marathon Oil is successful. First, it is a giant that holds onto the entire oil and gas value chain. It is among the world's leading integrated companies in the energy industry that operates in different countries. Marathon Oil's presence in exploration and production, storage and pipeline, refining, marketing, and retail distribution boosts its competitive advantage over rivals. The second reason is the geographical locations of its facilities in terms of refining, marketing, and transportation—Marathon Oil has extensive operations in various regions. The company strategically located its business to serve major markets by establishing a comprehensive terminal and transportation system, along with extensive marketing operations. Third, the company has had an impressive financial performance in previous years and a continuous trend of strong profitability.

Market Audit

A market audit examines a company from a marketing perspective, just as a financial audit, tax audit, or IT audit examines a company from each of their own perspectives. However, while those audits focus principally on internal data, a market audit gathers a great deal of information from outside the company, in order to compare the company's performance and character to those of its competitors. In this respect it has much in common with the Competitive Market Analysis. While other audits may be performed by accountants, a market audit is the work of a marketer.

The questions asked in a market audit begin very simply, by identifying the type of organization, the products or services it sells, and the customers to whom it sells them. These questions can be broken down very specifically, though, and as more and more specific answers are yielded, a clearer picture of the market is created. Two television networks may seem essentially similar—they both broadcast in the same regions, their programming includes comedies, dramas, news, and sports, and their flagship programming airs in the same hours. But a closer look reveals that one network appeals largely to families and older couples, while the other targets a college-age demographic; this information affects advertisers' decisions about which network to favor their advertising dollars with, and the networks' own decisions about how to maintain or change their appeal to their demographic.

As much data as possible and relevant is collected, in order to provide points of contrast between the company and its competitors. How much does the company charge for its product, and what is the comparative value of its competitors product? Pepsi-Cola made its mark in a crowded field of Coca-Cola competitors by charging the same price for its cola but selling it in bottles that were twice the size. When comparing prices, coupons, discounts, and other incentives are taken into account, as are factors that affect ease of purchase—such as availability, associated costs (a market audit of a resort or tourist attraction would take into account the cost of travel, and perhaps the "cost" of using up vacation days). Much of the data will bear on factors that are outside the company's control, or at least not the result of its choices: both Pepsi and Coca-Cola, for instance, likely sell better in stores that also sell salty snacks, which affects the market data even though it is not the result of a marketing decision. That they likely sell best in hot weather is another marketing point; consider Coca-Cola's long-lived advertising campaign associating the product with Christmas, Santa Claus, and polar bears, integrating its image with that of winter festivity and positioning the product with respect to the colder months.

A market audit will seek to identify key information to inform the company's marketing strategy. Is the company an industry leader? Is the general perception of its importance and leadership proportionate to its market share? How does the public think of the company, and to what demographics does it appeal? (In the case of the two television networks, does the audience perceive that it outgrows one and grows into the other, and if so, does the younger-skewing network want to retain that audience as it matures, or simply guarantee that there is a constant flow of new viewers?) The specifics, of course, will always depend on the industry. Market audits may depend to some extent on classic market research tools like customer satisfaction surveys, mystery shopping, and price elasticity testing, and may employ more recent devices such as commercial eye tracking or so-called "coolhunting," a marketing practice that developed in the 1990s to seek out and lay claim to the cutting edge of youth culture.

Market-Basket Currency

A market-basket currency is a form of money (medium of exchange) whose value is determined as a weighted average of the value of other currencies. The term is often confused with the term *currency basket*, which is actually the group of selected currencies. Typically, the currency basket is composed of a diverse set of four to eight currencies from around the world with no one currency holding a majority. As a composite, market-basket currencies are often used to reduce the risk associated with currency exchange rate fluctuations, especially compared to currencies pegged (or fixed) to one other currency. Governments have created market-basket currencies in response to local currency fluctuations that threaten their economy.

Market-basket currencies have been used since the 1970s after the collapse of the Bretton Woods Accord. For example, the European currency unit (or ECU) was created in 1979. The ECU was composed of a currency basket of all European Community currencies, mainly the British pound sterling, the German mark, the French franc, and the Italian lira. Although it was initially planned as the common currency of the European Community, it was replaced by the euro in 1999.

Israel has used a market-basket currency, the shekel, since 1986 (and from 1976–77). Originally, the shekel was based on the U.S. dollar, German mark, pound sterling, French franc, and Japanese yen until 1999, at which point the mark and franc were exchanged with the euro. In 2005 China changed the peg of their currency, the renminbi, to the U.S. dollar and converted to a floating exchange rate based on a market basket of foreign currencies including the U.S. dollar, euro, Japanese yen, South Korean won, British pound, and others. From 1975 to 2003, Kuwait's dinar was a market-basket currency, but was pegged to the U.S. dollar on January 5, 2003. Kuwait repegged the dinar to a currency basket in May 2007. The Cooperation Council for the Arab States of the Gulf (GCC) plans to create a market-basket currency, the khaleeji, by the year 2010. The GCC is composed of Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, and the United Arab Emirates.

In response to the Asian currency crisis of 1997, the Association of Southeast Asian Nations, or ASEAN, has proposed the creation of the Asian currency unit (ACU) as a market-basket currency for member countries China, Japan, and Korea to stabilize financial markets in the region. Although the project has endured several obstacles, discussions continue.

Special Drawing Rights (SDR) are considered a market-basket asset such that it is determined from the market exchange rates of the U.S. dollar, euro, Japanese yen, and British pound sterling. It is revalued once every five years.

Market Development

Market development implies seeking out new buyer groups as potential customers for a firm's existing products and services. These customers may be currently served by competitors or may not currently consume such offerings. For example, a firm that successfully makes and sells coffee to the retail market in Italy may try to reach into demographic segments (e.g., young or old people) that they currently do not reach; or they may market a similar product to Italian commercial coffee channels (like restaurants, hotel chains, or vending machines); or they may enter the Swiss market. This term excludes significant changes to the product—generally called *product development*—or efforts aimed at increasing market share among current customer groups—generally called *market penetration*. Also, strategies to make significant changes to market as well as product are called *diversification*.

Developing new market segments is a strategy close to the market penetration concept—both aim to increase sales close to the core product-market focus. Developing new market segments (or niches) involves conducting a segmentation analysis, defining those market segments in which the firm currently is not strong, and conducting evaluations of the attractiveness of these unserved markets. The firm may consider demographic, lifestyle, or psychographic variables to define segments. Russell Winer uses the examples of Kodak and Fuji aiming to attract children to the photography market by developing products to help with school projects, and the National Football League trying to attract more women to its TV broadcasts.

Developing new geographic markets is a key option for firms wanting to grow from their traditional markets, whether to new regions of the home country or perhaps to new international markets. The simplest form would be to move into markets that are close geographically and culturally—like a firm moving from one midwestern state of the United States to another, and then to Ontario, Canada; or an Austrian firm expanding to Germany. Entering geographic markets that entail complex supply chains and cultural adaptation is far more complicated—and several issues involved in entering foreign markets will be discussed below; for example, as Henry Mintzberg, Richard Pascale, and colleagues describe Honda's entrance into the United States, completely misjudging their products' suitability for local tastes.

A firm with a promising product, service, and/or brand can try to market a similar offering via different channels of distribution. For example, Starbucks, having done well selling coffee in its chain of coffee shops, began to market packaged coffee through retail outlets. Often new channels go along with new segments and/or geographic markets. For example, diapers for babies are generally sold retail, while diapers for adults can be sold via wholesale (or industrial) channels to hospitals and facilities for the aged; similarly, The Home Depot, Inc., uses alternate channels—like internet and specialty outlets—when developing commercial and governmental markets.

International Market Development

The internationalizing firm has several added strategic dimensions to consider when developing foreign markets, such as entry mode, national culture, international legal issues, organizational structural adaptation, and opportunities provided by regional integration. A significant body of research has considered the options and behavior of firms as they commit to foreign markets. Authors like Harry Barkema and

Rian Drogendijk, Tamer Cavusgil, and Jan Johanson and Jan-Erik Vahlne have emphasized the gradual and sequential nature of the decision-making process whereby the firm is assumed to build a stable domestic position before starting international activities—beginning with sporadic exports and then building overseas operations incrementally. Over time the exports generally lead to the creation of an export department. The next stage in this evolutionary process is the transfer of certain value-adding activities abroad. These firms then also increase the number of subsidiaries abroad, starting with countries close geographically and culturally to the home country, moving to more distant locations and countries less similar to the home country. The reason for this behavior is postulated to be a result of risk aversion. As explained by Yair Aharoni, risk declines as international experience accumulates. A different and more rationalistic explanation was proposed by John Dunning by which internationalization will occur only if firms with sufficient ownership advantages to compensate for the liability of foreignness in one country can transfer these advantages to exploit location advantage in another country.

More recently, the deterministic nature of these evolutionary processes has been challenged. In a study tracing 100 years of Alfa Laval, Ivo Zander and Udo Zander point out that Alfa Laval's growth shows an oscillating rather than a linear pattern of development. Another strategic option is championed by firms that do not develop their international activities in incremental stages, but rather start overseas activities right from their birth. Such firms have been labeled international new ventures, high-technology start-ups, and born global. While these are also, technically, forms of market development, these strategies are more suited to highly entrepreneurial firms willing to take the substantial risks associated with making substantial investments in foreign markets before attaining a strong domestic position. For example, the above-mentioned study by Barkema and Drogendijk of Dutch companies entering into eastern and central Europe demonstrated that, in many cases, expansion steps may be too great; and they thus argue that firms have to balance exploitation and exploration in their internationalization decisions.

An allied set of crucial decisions facing internationalizing firms concerns selecting partners—be they for international joint ventures, strategic alliances, or mergers. Some countries have restrictive foreign ownership laws that obligate international firms to enter with a local partner. However, even absent these legal issues, it is often wise to use local partners to help achieve access to distribution channels, local customers, and to supply knowledge of local laws and customs.

Mergers and acquisitions may be used to achieve rapid entry into high-growth markets, acquire expertise, technology, products, brands, market presence, experienced management, reduce exposure to risk, and complement ongoing internal product development. They minimize the costly time lag associated with the internal development of products, markets, and their required supporting structures; and are particularly useful where product life cycles are short or there are other indications of a profitable market window closing.

David Tse, Yigang Pan, and Kevin Au studied two dimensions of firms' foreign-market entry strategy, namely mode of entry and formation of alliances. They build a model that describes how host country–, home country–, and industry-specific factors affect foreign firms' decisions on how they enter the market and whether they will enter with a partner firm or not. The model also shows how operation-related factors, such as the location and the level of local government, affect these decisions. In all cases the firm faces a complex set of decisions when embarking on a market development strategy. Apart from choice of market (for example, considering the options given above), issues of timing and mode of business operation need to be considered. The latter issue is especially complex in foreign markets.

Market Imperfections Theory

Market imperfections arise from violating the assumptions of perfect competition as described in neoclassical economics. The neoclassical market model ensures an efficient allocation of all goods and incomes. Moreover, competing vendors can build their business strategy on the equilibrium price because nobody will be motivated to offer or buy products at a different price. However, vendors in real markets have to cope with departures from these assumptions. Four types of market imperfections can be identified:

1. Frequently, only a few suppliers compete in a market or the number of customers is fewer than many. In the first case, the models of oligopolistic or monopolistic competition become effective (e.g., Stackelberg pricing or Bertrand pricing); in the latter case, vendors face an oligopsony or a monopsony.
2. Other violations arise from the heterogeneity of products. The explicit goal of all branding strategies—but also all references to the country of origin and offering superior services—aims to create market imperfections. Consequently, if the measures are successful, marketing strategies introduce market imperfections.
3. A third source of market imperfections arises from entry barriers, which frequently become a relevant condition in the internationalization or even globalization of business activities. Already in the 18th century, Adam Smith and David Ricardo proved that international trade is useful, increases welfare, and extends production possibilities. Ignoring these basic insights, national governments do their utmost to protect their national vendors from international competitors by various means such as customs, or enforcing national engineering standards. However, vendors can create entry barriers themselves by, for instance, building product facilities with the capacity to meet, or even exceed, all the local demand. An incumbent would fear a price war if the already established vendors needed to operate with full capacity load to cope with fixed costs or benefit from economies of scale.
4. The fourth type of imperfections relates to information availability in real markets. Under perfect competition, the equilibrium price, margin profits, and margin cost are known to both sellers and buyers. In reality, the prices differ in terms of time and location, as well as with the heterogeneity of products. It is mainly the consumers who lack precise price knowledge as well as the ability (or the willingness) to take on the mental burden of acquiring and processing complete price information. The emergence of specialized price comparisons for technical durables on the World Wide Web (e.g., priceline.com) reduces, but by no means solves, the problem generally.

These imperfections are utilized for building management theories on two aggregation levels: (1) explaining strategic actions of competing organizations (e.g., "cross and counter" or "follow the leader"), and (2) explaining the existence of the multinational enterprise itself and the internationalization of business activities.

A basic element for the explanation of multinational enterprises is foreign direct investment: investment in building physical manufacturing, distribution, or service-providing facilities in a country different from the firm's home country. These differ from usual portfolio investments with respect to the aims of the investment. Portfolio investments target arbitrage between different markets, for instance, different rates of interests or the reduction of risks by diversification to markets that are not perfectly positive correlated.

In his seminal work, Steven H. Hymer emphasized the importance of direct control, which enables the creation of market imperfections, particularly the elimination of competitive attacks or responses. Hymer argues that a total fusion of two competing firms might maximize profits if (1) the firms are actual or potential competitors and (2) the entry barriers for the markets under consideration are high and the number of competing vendors is small. Otherwise, a monopolistic advantage of the cooperating incumbents would be threatened by the entry of new vendors. In this theoretical development, foreign firms are assumed to be at a disadvantage when entering foreign markets because domestic competitors might have more detailed knowledge of national laws, a better understanding of consumer preferences, and so on. Thus, foreign competitors always have to incur higher information costs. In addition, they have to cope with currency fluctuations and are always in danger of incurring superfluous costs due to cultural misunderstandings. Multinational enterprises emerge if the monopolistic advantages derived by direct control over foreign investments at least compensates for disadvantages.

Charles P. Kindleberger extended this theory of market imperfections by rigidities in the factors markets. If factors are not accessible to competitors or transferable to foreign markets, the multinational firms benefit from these rigidities. Technologies or product designs might be protected by patents, workers' wages may show substantial differences, and even the interest to be paid for credits may vary across national markets. These factor rigidities provide multinational firms with potential advantages if they locate the production facilities in different nations. This perspective enables the explanation of cross-border vertical integration in addition to horizontal integration already considered by Hymer. Moreover, the Kindleberger extension also allows the consideration of governmental restrictions of market entries and governmental trade barriers.

Criticism of this theoretical development has resulted in several innovative management theories. For instance, the market imperfection arguments are static in time. Knowledge-based monopolistic advantages are usually dynamic advantages by nature, because innovative technologies emerge and create markets or replace older technologies in the course of time. This critique resulted in the concept of the international product life cycle.

Marketing

Marketing identifies unfulfilled needs and desires and satisfies those needs and desires in the target market. Marketing entails an entire process that involves identifying opportunities in the market that have potential to make a profit, developing a new product, attracting the customer to the product or service, keeping the customers, building brand loyalty, and creating value for customers. Companies that do this well are successful marketers. Marketing is no longer just a department in a company; various departments work together to market a product or service. Nowadays marketing starts even before there is a product. It is effective only if the company is successful in delivering the promised value and satisfaction.

In simple terms, marketing encompasses everything a company does to place its product or service in the hands of its target market. The target market is the potential customers of that product or service. People no longer just buy the product; they buy the ideas behind the product—ideas of what that particular product would do for them. Dunkin' Donuts and Starbucks both sell coffee and both are successful chains. Dunkin' Donuts' target market is serious coffee drinkers who need a quick inexpensive cup of coffee on their way to work.

Starbucks, on the other hand, is marketing not just coffee but an entire experience, lifestyle, variety, flavor, and music to its target market. The Starbucks target market is customers who want not just coffee but ambiance, a place to relax, read, work, meet friends, listen to new music, etc. At Starbucks, people are buying the concept of flavor, ambiance, and fun. Marketers today take time to discover who their target market is and how to reach them.

There are two types of marketing: lateral and vertical. Lateral marketing is to create a new market. In lateral marketing, an existing product is transformed to satisfy new customers. Cereal manufacturers realized that the market was saturated and there was no more room for growth. A European company took cereal and turned it into a healthy snack that can be eaten any time, not just for breakfast, and thus a new market for healthy cereal snacks was developed. In vertical marketing, potential customers are converted and a new market is developed. It is a niche market. An example is technology-oriented products. The real goal of marketing is to own a market rather than compete for a market. Apple, Ikea, Wal-Mart, and Amazon.com are all great examples of companies that realized that to invent a new market is better than competing for share.

Marketing decisions can be categorized as a mix of the 4Ps: product, price, place, and promotion. Professor Jerry McCarthy introduced the 4Ps framework in the first edition of his book *Marketing,* published in 1960. Marketers make decisions based on these 4Ps in the target market.

Product

The integral part of the marketing mix is the product. A product is anything that can satisfy the target market's needs and wants. A product includes more than a physical good or service. It can be a person (Tiger Woods, political figures, Madonna), a place (Niagara Falls, Disney World, Hawaii), an organization (Red Cross, Girl Scouts), and also ideas (quit smoking, drive safely). A product is designed, manufactured, and presented to the target market for sale. In order to decide what product to offer to the market, the marketer researches and thinks about what product will add value, provide a benefit, fulfill the end user's needs. A product can be an existing product line or a new product. Brand name, quality, style, features, functions, etc., have to be kept in mind in terms of the product. Characteristics of a product need to be defined.

Marketers need to ask themselves: What makes the product better than the competitor's? What is the brand image? How do consumers perceive the product? What does the customer want from the product? What needs does it satisfy? What features does it have to meet these needs? What shape, size, color? Name of the product? How is it branded? Branding is an important part of marketing that falls under the product category. People are willing to pay a premium price for strong, well-known, trusted brands. Consumers have become very brand conscious and brand oriented, and companies are spending millions to establish brand recognition and awareness in the eyes of consumers. A great brand brings to mind certain attributes, such as the product features and brand characteristics. It should also suggest a visual of the brand users and the company values.

Price

Price is the cost that the consumer pays to receive the product. It is an integral part of the mix. Costs to produce and sell the product and pricing strategies need to be determined. Should the price be lower than competitors' or higher? How much are intended customers willing to pay for the product? What are the costs to sell and produce the product? These are some questions marketers need to answer at this stage. A marketer can adopt various pricing strategies:

- Penetration pricing: This is usually when a new product is being introduced in the market. A low price is set to enter and gain the market, increase sales and market share.

- Competition pricing: Determine a price based on what the competitor's product price is.
- Bundle pricing: Bundle a group of products and sell as a package.
- Skimming pricing: Start by keeping the price of the product very high and then at a later stage lower the price to appeal to a mass market.
- Product-line pricing: Price different products within the same product range at different price points. This lets the company maximize its profits.
- Psychological pricing: When the product is sold at $0.99 instead of at $1, or $1.99 instead of at $2.
- Premium pricing: Price is set at a high level as the product is premium and offered to an exclusive target market.

Place

Place or distribution is making sure the product is available where the target market wants it. Marketers decide how to distribute the product at the right time and in the right place. Manufacturers can choose to sell their products directly to consumers or through wholesalers and retailers. At this stage, marketers research where consumers look for the product. Decisions on market coverage (inclusive, selective, or exclusive distribution) are made. What are the distribution channels? What distribution channels do competitors use? Is a sales force needed to sell the product, or are there other channels such as the internet, specialty stores, supermarkets, or direct mail? For example, Dell uses direct distribution from manufacturer to consumer.

Promotion

Promotion is the final P in the marketing mix. It deals directly with the consumer. Promotion includes the various tools of marketing communication. Some methods of promotion are advertising, public relations, sales promotion, personal selling, direct mail, internet promotion, and promotional strategy (pull and push strategy). All this increases consumer awareness of the products that exist in the market and also provides knowledge about the product features and benefits. These marketing communication channels also help educate, inform, and persuade consumers. Companies use these promotional vehicles to enhance the product's brand image and encourage consumers to try the new product or remain loyal to their brand.

Pepsi succeeded in India using culture-specific marketing, such as using locals as brand ambassadors.

Important questions need to be answered at this point: What mode should be used to get across the marketing messages to the target market? How do we reach the audience? Do we use advertising in the newspaper or TV ads or on the radio, billboards, or internet? If it is a new product launch, when is the best time to promote the new product? What are competitors doing to promote their product? What factors influence the choices the company makes on its promotions? An effective marketing communication is needed. No matter what the mode of marketing is, it has to be successful in delivering a clear, concise, effective message to the target market.

This last P in the marketing mix also comprises promotional strategies. The marketer needs to develop the message strategies. What message do we want delivered to the target market? Will it be through branding, or perhaps a new logo? The message should reinforce the benefits of the product and develop the positioning strategy of the product. Companies that have been successful with effective message strategies include McDonald's ("I'm Lovin' It") and Nike ("Just Do It").

There are two important kinds of promotional strategies: push and pull. A "push" promotional strategy uses methods to create consumer demand for a product. The producer promotes the product to wholesalers, the wholesalers promote it to retailers, and the retailers promote it to consumers. A push strategy tries to sell directly to the consumer, bypassing other distribution channels. In push strategy, consumer promotions and advertising are the most likely promotional tools. It is all designed to have the retailer promote one product to the end users over a different product.

A "pull" selling strategy requires high spending on advertising and consumer promotion to build up consumer demand for a product. If the strategy is successful, consumers will demand the products from their retailers, the retailers will ask the wholesalers, and the wholesalers will ask the producers. Examples are "50 percent off today" or "bring in this coupon to save 25 percent" or "buy one, get one free," "spend $100 and get $25 off your purchase."

A successful promotional strategy is not just claiming that the product is better than any other product in the market but making a claim that is true. Example: If a company promotes a sofa as a product that is comfortable and of superior quality but the sofa does not live up to the claim or the claim is incorrect, it will only hurt the company. Wal-Mart, Ikea, and Southwest Airlines have all claimed to have low-priced products with good quality and all three have innovated ways to keep costs down while maintaining good quality.

Marketing Communication and Promotions

Advertising is a tool of communication used by marketers to inform potential consumers about the product, product features, benefits, and availability. Advertising also reinforces the brand image to maintain brand loyalty. Advertising media include newspapers, television, radio, magazines, movies, the internet, and billboards. Advertisements are usually placed where the target audience can easily see it/hear it. Companies spend billions on advertising, and it is the most effective and expensive tool of communicating persuasive messages to the target audience.

Subliminal or covert advertising is becoming very popular. Marketers are placing their products or brands on popular TV shows or movies. The audience sees the brand being used by a famous, well-liked person on TV or in a movie and does not realize that the product is being advertised to them. Subliminal advertising is the technique of exposing consumers to product pictures or brand names without consumers having conscious awareness that they are being exposed to advertising. Example: Omega watches and Aston-Martin cars were seen in the James Bond movies.

Other tools include public relations, which manages a company's internal and external communication to build and maintain the company's positive image. Also, sales promotion is an integral part of the promotion mix. Sales promotion is used to increase demand to enhance market share and profits. Examples include contests, coupons, rebates, loyal customer rewards programs, sweepstakes, etc.

Personal selling is the oldest form of promotion. Companies use a sales force to communicate the product and its benefits to potential buyers and close the deal and make a sale. It also involves developing a relationship with the potential buyer and extending exceptional customer service. The major advantage of personal selling is that it involves a personal face-to-face activity that allows room to customize the message to the consumer's needs. For example, pharmaceutical and consumer product companies employ a large sales force to sell their products.

Direct mail is unsolicited mail sent to consumers to inform them about the products and services available. It is commonly referred to as junk mail. Direct mail is marketing in which companies market and advertise directly to consumers without using media. Direct mail includes advertising flyers and catalogs. A major advantage of direct mail is that marketers are able to target the exact consumers they want. A major disadvantage is the cost. In internet advertising, companies use the internet to advertise their brands and communicate messages to their audience. This includes banner advertising, e-mail spam, search engines, pop-up ads, and affiliate advertising.

Many marketing gurus are now talking about a fifth P in the mix: positioning. This is part of the promotion mix, but many marketers feel that extra emphasis should be made on product positioning, market positioning, and corporate positioning. Spending more time earlier on positioning goes a long way for marketers. The success of a new product depends on how consumers perceive it, what they think of the product, what they take from the positioning. Companies that differentiate themselves can position themselves as a brand that is different from competitors and offer a unique product with benefits that succeed and reap profits.

Product Life Cycle

Understanding the product life cycle is very important as it impacts the marketing mix. There are four stages in the product life cycle:

1. Introduction stage: In the introduction stage, the company wants to introduce the new product and build product awareness and develop a market for the product. This stage includes (a) product: branding is established; (b) pricing may be low in order to build market share; (c) distribution is selective, just enough to introduce the product to consumers; and (d) promotion is aimed at innovators and early adopters. Marketing strategy is to build product awareness and to educate consumers about the product.
2. Growth stage: In the growth stage, the company wants to build the brand and increase market share. Product quality is sustained and any needed improvements are made. Pricing is maintained as the firm tries to gain more market share and gain new consumers. Distribution channels are added as demand increases and customers accept the product. Promotion is increased and aimed at the entire target market.
3. Maturity stage: At the maturity stage, the strong growth levels off. Competition increases. Product features may be enhanced to differentiate the product from that of competitors. Pricing may be lower due to increased competition. Distribution increases and more incentives are offered to consumers. Promotion now includes product differentiation.
4. Decline stage: As sales decline, the firm can choose to maintain the product, perhaps repackage, redesign, and rejuvenate by adding new features and finding new uses; or to discontinue the product or sell it to another firm that is willing to continue the product.

International Marketing Versus Global Marketing

In international marketing, marketers apply the marketing mix decisions to more than one country. In global marketing, marketers integrate marketing decisions across multiple countries. As an international marketer, a firm may start exporting to a foreign country or, if doing business seems lucrative in a foreign country, a firm may enter and start marketing to that specific country. As a global marketer, the firm makes decisions keeping the entire world market in mind. The home country is not the focus—marketing decisions are made keeping in mind how they will affect the product or firm globally.

Globalization has changed the way companies do business. It has also impacted marketing. Companies are no longer competing in their respective regions only but are now competing on a global level. Even if some marketers had not planned it this way, global marketing is now an integral part. In the past, a company only had to worry about marketing within its national boundaries, but due to rapidly growing technology and globalization, companies now focus on their home market as well as outside competition in their home market. A global marketer views the entire world as one market. In this scenario the global marketer makes marketing and business decisions based on how they affect the regional markets.

The same 4Ps of the marketing mix apply in global marketing, but marketing decisions and applications are different in global marketing. A global marketing company launches a single product and makes changes to the same product depending on the demands of the different markets around the world. The logo and brand remains the same in all the regions, for example, Nike, Coca-Cola, Pepsi, Microsoft, and Apple.

Price is different in every market. How the product is distributed is also a region-by-region decision that depends on the target market and competition in a specific region. Promotion is usually the most important P in the marketing mix in global marketing. Decisions as to whether the message will be the same or will be different in every country are made at this stage. In global marketing the biggest advantage is that companies can achieve economies of scale, increase and sustain their brand image worldwide, and increase their presence and brand recognition worldwide. The disadvantage, on the other hand, is that the competitive environment and consumer needs are different in every region. Local companies know the market; they understand the consumers better than a foreign company.

Some products are easy to sell globally like beverages and electronics such as iPods, laptops, and cell phones, but some products like clothing and food require local adaptation. Global marketers need to analyze their markets, conduct market research, and get to know the consumers in all regions and cultures before they mass market a product globally. Many developing countries now have an increased demand for products that are mature or declining products in the West, thus giving many marketers the opportunity to sell their products globally at a greater profit. Today global multinational marketers are everywhere. A person can fly American Airlines to Asia, rent a car at Hertz, have a McDonald's burger with fries and a Coke, buy an Apple or Microsoft computer, and catch *The Bold and the Beautiful* on a brand new Samsung, Sony, or Panasonic TV. This is an example of marketing in a borderless world. Companies such as Coke, Pepsi, and McDonald's are successful marketers—they have worked hard to understand their markets and the culture, tastes, and attitudes of their customers. McDonald's has a similar marketing strategy but has customized its burgers according to region. It offers burgers with no bacon options in Muslim-oriented countries that do not eat bacon or ham.

Marketers who have not studied their markets are not successful globally and experience resistance from the market. For example, Toys "R" Us, after doing well in Europe and the United States, tried to capture the Japanese market but faced much opposition and difficulty. They had to find a local partner to enter the market. Coke, when marketing to Indian consumers, had based its advertising on its worldwide image and had not made any changes in its marketing strategy. Pepsi, on the other hand, had customized their marketing strategy and advertising, keeping the Indian locals in mind and using local heroes as brand ambassadors. This practice put Pepsi in a better position in India than Coke.

Car manufacturers such as Honda, Toyota, and Nissan have developed their own niche markets globally. They do not sell standardized cars but customize the product and marketing strategy based on the region and its demands. Procter & Gamble is a good example of a successful global brand that has expanded rapidly into new markets by tailoring their products to meet local consumer demands in each country.

Market Maker

A market maker is a bank or brokerage company that continuously publicly displays (quotes) ask and bid prices (for a guaranteed number of shares) at which they will sell or buy during the trading days. This financial operator ensures the liquidity and efficiency of the financial markets (making easier the trade of blocks of shares) and, therefore, reduces the transaction costs.

There are two ways of treating financial orders: matching (fully or partially) the orders recorded in a book orders or having a market maker that accepts directly the orders given by the market participants. On the one hand, a book orders matches the bid prices with the ask prices. If the highest bid price is equal (or above) the lowest ask price and there are enough shares available, the trade is immediate. However, if the highest bid price is below the lowest ask price, the order is recorded and displayed to later traders. On the other hand, a market maker buys or sells the security, and adjusts the price after according to their beliefs. For example, when a customer places an order (with a broker) to buy (sell) shares of a stock, the market maker will actually sell (purchase) the stock (even if he does not have a buyer [seller]), "making a market" for the specific stock.

It is possible to run a market using both a market maker and a book orders. Indeed, a market maker will work better in a small market (few offers) and a book order will work better in a large market (plenty of offers). The rule is that the market maker's orders must have the priority. Using a market maker enlarges the set of potential trades. This observation is even more visible in thin markets where the book orders is almost empty. The inclusion of the book orders method simplifies the adjustment of the market to increasing volume. Then the book orders procedure intervenes more significantly when the market gets thicker (lowering volatility).

The majority of the stock exchanges operate on an order-driven basis (matching the buyer's bid and the seller's offer) instead of using market makers. However, the integration of market makers is growing rapidly and presents some advantages for investors. For instance, the NASDAQ is an operation of market makers (more than 500 member firms that act as NASDAQ market makers). Generally, each market maker competes with the other market makers (who are dealing on the same security) to obtain the deal with the client. In this way, this ensures the market to be more efficient and competitive. Note that many over-the-counter (OTC) stocks have more than one market maker. There is generally a clear separation between the market-making side and the brokerage side to avoid brokers' recommending specific securities for which the firm makes a market.

The market makers take no commission on the sale but instead make their money on the bid/ask spreads or on the offsetting of their positions. The bid/ask spread is the difference between ask and bid prices. This spread is rarely equal to zero, and the market maker will only make a trade when there is sufficient profit on the sale, i.e., a sufficient spread. On heavily traded stocks, this compensation for the risk they take (holding a certain number of shares of a particular security) can represent a handsome profit even if the bid/ask spread is very small. Note that a market maker makes a profit on every sale, whether the market goes up or down. Obviously, the opportunity to become a market maker is very rare and controlled.

Market makers support different principal kinds of risk:

- Liquidity risk: A market maker provides liquidity to his working market; however, he is not certain to find the necessary liquidity to reverse the positions that he has inherited. In this way, a market maker needs to find a trade-off between highly liquid markets (with low bid/ask spreads and therefore low profits) and illiquid markets (with high bid/ask spreads and therefore high potential profits).
- Operational risk: A market maker is also exposed to potential operational risk arising from business functions and the practical implementation of his management strategy. This concept integrates notably information, fraud, physical, and environmental risks.
- Information asymmetry: The market maker should pay the correct prices for his positions, but he will never have all the information because the markets are not perfectly efficient (the information is not homogeneous and not perfect).

There are some differences between a market maker and a market specialist (NYSE). However, they serve the exact same purpose.

Market Research

Market research examines the operating environment of a corporation. It includes all of the processes and operations that deal with the systematic acquisition of knowledge, including searching for, collecting, analyzing, and interpreting information. This knowledge supports the marketing activities of corporations.

Market research is generally divided into four categories: market research, consumer research, product research, and media research. It can be performed either by using secondary sources such as data and information that has been collected beforehand or through primary research that refers to collecting data on a specific topic directly in the market. When conducting market research, researchers apply qualitative and quantitative research methods.

Market research aims at investigating the conditions in which a corporation operates. The acquisition of market information has two main goals. First, market information can help to solve problems that the company is facing and allows managers within the corporations to make better decisions. If sales of a certain product decrease, market research can present answers as to why consumers do not buy the product anymore or why they prefer the product of a rival. Market research can help to locate and identify corporate problems and to develop solutions for them.

Second, market research helps to identify future trends and challenges for corporations. Firms are facing increasing competition from an ever-growing number of competitors. In order to bring successful and profitable product ideas to market as fast as possible, the corporation needs to identify any changes or trends in customer needs so that they can be integrated into marketing planning. Thus the company needs information about market potential, market share, and trends in consumer behavior.

Stages of Market Research

Market research is performed in several stages. At the beginning of the market research process, the problem or challenge the corporation faces has to be defined in order to be solved. Information to accomplish this can be found in the market. The company can either carry out the research activities itself or hire a market research agency to do so. In some cases, information on the topic of interest already exists within the company or in official organizations, such as ministries, research institutions, or market research agencies. The next step, namely the analysis and interpretation of the data and information acquired, is the most important one. Finally, the acquired data is integrated into the marketing activities of the corporation.

The acquired information is communicated via marketing-information systems within the company. A marketing-information system facilitates the organized and regular dissemination of information to all managers within an organization to support their decision-making processes. At the end of the market research process, collected information will influence the marketing activities of corporations.

Areas of Market Research

Market information has various forms. They include information about the researcher's own company, its market position, its development, and its growth prognosis as well as competitive strategies and information on rival corporations. As its name suggests, market research investigates the operating market of a corporation and the changes that can be observed in these markets. Another relevant area is the research of consumers, their attitudes, needs, and behavior. Market research can further investigate products and their acceptance and usability. Product research aims at avoiding problems in product usage and acceptance by applying product, color, or flavor tests. Market research is also conducted to investigate the effectiveness of media used in marketing activities. Questions investigated in this field concern the image of communication channels, how many and which consumers they reach, and the efficiency in communicating the corporation's advertising messages.

Market research is divided into secondary and primary market research. Secondary research is based on data, which has been investigated beforehand. Secondary data is often found in governmental organizations, such as chambers, ministries, or research institutes. Primary market research, on the other hand, is data that is only collected to answer particular questions that a company may have.

If a company is interested in offering a new product (e.g., yogurt) in a new market, it can support its market entry decision with secondary data on the market conditions. Secondary data may include information about market conditions, market volume, country sales numbers, or general market trends such as changes in consumption styles. The question of which yogurt flavor customers in a market prefer cannot be solved with secondary data. It must be investigated via primary research within the target consumer group. Primary market research involves product tests and integrating the results into new product development processes. This is to decrease the risk that the product will not be accepted by consumers.

Market information can be collected via internal and external resources of the company. Internal sources are company statistics, consumer data, and sales data as well as data on cost accounting. External sources refer to information that derives from market research institutes, consultancies, experts, journals and industry indexes, governmental organizations, commercial chambers, universities, or other research institutes.

Qualitative and Quantitative Research

Market research methods are further divided into qualitative and quantitative methods. Qualitative market research attempts to provide in-depth information on certain topics and can therefore find out consumers' attitudes or their changes in them, their values, and their reasons for making purchase decisions. Qualitative market research methods include qualitative interviews, focus groups, observations, and experiments. Qualitative interviews consist of open questions that allow identifying psychological and sociological backgrounds and the relationships of a certain topic. Focus groups are group discussions in which a group of consumers discuss their use and impressions of a certain product. This discussion is moderated and guided by a market researcher and in most cases also videotaped. During the discussion, different and often new aspects concerning the product are presented that enable the company to find out about consumer attitudes.

Observations investigate consumer behavior in greater depth. In consumer research, observations take place in the form of test purchases (mystery shopping), customer frequency surveys, or direct observations of consumers' purchasing processes. Observations permit investigation of consumer behavior without interference by interviewees. Despite these benefits, observations are only partly usable because market researchers are only observing consumer behavior without investigating the background and reasons for it. Observations are often considered a subjective research method.

Experiments simulate real situations and observe and analyze the behavior of consumers in them. Experiments are used to perform product tests on acceptance, usability, flavor, and store tests. Causal relationships can be discovered in this way. The company can find out the conditions, the store design, and the packaging that positively influence consumer behavior.

Quantitative research methods refer to methods that generalize consumer behavior. Whereas qualitative research methods investigate in depth the consumers' reasons and attitudes, quantitative research methods find out if these attitudes and reasons are representative for a majority of consumers. Quantitative research methods include surveys conducted in the form of standardized questionnaires. Another quantitative method is a panel, a regularly performed survey on media and purchase behavior of consumers.

Markets

Almost everyone appears to understand the term *market*. However, different people answer the question "what is a market?" in different ways. Some consider a market as a designated geographical location where buyers and sellers meet to trade goods and services. Others define *market* in terms of specific characteristics of the potential buyers for a product or service. This entry examines the various ways in which *market* can be defined and understood.

Theodore Levitt argued that a market is composed of people who have various needs and wants. Economists across the world consider markets as the group of buyers and sellers. Marketers differ from economists in that they consider sellers as the constituents of industry and buyers as constituting the market. Jack Z. Sissors argued that market consists of many things related to selling products that meet consumers' needs and wants. He further argued that there are two main dimensions of a market: physical and behavioral. Physical dimension considers the physical attributes of the market for a product or product class such as market size, location, and prospective buyers' demographical characteristics. Physical dimension helps define the market in terms of the product or product class whereas behavioral dimension helps in developing a customer-oriented perspective of the market. Behavioral dimension focuses on behavioral characteristics of the prospective buyers such as the influences, reasons, quantities, frequencies, and timing of purchases as well as their social and psychological characteristics. There are several ways in which markets have been classified.

Traditionally, markets have been defined and classified either in terms of geographical locations or product class. Examples of markets identified by product class include a cotton market, cheese market, food grains market, fruits and vegetables market, etc. Some examples of location-based markets include New York market, London market, Calcutta market, Valencia market, etc. Some of these locations were also very strongly identified with a product class. For example, Valencia market in Spain was traditionally known for cotton and Calcutta market in India was known for jute.

Since more and more companies are selling their products and services abroad, it is now common practice to classify markets as domestic markets and global markets. Some of them classify and identify their international markets based on regions, e.g., U.S. market, European Union market, southeast Asian market, Asian market, Pacific market, Indian market, Chinese market, French market, etc. Many people continue to identify markets in terms of geographical location or product class. Markets are also classified as business markets and consumer markets based on the nature of consumption.

Business Markets and Consumer Markets

Business markets are constituted by those buyers who buy goods and/or services to resell to others or to use them to produce another product and/or service. These buyers are known as organizational buyers or business buyers, and they sell or rent or supply their outputs to other businesses or to individual consumers. Business buyers, although few in number, usually buy in bulk. Industrial markets, institutional markets, and government markets are among the key business markets. Industrial markets include buyers for raw materials, components, finished goods, and/or services. Organizations that are created to provide goods and/or services to people in their care constitute institutional markets. Medical and educational institutions are good examples of institutional markets. They usually operate with a low budget and hence look for good-quality products and services at lower prices. In several countries including the United States, government constitutes the biggest market for several firms. Some estimates show that the U.S. government is the largest customer in the world. Government markets are often good for domestic suppliers as most government organizations tend to favor them and formulate their purchasing systems and policies accordingly.

Consumer markets, on the other hand, are constituted by those buyers who buy things for their personal or household consumption. Professional marketers now use demographic and nondemographic (psychographic) characteristics of the prospective buyers to define and classify consumer markets. Age, family size, gender, income, occupation, education, ethnicity, etc., are among the key demographic characteristics used to identify and define consumer markets. A large number of consumer product companies use age as a criterion to categorize their markets as kids market, teenagers market, youth market, adult market, and seniors market. Some define markets even further, for example, classifying kids market into submarkets such as newborn market, infant market, toddler market, and preschooler market. Due to different genetic and social factors, markets for certain product classes such as clothing, grooming, entertainment, etc., require businesses to define their markets and products on the basis of gender. It has always been very easy to notice that airlines, hotels, clothing companies, banks, etc., often come up with different products and services for market classifications based on the income level of their prospective buyers. Similarly, many restaurants across the world thrive as they identify their market based on ethnicity. One can easily locate Chinese and Indian supermarkets outside China and India that define their markets on the basis of ethnicity.

A cluster of buyers' characteristics such as education, occupation, income, personal wealth, etc., create an enduring division in several societies that is commonly termed *social class*. Many businesses identify and define their markets on the basis of social class because social classes exhibit distinct preferences and behaviors. Automobile manufacturers often use social class to identify their markets and develop specific products and services to suit the taste of consumers belonging to a particular social class.

Characteristics

Advances in behavioral science discipline have made it possible for businesses to combine both demographical and psychological characteristics of prospective buyers to better define and classify their consumer markets. Since people within a demographic group often vary significantly in terms of their personality traits, attitudes, beliefs, values, self-image, lifestyles, and aspirations, businesses develop psychographic profiles of their prospective buyers to identify appropriate markets. It works very well for niche marketers because psychographics delves deeper into people's lifestyles and behaviors, including their interests and values.

More and more businesses today construct their markets on the basis of behavioral characteristics of prospective buyers. For this purpose, they attempt to understand who and what influences their buyers to buy what they buy, why they buy a particular product and brand, when and how often do they buy, are there any special occasions to buy for, in what quantities do they buy, and from where? They try to understand their consumption and postconsumption behavior including disposal behavior. Several purchases involve planning by buyers to varying extent. Yet, kids buy candies, chocolates, ice cream, chips, and toys; and adults buy beverages and tobacco products on impulse. Such buyers constitute an important market for marketers of such products.

Businesses also define their markets based on the benefits their prospective buyers seek. Buyers who always seek the lowest price for an item constitute a key market for many businesses. On the other hand, some businesses focus on those markets that are constituted by non–price sensitive buyers who are looking for specific benefits other than economy. Businesses charge premiums in such markets and thus make more money even though they sell fewer quantities.

Consumption quantity is another important behavioral characteristic of buyers that businesses use to identify their markets. Many firms develop bulk packages for their market of heavy users and small packages for their light users. Some firms invest huge amounts of money and effort to develop specific programs for the market constituted by nonusers as they expect them to become heavy users in the future.

Some buyers buy and consume certain products on specific occasions. For example, wedding dresses are purchased or rented at the time of wedding; families go on vacation during school holidays and thus significantly increase the demand for air travel and hotel rooms among many other things; some save throughout the year to splurge during Christmas time; Valentine's Day, Mother's Day, and Father's Day are other occasions on which many people across the world spend good amounts of money to buy gifts. Businesses use these temporal aspects of prospective buyers' lives to identify markets and develop unique products and strategies for such occasions.

Some businesses operate in several markets. Others focus on specific markets. They evaluate the attractiveness of markets by estimating the size, profitability, potential, and associated risk and then develop appropriate products, services, and programs to market them.

Market-Seeking Investment

Market-seeking investment is one of the types of foreign direct investment. According to Rajneesh Narula and John Dunning, it occurs when companies internationalize to a particular country because they want to supply this particular market with goods or services to grow in that market, and to be competitive within the industry as well as to provide opportunities to achieve production economies of scale. To benefit from the production economies of scale requires a sizable population and the ability of the market to support the expected demand on which the investment is based. Therefore, Dunning states that market-seeking foreign direct investment is based on a single central location (L) advantage. According to Narula and Dunning, market-seeking investment becomes preferable either if there are substantial barriers to exporting from the home country or if the local markets offer potential foreign investors significant opportunities to achieve scope and production economies of scale as well as a chance to grow.

Therefore, for John Dunning, the most important reason for market-seeking investment is the attitude of host governments toward such investment and their encouragements. However, there are four other reasons to explain why and how firms engage in market-seeking investment in foreign markets through a subsidiary.

Companies engage in market-seeking investment in foreign markets through (1) becoming accustomed: When goods and services are modified to local culture, to indigenous resources and to standards, companies can survive and become more successful in a foreign environment. In particular, it is commonly believed that if foreign companies do not adapt themselves to local customs, they might find themselves disadvantaged compared to local firms; (2) lowering costs: One of the most important reasons for companies to establish a subsidiary in a foreign market is to reduce transportation costs in that particular market. Otherwise, serving that market from a distance by exporting from the home market to the foreign market would be much more expensive; (3) following customers or suppliers: When main suppliers or customers move overseas, the firm may need to follow them in order to retain their business. If they do not do this, there is a high risk that they might lose their business to another competitor; and finally, (4) global positioning: A multinational company establishes subsidiaries as part of its global production and marketing strategy to have physical presence in the leading markets served by their competitors.

Therefore, John Dunning, Bruce Kogut, and Magnus Blomstrom explain that companies aim either to maintain existing markets or to penetrate new markets. Nevertheless, it is argued that businesses are more likely to be pushed toward this type of investment out of fear of losing a market rather than discovering a new one.

According to UNCTAD Global Survey results, market-seeking investment mainly concentrates on industries such as chemicals, food, finance, transport, and communication largely because of local or neighboring multinational companies and their specializations. The multinational companies from a few developing countries specialize in manufacturing industries like China, information technology (IT) services like India, and consumer electronics like Korea, and invest mainly in other developing countries.

In addition, the motives of multinational companies from developing countries are substantially different from the motives of multinational companies from developed countries in the same industry. Whereas multinational companies from developing countries invest in extracting oil or gas for the reason of market-seeking investment, multinational companies from developed countries invest in these industries for resource-seeking motives. According to the UNCTAD *World Investment Report,* foreign direct investment in neighboring countries is the most common feature of internationalization because of cross-border spillovers, factor similarities, and cultural familiarities in different markets.

Market Share

Market share of a firm's product can be defined as the amount of product that the firm sells into a market expressed as a proportion of the total amount sold in that particular market. It is, as its name suggests, a measure of how much of the market a firm accounts for, given that it shares the market with its competitors. A firm's market share is often considered to be a strong market-based measure of its strength, but one must be wary of the limitations. These limitations tend to lie in one fact: many assumptions are made in the calculation of what appears to be an objective measure of firm (or brand) strength.

A simple illustration of market share is that a firm with 100 percent market share would be described as a monopoly, and that the average market share for a market that contains *n* competitors is equal to 100 percent divided by *n*. That is, a market with five competitors would give each competitor an average market share of 20 percent. From this illustration it can be seen that averages are misleading, and it would be a rare market, indeed, that is shared evenly between its players.

Sometimes it helps to think of a market as being comprised of different types of competitors. A market leader and a challenger may compete for the top position, with one or more market followers who do not directly challenge for the position of number one. Finally a "market nicher" may choose to operate in a very narrow section of the market, posing little direct threat to the market leader, challenger, and followers.

Furthermore, it may not be the firm itself that competes in a market. Often a firm will create a number of brands to compete in the same market. For example, Dutch consumer goods firm Unilever currently competes in the detergent category with the brand names Omo, Persil, Surf, and Drive. Therefore, a different market share exists for the parent company and also for each of the individual brands owned by the parent company. Often markets are simply described on a brand-by-brand basis regardless of which parent company owns which brand. From here on, brand-level competition will be referred to.

When discussing market share for a brand, one must be clear on how the market share measure is calculated. Prudent managers must decide on the unit of sales, define the geographical boundaries, and determine the product class. The unit of sales is normally either some measure of volume or some measure of monetary value. Therefore, a wine brand's volume share may be calculated by dividing the number of cases (of wine) they sell by the total number of cases sold in the market. The same company's share by value could be calculated by dividing the value of their sales by the total value of the market. Brands that sell for a higher price than their competitors will have a higher share by value than their volume share in the same market.

Market share often has a high correlation to brand penetration and customer loyalty.

The geographical boundary of the market is the first step a firm may take in defining its competitors. One may define a market very broadly (e.g., the United States) in order to address strategic concerns, or in a narrower sense (e.g., California). It is common for firms to consider market share on a number of geographical levels depending on the purpose of the analysis.

The product class is an important second indicator of a firm's competitors. Consider a brand of Australian cabernet sauvignon for US$8 per bottle. The brand may be thought of as belonging to one or more of the following product classes: all wine, Australian wine, table wine, red wine, cabernet sauvignon, wines in price tier US$6–10. The product class is largely a function of how the consumers see the market and is often the focus of some argument between brand managers and their colleagues. Different pictures of brand performance may be arrived at simply by deciding that one's brand competes in a different product class, because of a different set of competitors.

Market share has been shown to correlate very strongly with other measures of brand strength. An example is the law of double jeopardy; brands with lower market share are penalized twice. Smaller brands have a lower proportion of shoppers buying them—even once—in a given period of time than do larger brands. Second, smaller brands are bought slightly less frequently than are larger brands. Market share tends to have benefits for a brand that go beyond simply the amount of product sold—it tends to have a high correlation to brand penetration and customer loyalty.

Therefore, when discussing market share, one must be clear about whether they mean firm or brand market share, the unit of sales, which geographical market they mean, and the product class they are referring to. Finally, double jeopardy is an empirical law that recognizes the relationships between a brand's market share and its other performance measures in repeat purchase markets.

Mark-to-Market Valuation

Mark-to-market is an accounting and financial term used to define the act of assigning a value to an asset based on its present market value (for example, the value at which the asset is being traded), rather than the book value (price paid when it was purchased). This concept is used when the asset's expiration date is undefined, or when its value varies from one day to the next. For example, shares that have no "final value" are subject to mark-to-market valuation.

Regulators encourage the use of mark-to-market accounting by institutions because they believe it leads to greater transparency and better reflects the value of equities, while critics blame this accounting measure for increasing financial instability of traditionally "stable" assets (such as bonds and mutual funds) as well as triggering downward spiral evaluation of some securities.

In the United States, mark-to-market is regulated under Internal Revenue Code Section 475, which dictates that securities should be valued at fair market price, and that dealers should recognize gain or loss of the security as if it were sold at fair market value at the end of the current year. Gain (or loss) is taken into account in the financial statements for that taxable year.

In the case of highly liquid securities, fair market value is easy to estimate. This becomes much more difficult when equities are not frequently traded, or are structured in highly complex manners. As such, Statement of Financial Accounting Standards No. 157 (SFAS 157) recognizes that there are three levels of assets; a Level 1 asset is valued by comparing the price of identical assets or liabilities. Level II assets use directly or indirectly observable events to determine fair market price, while Level III asset values are reflected by management's best estimate of market participants' perception.

Typically, mark-to-market valuation is used with goods for which the final value cannot be formally evaluated. For example, in the case of stocks or mutual funds, the overall value changes daily, so they do not have a final value assigned to them. Hence, mark-to-market is used to give these assets a "current" value so they are properly priced in accounting statements.

Mark-to-market is also used in futures trading to ensure that trader margins are still positive; hence the financial institution protects itself against depreciation by verifying daily that futures traders have sufficient funds on hand. If they do not, the institution will emit a margin call to protect itself. Mark-to-market is also used by institutions managing mutual funds so that investors can ascertain the current value of their investment, rather than waiting for quarterly or monthly valuation.

Mark-to-market was initially introduced by legislators as a way to protect investors and is believed to be critical in managing the value of long-term assets. In the past, some companies valued assets at the purchase price. This valuation did not always reflect the current value of the product, allowing them to conserve an inflated value over prolonged periods. In some situations, valuing assets at the price purchased allowed companies to increase the value of assets while misinforming investors.

Some people have criticized that mark-to-market increases short-term valuation of equities by increasing the daily valuation of equities, even if these have traditionally been defined as long-term investments. For example, when bonds are reported with mark-to-market valuation, they essentially vary like shares and other volatile equity. Hence, some people criticize the shortsightedness that inevitably emerges from using mark-to-market.

Critics have also emphasized the unstable financial environment this type of valuation creates. The time period becomes shortened for valuations for financial elements that should be done over a long period of time, increasing market volatility of stable instruments due to human psychology; investors are at risk in mark-to-market valuation in markets where liquidity is limited and instrument issuers have an incentive to avoid markdowns by triggering a transaction.

Another critical issue is that in times of economic downturns, equities that are valued in mark-to-market terms can quickly deflate due to market psychology. Hence, as investors rush to sell equity, the market price drops further, lowering the value, leading more investors to sell until the asset is left with no value. Hence, mark-to-market can further inflate a bubble economy, while further encouraging a downward spiral. Nonetheless, the financial instability is perceived by regulators as an acceptable trade-off to miscounting of assets that have lost value, and is believed to be the best way to protect investors.

Marshall-Lerner Condition

The Marshall-Lerner condition, named after British economist Alfred Marshall (1842–1924) and American economist Abba Lerner (1903–82), is an often-asserted economic statement that specifies the circumstances under which a downward movement of the exchange rate, arising from either market-determined depreciation or monetary authority devaluation, will exert a favorable influence on a nation's balance of trade.

A decrease in the value of the domestic currency with respect to a specified foreign currency will alter the relative price of imports and exports. The price of imports will increase, relative to domestically produced goods, while the price of exports will fall relative to other countries. Such price movements will result in a switching of domestic and foreign expenditure, with domestic consumers buying fewer imports and foreign consumers buying more exports. The net influence of these movements on a country's balance of trade will be determined by the price elasticities of demand for both exports and imports.

As a general definition, the price elasticity of demand is a descriptive statistic that represents the relative responsiveness (or sensitivity) of demand to changes in price. It is calculated as the percentage change in the quantity demanded divided by the percentage change in price. If the price elasticity of demand for a particular good is given as 2.7, it implies that a 1 percent reduction in price will, all other things being equal, lead to a 2.7 percent increase in the quality demanded (and visa versa).

Assuming that the economy begins in trade balance, the Marshall-Lerner condition states that, all other things being equal, depreciation/devaluation will improve a country's balance of trade, providing that the sum of the price elasticities of demand for the country's imports and exports, in absolute terms, is greater than one. A simple example will illustrate the condition. A nation's trade balance, *BT*, may be defined as $BT = X – pM$, where X = the value of exports, M = value of imports, and p = the ratio of the prices of imported goods to domestically produced goods. The value pM indicates that any alteration in the relative price of foreign to home goods will alter the cost of goods imported. All values are expressed in terms of the domestic currency for the nation. Assume that, prior to devaluation/depreciation, the economy is in trade balance with $X = 100$ and $pM = 100$. Assume also that the elasticity for demand for imports is 0.9, and the elasticity of demand for exports is 0.8. Following devaluation/depreciation, what will be the effect of a 1 percent rise in the price of imported goods to domestically produced goods? The respective elasticities dictate that imports will fall by 0.9 per cent to 99.1, while exports will rise by 0.8 per cent to 100.8. Total expenditure on imports will also increase given the alteration in the relative price of foreign to home goods. The new balance of trade will therefore show an improvement, $BT = 100.8 – (1.01 \text{ x } 99.1) = 0.709$.

Now let us violate the Marshall-Lerner condition by setting the sum of the elasticities for exports and imports, in absolute terms, to less than one. Assume, for example, that the elasticity of demand for imports is 0.3, and the elasticity of demand for exports is 0.4. Allow also, as before, for the nation to be initially in trade balance, and for a similar 1 percent rise in the price of imported goods to domestically produced goods. Under these conditions, the new trade balance will show a deterioration, $\text{BT} = 100.4 – (1.01 \text{ x } 99.7) = – 0.297$.

Although the Marshall-Lerner condition highlights the ways in which depreciation/devaluation could improve a nation's balance of trade, a number of complicating factors must be taken into account. For example, underlying the condition is the assumption that depreciation/devaluation will lead to an immediate switch of domestic production to satisfy both increased domestic demand and increased foreign demand. Yet in the short run, there will probably be insufficient spare capacity within the home country to successfully switch production in order to satisfy the increases in domestic and foreign demand. Furthermore, we cannot ignore factors that undermine the assumption of an immediate increase in domestic and foreign demand. The existence of long-term contracts, for example, would cause the home country's short-run elasticity of demand for imports to be relatively unresponsive to price changes, implying that the nation's imports would not immediately tend to decline. A similar consideration must be given to the short-run demand for exports, for if this demand is also relatively unresponsive to price changes, foreign consumers would take time to switch toward cheaper imports.

Given that the effects surrounding export creation and import substitution will not be instantaneous, but will only take effect over time, the initial effect of depreciation/devaluation would tend to be a worsening of the balance of trade. However, as circumstances adjust over time, the nation would gradually experience an improvement in the balance of trade. This initial deterioration and subsequent improvement is referred to as the "J curve" effect.

Masculinity/Femininity

Masculinity/femininity is one of the five cultural dimensions identified by Geert Hofstede in his book *Cultures and Organisations: Software of the Mind*, where he presents the results of research on cultural variability or national cultural differences using survey data collected from IBM in 50 countries. Hofstede argues that this dimension is fundamental to understanding how societies cope with the duality of the sexes, suggesting that coping strategies would indicate how sex roles are distributed in the division of labor and how they impact hierarchies of work goals at the national level. He states that the decision to use masculinity/femininity as a label for this dimension is rooted in the findings, which indicate that this was generally the only dimension where men and women surveyed scored consistently differently. Nonetheless, it must be highlighted that the main trait is masculinity, which can be identified in the use of the Masculinity Index (MAS), where feminine is the low or nonmasculine, used to construct the dichotomy.

In theoretical terms, the dimension draws on ideas about how people "do" sex differences in organizations or how dynamics of gendered normative are constructed around understandings of sex roles. In operational terms, it refers to the degree of value placed on behaviors associated with masculinity or femininity. It could be said that the use of the dimension aims to illustrate the interaction between understandings of masculinity/femininity, culture, and behavior by focusing on how specific orientations reveal differences in emotional roles, cultural constructions of gender, and traits of "national character."

In that respect, both masculinity and femininity behaviors are categorized based on socially accepted sex-role patterns in traditional societies. For instance, Hofstede suggests that the main associations with masculinity and femininity can be identified as male assertiveness and female nurturance. He argues that

> masculinity stands for a society in which social gender roles are clearly distinct: Men are supposed to be assertive, tough, and focused on material success; women are supposed to be more modest, tender, and concerned with the quality of life.

On the other hand,

> femininity stands for a society in which social gender roles overlap: Both men and women are supposed to be modest, tender, and concerned with the quality of life.

Based on the previous understandings, the dimension opposes ego-goals (masculinity) to social goals (femininity), therefore suggesting that masculine behaviors prioritize the self while feminine behaviors prioritize the social. Masculinity behaviors include assertiveness, wealth acquisition, and achievement, and femininity behaviors include offering social support, focus on quality of life, and caring for others. The impact and presence of these behaviors on culture norms would indicate the level of masculinity or femininity, hence the cultural orientation for this particular dimension.

Hofstede's Evidence

Using a Masculinity Index (MAS) based on social-ego factor scores, 14 work goals items were scored, asking participants to think about factors that would be important to them in their ideal job (regardless of whether these factors were present at their actual job). The score results represented the importance attached to these factors. In line with what was previously mentioned about the traits associated with masculine and feminine, results were classified based on importance given to earnings, recognition, advancement, challenge, relationship with manager, cooperation, living area, and employment security. Earnings, recognition, advancement, and challenge were considered masculine, while relationship with manager, cooperation, living area, and employment security were considered feminine.

The index used a range between zero and 100, where zero was the feminine or nonmasculine score and indicated high importance of manager and cooperation and low importance of earnings. Conversely, lower importance of manager and cooperation and high importance to earnings increased the score, hence a higher masculinity.

Findings suggested that the country with the highest MAS was Japan with a score of 95, and the country with the lowest MAS was Sweden, with a score of 8. In the case of the highest-scoring countries, the top positions after Japan comprised a mix of countries from different geographical and cultural regions, namely, Austria scoring 79, Venezuela scoring 73, Italy scoring 70, and Switzerland scoring 70. On the other side of the spectrum, at the lowest end, Nordic countries dominated, with Norway scoring 8, Denmark scoring 16, and Finland scoring 26. The middle scores of the index presented a combination of regions scattered throughout the scale; for example, South Africa (63) and the United States (62), Canada (52), Pakistan (50), and Iran and France both with a score of 43.

Countries with high MAS, such as Japan, Austria, Venezuela, Italy, and Switzerland, give importance to manliness and masculine traits, behaviors, and products. As such, in these countries, it is expected that national cultures stress tougher values in men and tender values in women. Countries with low MAS, such as Sweden, Norway, the Netherlands, Denmark, and Costa Rica, have a closer degree of equality between men and women and behaviors are less prescriptive in regard to gender roles.

In view of the general patterns of masculine/feminine orientation, Hofstede explains how dynamics operate in the workplace, within occupations, in the family, and at school. He stresses the importance of socialization as a key instance where understandings of individual sex/gender roles are learned and then continuously reenacted by individuals in different contexts.

Nonetheless, it is important to highlight that Hofstede suggests that a country's location within the masculinity/femininity dimension is relative and mainly reflects prioritization of specific work goals. Furthermore, for some dynamics gender is not considered a relevant variable for values. This in itself raises issues pertaining not only to the exact nature of Hofstede's work (what are the theoretical foundations of Hofstede's work in terms of gender dynamics, masculinities and femininities?), but also to its focus (is the study about national cultures or organizational cultures?) and the relevance of the data collected to illustrate the dimensions identified (can it be argued that the masculinity/femininity dimension illustrates gender normative?).

Criticisms

The work of Geert Hofstede has been both widely praised and severely criticized. Brendan McSweeney and Rachel Baskerville-Morley are the sharpest critics; they argue that the two main fundamental flaws in Hofstede's work are its methodology and theoretical foundations. In that sense, several points can be highlighted; for instance, methodologically, the lack of representativity of the sample in each of the countries raises questions about the possibility to speak of "national" cultures.

The research assumes that generalizations about entire national populations can be made based on a few questionnaire responses, that occupational cultures are universally the same, and that findings are situationally nonspecific. Furthermore, the research does not consider issues pertaining to the nation-state debate, such as dynamicity, variability, and complexity. This last point brings to light issues about the theoretical outdatedness of Hofstede's model. Lastly, the simplicity of Hofstede's model is particularly important as the bipolarity of Hofstede's dimensions is problematic because it obscures that organizational reality is not dichotomous; for instance, there are masculinity and femininity, and it is not always masculinity versus femininity.

The main theoretical criticisms that can be made broadly pertain to culture in terms of assumptions that it is measurable, objectively observable, immutable, shared, and homogenous and to organizational culture in terms of assumptions that it is uniform and monopolistic. This is particularly important in terms of how masculinity and femininity are understood, as understandings of masculinity/femininity vary across cultures and reflect wider matrices that include combinations of national culture, institutions, structures, occupations, and individuals.

Maslow's Hierarchy of Needs

One of the well-known complaints about the limitations of economics is that economic theorizing is often based upon unquestioned assumptions about the nature of human agents. The model of *homo oeconomicus* has often been taken as an abstraction of human behavior in order to highlight major rules of economic functioning in a simplified way. A fundamental problem is that *homo oeconomicus*'s underlying assumptions clash increasingly with everyday experiences by observers inspired by social sciences like psychology or sociology. According to these assumptions, human agents are isolated from social networks and they are reduced to rational calculating machines following ultimately egoistic aims of maximizing individual profit. The sterile world that operates with ideas of a *homo oeconomicus* takes motivation as granted and treats human behavior as a black box.

In contrast, the primary aim of psychology is to ask for forces, grades, and types of motivation. Abraham H. Maslow (1908–70), a psychologist, offers a systematized typology of human needs that are organized hierarchically and that operate as motivation incentives at different levels. Maslow's work has a prominent place within the academic area of psychology but is also very well known by a wide field of neighboring disciplines concerned with questions of needs and motivation. His book *Motivation and Personality* (1954) reads as an address not only to psychologists but also a plea to refer more systematically to a concept of meaning in science:

> A psychological interpretation of science begins with the acute realization that science is a human creation, rather than an autonomous, nonhuman, or *per se* "thing" with intrinsic rules of its own. Its origins are in human motives, its goals are human goals, and it is created, renewed, and maintained by human beings. Its laws, organization, and articulation rests not only on the nature of the reality that it discovers, but also on the nature of the human nature that does the discovering.

Maslow inspired a new school of thought in academic psychology that tried to establish a platform beside behavioristic and psychoanalytic approaches and that was coined *humanistic psychology*. The approach had clear proximity to phenomenological thought and was distant to methods employing large data sets. Maslow's taxonomy of needs serves as textbook knowledge still today, and it is basic introduction in courses on management training or personal development. Initially, Maslow suggested five stages of needs that were later further developed to seven and finally eight stages. The first edition of *Motivation and Personality* (1954) summarized Maslow's work undertaken between 1943 and 1954. Maslow's hierarchy of needs has been often misunderstood as a very strict corset by which "higher" needs only come into discussion when "lower" needs are already satisfied "but actually it is not nearly so rigid as we may have implied."

Distinguishing between higher and lower needs means that lower needs are—anthropologically viewed—basic needs that cover physiological necessities such as getting or having food and shelter but also warmth, sexuality, and sleep. Maslow argues that even physiological needs can be ordered in a subhierarchy. On the other side, a higher need signals a later phyletic or evolutionary development. The need for food is shared by all living entities whereas the need for love or self-actualization is shared by fewer species. Another point is that higher needs are later ontogenetic developments.

In Maslow's hierarchy model the first and lowest stage of needs is represented by those biological and physiological needs whereas the second stage represents safety needs as provided through stability, protection, and security. Maslow's idea is that a firm order, laws, and limits belong to this area of safeness. The third stage of Maslow's introduced needs represents love needs and belongingness needs that aim at affected and emotional inclusion of human beings into categories such as family, work groups, partnerships, or further social relationships.

Esteem needs represent the fourth stage of Maslow's hierarchy. Here, self-esteem, mastery, or independence are listed as well as status dominance, prestige, or managerial responsibility. With the third and fourth stages, Maslow proves to include clearly more sociopsychological dimensions into his framework of thought that regards human beings as being part of a social context and belonging to a social matrix of relations. The fifth stage, finally, is in line with those stages before: it is the level of self-actualization needs. By those needs, motivation for self-fulfillment is addressed. Realizing one's individual personal potential, seeking personal growth and personal aims, and collecting one's own experiences are moments that belong to this type of needs at the top of the hierarchy pyramid.

The principle of hierarchy organization is that the higher the need, the less imperative it is for sheer survival, and the longer gratification can be postponed. Maslow argues in line with psychometric and psychomotoric findings that meeting with higher need levels means greater biological efficiency, greater longevity, less disease, better sleep and appetite, and he says that psychosomatic researchers proved to find out that anxiety, fear, lack of love, or domination tend to encourage physical as well as undesirable psychological results, whereas higher need gratifications have survival value and growth value as well. Higher need gratifications result in better subjective results, e.g., more profound happiness.

Maslow's hierarchy of needs is led by a conceptualization of human beings that is not unidimensional. Later Maslow added further dimensions as cognition, aesthetic, and transcendence. Although Maslow's hierarchy of needs is primarily developed by conceptual reflection, the attempt is far from being abstract. Maslow sheds light on human motivation and different sources of needs as they are very often neglected in economic models where human incentives are reduced to principles of *homo oeconomicus*. All that has been learned by human relations theory in management research and organization theory is fitting well with Maslow's thought. As more differentiated and wealthy societies and organizations prove to be, intrinsic motivation is increasingly becoming a major source of organization and restructuring. Even current voices in leading international economics are going to refer explicitly for a better understanding of motivation and are matching with some pieces of principle thought provided by Maslow.

Motivation and Personality is not only a book by a psychologist for psychologists but it is of interest for all social scientists. The argumentation is based upon broad knowledge of the division of science. Maslow reads as presenting his hierarchy of needs primarily as a heuristic scheme knowing that this scheme has to be modified according to concrete societies. Even in the beginning of his study, Maslow expresses that sociology matters:

> The study of the sociology of science and of scientists deserves more attention than it is now getting. If scientists are determined in part by cultural variables, then so also are the products of these scientists ... these are questions of the type that must be asked and answered for fuller understanding of the "contaminating" effect of culture upon perception of nature.

During the last 50 years, Maslow has emerged as a classic for different academic disciplines.

Maternity Leave

Maternity leave is a job-protected leave from employment provided to mothers around the time of childbirth, sometimes with full or partial income replacement. The purpose of maternity leave is to give mothers time to prepare for or recover physically from childbirth and to care for newborn children without losing their employment. Most developed countries have national legislation that specifies minimum levels of maternity leave benefits to workers meeting certain qualifications. Employers may also have firm-level maternity leave policies surpassing the legally required minimum.

Family leave policy in Europe originated in policies introduced more than a century ago in order to protect the health of working mothers and their newborn children. The first maternity leave law was enacted by Germany in 1883. In 1919 the International Labour Organization (ILO) Convention of Maternity Protection recommended paid maternity leave of 12 weeks with a compulsory six-week postpartum period. The development and expansion of maternity leave policies in several countries was based on the ILO recommendations. In 1952 a second ILO Maternity Protection Convention recommended leave of 14 weeks with full wage replacement, with six weeks prior to and eight weeks after the birth of the baby. However, family leave policies were not widely adopted in Europe until the 1960s. Beginning with Sweden in 1974, many countries introduced dual parental leave policies, either by extending benefits to fathers in addition to mothers (paternity leave) or by replacing maternity leave with gender-neutral policies (parental leave).

Among OECD countries, the average maternity leave provided is 10 months, but in the United States, it is only 12 weeks.

Across countries, maternity leave policies differ along three dimensions: benefit duration, replacement rates, and eligibility criteria. Benefit duration varies widely across countries. The developed nations that make up the Organisation for Economic Co-operation and Development (OECD) provide an average of 10 months of maternity leave. Continental European countries have generous leave policies relative to the United States, providing leaves ranging from 11 months in Italy to 3.3 months in Germany. Nordic countries guarantee leaves ranging from 18 months in Denmark and Sweden to three years in Norway and Finland. Canadian law mandates approximately six months of childbirth-related leave; in the United States, the legal requirement is less than three months (12 weeks) of maternity leave.

Nations also vary in the extent of income replacement required during maternity leave. Austria, Germany, and France require 100 percent income replacement during the initial period of maternity leave. Other European countries require between 60 and 90 percent income replacement. Canada requires the replacement of 55 percent of prior earnings. The United States stands out among developed nations in requiring no income replacement.

Finally, eligibility criteria for maternity leave vary across countries. Most developed nations have universal leave policies, covering all new mothers (maternity leave), all new fathers (paternity leave), or all new parents (parental leave). In the United States, only those who work in firms with at least 50 employees and only those who have worked 1,250 hours in the prior year are legally guaranteed maternity leave. As a result, only about half of private-sector employees in the United States are legally entitled to maternity leave.

Legally required maternity leave has both costs and benefits. Lengthy leaves may hinder women's career advancement and impede progress toward gender equity in the labor market. They may also reinforce the traditional gender division of labor in the home. Subsidized child care or early childhood benefits may be forms of assisting new parents more favorable to gender equity.

On the positive side, lengthy maternity leave (leave beyond the first few months) is associated with improved health outcomes for both mothers and children. Women who take leave are more likely to breast-feed, and breast-feeding is associated with a number of positive health outcomes. Studies have also found positive effects on children's cognitive and social development for children whose mothers stay home during the first year of life.

Matrix Structure

The matrix structure is one of the most prominent organizational structures used by multinational corporations (MNCs). Made up by the combination of some elementary organizational structures, the matrix structure is meant to cope with the increasing internal and external complexity MNCs face as a result of their growing internationalization and diversification. While up until the 1970s the matrix structure was embraced as a kind of best practice to organize large, multidivisional MNCs, the following years have seen some disenchantment, due to the many difficulties MNCs faced in designing and managing matrix structures. Nevertheless, many large MNCs nowadays still adopt a matrix structure.

The matrix structure is one of three basic structural models MNCs have at hand to cope with the problems that arise from the geographic dispersion of their business activities. If internationalization is still rather piecemeal, MNCs often opt for an international division structure in which all foreign business activities are taken together and managed separate from the domestic business. In a later stage of their internationalization many MNCs turn to elementary forms of global structures, i.e., to the global functional, the global geographical, or the global product structure. These elementary forms of global structures integrate national and international business activities according to one organizing principle. For instance, in a global product structure, business activities are organized in different product divisions that have worldwide responsibility. Elementary forms of global structures overcome some problems associated with the international division structure such as resource duplication or slow knowledge flow. However, they are not sufficiently responsive to the multiple and sometimes conflicting demands that strongly internationalized MNCs face. This is what the matrix structure is meant for. The matrix structure is a grid-like combination of two elementary organizational structures, which have equal priority. This implies two lines of command and reporting. For instance, in a matrix combining global product and global geographical structures, a foreign subsidiary reports to the headquarters simultaneously through a specific product division and a specific regional organization.

MNCs from many industries have adopted matrix structures, including aerospace, automotive, chemical, and banking. Three conditions seem to be instructive for a particular MNC to choose a matrix structure: (1) there are outside pressures for the equal recognition of two foci (e.g., product and region); (2) a high level of information-processing capability is needed to stay competitive; and (3) there is strong need to share resources (e.g., technologies or human resources) within the MNC. In such situations a matrix structure promises significant advantages. It allows for a mutual recognition of the different requirements global and local customers have. It facilitates access to resources, skills, and technologies across incumbent functional, geographic, or product-related divides. It supports economies of scale and increases information flow through the introduction and use of lateral communication channels.

However, these advantages are not easy to achieve, leading to a certain disenchantment and decline in the use of matrix structures by MNCs from the 1980s onward. For one, problems occurred in designing matrix structures. Matrix structures can take rather different shapes and depth. With only limited practical experience and theoretical understanding available, many MNCs found it rather difficult to design a matrix that represents a differentiated fit with their specific environment and strategy. Moreover, business goals and objectives turned out as rather difficult to align in the matrix. Many problems occurred with regard to managing the matrix structure; thus it turned out that keeping the two reporting lines equal in importance is difficult to achieve. This often resulted in strong political conflicts between the reporting lines. Moreover, roles and responsibilities in a matrix tended to be unclear and prone to misunderstandings. Overall, the speed of decision making slowed down.

There are two key remedies proposed to overcome these problems and to make the matrix a more successful and forward-looking organizational structure (again). First, more in-depth research needs to be conducted to better understand the functioning and applicability of different types of matrix structures. Second, the design and application of an appropriate matrix structure needs to be accompanied by measures that develop the abilities and behaviors of individual managers in order to successfully perform in a matrix structure. These measures include the development and communication of a consistent corporate vision, some training to broaden the individual perspectives, as well as the co-optation of managers in project teams that cross reporting lines.

Matsushita Electric Industrial

Matsushita is a leading global provider of electronic products. The firm offers a diverse product lineup ranging from video equipment, information communications equipment, home appliances, components, and devices. In fiscal 2007, Matsushita had sales of over $77.9 billion—second among Japanese firms after Hitachi, and fourth worldwide. Matsushita is often viewed as Sony's rival, although the former is much stronger in entertainment and the latter more so in white goods. Based in Osaka, Japan, Matsushita has a truly international presence, with over 328,000 employees working in more than 45 countries worldwide. The company was renamed Panasonic Corp. in October 2008.

Established in 1918 as Matsushita Electric Housewares Manufacturing Works, Matsushita was formed by entrepreneur Konosuke Matsushita to launch his electric attachment plug. Under his leadership, Matsushita grew quickly during the interwar years, from 25 workers in 1918 to 6,672 workers in 1939. The firm offered a range of products, such as the electric iron, radio, and dry-cell battery. Matsushita offered 200 products by 1931, and more than 2,000 products by 1937. During World War II, Matsushita shifted away from the production of electric goods into the production of military goods.

During the Allied occupation of Japan, Matsushita's business was severely restricted because of the firm's participation in the war effort. Matsushita, however, gained permission to rebuild its business as an electrics firm. As Japan regained its independence as a sovereign nation in 1952, Matsushita moved quickly to strengthen its scientific and technological capacity through imports of foreign technology. The company formed foreign alliances with the Dutch electronics company Philips in 1952, established various manufacturing plants, and built a central research facility in 1953. By the end of the decade, Matsushita had established a strong market position in consumer electronics, particularly in white goods, and was prepared to expand abroad. Indeed, the firm established Matsushita Electric Corporation of America in 1959, National Thai in 1962, and a European sales office in 1963.

After listing on the Tokyo Stock Exchange in 1971, Matsushita gained much publicity in the 1970s and 1980s when it entered a videotape formatting war. Matsushita was the parent company of JVC, whose VHS format eventually won over Sony's Betamax format. The firm's success was attributed to its greater flexibility in collaborating with other firms, and responsiveness to consumers who tended to value longer running times and portability over technological sophistication.

Matsushita also gained some notoriety for its second-mover strategy. The company's sales strategy was to identify new products that proved successful among rival firms and to launch similar products. What it saved in product development, Matsushita invested in an extensive network of affiliated wholesalers dedicated to capturing greater market shares.

In the 1990s, Matsushita ventured briefly into the entertainment industry. But while it acquired MCA in 1990, it sold 80 percent of its stake to the Canadian alcoholic beverages firm Seagram's three years later. Matsushita also began to offer cell phones and digital television sets in step with the information technology boom. With rapidly changing market conditions, Matsushita also underwent a series of organizational restructurings that would streamline management and eliminate the duplication of businesses.

Matsushita is widely known for its founder, Konosuke Matsushita, who achieved renown as one of Japan's leading entrepreneurs. He was credited for creating Japan's first decentralized company in 1933. Under Matsushita's guidance, the firm was long managed as a group of subsidiaries organized along product lines. These subsidiaries competed against each other to produce superior products within the Matsushita Group.

Matsushita currently offers a diverse range of products through several business segments, including home appliances, components and devices, Matsushita Electric Works and Panahome, AVC Networks, Victor Company of Japan. Matsushita derives around half of its revenues from Japan. With a 60 percent share of the domestic market, it has particular strength in household appliances.

Matsushita faces several challenges amid globalization and increasing competition. One is a threat from foreign rivals such as Royal Philips and Samsung, who have larger global market share, larger research and development (R&D) facilities, and more expansive distribution networks. In addition, the firm faces competition from companies in developing countries who can offer low-priced alternatives. As well, Matsushita faces increasing cost pressures from rising raw material prices. Matsushita's future lies in its ability to capitalize on its brand image, form strategic alliances to pursue collaborative R&D, and expand its market reach, as well as invest in growing markets such as LCDs and semiconductors.

Media

The media is a significant industrial sector in its own right and it is also part of the infrastructure of the global economy. Its dual function as a site of important business transactions and as a market creator has increased materially since World War II in conjunction with the emergence of computer technology, particularly the internet, and the return of globalization. Determining the boundaries of the global media industry and assessing its role in the international economy remain problematic. *Media* is a relatively porous term that encompasses the means of mass communication, which include the internet, newspapers, radio, and television. It is difficult to monitor accurately the global trade of media content and products or to measure their impact on the economy.

The word *media*, like other metonymies, elides important distinctions by aggregating disparate mediums under a single name. It remains a useful term because the variety of communication and content that falls within its wide remit share certain characteristics. These features are best observed in relation to technology and trade. The tripartite relationship, or nexus, of media, technology, and trade is not linear, but circular. New technology influences the media and the media may influence the structure of technology. Trade affects the media and the media may affect trade. Likewise, the media may act as a catalyst in the interaction between technology and trade.

Media and Telecommunications

The development of communication technology often gives rise to new media. The advent of telegraphy during the 19th century enabled the creation of news agencies, such as the Associated Press and Reuters, which permitted the rapid collection and distribution of news. An abundance of news matter, in conjunction with the availability of cheaper newsprint and improved printing presses, was a necessary precondition for the rapid increase of daily newspaper publication during the 1870s. Improved access to information facilitated publication of evening newspapers. The issuing of newspapers in the early afternoon and subsequent editions throughout the evening had hitherto been curtailed because morning newspapers containing the latest news circulated to suburban areas via train, forestalling publication of papers later in the day.

Subsequent advancements in telecommunications had similar effects. Radio gave rise to broadcasting and television to video. Satellites permitted companies such as CNN to provide round-the-clock televised news. This new medium operated on the same principle as telegraphy; namely, information collected was transmitted and then distributed to a variety of users before being translated into a secondary medium, such as stereos, television sets, etc., and relayed to the wider public. The internet has altered this order of operations by removing the intervening step between transmission and reception. Users may now directly access and contribute to the creation of information.

This development has led to the creation of “new media” and altered the structure and course of the industry. New media include platforms and tools for information gathering (internet search engines), production and editing (audio, publishing, and Web development), digital storage and retrieval, distribution (digital subscriber lines [DSL]), access, design, and display (GPS, voice recognition software, etc.). Changes in technology have generated potential economies of scale and scope that have led to concentration and conglomeration. The press barons of the late 19th and early 20th centuries—Beaverbrook, Hearst, Northcliffe, Pulitzer—controlled horizontally integrated businesses, such as films and magazines, and vertically integrated concerns, such as paper mills and publishing houses. These companies were behind a series of mergers, particularly during the interwar period, which led to industry concentration, especially in newspaper publishing. The economies permitted by the confluence of new and old media technologies, often referred to as *synergy*, have enabled the rise of global media conglomerates on an unprecedented scale.

These companies, among which AOL Time Warner, Bertelsmann AG, News Corporation, Viacom, and Walt Disney are the largest, may strategically employ one company product, such as television, to promote another, such as newspapers. By virtue of their ownership positions in a multitude of different sectors, these leviathans control a large percentage of media production and output. Scholars and critics of the mass media have perceived in the development of these conglomerates a threat to the public sphere, the civic utility of the press, and the marketplace of ideas. Conversely, others have seen in their emergence the rise of professionalism, improvement in content, and greater access to information. The internet has materially reduced the costs of production and thus the number of content providers has increased dramatically. Entrenched media interests are attempting to influence the structure of the internet and to control access to information in the face of competition from such independent organizations.

Established media concerns have historically attempted to shape, if not control, the development of telecommunications. The way in which these technologies are structured has depended upon policy decisions that are subject to influence. In England during the 19th century, publishers in the provinces and in London attempted to prevent legislative changes to the Stamp Taxes, which placed an onerous levy on newspaper publication, to prevent the establishment of competitors. In 1870, British newspapers successfully influenced telegram tariffs charged to the press by the General Post Office after telegraph nationalization. In the United States, newspaper publishers affected congressional debates about the ownership of telegraphy. In both countries, newspapers attempted to block and then to control the development of broadcasting. These conflicts, which were in part generated by the development of new technology, consistently turn on questions concerning access to information.

Contested conceptions of intellectual property and the juridical solutions devised to secure copyright and ownership of information may advantage particular media interests and shape the structure of the industry. For example, in 1918, the Associated Press gained a quasi-property right in news through the United States Supreme Court that enabled it to restrict the distribution and use of its news reports. More recently, media companies have filed copyright suits to prevent the sharing of music, images, and texts via the internet. Solutions to such problems have led to the creation of new platforms for the distribution of media, such as Apple's iTunes and iPod, which take advantage of copyright restrictions by vertically integrating music-purchasing and listening platforms. These questions of access to information thus also hinge on trade and telecommunications regulation.

Media and Globalization

Trade generates information and is generated by it. Reuters, the news agency, was established in London in 1851 after the completion of a telegraph cable connecting England and France. The company provided clients in England with commercial information from continental European bourses and vice versa. Scholars have shown how similar services contributed to price convergence, the development of arbitration, and the facilitation of trade. Flows in the direction and volume of information change according to patterns of trade. During the 19th century, Reuters' profit streams from foreign clients closely followed the ebb and flow of British foreign direct investment. This example also illustrates how the regulation of technology may affect the relationship between trade and media.

The development of an international network of telegraph cables during the 19th century contributed to the advancement of global trade by facilitating the rapid distribution of information around the world. These cables, although typically constructed and owned by private companies, were closely aligned with national and political interests. Cables often snapped and failed to function. To encourage companies to undertake the relatively risky business of laying submarine telegraph cables, governments often provided subsidies or concessions to domestic companies. Until World War II, Britain dominated international telecommunications. Its advantage lay in naval power and easy access via imperial possessions to the natural resources necessary for submarine telegraph cable insulation. In terms of miles of cable owned, France, Germany, and the United States lagged significantly far behind. Much of the world's news and commercial information passed through London, contributing to the development of British trade and financial services.

The way in which these international cables coupled with domestic telegraph lines determined how information traveled from country to country. Different regulatory environments, such as the nationalization of domestic telegraph lines, as in much of Europe, or private ownership, as in the United States, determined whether or not information passed from one carrier to another or moved seamlessly across national boundaries. European countries formed an International Telegraph Union in 1865 to develop standards, tariffs, and regulations pertaining to the transmission of information and to facilitate easy communication among their respective government-controlled telegraph and telephone networks. The United States for many years abstained from such organizations in part because it refused to restrict the movement of the private American companies that controlled domestic telecommunications.

In this environment the development of global media roughly adhered to the boundaries of imperial interest. Reuters, the news agency of the British Empire, was at the head of an international cartel consisting of numerous other national news agencies, among which the most prominent were Havas, the French agency; Wolff, the German agency; and the Associated Press, the U.S. agency. These organizations divided the international news market among them and exchanged their respective news reports, which raised barriers to entry against potential competing news organizations by controlling trade in and access to information. Although such practices restricted the distribution of information, exchange among cartel members generated a larger news report for each agency's clientele than would have been possible had they operated independently. International syndication of news content and foreign ownership of media outlets was rare at this time.

Changes in patterns of trade during the interwar period, particularly following the Great Depression, contributed to realignment in the international movement of information and the structure of the global media industry. The advent of international broadcasting during the 1920s also contributed to this process. Radio undermined the British advantage in international telegraphy. American, French, and German concerns actively competed in territories that had been the sole preserve of British firms. American news organizations, such as the United Press and the Associated Press, quickly infiltrated areas of informal empire, such as Japan, which Reuters had dominated. These developments contributed to a rearrangement of the news agency cartel according to which each agency obtained rights to enter, but not to actively compete with, the national territory of the others. After World War II, Reuters redirected its news services away from Britain's colonies and dominions and toward Europe and North America.

The development of computer, fiber-optic, and satellite technology contributed to the rise of media conglomerates and to the deregulation, privatization, and liberalization of international telecommunications. In the 1960s, these changes precipitated the final dissolution of the international cartel of news agencies and gave rise to new competition from emergent global media companies. Changes to the regulatory regime during the 1970s and 1980s, which coincided with shifts in domestic industrial policy, most notably in Britain and the United States, facilitated a significant expansion of the global media industry and enabled corporations to enter foreign markets. Foreign ownership of news and media outlets upset nationalistic conceptions of the fourth estate, but the number of global media products has not significantly increased. Global integration has tended to take place in the financing of media products rather than in the content of the products themselves. There has, however, been a significant increase in the international export of commercial information services since the collapse of the international monetary system since the 1970s.

Critics have noticed in these developments the perpetuation of traditional colonial power relationships and have bemoaned an imbalance in the transmission of information and media products between the developed and developing worlds. Concerns about cultural imperialism have rallied activists who perceive in globalization and the standardization of media content the seeds of hegemony and homogeneity. Concerns about the corporate pursuit of profit trumping public interest have motivated the development of alternative media projects and organizations empowered by the internet that aim to provide a voice to underrepresented parties. Conversely, proponents of deregulation and privatization of telecommunications argue that a competitive regulatory environment predicated on free trade is not only the best way in which to surmount market imperfections, but that government intervention in the free flow of information and cultural artifacts is circumspect and threatens to infringe upon freedom of expression.

Conclusion

The media, because of its importance to international trade as well as the dissemination of financially and culturally valuable information, is a contested and, therefore, visible industry. Everyone has an opinion on the news and where it derives. Changes in telecommunications and trade affect the media industry and the shared characteristics of the different means of communication that it comprises. These changes in turn have a profound effect on the way in which people receive information about the world in which they live. The tripartite relationship among media, telecommunications, and trade is cyclical and so too is the relationship among the media and the public.

Commercial media outlets operate in a dual market. They sell content to viewers, readers, and other participants. The attention of these consumers is in turn sold to advertisers. Since the rise of mass circulation newspapers during the 1870s, media outlets have depended less and less for their profits upon circulation and more upon advertising. Media companies have been thus propelled to devise methods for attracting either a large or a lucrative audience. A general effect of this development has been a reduction in the cost of media products. It has also meant that media companies must alter their means of attracting audiences in accordance with technological shifts affecting the way in which the public prefers to imbibe information.

Although radio and television have diminished newspaper sales in the past, there has hitherto been no written alternative to the press. The internet has challenged the newspaper by luring away its readers, and, in so doing, depleting its sources of advertising. Companies believe they can reach a larger pool of potential consumers more directly via advertisements placed on frequently visited Web sites. This development has led to a proliferation of internet-based platforms that combine the provision of information with advertising. A prime example of this phenomenon is Google, the internet search engine, which directs users to advertising Web sites based on the items for which they are searching. This sort of interactive ad placement has improved the efficacy of advertising and provided internet companies with the capital necessary to amass vast quantities of information that is then made accessible to people throughout the world. In light of this competitive threat to traditional media, pundits now speculate about the demise of the newspaper and the disappearance of the printed word.

Media and Direct Marketing

Organizations and individuals seeking to reach a target audience have a growing array of media choices. While traditional approaches involving media such as newspapers, magazines, television, and radio are associated with reaching relatively large audiences, there are many other approaches such as e-mail, telephone, fax, and direct mail that may also be used to reach target audiences of substantial size, but which are also associated much more with efforts to elicit and obtain a measurable response from those within the target audience. This latter characteristic is an essential element of direct marketing and, further, is becoming increasingly prevalent as a result of increased availability and use of specialized databases. Ultimately, however, virtually any media can be used for direct marketing, also referred to as direct response marketing, provided there is an element of communication that asks the member of the target audience to take some specific action. Whether the action involves

Even with low reply rates, direct mail can provide companies valuable information from customer responses.

calling a telephone number, visiting a Web site, or returning a completed form by mail, the main benefit achieved from a direct marketing initiative is that it enables the response from the communication approach to be measured directly and often relatively quickly. A growing interest among marketers in being able to evaluate more readily both the effectiveness and efficiency of any given communication effort is clearly one reason why direct marketing is one of the most popular marketing approaches of any available to marketers today.

Beyond measurability, a further benefit of the use of media involving a direct marketing approach is the ability to tailor message content. For example, a car dealership seeking to promote interest in its new car models may find it beneficial not only to mail postcards to all of its past customers by name but also to tailor the message to each given the dealership's detailed knowledge of the customer's past car purchase including the purchase timing, price, and benefits sought.

Whether an organization or individual finds a direct marketing approach to be most beneficial relative to other communication approaches can also depend on the characteristics of any offering involved as well as consumer attitudes and preferences. Some consumers, for example, may consider a large-scale direct mail campaign that has a 1 percent response rate as wasteful while other consumers subject to telemarketing by a firm may view the approach as being intrusive. Even so, there are ways in which marketers can manage their media and direct marketing choices so as to increase consumer receptivity to such approaches, such as when consumers are initially given a choice of voluntarily "opting in" to a system where they will receive subsequent, periodic communications via e-mail, mobile phone text message, or posted mail. Alternatively, consumers may be able to "opt out" of a direct marketing approach upon request. Either way, an additional consideration in the management of media and direct marketing is ensuring there is conformance to legal and regulatory requirements relating to the use of customer information (e.g., sharing customer information with a third party)—something that may be clearly facilitated to the extent that recipients of direct marketing grant permission to those initiating such approaches.

Beyond legal and regulatory requirements involving consumer information, there may also be issues related to the nature of the products or services offered that demand attention and understanding by organizations or individuals seeking to engage in direct contact with current or prospective customers. In particular, in product markets where the relationship between consumers and manufacturers or other organizations is typically indirect, such as in the pharmaceuticals industry where doctors are important professional intermediaries between pharmaceutical firms and patients, there may be both opportunities and restrictions in pursuing what is termed *direct-to-consumer marketing*, an approach that is increasing in prevalence where there is direct communication between consumers and manufacturers and other organizations. Such an approach has the potential to educate consumers about a firm's offerings to a far greater extent than is possible or likely through intermediaries and, hence, another potential benefit of direct marketing more generally, although certainly not all direct-to-consumer marketing involves an effort to elicit a consumer response that can be easily assessed.

Ultimately, the media and associated message content and strategy chosen by the individual or organization seeking to engage in direct marketing must balance the short- and long-term objectives of the communication with the costs and benefits involved. To be sure, some direct marketing approaches are only increasing in cost (e.g., door-to-door marketing as a result of the associated labor expense) while others are predictably decreasing in cost (e.g., voice mail marketing that involves the use of telecommunications equipment and networks as a one-way medium for communicating indirectly with consumers by leaving automated voice messages on voice mail systems/answering machines). When one considers the possibility that multiple media and direct marketing approaches can ultimately be used in combination for synergistic effects, the communicator engaging in any aspect of global business can be seen as having an increasingly rich set of methods and strategies to employ in the pursuit of customer value creation and competitive advantages.

Mediation

Mediation is a form of dispute resolution where a third party—an impartial mediator—assists two or more persons in finding a viable solution to problems. There are distinct differences between mediation and litigation. An obvious distinction is that the mediator, unlike a judge, has no say in the outcome of the case. Litigation is a process in where courts impose binding decisions in a determinative process. Now, more than ever, mediation has found widespread use in the realm of business, especially in the field of international law.

Generally, one can define mediation as a simple, informal approach to resolving disputes. Litigation, by contrast, entails a more complex proceeding. No formal rules of evidence or procedure control mediation: the parties agree to the terms. Although these two processes—litigation and mediation—sound very different, both are used to resolve disputes. Mediation often aims at resolving problems associated with litigation: high costs, excess duration, and the complexity of the judicial process. Still, mediation does not result in binding agreements, unless the parties agree to it.

Arbitration is not uncommon when engaging in mediation. Mediation has proven to be effective when paired with arbitration or even binding arbitration. In these cases, the mediator becomes an arbitrator, converting mediation into arbitration after the parties have been unable to come to an agreement through mediation. As a result, the arbitrator seeks additional evidence from witnesses, unlike a mediation proceeding, where witnesses are not called upon by a mediator. Sometimes the purpose of mediation is to improve relationships among parties who will have to deal with each other again. Other times mediation is for the sole purpose of helping the parties learn how best to handle conflicts in the future.

Voluntary agreements by the parties are central to the mediation process. Consequently, a mediator should conduct the process to maximize its voluntariness. Parties to mediation can decide whether to submit their dispute to mediation prior to arbitration. Conversely, parties may also decide to forego mediation and immediately delve into arbitration. For instance, the parties may decide that if the dispute cannot be settled through negotiation, they will first try to settle the dispute by mediation in good faith. Additionally, the parties may agree that the proceeding be administered by the American Arbitration Association under its Commercial Mediation Procedures. But if the parties immediately want to adopt mediation as a part of their contractual dispute settlement procedure, they can insert a mediation clause into their contract in conjunction with a standard arbitration provision.

The mediator plays an integral role; yet, his or her role is attenuated. This, of course, varies from case to case. A mediator works to help the parties fashion an agreement. But he or she does not have the authority to make a binding decision or award—that is, a mediator has no power to impose a solution. The mediator, therefore, serves as a catalyst between opposing interests, attempting to define issues and eliminate obstacles to communication. On the one hand, it can be said that the stronger the parties' need for settlement, the more leverage the mediator has. On the other hand, the weaker the parties' need for settlement, the more the mediator must work to create the perception of greater need; moreover, the mediator must create external leverage by way of incentives. Finally, the mediator helps the parties draft an agreement. If signed, a legally binding contract is formed.

Mediation is used in the United States and other countries for handling divorce and child custody cases. Additionally, it is used for interpersonal disputes—between employees, family members, and even friends—and has gained popularity with environmental and international disputes. As mediation continues developing, an increasing trend in the public and judicial spheres toward using mediated negotiation as an alternative to more traditional means of dispute resolution will become even more prevalent. Accordingly, mediation will continue gaining widespread use and may eventually replace many of the formal judicial processes used in many countries today.

Mentoring

Mentoring, from the Greek word meaning enduring, is defined as a sustained relationship between a youth and an adult. This word explains the relationship between two individuals where one individual (mentor), ensures the overall development of another individual (mentee). The mentor is responsible for the personal as well as professional growth of the mentee. Mentor can also be defined as coach, counselor, facilitator, teacher, sponsor, and model for the other individual. The mentoring partnership may be defined as an agreement between two individuals sharing experiences and expertise to help with personal growth and development through continued involvement. The adult offers support, guidance, and assistance as the younger person goes through a difficult period, faces new challenges, or works to correct earlier problems. In particular, where parents are either unavailable or unable to provide responsible guidance for their children, mentors can play a critical role.

The word originates from Greek mythology. Around 1200 b.c.e., when Odysseus left for the siege of Troy, he requested his friend Mentor to take care of his son Telemachus. Over a period of time Mentor looked after the personal and professional growth of Telemachus. In fact, at one time he saved his life. Thus the word originates from there, explaining the relationship between two individuals.

There are two types of mentoring: natural mentoring and planned mentoring. Natural mentoring occurs through friendship, collegiality, teaching, coaching, and counseling. In contrast, planned mentoring occurs through structured programs in which mentors and participants are selected and matched through formal processes. The mentor shares personal wisdom, technical expertise, and life experience with the mentee. He or she has to be a good listener, empathizing and understanding the goals and interest of the mentee. But a clear distinction must be made between friendship and favoritism.

To be a mentor, one must have time, desire, knowledge, and skill to share with the mentee. He or she first assesses the mentee's skills, discusses goals, and facilitates the mentee's becoming a confident person who may make good decisions. Mentors get a chance to pass on their successes, which can give great personal satisfaction. Mentors get an opportunity to practice their interpersonal and management skills on an ongoing basis, which can help the mentor to succeed even more. Mentors often become recognized as positive role models and are sometimes sought out by others. Many mentors find that being in a mentoring partnership helps them expand their own horizons and keeps them in touch with what's going on at other levels of the organization. Mentors often insist that they gain more from the mentoring partnership than their mentee does.

The role of mentee is also important in the mentoring process. Mentees must be willing to learn. They must be able to accept constructive feedback. Mentees must be willing to "stretch" to try new things and take risks. Many people have achieved success because someone encouraged them to aim higher. They must be able to identify short-term and long-range career goals and accept that those goals may change.

The ancient education system in India followed the same system and was known as *Guru-Shishya Parampara* (teacher-student relationship), where the student resided in the teacher's *ashram* (campus) and *guru* (teacher) took care of the student and ensured his overall development according to his capabilities.

Every one of us is ultimately responsible for our own career. However, it can help tremendously to have someone to talk with who can provide a listening ear and share what they have learned about the organization and the things that helped them succeed. Mentors can provide valuable direction and clarification in uncertain times. Mentors can help the mentee figure out what they need to do to fill in the gaps between where they are now and where they want to be in the future. Mentors can sometimes serve as "door openers," informing the mentee of opportunities they may not be aware of (for example, referral to a program or training, introducing them to people in their field of interest, or recommending them to assist in a project that expands their skills). The most valuable and important assets mentors contribute are a listening ear and a different perspective.

The mentoring process emphasizes clear expectations, clear context, and commitment of both parties involved in the process using clear and precise communication, coordination, and cultural change.

Mercantilism

Mercantilism is a system of economic and political doctrines about how to organize and carry out international commerce. Mercantilism generally advocates that governments should regulate international trade in order to gain competitive advantage. While variations and differences in what constitutes mercantilism have existed over the centuries, the essential and commonly accepted characteristic of mercantilism is "the assignment to the state of the central role in shaping economic well-being." Consequently, mercantilism is a system that justifies—indeed, demands—government regulation and creative state control and, therefore, rejects the free-market theories of Adam Smith and David Ricardo. Because mercantilism was (and is) as much a political as economic theory, it has been called the "most comprehensive theory of the modern state."

The underlying principle of mercantilism is a "net zero sum" concept of international economies. This principle—also referred to as "cash box thinking"—states that the wealth in the world is constant and so the gain of one economic player or country must come about through loss to another. Mercantilism as a concept and policy directly opposes the capitalistic ethic. The latter embraces the "Net Positive Sum" view of international economics that contends that, in markets unhindered by regulations, buyer and seller both gain optimally (net gain in social welfare) through the unhindered movements and interactions of supply and demand mechanisms.

At its most practical level, mercantilism directs governments to regulate in such a way as to increase exports out of the country and to reduce imports into the country, thus increasing the net amount of cash (or gold) that a nation possesses. For mercantilists, government policies should especially compel the importing of low-valued materials and products and the exporting of higher-valued finished goods.

An extensive collection of options are open for a mercantilist government to regulate its trade. Tariffs, quotas, local content requirements, antidumping actions, and administrative barriers and (or nontariff trade restrictions) serve to reduce imports into a country; and the broad range of government actions that we term subsidies as well as other industrial and monetary policies (including currency manipulations) can effectively spur the growth of exports. Today, penalties to individuals and institutions for flaunting a government's trade policies generally involve economic sanctions of varying degrees of severity.

Various arguments have been leveled against mercantilism, especially by advocates of free trade. Critics point out that mercantilist policies can instigate disastrous trade wars internationally as well as cause severe inflationary pressures within a country. Overall, those opposed to mercantilism stress that government regulations involving international commerce subvert the proper functioning of comparative advantage and thus result in inefficient (or nonoptimal) allocation of resources and long-term reduction of the true wealth of a nation.

History

Mercantilism emerged with the rise of the centrally governed nation-state. It was perceived by sovereigns of the 16th and 17th centuries as an important instrument by which the states can amass wealth and influence among other nations. Important writers of the time who developed the concept of mercantilism include John Hales (*Discourse of the Common Weal of This Realm of England,* 1581) and Thomas Mun (*England's Treasure by Foreign Trade,* 1620).

These and other writers and economic thinkers showed that the ultimate purpose of mercantilism was not simply to increase the wealth of a nation (or nation-state) as an end in itself, but as a means—through increased purchasing power—to the ability to carry out war and conquest and to defend one's land from the attempted conquest of others. Jean-Baptiste Colbert, minister of finance under Louis XIV, famously expressed the notion that the rising state had to control trade in order to amass the means to defend the nation against aggression.

Mercantilist thinkers traditionally emphasized that the ability of princes to employ mercantilism to accumulate gold (and equivalent) has a decisive effect upon the fates of government. In his famous summary of the principle, 17th-century writer Sir Francis Bacon wrote: "The increase in any estate must be upon the foreigner, for whatsoever is somewhere gotten is somewhere lost." It was generally believed at the time, for example, that if he had been as successful in acquiring the wealth that Philip II of Spain amassed through mercantilist policy, England's Charles I could have "bought off" the Parliament and ultimately saved his throne (and his head). Consequently, in these centuries, the most severe punishments—imprisonment, torture, and execution—were commonly ordered upon those who attempted to subvert a government's mercantilist policies since such "traitors" in effect were acting to weaken the state's ability to protect itself.

The Habsburgs, who dominated 16th century Europe, were arguably the most successful practitioners of mercantilist principles, and none more so than Philip II of Spain. By the 17th century, France, England, and Holland replaced Spain as dominant European powers. France and England remained rigorous mercantilists; but the Dutch merchants, accumulating wealth through their shipping operations, offered a free trade model of economic prosperity. The wars waged between England (and France) against Holland in this century can be interpreted as a conflict between the "old" (mercantilist) and "new" (free trade) ways of structuring business and international commerce.

By the mid- to late 18th century, mercantilism was in a brisk and ever-accelerating retreat. In addition to the continuing stream of evidence as to the advantages of free trade that had come to the fore for over a century and had been noted as early as the 17th century by perceptive observers (such as Samuel Pepys), the continued rigorous exercise of mercantilist practice began having disastrous political consequences as well. The British monarchy suffered mightily when it attempted to institute a mercantilist regime upon its American colonies. By imposing mercantilist regulations that compelled the Americans to export cheap raw materials to England and import more highly valued manufactured products from the mother country, the government of King George III stirred up severe discontent within the colonies and so created conditions ripe for revolution.

It is no coincidence then that the first great theorists of free trade came from the United Kingdom. Adam Smith's *The Wealth of Nations* threw down the gauntlet against the centuries-old mercantilist assumptions of the constancy of the world's wealth and the need to strategize policy from a net zero sum position. In its place, Smith (and a few decades later, his disciple David Ricardo) thrust into the world the revolutionary idea that the true wealth of a country is the sum—not of the amount of gold and silver in its treasury—but of the goods and services available to its people. He further stated that a laissez-faire policy of government—that is, no government regulation at all—assures that all trading nations must optimize true wealth because of the principles of "absolute advantage" (a net-positive sum principle). This new force unleashed by Smith was nothing less than a call to arms of modern capitalism against the traditional and economically inefficient mercantilist system. The decline of monarchism following in the wake of the American and French Revolutions urged further to undermine the legitimacy of mercantilism, which traditionally was seen as an important instrument for augmenting the wealth and security of both king and state, two entities inextricably bound together by "divine right." By the 19th and 20th centuries, free trade policy, if rarely implemented in its pure form, seriously challenged regulated commerce in political discourse as the most efficient means to accumulate wealth within an increasingly global world.

Neomercantilism

Mercantilism is not merely a relic of the past, of interest only to historians. Indeed, mercantilism never has really died off; it has remained a living force in some form in the political economy of governments. Since the time of Smith and Ricardo, national governments have had to contend with balancing the pros and cons of regulated versus free trade. Political as well as economic arguments play an important role in these decisions. Today, economists and policy makers debate how a modern form of mercantilism ought to be shaped. Countries continue to search for securing that mercantilist ideal: a favorable balance of trade, and a modern form of mercantilism—neomercantilism—has emerged. Neomercantilism advocates the regulation of trade for economic, social, or political objectives. For example, import restrictions might be imposed to protect a crucial industry or an industry in a politically sensitive region against external competition. This policy is especially crucial for protecting fledgling industries that can "upgrade" a country from predominantly low-value (e.g., agricultural) to high-value (advanced technology) production. Also, countries impose trade regulations to advance human rights internationally—such as trade embargoes—against countries to force social agendas (e.g., trade embargoes against South Africa in the 1980s to speed the demise of apartheid).

Then, too, neomercantilism plays the central role in strategic trade policy (also known as "new trade theory"). Strategic trade policy is relevant in industries such as aircraft production where economies of scale come into play and total market demand globally is limited and can support only one or two multinational companies (MNCs) efficiently. In these cases, government regulations of international commerce, such as providing subsidies to an MNC (e.g., Boeing), can be instrumental in that company achieving a first-mover advantage. In this way, the MNC achieves sole producer status in international markets thus allowing it to manufacture its products (airplanes) the most efficiently for customers (airlines) worldwide. In this sense, neomercantilism posits government regulation within a new positive sum context.

In response, critics of neomercantilism point to the influential work of Michael Porter. Calling upon Porter's "Diamond" model of national competitive advantage, they argue that, rather than directly regulating international trade through subsidies to selected industries, and tariffs against certain products, it is far better for governments to focus internally on generally upgrading high-value-added industries by adopting domestic incentives for fostering clustering, skills (education), infrastructure (transportation, communications, capital markets, utilities) and by strategically inducing demand, thus making their industries more competitive internationally and allowing comparative advantage to "kick in."

Mercosur/Mercosul

The Southern Common Market—Mercosur in Spanish, Mercosul in Portuguese—is an international and intergovernmental organization with the objective to create first a free trade area, and subsequently, a customs union and a common market. It was instituted on March 26, 1991, by the signing of the Treaty of Asunción that constituted a common market between Argentina, Brazil, Paraguay, and Uruguay, as a culmination of the process of a bilateral program of integration and cooperation already engaged by Brazil and Argentina since 1985.

The initial stage of the Latin American integration process was the creation of the Latin American Free Trade Association (LAFTA) with the first Treaty of Montevideo in 1960. The objective was a free trade area in South America, with expanded markets and facilitated trade with the elimination of protectionist measures through multilateral negotiations.

Political problems and a lack of flexibility posed practical difficulties to this negotiating process. Thus, a more flexible Regional Integration Agreement was created in 1980, the Latin American Integration Association (LAIA), with the signature of a second Treaty of Montevideo. It is an intergovernmental organization that continues the process started by LAFTA. Its main objective is the establishment of a Latin American common market in order to assist economic and social development of the region.

Under the LAIA system, Brazil and Argentina in 1986 signed the Brazil-Argentina Integration Treaty, at Foz de Iguaçu, among 12 commercial protocols. The Integration, Cooperation and Development Treaty was signed in 1988 and the Economic Cooperation Agreement in 1990, setting the stage for a common market between the two countries within 10 years with the gradual elimination of all tariff barriers, harmonization of the macroeconomic policies of both nations, and with the achievement of the free movement of goods, services, and production factors in line with the objective of creating a bilateral common market. These agreements were the immediate precursors of Mercosur.

Uruguay and Paraguay feared becoming isolated economically, leading to their joining these agreements, and later to the creation of Mercosur. With them, the integration process evolved from bilateralism to multilateralism, as first envisaged in the LAFTA model.

In 1996 free trade agreements were signed with the governments of Bolivia and Chile, thereby enhancing the geographic scope of the group, but both countries are just partners of Mercosur, not members yet. Colombia and Peru have already evinced interest in joining, and on July 4, 2006, Venezuela became the fifth member of Mercosur with the signing at Caracas of a membership protocol.

The integration of these four member states represented an effort toward the progressive development of Latin American integration through the free transit of goods and services and factors among them, with, inter alia, the elimination of customs rights and lifting of nontariff restrictions on the transit of goods, or any other measure with similar effect. It also fixed a common external tariff (TEC) and adopted a common trade policy with regard to nonmember states, and the coordination of positions in regional and international commercial and economic meetings.

The agreements contained the coordination of macroeconomic and sectorial policies of members relating to foreign trade, agriculture, industry, taxes, monetary system, exchange and capital, services, customs, transport, and communications in order to ensure free competition between member states. And it provided, in addition, the commitment by the member states to make the necessary adjustments to their laws in relevant areas to allow for the strengthening of the integration process.

In December 1994 the Protocol of Ouro Preto was adopted, establishing Mercosur's institutional structure and providing it an international juridic director. Because it has no supranational institutions or authority, the negotiation and conclusion of agreements within the organization require the consensus of all the members, and international agreements have to be accepted or ratified by each member in order to become binding.

The main institutional organs are the Common Market Council, the political body that issues decisions; the Common Market Group, the executive organ that issues resolutions; the Mercosur Trade Commission, the central organ for trade policy that issues directives and proposals; the Joint Parliamentary Commission, which acts as a liaison between Mercosur and the parliaments of the members; the Economic and Social Consultative Forum, the channel between civil society and the private sector and Mercosur; and the Mercosur Administrative Secretariat, which provides operational support to the organization and its organs.

In 2000 the states' parties decided to take a new step in regional integration called the "relaunch of Mercosur," with the objective to strengthen the customs union in both intralevel and foreign relations. In this context, the governments recognized the central role that convergence and macroeconomic coordination play. Additionally, the new common trade policy tends to reaffirm and strengthen the individual processes of market openness of the state parties, and their integration into world trade, as Mercosur is part, now, of the international agenda concerned with production, foreign direct investment, and trade.

Merrill Lynch

Merrill Lynch is one of the world's leading wealth management, capital markets, and advisory companies, with offices in 40 countries around the world. It was founded in 1914 and employs approximately 60,000 people; its total client assets are approximately $1.6 trillion (as of June 2008). The company offers capital markets services, investment banking and advisory services, wealth management, investment management, insurance, banking, and related products and services on a global basis.

Merrill Lynch has organized its activities into two interrelated business segments: Global Wealth Management and Global Markets and Investment Banking. Global Wealth Management offers proprietary and third-party wealth management products and services globally to individuals, small and mid-sized businesses, and employee benefit plans. It comprises two business divisions: Global Private Client and Global Investment Management.

The Global Private Client group provides advice-based wealth management services and products to individual clients and businesses. The group's business model is based on its network of more than 15,930 financial advisers in approximately 680 offices around the world and on one-to-one relationships with clients. It provides support to financial advisers through five core functional areas: global banking, marketing, investment and wealth management, retirement, and direct services. Its financial advisers integrate guidance with a range of products and services.

First Republic Bank, a division of Merrill Lynch Bank & Trust, Co., in the Global Bank Group focuses on personalized services including private banking, private business banking, real estate lending, wealth management, and trust services delivered through a team of financial professionals. An International group serves the needs of investors outside the United States. Products and services include advice and market intelligence, professional money management, investments, wealth protection, cross-border solutions, banking and cash management, and tracking progress.

The Global Investment Management group focuses on businesses that create and manage wealth management products for individual investors and small businesses, including (1) a business that creates and manages hedge funds and other alternative investment products; unlike traditional investments such as mutual funds, whose performance is largely dependent on the direction of the broader market, many alternative investment strategies seek positive returns in any market or economic environment; and (2) Merrill Lynch's ownership positions in investment management companies, including BlackRock. The latter manages assets on behalf of institutions and individuals worldwide through a variety of equity, fixed income, cash management, and alternative investment products.

Finally, Multicultural Marketing is a division of the Global Wealth Management group's Strategic Marketing and Brand Management. It works to build brand relevance and assists financial advisers in the development and expansion of new business from high-net-worth investors and businesses.

Global Markets and Investment Banking provides institutional sales and trading, investment banking advisory and capital-raising services to corporations, governments, and institutions worldwide. The Global Markets group deals with financial markets around the world, providing liquidity, industry-leading insights and analytics, and added value across the spectrum of debt and equity markets.

The Fixed Income, Currencies, and Commodities group deals with interest rate, credit, and asset-based products, liability management, foreign exchange, commodities, derivatives, and other securities. The group also offers a wide range of risk management solutions to clients around the world. The Global Equities group provides a full range of equity and equity-linked sales and trading services, including sophisticated portfolio analytics and electronic trading. The group's brokerage services include transaction and portfolio financing, stock lending, clearing, settlement, reporting, and custody.

The Global Investment Banking group serves a diverse client base that includes corporations, financial institutions, financial sponsors, hedge funds, governments, and government agencies. It has presence in the Americas, Europe, the Middle East, Africa, and the Pacific Rim, serving clients in virtually all countries. It offers strategic advice, financing, restructuring, and risk management, as well as capital-raising from both public markets and private sources.

In the midst of the 2008 mortgage credit crisis Bank of America acquired Merrill Lynch, which had suffered steep losses, and the two companies were scheduled to officially join forces on January 1, 2009.

MerVal

The Mercado de Valores (MerVal) is the most important index on the Buenos Aires Stock Exchange (BASE), the primary stock exchange of Argentina. The BASE was founded in 1854, succeeding the Banco Mercantil that had been established in 1822. The MerVal Index is computed continuously throughout every trading

The MerVal and MAR indices track important Argentinian businesses such as utilities, sugar producers, and banks.

day, and is available online and displayed on screens on the trading floor.

The Burcap and MerVal indices track the same stocks, those stocks deemed most important on the BASE, based on the volume and number of their trades over the last six months (the composition of the indices is redetermined quarterly)—up to 80 percent of the total stocks on the exchange. The Burcap index weights the stocks proportionally to their capitalization, while the MerVal weights according to the number of trades and the stock's value. In addition to this, the MAR (Merval Argentina) Index specifically tracks the performance of Argentinian corporations on the MerVal Index. Argentina is not a highly industrial nation; much of the MAR is taken up by banks. Notable companies on both MerVal and MAR include Pampa Holdings (a holding company for power companies), Telecom Argentina, Molinos Rio de la Plata, Grupo Clarin (a media company), and sugar and ethanol company Ledesma.

MetLife

MetLife, Inc., is one of the biggest insurance companies in the world. It represents a group of companies offering insurance and other financial services in the United States and internationally. MetLife maintains its operations from the principal executive office in New York City. It was incorporated in 1999 and now employs around 49,000 people (as of January 1, 2008). MetLife is quoted in the New York Stock Exchange with the ticker symbol MET. The company has approximately 87,000 shareholders (as of January 1, 2008).

In addition to its U.S. operations, MetLife provides direct insurance products in Asia-Pacific, Europe, and Latin America. However, the United States is MetLife's largest geographical market (87 percent of 2006 revenues). MetLife operates in five business areas: institutional, individual, auto and home, international, and reinsurance, which generated revenues in 2006 as follows: institutional (42 percent), individual (31 percent), reinsurance (11 percent), international (10 percent), and auto and home (6 percent).

Metlife's products include life insurance, annuities, automobile and homeowners insurance, and mutual funds to individuals, as well as group insurance, reinsurance, and retirement and savings products and services to corporations and other institutions. Metlife's institutional division offers group insurance and retirement and savings products and services to corporations and other institutions. These include group life insurance and nonmedical health insurance. The individual segment offers insurance products such as traditional, universal, and variable life insurance and variable and fixed annuities. Auto and home division offers personal property and casualty insurance through employer-sponsored programs, as well as through a variety of retail distribution channels, including career agency system, independent agents, specialists, and direct response marketing. The international segment provides life insurance, accident and health insurance, annuities, savings, and retirement products to both individuals and groups, and auto and homeowners coverage to individuals primarily within Latin America and the Asia-Pacific market. MetLife operates in international markets through subsidiaries and joint ventures. The reinsurance segment provides traditional life, asset-intensive products, and financial reinsurance primarily in North America. This involves indemnifying another insurance group for all or a portion of the mortality insurance risk it has written.

MetLife has numerous subsidiary companies. These include RGA Reinsurance Company, MetLife Life and Annuity Company of Connecticut, Metropolitan Property and Casualty Insurance Company, New England Life Insurance Company, Texas Life Insurance Company, MetLife Limited, Sino-U.S. MetLife Insurance Company, and United MetLife Insurance Company.

The executive team of MetLife includes C. Robert Henrikson (chief executive officer and chairman), Ruth A. Fattori (chief administrative officer), Steven A. Kandarian (chief investment officer), James L. Lipscomb (general counsel), Maria R. Morris (subsidiary officer), William J. Wheeler (chief financial officer), William J. Mullaney (division officer), William J. Toppeta (division officer), and Lisa M. Weber (division officer). MetLife's board of directors includes Sylvia Mathews Burwell, Eduardo Castro-Wright, Cheryl W. Grise, William C. Steere, Lulu C. Wang, John M. Keane, Hugh B. Price, Kenton J. Sicchitano, Burton A. Dole, R. Glenn Hubbard, James M. Kilts, and David Satcher.

The success of MetLife is a result of many factors including its strong market position. It is a well-known company. In the sales of some of its products, MetLife is the largest provider in the U.S. market. Its leading role in insurance sales gives it a key competitive advantage. Considering the hypercompetitive insurance market, MetLife performs better than its rivals in many insurance products, especially in group life insurance and group auto and home insurance sales. Another reason may be regarded to be the company's well-organized sales network. MetLife is able to reach a wide range of customers through multiple distribution channels. These include direct marketing, independent agents, agency network, brokerage, direct employer sales, and the internet. Also, MetLife's multiple range of products makes the company stronger than its rivals. Its life and nonlife insurance, savings, and investment products are among the highest-selling products in the insurance industry. Using its massive financial power, MetLife can provide insurance solutions designed specifically for diverse customers by considering their differentiated needs. This is not limited to institutional customers with sales of life, nonmedical health, and retirement and savings operations, but also available to individual customers via individual life and annuities operations. These several revenue-generating operations with their similarity in relevant products and services enhance cross-selling opportunities between product segments. At the same time, they decrease MetLife's business risk across various market segments.

METRO

METRO AG is the holding company of the METRO Group, an international retail company headquartered in Dusseldorf, Germany. METRO AG was formed through a merger of Asko Deusche Kaufhaus AG, Kaufhof Holding AG, and Deutsche SB-Kauf AG and became a public company on July, 25, 1996. The METRO Group employs approximately 280,000 people working at some 2,200 outlets in 31 countries in Europe, Africa, and Asia. Total sales for METRO for fiscal year 2007 were approximately €64.3 billion. Its 2007 sales from outside Germany represented 59.1 percent of revenues. The company is organized around four customer-centered sales brands and a group of shared-services companies. Its four brands are Metro

Cash & Carry (wholesale), Real (food retail), Media Markt and Saturn (consumer electronics and appliances), and Galeria Kaufhof (department stores).

Retail Brands

Metro Cash & Carry operates some 619 locations totaling 4.9 million square meters of selling space across 29 countries and employs approximately 103,915 persons. Its total sales for its fiscal year 2007 were €31.7 billion. Metro Cash & Carry stores typically stock about 20,000 food items and 30,000 nonfood items. This self-service wholesaler began as Metro SB-Grossmarkte Gmbh & Co. KG in Mulheim/Ruhr in 1964. This food and nonfood business is targeted at commercial customers such as hotels, restaurants, kiosks, caterers, small food retailers, hospitals, and institutions. The company tailors its assortment of offerings to each respective location and nationally based demand patterns. Its slogan is "from professionals to professionals." Metro Cash & Carry also has a wholly-owned subsidiary C+C Schaper that involves wholesale plus a delivery service. This Hanover, Germany–based unit operates some 63 stores.

The METRO Group brand Real operates 350 hypermarkets throughout Germany and about 90 additional markets in Poland, Russia, Romania, and Turkey totaling 3.1 million square meters of selling space and employs approximately 54,734 persons. Its total sales for its fiscal year 2007 were €11 billion. Real stores typically stock about 80,000 food and nonfood items. Real was formed from the merger of several regional hypermarkets in 1992, and has expanded, in part through the acquisition of the Allkauf and Kriegbaum companies, Wal-Mart's former German hypermarkets, and the Polish hypermarkets of Geant. The Real hypermarkets are targeted at young families with children and seniors (age 50+), segments particularly interested in value. The food offerings, with emphasis on freshness and quality, account for the bulk of Real sales, though it offers other typical hypermarket goods such as books, clothing, electronics, household goods, leisure products, shoes, sports products, and toys. As part of its customer-value orientation, Real was a founding member of the German PAYBACK bonus program, the country's most successful customer loyalty system.

Media Markt and METRO Group Saturn are the leading European retailers of consumer electronics, totaling 2.2 million square meters of selling space and employ approximately 49,046 persons. Their combined total sales for fiscal year 2007 were €17.1 billion. Media Markt operates 508 locations in about 15 countries and Saturn operates 200 stores in nine countries. Media Markt stores offer a comprehensive assortment of about 45,000 items encompassing telecommunications, computers, photographic equipment, audio systems, and electrical appliances. The first Media Markt opened in Munich in 1979. The core concepts behind the brand were to offer customers a broad selection at permanently low prices, professional advice, repair services, and a guaranteed low price vis-à-vis its competitors, in a location close to a given city but away from parking limitations. In 1988, the brand was acquired by Kaufhof Warenhaus AG, which acquired Saturn consumer electronics stores in 1990.

Saturn offers a comprehensive assortment of about 100,000 items encompassing telecommunications, computers, photographic equipment, audio systems, and electrical appliances. Historically, Saturn stores were known for their extensive selection of music compact discs, some 60,000 titles available. Unlike Media Markt, Saturn stores are located in central downtown locations, as well as in shopping centers. Saturn's 18,000-square-meter store on Hamburg's Monckebergstrasse has been described as the world's largest consumer electronics selling space. The first Saturn opened in Cologne in 1961. The two independent brands became part of METRO in 1996. Media-Saturn Holding Gmbh is headquartered in Ingolstadt, Germany. One unique aspect to both Media Markt and Saturn is the organizational structure in which each managing director of a store is a co-owner of the store, thus linking manager rewards to store success.

Kaufhof Warenhaus AG is the management company for the METRO Group's department stores, operating 141 stores totaling 1.5 million square meters of selling space in Germany and Belgium and employing approximately 18,820 persons. The total sales for METRO Group's department stores was €3.6 billion for fiscal year 2007. METRO Group department stores are mostly located in prime inner-city locations and are known for providing fashionable premium products and international brands, merchandise presentation, and customer service. Galeria Kaufhof began in 1879 in Stralsund, Germany. Inno, S.A. was the sole department store in Belgium when the 100-year-old retailer was acquired in April 2001, and subsequently all of its 15 stores were converted to Galeria Inno by 2004. The Galeria concept is targeted to consumers who are seeking shopping experiences centered on brands, fashion, and lifestyles combined with lavish merchandising and extraordinary service.

Services

METRO's shared services units provide for centralized efficiency for its operating brands. Its cross-divisional service companies provide the following services: procurement, logistics, information technology support, advertising, real estate, catering, and invoice settling. These pooled services create synergies for the METRO Group that cut its costs.

METRO Group's market capitalization of €18.7 billion makes it one of Germany's largest corporations and places it on the DAX blue-chip index. Three principal shareholders, Franz Haniel, Schmidt-Ruthenbeck family, and Otto Beisheim, control 68.47 percent of the voting rights in METRO AG.

Mexico

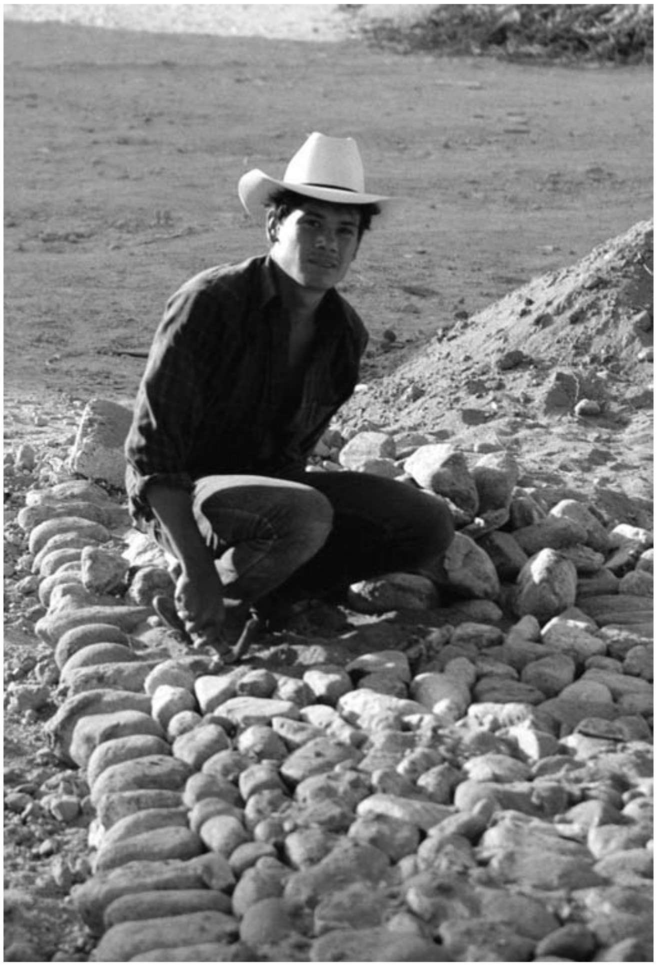
Mexico (population 106,682,500 in 2008, the 11th most populous country in the world; gross domestic product $1.022 trillion in 2007) is a nation in search of itself. Over the last century it has undergone changes which, while fundamental, have not yet enabled it to sustain substantive improvements to the welfare of its population. A federal republic composed of 32 states, its most urgent problems are unemployment, poverty, migration, violence, and public safety. The free market initiatives of the last 25 years have brought about major changes to the country's industry, but have not yet translated into the sort of economic growth rate necessary to reduce unemployment and poverty to more reasonable levels.

In the political arena, changes have been slower and less profound because theoretical democracy has not quite translated to practical democracy. The leadership of the country remains authoritarian in its approach, and many of the old structures remain intact, obstructing the administration of justice and the objective rule of law. Corruption is rampant, deteriorating public confidence in the government both domestically and abroad, where such confidence is necessary to encourage foreign investment in Mexico.

Politics has prevented various factions in government from agreeing on the model of development that Mexico should be following, the shape of its future, and the means of getting there. Political parties have served their constituencies and special interests at the expense of building strategic agreements on the structural transformations necessary to long-term national development. Such agreements would in the long run benefit those same constituencies, by leading to fairer, more efficient government.

Mexico's principal challenge in the 21st century is the need to develop a new social contract that will allow the country to participate competitively in the world economy. Its geographical location is a huge potential benefit because of its extensive border with the United States, the largest market for goods and services in the world. The abundant natural resources, favorable climate, and biodiversity are still virtually untapped compared to the use to which a healthier nation could put them, and the nation's history and culture contribute to its appeal as a tourist destination.

In terms of human capital, Mexico is one of the largest countries in the world, with a population expected to reach 130 million by 2030. A mere generation away, that population will be primarily middle-aged, with extraordinary potential in production, skills, experience, and intellectual capital. The promotion of science, technology, and education today represents an investment in that near future.



Mexico is one of the world's largest exporters of labor, with 9 percent of its total population working in the United States.

History

Mexico's origins are in the splendor of the Aztec Empire, still an object of fascination to the modern world by dint of its prowess in agriculture, mathematics, science, and the arts. The Spanish conquest of Mexico then put it on the path of a difficult transition toward modernity, the start of its mestizo heritage. In the 19th century, Mexico gained independence, but saw an extensive period of instability and chaos marked by disputes between conservatives and liberals, monarchists and republicans. A long period of wars, invasions, and losses of territory to the United States and Texas marked the national consciousness, and led to the establishment of the Porfiriato regime from 1876 to 1911, a dictatorial regime masquerading as a democracy. Mexico entered the 20th century rife with instability, with the Mexican Revolution of 1910 eventually leading to an adoption of a constitution in 1917, and a firm commitment to modernization.

After a period of struggle among the factions of the Revolution, the political class that emerged succeeded in creating new institutions that brought economic growth and political stability to the country. The new government called for sharing benefits and power among economic groups, and state-controlled institutions promoted social stability. The successive governments of the Mexican Republic ensured political stability through education, housing, and improvements to public health, leading to a period from the 1950s through the 1970s called the "Mexican Miracle." The Miracle period also saw improvements to industrialization, based on a model of import substitution that protected national corporations from foreign competition through tariffs and import bans. Inflation remained low, domestic consumption and economic growth remained high.

However, the development model showed its limitations by the end of the 1960s, in a series of internal conflicts that are remembered for the student movement of 1968 that led to the brutal massacre at Tlaltelolco. The model's flaws reached crisis levels in the following decade, when the growth fueled by the domestic market began to exhaust that fuel, and the government made no significant move to take advantage of the availability of foreign markets. The government's handle on macroeconomics was shaky, its activity in that arena erratic, and it quickly lost face and public confidence. The government's economic policy was based on public spending, the monetary policy was inadequate, the problem of balance of payments was ignored, and the government was not prepared to handle the resources of an oil surplus in the 1970s. The deficit and external debt rose unacceptably, devaluing the currency.

The cost of the government's missteps was tremendous. Mexico has faced cyclical crises since, with particular increases in poverty and unemployment in 1976, 1981, and 1994. The annual economic growth from 1970 to 2000 barely averaged 1.5 percent, and the job market has not been able to keep pace with the growth of the population. The last decades have been marked by the devaluation of the erratic peso, rampant inflation, and rampant migration, largely to the United States. Additionally, the "informal economy" has become gradually institutionalized. Two out of three jobs in the country are informal, paying under the table with no tax revenue yielded to the government to keep up with the costs of infrastructure and public welfare. The excessive procedures and regulations imposed by the government, and its reputation for corruption especially at the local level, do much to maintain this situation. Most alarming has been the growth of drug trafficking and a kidnapping industry (ransoms are small, but so are legitimate paychecks).

Challenges

The transformation of Mexico's economy dates to the beginning of the 1980s, when the country faced a deep economic crisis from which it has been attempting to depart ever since. The government has done its best to adopt the recommendations of international financial institutions like the IMF and the World Bank in order to improve the health of its economy through fiscal discipline, monetary stability, and restrictions on public spending. It has renegotiated its external debt, privatized many public enterprises and the banking system, encouraged foreign direct investment, and redefined the social security institutions.

In a short time, Mexico became one of the most open economies in the world. In order to promote economic growth and competition, the government opened the economy to external markets and joined the GATT treaty, eliminating many of its foreign tariffs and domestic subsidies, and signed more than a dozen free trade agreements leading up to the North American Free Trade Agreement (NAFTA). But after almost three decades, this new model has not yet been able to solve the deep problems of economic inequality facing the country. Social problems have shown that the necessary solution cannot be simply economic, because growth without distribution is not wealth. Mexico's socioeconomic problems require a political transformation as well, to encourage democratic government, eliminate corruption, and administer justice correctly. It is in these areas that advancements have been most insufficient.

At least half of the population lives in moderate poverty, more than 20 percent in extreme poverty. Mexico is one of the largest exporters of labor in the world, with 9 percent of its population working in the United States; 10.6 million Mexicans were living in the United States in 2005, half of them undocumented. Out of every 100 criminal offenses, 97 go unpunished. The country operates on arbitrariness and arrangements outside the law, from the court systems to the informal economy of the typical employer.

For Mexico to shape its future, it needs to design and implement a new model of economic growth and political health to reduce poverty, retain its citizenry and reduce immigration to the United States, and reduce the scope of the informal economy. It needs to maintain an economic growth rate of at least 4 percent, and to strongly support education, science, and technology for the sake of the coming generation. It must boost its export capacity through the promotion of competition in the market, the improvement of infrastructure, and the attraction of foreign direct investment. In politics, democracy must be upheld, corruption eliminated, and human rights protected.

MibTel Index (Milan)

The MibTel Index tracks stocks on the Borsa Italiana, Italy's main stock exchange, located in Milan. Privatized in 1997 and purchased by the London Stock Exchange 10 years later, the Borsa is responsible for Italy's stock market, derivatives market, and fixed-income market. One hundred thirty brokers, both domestic and foreign, operate on the market through its purely electronic trading system. Bonds, stocks, options, and warrants not admitted to the exchange are traded on the Mercato Ristretto (restricted market).

There are several indices tracking stocks on the Borsa Italiana. The MibTel tracks all Italian stocks and a selection of foreign ones. The MIB30, no longer as relevant as it once was, tracks the performance of 30 top stocks from the MibTel. Increasingly important is the S&P/MIB, a capitalization-weighted index of 40 companies chosen both for their size and to represent 10 specific economic sectors. Since 2004, this has been considered the benchmark index for the Italian market.

The 40 companies as of summer 2008 are A2A, a utility company formed in 2007 by the merger between AEM and ASM Brescia; Alleanza, a Milanese insurance company; Assicurazioni Generali, Italy's largest insurance company (with a controlling stake in Alleanza), dating back to the Austro-Hungarian Empire; Atlantia, a holding company; Autogrill, a multinational retail and catering company; Banca Monte dei Paschi di Siena, the oldest bank doing business today—it was founded in 1472, 20 years before Columbus sailed to the Americas, and is known internationally for its sponsorship of Italian basketball; Banca Popolare di Milano, a cooperative bank; Banco Popolare, a cooperative bank; Bulgari, a jeweler and luxury goods retailer; Buzzi Unicem, a producer of cement and concrete; Enel, the third-largest power company in the world; Eni, an oil and gas company; FASTWEB, a broadband communications company; Fiat, best known as an automobile manufacturer, but also a financial group; Finmeccanica, a high-tech conglomerate working in defense, aerospace, energy, and other fields; Fondiaria-Sai, a financial services company; Geox, a shoe and clothing manufacturer; Gruppo Editoriale L'Espresso, publishers of a weekly Italian newspaper; Impregilo, a construction and civil engineering company; Intesa Sanpaolo, a banking group; Italcementi, a cement and concrete company; Lottomatica, a company responsible for lotteries and gambling; Luxottica, the world's biggest eyewear manufacturer, owners of the Ray-Ban and Oakley brands of sunglasses.

Others included in the index are Mediaset, Italy's major television network; Mediobanca, an investment bank; Mediolanum, a financial services company; Mondadori, Italy's biggest publishing company; Parmalat, a dairy and food producer, best known for their shelf-stable milk; Pirelli, a multinational company focused principally on tire manufacturing; Prysmian, a producer of cables for energy and telecommunications; Saipem, an oil and gas contractor; Seat Pagine Gialle, a publisher of phone directories; Snam Rete Gas, a gas company; STMicroelectronics NV, a semiconductor manufacturer; Telecom Italia, a telecommunications company; Tenaris, a manufacturer of pipes, especially for the oil and gas industries; Terna, a Roman company that owns and operates 98 percent of the Italian power grid; UBI Banca, a cooperative bank; Unicredito, a pan-European bank based in Milan; Unipol, the third-largest insurance provider in Italy.

Microfinance

The development of the microfinance sector is based on the assumption that the poor possess the capacity to accomplish income-generating economic activities but are limited by lack of access to and inadequate provision of savings, credit, and insurance facilities. The microfinancial services capture the various financial needs of the poor, and currently microfinance is a major component of poverty reduction and economic regeneration strategies around the world. As a concept, microfinance pays close attention to the incentives that drive efficient performance in the context of small transactions and large numbers of clients. Most of the institutions in microfinance are based on group-based lending approaches and thus reduce the administrative costs of gathering information, contract design, and enforcement of credit transactions, including loan recovery. Recently, the microfinance sector has come more into the domain of commercial organizations and the idea of sustainable microfinance has become an integral part of the development of financial markets in many countries.

Microfinance activities usually involve (1) small loans, (2) informal appraisal of borrowers and investments, (3) collateral substitutes such as group savings or compulsory savings, (4) access to repeat and larger loans, based on repayment performance, (5) streamlined loan disbursements and monitoring, and (6) secure savings products.

According to the Consultative Group to Assist the Poor (CGAP), the key principles of microfinance are (1) the poor need a variety of financial services, not just loans; (2) a powerful instrument against poverty; (3) the need to build financial systems that serve the poor; (4) financial sustainability; (5) the need to build permanent local financial institutions; (6) requires more than microcredit; (7) interest rate ceilings can damage poor people's access to financial services; (8) the role of government as an enabler of financial services; (9) donor subsidies should complement private sector capital; (10) the lack of institutional and human capacity; and (11) the importance of financial and outreach transparency. These principles are generic and provide a broad foundation to the core idea of enhancing access to finance.

The CGAP principles suggest the need for a wide range of financial services that are suitable, flexible, and reasonably priced. The financial diaries prepared by poor households in urban and rural areas in Bangladesh and in India reveal that the respondents patch together a wide array of informal arrangements with semiformal and formal services. These diaries reveal that poor people want reliable, convenient, and flexible ways to store and retrieve cash and to turn their capacity to save into spending power, in the short, medium, and long term on a continuing basis.

The ideas of sustainability in microfinance allow the continued operation of the microfinancial services without subsidies and help from the donor. Financial sustainability helps to reduce transaction costs, which leads to client-based products and services. The idea of the poor as a heterogeneous group of vulnerable households with complex livelihoods demonstrates the need for client-based microfinancial services. In some cases nonfinancial services are essential for the effective use of financial services, and many microfinance institutions integrate both services in their operations. According to CGAP, microfinance combines banking with social goals, and capacity needs to be built at all levels, from financial institutions through the regulatory/supervisory bodies and information systems, to government entities and donor agencies.

New Institutions

There is an increasing level of interest from formal sector financial institutions in microfinance activities. For instance, Bank Rakyat Indonesia's (BRI) experience shows that with attractive savings and credit products, appropriate staff incentives, and an effective system of internal regulation and supervision, the microfinance operation can be highly profitable. The flexibility in saving services, an important part of Unit Desa Scheme of BRI, offers convenient banking hours, a friendly atmosphere, unconstrained withdrawals, and a range of incentives such as bonuses and raffles.

In India, the Self Help Group (SHG) program, a distinctive microfinance program, is based on the existing banking network in delivering financial services. The formal financial sector institutions extend loans to highly performing SHGs in certain multiples of the accumulated savings of each SHG. The Reserve Bank of India (RBI) has instructed all commercial banks to participate and extend financing to SHGs, extending this to cooperative banks and regional rural banks. However, by the early 21st century, microfinance institutions have become a vast global industry involving large numbers of governments, banks, aid agencies, nongovernmental organizations (NGOs), cooperatives, and consultancy firms and directly employing hundreds of thousands of branch-level staff. The presence of more players in microfinance has raised certain concerns about the quality and sustainability of the services for several reasons.

The higher number of players attracts competition and brings high levels of professionalism to the industry. But there are concerns about more players targeting the same market, which questions the

This family in Santa Cruz, Bolivia, stands in their food stall in December 2007; they had just been able to rebuild their business after a fire because of their access to microcredit. Like Bangladesh, Bolivia has been an important market for microfinance efforts.

absorptive capacity limits on the part of both lenders and of borrowers. Irrespective of the successful citations of microfinance, there is a view that microfinance has failed to see the slippery slope toward consumerism. This type of concern goes back to the ages of the previous debates on whether microfinance is a successful tool to address poverty alleviation. It is beyond doubt that microfinance raises the prospects for low-income households, and some poor people, to achieve their goals—in business, consumption, education, health, and other areas—and is not a magic bullet that automatically lifts poor people out of poverty through microenterprise. The time has come for microfinance institutions as well to take up the challenge to develop diversified financial services while maintaining financial sustainability.

Microfinance Institution

Microfinance institutions (MFIs) provide financial services to the poor, who are normally excluded from the formal banking sector. The failures in reaching out to the poor by government schemes had generated a group of MFIs to engage in income-generating activities due to inadequate provision of savings, credit, and insurance facilities in several countries, especially in Bolivia, Bangladesh, and Indonesia. In 2006 Grameen Bank—the first microcredit institution, started with loans of less than $1 each to 42 destitute Bangladeshis—had grown to reach 7 million clients. Over the years, Grameen Bank is credited with proving that "the poor are bankable," and the Grameen model has been copied in more than 40 countries.

Currently, there are 3,316 MFIs reportedly reaching over 133 million clients by the end of 2006, and loans to 92.9 million poorest clients benefit a total of 464.6 million people, including both clients and their family members. In terms of ownership patterns, the microfinance institutions provide different structures such as government-owned (rural credit cooperatives in China), socially minded shareholders (transformed NGOs in Latin America), member-owned (credit unions in west Africa), and profit-maximizing shareholders (microfinance banks in eastern Europe).

In the early stages, the MFIs had only concentrated their activities on micro credit, but changed to a range of services in due course. The MFIs introduced concepts such as group-lending contract, character-based lending, short-term repeat loans, and incentives for loan repayments. The extensive Microcredit Summit Campaign Report 2007 argues that although microfinance is not a panacea, it is still a powerful tool to fight global poverty and works well with other development interventions that promote health, nutrition, housing, democracy, and education, offering dignity and empowerment to the very poor.

The flexibility in repayment options allows borrowers to repay out of existing income, freeing the borrower to invest the loan in relation to their needs. Many microfinance institutions permit people to access useful lump sums through loans and allow borrowers to repay the loan in small, frequent, manageable installments, which is further supported by quick access to larger repeat loans. Most of these institutions are successful financially due to high repayment rates and an enhanced awareness of the levels of subsidy. These features make microfinance institutions different from small-scale commercial and informal financial institutions and from large government-sponsored schemes, and are either independent of government and/or have a high degree of autonomy from bureaucrats and politicians. However, a better understanding of the financial service preferences and behaviors of the poor and poorest is still required to expand the scope of microfinance in addressing the concerns about welfare implications of MFIs.

In the 1990s a debate emerged around two leading views in microfinance services available to the poor—financial systems approach and poverty lending approach, both of which share a commitment to make these services available to the poor. The financial system approach framework is based on the principles of financial self-sufficiency, as seen in institutions such as Banco Solidario (BancoSol) in Bolivia and the Bank Rakyat Indonesia (BRI). The poverty lending approach focuses on credit and other services funded by donor and concessional funds as an important mechanism for poverty reduction. This approach is interested in improving the well-being of participants and their families. The examples of this category are Bangladesh Rural Advancement Committee (BRAC) and FINCA-style village banking programs in Latin America. However, this debate is largely resolved now and the microfinance sector is adopting operating on commercial lines or systematically reducing reliance on interest rate subsidies and/or aid agency financial support. This is evident by the experience in Bangladesh where the Grameen Bank has shifted from its classic "Grameen I" group—lending to the poor model—to "Grameen II," which is much closer to the financial systems model.

Recently, the growth in new products such as smart cards and the use of technology in developing new points of sale has been helping microfinance institutions to enhance their outreach. Even the conventional banking institutions have entered into the provision of microfinance in a big way. The private sector has built a significant presence in microfinance operations and the microfinance institutions are successfully raising commercial funds from the capital market and social investors.

Micro-Multinational

A micro-multinational (mMNE) is a firm that, from birth or soon thereafter, controls and manages value-added activities in more than one country. Other common terms for the phenomenon of a rapidly internationalizing firm are *international new venture, born global, global start-up, metanational downstairs*, and *infant multinational*. The major differences between a micro-multinational and a large multinational enterprise (MNE) are firm size and age, and speed and choice of market internationalization. Micro-multinationals are, by definition, young and small—often classified by having 250 or fewer employees. Unlike most MNEs that embark on a staged, incremental process of internationalization to countries of geographic and psychic/cultural proximity, mMNEs' international choices are influenced by market-efficiency and strategic asset (often physical and knowledge resources)–seeking factors.

A key distinction between mMNEs and other early internationalizing firms is that mMNEs tend to utilize more advanced service modes (beyond exports) in controlling and managing value-added activities around the world. Kevin Ibeh, Jeffrey Johnson, Pavlos Dimitratos, and Jonathan Slow report the following service model usage by Scottish MNEs: overseas office (42.6 percent), foreign subsidiary (29.9 percent), international joint venture (24 percent), overseas manufacturing (22.5 percent), international licensing (21.1 percent), and international franchising (4.9 percent).

There are increasing numbers of micro-multinationals starting in countries all over the world, and these firms play a key role in the growth and development of their home and host national economies. The growing numbers of mMNEs is attributed to factors related to the competitive environment, firm, and manager experience. First, a number of developed and developing country governments have established policies intended to assist the development of "home grown" MNEs. Second, the growing use of the internet and the dominance of companies such as Google, Yahoo, MSN, eBay, and Amazon makes it easy for micro-multinationals to reach potential customers all over the world. Third, although micro-multinationals can be found across all industry sectors, the highest potential mMNEs are found in but are most prevalent in fast-growing sectors that are knowledge based, such as software development. Fourth, across the world, individuals are gaining experience living in other countries. Increasing numbers of students pursue part or all of their degrees overseas and managers devote substantial time and energies to overseas projects. Through this experience, individuals gain knowledge about how to function and succeed in foreign markets and may also see viable opportunities for new businesses. For example, many of China's micro-multinationals are founded by "sea turtles": Chinese nationals who studied and/or worked abroad, often in the United States, for many years before returning to China to start export-oriented firms.

Ben Oviatt and Tricia McDougall classify international new ventures on two dimensions: coordination of value-chain activities (few versus many) and the number of countries involved (few versus many). They identified four types of firms that export directly from near their incipience: export/import start-up, multinational trader, geographically focused start-up, and global start-up. The export/import start-up and multinational trader firms are "new international market makers" that coordinate few activities across countries, most commonly systems and knowledge of inbound and outbound logistics to aid import and export. These firms' advantage generally depends upon their ability to discover and act upon an imbalance of resources across countries, create new markets, and attract and maintain local business networks. Geographically focused start-ups focus on the specialized needs of a particular region and coordinate a range of activities beyond simple inbound and outbound logistics that often require socially complex networks with tacit knowledge. Global start-ups describes those firms that derive a significant competitive advantage from coordinating multiple activities across multiple countries. These firms are often the most time- and resource-intensive to develop but can have the most sustainable long-term competitive advantages due to the inability of other firms to mimic their historically unique, casually ambiguous, and socially complex alliances.

Micro-multinationals face a number of barriers to entry, including a lack of financial, information, management, and intellectual property protection resources. In order to compete overseas, firms often require access to financial capital; however, new firms are generally less able to receive financing or access foreign collateral. Overseas operations often require new knowledge about legal, bureaucratic, and social structures, and new venture management may lack this expertise. Finally, overseas markets may not protect intellectual property rights. Small firms attempting to go overseas may not be able to protect against the theft of intellectual property while large firms' greater credibility and ability to pursue retribution might limit their theft.

Given these obstacles, micro-multinational managers seek integration in key business networks. These collaborations can be formal or informal and enable the mMNE to acquire greater access to resources (including financial), learn new skills, gain legitimacy and control, guard property rights, and control transaction costs. Zoltan Acs, Siri Terjesen, and Colm O'Gorman describe how micro-multinationals often begin by pursuing an indirect path to internationalization using intermediaries to facilitate exports. Micro-multinationals often internationalize by becoming one or more of the following: suppliers of foreign MNEs, licensors/franchisors of foreign brands, and alliance partners of foreign direct investors. Intermediaries include agents and distributors located at home or abroad or the local subsidiaries of multinational firms; they can help their clients overcome knowledge gaps and reduce uncertainties and risks associated with operating in foreign markets. Jolanda Hessels and Siri Terjesen's study of Dutch SMEs reports that exporters were most likely to have an owner/manager that perceived an increased international presence of their domestic competitors, customers, and suppliers and an increased use of foreign suppliers. Micro-multinationals that exported directly were most likely to have owner/managers who perceived favorable home market access to knowledge and technology and reasonable production costs and government regulation.

Microsoft

Microsoft is a multinational information technology company that manufactures, licenses, acquires, and supports a range of software for use on computing devices. Its portfolio of interests also includes publishing, computer hardware, and a cable TV channel. The history of Microsoft is, to a great extent, the history of its products. Due to the manner of the development of its product portfolio and the strategies behind it, Microsoft is often portrayed as aggressive and predatory; an innovator, rather than a creator. However, the same evidence can also be construed as demonstrating a vigorous competitor that has benefited the global marketplace by supplying innovative, integrated products, enhancing the productivity of businesses and the lifestyles of consumers, and promoting corporate philanthropy while meeting new threats to profitability.

Microsoft was founded in 1975 by Bill Gates and Paul Allen in Albuquerque, New Mexico, to produce a programming language for the popular Altair 8800 computer. The pair had met at Seattle's Lakeside School over their interest in computers, and together they had dropped out of Harvard to pursue the Altair opportunity. In 1981 Microsoft won the contract to produce an operating system (OS) for the IBM personal computer (PC). For this, Gates purchased an OS from Seattle Computer Products, developing and rebranding it as MS-DOS. This gave them a pricing and a first mover advantage over competing products. In a masterstroke of contracting, Microsoft was allowed to license the operating system to other PC manufacturers, essentially becoming a premium paid to Microsoft on sales of all PCs as the market exploded. For most of the 1980s, MS-DOS accounted for 40–50 percent of revenues.

Although a usable OS was significant, it was "productivity" application software such as the VisiCalc spreadsheet that established the PC as an office tool. As users became accustomed to the possibilities offered by these kinds of software, a need for multitasking between applications and increased usability became apparent. A "windowing" graphical user interface (GUI) was seen as the solution, such as Apple had produced in 1984. In 1985 Microsoft released Windows as a GUI to the MS-DOS. This set the ground for Microsoft's growth in the 1990s from integrated productivity applications for office workers. Bundling MS Word, Excel, and PowerPoint into MS Office allowed Microsoft to build the cash reserves necessary to take on established one-application specialists such as WordPerfect and Lotus.

In the mid-1990s, after a momentary error in reading the strategic opportunity of the internet, Gates moved Microsoft strongly in that direction with MS Internet Explorer (IE), a Web browser that began as a separate application but became an integrated part of the Windows OS. The major controversies over Microsoft's strategies became apparent in this phase of its development—first over MS Windows, where Apple Computer claimed copyright infringement of their GUI, and then with MS Internet Explorer with charges of bundling and monopoly leveraging. This second charge included tactics in the so-called Browser Wars against the competitor Netscape, such as bundling IE with Windows. These various strategic moves and legal/commercial consequences contributed to a growing anti-Microsoft sentiment in popular culture.

On April 3, 2003, following the antitrust case brought against Microsoft by the U.S. government, Microsoft was broken into two divisions: operating systems and software. It has subsequently been divided into the platform product and services division, the business division, and entertainment and devices division. How U.S. action will reduce Microsoft's monopoly on the personal computing market is unclear. It is likely that the divisions will exploit their commonality and Microsoft's users will continue to seek integrated products. Despite the breakup, for the fiscal year ended 2007, Microsoft revenues saw a 15 percent increase over the previous year. However, Microsoft profits have been built on charging for OS and productivity software that runs on PCs. Such software is increasingly available as a free online service, developed by open communities of programmers. It is often OS-independent, representing a double threat to Microsoft's traditional sources of profit. Microsoft has been successful due to its founders' ability to discern opportunity. The diversification represented by its business units demonstrates Microsoft's response to threats to its core business. As Bill Gates leaves to pursue philanthropic activities, new generations of leadership will be required to sustain that ability across an increasingly diverse set of activities.

Middle East

The term *Middle East* has no objective basis. It is an idea of late-19th-century imperial geography used to define a group of countries that stretch around the Mediterranean. Depending on which countries are included, the Middle East is said to encompass the region of modern-day Turkey; the eastern Mediterranean (Levant) on some accounts extending to Iran and Afghanistan; down into the Gulf and Arabian Peninsula; and along the southern shores of the Mediterranean. The International Monetary Fund (IMF) and the World Bank treat the Middle East and north Africa as a single region. The Middle East incorporates the area once seen as the cradle of civilization, the fertile crescent of Mesopotamia and the Nile Valley. In terms of medieval religious geography, this area was seen by Christians, Jews, and Muslims as the center of the world. But by the late 19th century, European industrialization and expansion made it seem an intermediate "middle Eastern" area separating Europe from the East. The continued use of this term reflects the ongoing importance of geopolitical considerations and the way that they are sunk into popular consciousness. The Middle East is often thought to be synonymous with the Arab world, but the definition of an Arab is itself contested. The region is often associated with Islam, but there are substantial Islamic minorities in some states, and most of the world's Muslims do not live in the Middle East.

Politically, much of the area of the Middle East was once part of the Ottoman Empire. The modern-day states emerged from imperial conflicts, and especially Anglo-French influence as the Ottoman Empire collapsed. The secret Sykes-Picot agreement of 1916 formalized Anglo-French spheres of influence, and in 1917 the British made the Balfour Declaration, viewing with favor a national home of the Jewish people in Palestine. In this division, too, the Kurds must not be forgotten as they emerged the losers as the world's largest stateless people.

After World War II, Anglo-French influence gradually gave way to U.S. influence. This reflected a continuation of older strategic concerns over the area, the Cold War, and, most importantly, the role of the area as an oil-producing region. These concerns led to U.S. support for local forces—states, princes, families, and the military—that might help it achieve its aims. But it also accounts for continuing hostility to Western intervention and pressure. History plays an important role in the area and helps to explain the continuing tensions. Some sensitivity to the complexity of the region and even the term *Middle East* itself is therefore necessary. Often the term carries a negative connotation, as when David Ben-Gurion said that "the state of Israel is a part of the Middle East only in geography."

Standard accounts of business in the Middle East point to positive factors encouraging trade and investment. These include the geographical ease of access, cultural uniformities (the Arab language, Islam), pressures to emulate Western consumption practices including the worst aspects of environmental degradation, public sector demand, and so on. Against these must be set more negative issues.

In the 1960s much of the debate about the Middle East tended to exaggerate its potential. Today there is a pessimistic concern with "failure." This has been heightened by Western concerns related to the war on terror. One major trend of Western opinion sees the region in terms of a "clash of civilizations." Writers like Bernard Lewis ask "What went wrong?" and talk of the way in which the region is characterized by "the politics of rage" against Western modernity and a misplaced sense of victimhood and grievance. Others insist that such arguments stand in a long tradition of what is called Orientalism. This exaggerates the threat from a region where demoralization is widespread. The alleged negative traits are explained by culture and then reduced to religion and its most fundamentalist forms.

Much discussion of the alleged deficiencies of Middle Eastern, Arab, Islamic culture is ill informed. Culture is no less significant in the Middle East than elsewhere, but it is also no more important. If culture is such a decisive and unifying force, it is difficult to see, for example, why economic performance varies so much. Too often culture in the region is seen as an independent variable whose content can be deduced from ancient religious texts. It is more often a dependent variable formed from the modern world. It varies in the Middle East, as elsewhere, by country area, minority, social class, and so on. Regional averages and generalizations can be quite misleading.

It is important to be aware of the scale and breadth of diversity in the Middle East as well as the linking elements. The stereotypical Middle East and the stereotypical Arab of Western popular culture, and even some business culture books, are misleading bases for relationships. The diversity and even clash of interests help account for the weak political unity of the region. Turkey is a member of NATO and a long-time aspirant for membership in the European Union. Pan Arabism as an ideology quickly faltered. The League of Arab States was founded in 1945 and has grown to include 21 members, but it has weak influence and unity. An attempt to merge Egypt and Syria into a United Arab Republic lasted only between 1958 and 1961. The Organization of Petroleum Exporting Countries (OPEC) was founded in 1960 to bring together oil producers, but it incorporates non–Middle Eastern states and has not been able to sustain agreements. In 1965 an Arab Common Market was created, but it is of minimal significance compared to the European Union. Even where seemingly common political ideas exist, such as Ba'athism—an ideology that combines nationalism and state socialism—interstate conflicts and tensions still occur.

Geographical and Economic Diversity

Diversity is apparent in the geography of the region. Its climate tends to be arid to semiarid, which makes agriculture difficult in many areas and helps account for low population densities. Contrary to many Western images, the topography is extremely varied. The region has a population in excess of that of the United States but a total output level of perhaps only one-tenth the U.S. total. Many Middle Eastern states are small in population terms. The largest, with populations of around 70 million, are Turkey, Iran, and Egypt. Levels of development vary from the very-low-income Yemen to the high-income states of Kuwait, the United Arab Emirates (UAE), and Qatar. Most states are middle ranking in terms of development.

Since oil was first commercially produced in Iran in 1908 it has come to play a major role in the region's fortunes. The main energy producers are Saudi Arabia, Iran, UAE, Kuwait, Iraq, Algeria, Libya, and Qatar, but other states have indirectly depended on oil as the oil producers have given out various loans and attracted several million workers who have sent back remittances.

Dependence on oil also means dependence on its changing price. This has proven volatile. In the first three to four decades after 1945, economies in the region grew quite fast. Growth then decelerated to the start of the 21st century, and the region acquired its more negative reputation for poor economic performance. But the price of oil surged again, bringing with it an economic upturn.

Socially, the Middle East has experienced rapid modernization and urbanization. Its demographic transition has been fast, but there is still a legacy of very high labor force growth. Educational levels have risen but job opportunities have not kept pace with these. There is a relatively high level of unemployment and a past pattern of poor real wage growth. State policy has tended to be interventionist with strong public sectors run by undemocratic governments. Both political and economic reform continues to prove difficult, but this seems in line with what is sometimes called "the natural resources curse." Oil revenues enable governments to avoid the need for a more popular mandate.

State redistributive policies mean that the level of absolute poverty is relatively low compared to other developing regions. Social inequality, however, is real and extends far beyond the notorious wealth of the oil families of the Gulf. But in many countries there is a reluctance to admit and explore the scale of social inequality. Governments have used social provision as a way of consolidating an "authoritarian bargain" to reduce discontent and the pressure for change.

Prosperity in the oil states has been the basis for large-scale imports of manufactured goods, consumer goods, and foodstuffs. Oil revenues have also provided the basis for huge sovereign wealth funds in the Gulf States, which have then been invested in the West. In addition, the Gulf States have also developed a tourism industry and shipping services. Dubai is one of the largest free trade zones in the world. By contrast, the larger states and especially Iran, Egypt, and Turkey have much more diversified economies with important agricultural and industrial sectors. Israel, too, has a diversified economy with a significant high-technology defense sector.

Major sources for an understanding of the situation in the Middle East are the Arab Development Reports of 2002–05 prepared by the United Nations Development Programme (UNDP). These not only provide information but were intended as part of a reform program to deal with a "crisis of human development in the Arab region." This is explained not by alleged traditional shortcomings but institutional problems reflecting the rentier nature of key states and the narrow self-interested visions of their rulers. The reports regretted that "the Arab spring has yet to bloom" and that in some respects the global and regional context was worsening.

Women learning sewing skills in a 2006 summer program in Yemen, one of the poorest countries in the Middle East.

Three related areas of regionwide reform were identified—knowledge, political freedom, and the empowerment of women. The Middle Eastern states have too often depended on importing knowledge without creating the structures to generate and use it. Rising education levels sit alongside a fear of unrestricted knowledge—a crude but telling indicator is the low level of book publishing. The result is an inability to capitalize on knowledge transfer and a significant brain drain. This can be contrasted with the breadth and generosity of the region's culture at a previous stage of human history when the West was relatively backward.

Social and Political Flashpoints

Freedom is associated with economic, civil, and political rights, and good governance based on political representation and democratic accountability. Most Middle Eastern states perform badly here. This helps to create frustration as education levels rise. The fear of democracy and the attempt to repress forces for change or to buy off parts of the opposition inevitably push those who want change in a more radical direction.

Images of the Middle East are often molded by the perception of the subordinate position of women. But Islam does support male and female equality—it is only certain interpretations (as in Christianity) that insist on female subordination. There is a need to recognize that there have been real achievements. On a regional basis, male to female school years have converged from around 2.5:1 in 1960 to 1.4:1. But some states still need to achieve the relatively modest goals of ensuring the elimination of female illiteracy and universal education for girls to the age of 12 by 2015. Reformers see no intrinsic reason why the Convention on the Elimination of All Forms of Discrimination against Women is inconsistent with the traditions of the region.

These arguments can be used to appeal to the enlightened self-interest of the ruling groups in the Middle East. The difficulty is that leaders do not necessarily recognize the merits of these arguments. Even if they do, they are reluctant to allow an opening up of the political systems for fear of where this might lead. Western policy too remains caught on this contradiction—encouraging "democratization" in the abstract but fearing its real consequences.

Readers should refer to the separate entries on individual states, but no survey would be complete without a brief identification of the major regional flashpoints. The Middle East has been one of the least stable, most conflict-ridden regions in the world since 1945. The first flashpoint is Israel. What some see as the "victim" state, others see as the "oppressor state." There can perhaps be some agreement that it is a "fortress state," having for many years been the most important recipient of U.S. aid. What it sees as its necessary defenses (including its unofficial nuclear weapons), others see as a regional threat. Moreover, the attempt to link anti-Semitism to any criticism of the Zionist ideology on which Israel is built is seen by its critics as a way of delegitimizing any attempt to criticize the long-running sore of Palestinian oppression and repression and the continual ignoring of UN resolutions. This polarization of views seems likely to continue.

The second flashpoint is Egypt. Once the leading state of Arab nationalism, its leaders have gradually accommodated to the West and Israel to such an extent that Egypt has also been a recipient of huge U.S. aid. This has done little to enhance its leadership in the eyes of some of its population. Much attention has been focused on radical Islamic tendencies, but arguably more important are the social tensions in Egypt and the emergence of a significant labor movement that challenges the social basis of that society.

The third is Saudi Arabia. This highly secretive state claims a quarter of the world's oil reserves. It is seen as a key Western strategic ally. This has allowed the West to tolerate both the backward nature of its society and its role as a base for the extreme Wahhabi form of Islam that is especially associated with one aspect of the fundamentalist tradition.

Fourth is Iraq, which claims the world's fourth-largest oil reserves. The U.S. invasion of 2003 has increased regional instability, without securing either the Iraqi state or its oil supplies. Fifth is Iran. Before 1979, like Saudi Arabia, this state was considered central to Western influence. The popular revolution of that year put into power an anti-Western regime that combined nationalism and religion. Today Iran is the subject of enormous suspicion and hostility with little attempt to understand it.

Western policies in the region have often backfired, partly because they have tended to support the status quo, but also because they have been frequently opportunistic. Support of the mujahideen resistance to the Soviet occupation in Afghanistan helped create the threat of Osama bin Laden and Al Qaeda. Support for Saudi Arabia has helped to give a strategic role to its Wahhabi religious extremism. Support for Israel alienates the mass of the population of the Middle East and also puts Western policy in the hands of the leaders of that society. They too have experienced "blowback." Israel, for example, is alleged to have supported the Gaza Islamic University to weaken the Palestine Liberation Organization (PLO) only for it to become a center for the more radical politics of Hamas.

The Middle East, therefore, is best approached with an open mind and a willingness to demonstrate some empathy with its diverse inhabitants and cultures.

Millea Holdings

Millea Holdings, Inc., a holding company headquartered in Tokyo, Japan, was created in April 2002 as the umbrella structure for the international insurance businesses of Tokio Marine and Nichido Fire. Millea Holdings was the first publicly owned holding company in Japan integrating life insurance and nonlife insurance operations. One of the key objectives in the corporate vision of Millea Holdings is to become one of the world's top-tier insurance groups through customer trust and to make a positive contribution to society by offering safety and security products and services.

Millea Holdings breaks its insurance lines into five segments plus another category. These segments and their percent of premiums written are as follows: fire and allied lines (15.6), hull and cargo (4.2), personal accident (7.5), voluntary automobile (45), compulsory automobile liability (15), and other (12.6). The Millea Group plans to grow its businesses through the expansion of products and services (prevention services and care services), sales channel expansion as a result of government regulatory liberalization, and the expansion of its global regional businesses through mergers and acquisitions, equity partnerships, and business alliances.

The operating subsidiaries of Millea Holdings include the following: Tokio Marine & Nichido (nonlife insurance), Nisshin Fire (nonlife insurance), Tokio Marine and Nichido Life (life insurance), Tokio Marine & Nichido Financial Life (life insurance, especially variable annuity and life policies), Millea Nihon Kosei (small-amount, short-term insurance), Tokio Marine & Nichido Anshin Consulting (agent for nonlife and life insurance, as well as, individual financial consulting services), Tokio Marine & Nichido Career Services (staffing and employment services), Tokio Marine Nichido Samuel (operator of elderly care facilities), Tokio Marine & Nichido Facilities (property and equipment management), Tokio Marine & Nichido Medical Services (medical care and health-related services), Tokio Marine & Nichido Risk Consulting (insurance underwriting risk investigations and risk consulting services), Millea Mondial (assistance and business process outsourcing services), Millea Real Estate Risk Management (real estate investment advisory services), Tokio Marine Asia (a subsidiary holding company for Asian insurance operations excluding Japan), Tokio Marine Bluebell Re (reinsurance for variable annuities), and Tokio Marine Seguradora (life and nonlife insurance in Brazil).

The Millea network of companies, subsidiaries, affiliates, branches, offices, and agents has a worldwide presence. In North America it is represented in the United States, Canada, Bermuda, and the Cayman Islands. In Central and South America it is represented in Mexico, Brazil, and Paraguay. In Europe it is represented in the United Kingdom, France, Germany, the Netherlands, Belgium, Italy, Spain, Ireland, Norway, Denmark, and Greece. In Eurasia it is in Russia. In the Middle and Near East it is represented in the United Arab Emirates, Saudi Arabia, Bahrain, and Turkey. In Oceania and Micronesia it is represented in Australia, New Zealand, Guam, and the Commonwealth of the Northern Mariana Islands. In Asia it is represented in Korea, mainland China, Hong Kong, Taiwan, the Philippines, Vietnam, Thailand, Malaysia, Singapore, Brunei, Indonesia, India, and Myanmar.

Millea Holdings has a market capitalization of some 150 billion yen for the approximately 824,524,375 shares issued. For fiscal year 2007, Millea reported net assets per share of 4,127.60 yen. The Millea Group uses embedded value (EV) and return-on-equity (ROE) as its method of evaluation value and performance in its insurance businesses. For its fiscal year 2006, Millea had an EV of 335.2 billion yen, which consisted of the sum of its net asset value of 97.6 billion yen and its in-force business value (net earnings) of 237.5 billion yen. Millea contracts with Tillinghast, the financial services consulting unit of Towers Perrin, to verify its reported EV. The Millea Group targets an adjusted ROE of approximately 5 percent annually.

Millea Holdings is listed on the Tokyo Stock Exchange and the Osaka Stock Exchange. American depository receipts (ADRs) for its common stock are handled by JPMorgan Chase Bank and quoted on the over-the-counter market in the United States. Typical of ownership patterns in Japan, about 31.2 percent of its shares are held by some 10 shareholders: State Street Bank and Trust Company (6.2), Moxley & Co. (5.4, representing the ADRs), Master Trust Bank of Japan (4.5), Japan Trustee Services Bank (3.7), Meiji Yasuda Life Insurance Company (2.5), Trust & Custody Services Bank (1.7, retirement trust account for Mitsubishi Heavy Industries), Mizuho Corporate Bank (1.7), State Street Bank and Trust Company 505103 (1.6), and Master Trust Bank of Japan (1.4, retirement trust account for Asahi Glass Company).

The consolidated subsidiaries of Millea Holdings are intensely engaged in a variety of global derivative transactions for risk management purposes and to maximize their investment gains. Millea subsidiaries engage in currency-related derivative transactions that include forward contracts, currency swaps, and currency options. For fiscal year 2007, Millea subsidiaries had a total of 2,108,029 million yen in foreign-currency related instruments. Millea subsidiaries engage in equity-related derivative transactions that include equity index futures and equity index options. For fiscal year 2007, Millea subsidiaries had a total of 148,423 million yen in equity-related instruments. Millea subsidiaries engage in bond-related derivative transactions that include bond futures, bond future options, and over-the-counter bond options. For fiscal year 2007, Millea subsidiaries had a total of 171,633 million yen in bond-related instruments.

Millea subsidiaries also engage in other derivative transactions such as credit derivatives and weather derivatives, among others. For fiscal year 2007, Millea subsidiaries had a total of 13,707,398 million yen in interest-related instruments, 1,157,328 million yen in credit-related instruments, 72,528 million yen in commodity-related instruments, and 1,909 million yen in weather-related instruments.

Millennium Development Goals

The Millennium Development Goals are outcome-based international development targets that were agreed at the United Nations Millennium Summit in New York in September 2000. Eight Millennium Development Goals are defined. These goals incorporate 18 more precisely defined targets with a total of 48 indicators. Development targets were set out initially by the Organisation for Economic Co-operation and Development (OECD) in 1996, following previous attempts to set out aims and objectives for the promotion of economic growth and basic needs between the 1970s and the 1980s, and the definition of the aim of sustainable development in the 1990s incorporating environmental concerns next to the aim of poverty reduction. The agreed set of targets was set out in the *Road Map Towards the Implementation of the United Nations Millennium Goals* in 2001.

The Millennium Development Goals define the objectives of development policy based on the desired outcome. They act as a measurable set of objectives against which the performance of the international community and individual nations in their development efforts can be measured. It is also argued that accepted development goals and targets ascertain international responsibility and establish a common purpose for the international community.

The first seven Millennium Development Goals are the following:

1. Eradication of extreme hunger and poverty. This goal contains two targets: first to halve, between 1990 and 2015, the proportion of people whose income is less than a dollar a day, and second, to halve, between 1990 and 2015, the proportion of people who suffer from hunger.
2. Achievement of universal primary education. The target here is to ensure that by 2015 all children will be able to complete a full course of primary schooling.
3. Promotion of gender equality and empowerment of women. The fourth target related to this goal is to eliminate gender disparity in primary and secondary education preferably by 2005 and to all levels of education no later than 2015.
4. Reduction of child mortality. The target is to reduce by two-thirds, between 1980 and 2015, the under-five mortality rate with the indicators of the under-five mortality rate itself and to increase the proportion of one-year-old children being immunized against measles.
5. Improvement of maternal health. This goal has the target to reduce by three-quarters, between 1980 and 2015, the maternal mortality ratio. This is to be measured by the maternal mortality ratio and proportion of births attended by skilled health personnel.
6. Combat HIV/AIDS, malaria, and other diseases. One target is to have halted by 2015, and begun to reverse, the spread of HIV/AIDS that is indicated by the HIV prevalence among 15-to-24-year-old pregnant women, contraceptive prevalence rate, and the number of children orphaned by HIV/AIDS. Another target is to have halted by 2015, and begun to reverse, the incidence of malaria and other major diseases.
7. Ensuring environmental sustainability. This goal integrates the principles of sustainable development into country policies and programs as a target and is to reverse the loss of environmental resources. The proportion of land area covered by forest, land area protected to maintain biological diversity, GDP per unit of energy use as an energy efficiency measure, and carbon dioxide emissions per capita are utilized as indicators. Furthermore, this incorporates the target of halving, by 2015, the proportion of people without sustainable access to safe drinking water, as well as the target of having achieved, by 2020, a significant improvement in the lives of at least 100 million slum-dwellers. The proportion of people with access to improved sanitation and the proportion of people with access to secure tenure acts as a means of measurability.

Many of these indicators linked to the first seven Millenium Development Goals are accessible via the *World Bank Atlas* of the Millennium Goals. The eighth goal is the Development of a Global Partnership for Development. This goal encompasses seven further targets. It is aimed at developing an open, rule-based, predictable, nondiscriminatory trading and financial system with a commitment to good governance, development, and poverty reduction—both nationally and internationally. It addresses the special needs of the least developed countries (LDCs) and includes tariff- and quota-free access for LDC exports, an enhanced program of debt relief for heavily indebted countries, and cancellation of official bilateral debt as well as more generous official development assistance (ODA) for countries committed to poverty reduction. It addresses the special needs of landlocked countries and small island developing countries, whereby a comprehensive consideration is given to the debt problems of developing countries with the aim of making debt sustainable in the long term.

In cooperation with pharmaceutical companies, the provision of access to affordable essential drugs in developing countries is aimed at, as well as making available the benefits of new technologies, especially information and communication, in cooperation with the private sector. This broad goal uses indicators that focus on ODA, the target for which is 0.7 percent of a developed country's gross income, the allocation of ODA to social services, transport, and environmental areas. Another category of indicators focuses on market access, whereby a calculated proportion of exports is admitted with no tariffs or quotas, with a particular focus on agricultural products. A further set of indicators aims to measure the achievement of debt sustainability.

Mitsubishi

Mitsubishi is the name of the one of the most powerful Japanese *keiretsu*. A keiretsu is a business group loosely held together through cross-holding of stock, meetings of the chief executive officers of the constituent companies, and use of a common logo. It is a format that has flourished in Japan in the aftermath of the postwar American occupation.

During the occupation the largest of the prewar financial cliques, *zaibatsu*—conglomerates that were tightly held together through subordination to a holding company that served as the zaibatsu head office—were dissolved, their stock sold off. Along with other great zaibatsu like Mitsui, Yasuda, and Sumitomo, Mitsubishi was dissolved by the Holding Commission Liquidation Commission during the late 1940s. In tandem with most of the other former zaibatsu, the companies that had operated under the Mitsubishi logo prior to World War II reassembled as the Mitsubishi keiretsu, albeit forging ties that were far weaker than those characteristic of the prewar period when the typical structure was extremely hierarchical.

The Mitsubishi zaibatsu began as a shipping company created by former samurai Yatoro Iwasaki in the 1870s. Brought into an alliance with another important zaibatsu, Mitsui, the two emergent financial cliques became the backbone of the N.Y.K., a great steamship company designed to be competitive with the Western shipping firms that had captured most of Japan's oceanic trade after the Meiji Restoration in 1868. Iwasaki soon diversified into other activities, including both light and heavy manufacturing and mining.

Why did the zaibatsu emerge in early industrializing Japan? Economic historians point to three factors: scarcity of entrepreneurial talent; scarcity of professionals, engineers, and accountants who could successfully import and adapt techniques already developed in the West; and "distance," both cultural and geographic. Writing and speaking a language radically different from European languages, few Japanese active in industry during the period between 1870 and the 1920s could master English, French, or German, the global languages of the day. A scale economy is created by bringing together skilled professionals under a single structure, one that mobilizes capital by diversifying into banking, one that carries on international trade largely through a single large shipping company, one that centralizes global trade negotiations in a few competent hands.

To some extent these same arguments can be used to explain why the dissolved zaibatsu reassembled as keiretsu after the American occupation ended, and why they continue to operate to this day. For instance, the global information-gathering capacity of a great keiretsu like Mitsubishi is considerable, greater than that marshaled by many governments in the world. Other potential advantages of the keiretsu format include reputation—exploiting the common brand or logo name—and the fostering of externalities in innovation, breakthroughs in one industry within a keiretsu potentially spilling over and stimulating technical advance in other industries that operate under the same keiretsu umbrella. This is the logic behind the idea of "one-setism," all major Japanese keiretsu seeking to foster or acquire through takeover the same set of companies that are in each of their competitor keiretsu. In short, under the "one-set" principle keiretsu aggressively compete against other keiretsu. Competition in mainstream manufacturing is largely competition among the few, among great keiretsu like Mitsubishi.

It should be noted that some scholars are skeptical about the strength of the ties that supposedly hold together postwar keiretsu, being particularly critical of the view that a main bank provides the crucial financial glue holding together the group, ridiculing the idea that weekly get-togethers of keiretsu executives are more than social.

A typical post-1960 keiretsu includes a bank, marine and fire insurance, heavy and light manufacturing firms, and a general trading company. For instance, the Bank of Tokyo-Mitsubishi (formerly the Mitsubishi Bank prior to 1996) is in the Mitsubishi keiretsu, as is Mitsubishi Motors, Mitsubishi Electric, Nikon, Mitsubishi Chemical, Mitsubishi Heavy Industries, Mitsubishi Plastics, Mitsubishi Steel, Mitsubishi UFJ Securities, and Mitsubishi Paper Mills Limited. The symbol for Mitsubishi is derived from its name—"three water chestnuts" is one translation, "three diamonds" another—looking most like three diamonds connected at a common central point.

Are keiretsu like Mitsubishi likely to survive indefinitely? In the wake of the bursting of Japan's bubble economy in the early 1990s and the subsequent slow growth, the position of many Japanese banks became precarious, leading to mergers of banks that were supposedly central to particular keiretsu. A good example of this is Mitsubishi Bank that merged with the Bank of Tokyo in 1996. Presumably, consolidation in the financial field may lead to an attenuation of the networking ties holding together keiretsu like Mitsubishi.

Mitsubishi Electric

Mitsubishi Electric is one of the world's largest industrial electronics companies. The firm conducts its business through six business segments: energy and electric systems, industrial automation systems, information and communication systems, electronic devices, home appliances, and others. Mitsubishi Electric offers a range of products, from security systems to circuit breakers to air conditioners. In the fiscal year ending March 2007, the company employed over 102,000 workers and recorded sales of over $30 billion. Based in Tokyo, Japan, Mitsubishi Electric operates primarily in Japan with overseas business in Europe, Asia-Pacific, and the Americas.

Mitsubishi Electric is most commonly associated with the Mitsubishi group of companies, one of Japan's largest corporate groups. Member firms of the Japanese corporate groups have been credited with playing a major role in Japan's economic development. Despite its prominence as a leading integrated industrial electronics manufacturer, however, the Mitsubishi Electric name is not widely recognized beyond Japan. This is largely because Mitsubishi Electric has grown much more from a national rather than international base—and still derives most of its business from the Japanese market.

Mitsubishi Electric evolved out of the Mitsubishi shipping business founded by Yataro Iwasaki in the late 19th century. This shipping business developed into a family-owned conglomerate (*zaibatsu*) in the years up to World War I, as the company diversified into coal mining, shipbuilding, and electrical equipment. Mitsubishi Electric itself was spun off in 1921 as an independent company.

The firm grew rapidly during the interwar years, mainly through imports of technology from foreign firms. Perhaps most prominent was Mitsubishi Electric's alliance with the American electrical firm, Westinghouse Electric, in 1923. As might be observed from Toshiba's alliance with General Electric or NEC's alliance with ITT, it was a time when Japanese firms tried to develop their own modern industries by learning from Western firms. Building upon foreign knowledge, Mitsubishi Electric produced its first hydraulic generator in 1924, followed by an elevator in 1931, and an escalator in 1935. By 1937, the firm had listed on the Tokyo Stock Exchange.

Like many zaibatsu firms at the time, Mitsubishi Electric began to provide supplies for the Japanese military during World War II. As a result, the firm's operations were suspended during the Allied occupation of Japan between 1945 and 1952. But Mitsubishi Electric reemerged after the occupation as part of a more loosely affiliated group of firms that featured interlocking shareholdings and were centered around a main bank (*keiretsu*).

Much like the interwar years, Mitsubishi Electric rebuilt its postwar business through technology imports from foreign firms. In fact, many of these imports were based on relationships formed in the prewar era. Over the 1950s and 1960s, the firm launched its first television, computer, and domestic satellite. Equipped with a strong product range, Mitsubishi Electric then began to expand into overseas markets, such as the United States, Britain, and Germany. The firm also began to collaborate with foreign firms to codevelop and distribute original products. These included projects with leading global firms such as AT&T, Westinghouse, and Siemens.

Mitsubishi Electric is unique among the former zaibatsu firms in its continued business of military procurement. The firm has been a major provider of Japan's Self Defense Forces, in products such as avionics and radars—which has been useful in developing civilian industrial products such as for air traffic management.

Mitsubishi Electric struggled to adjust to competitive pressures stemming from globalization and the information technology revolution in the 1990s. The firm still featured many traditional characteristics of Japanese business, such as lifetime employment and consensus-based decision making. Facing a new business environment that demands greater flexibility and swift responses, Mitsubishi Electric has been pushed to reform.

Mitsubishi Electric's logo makes use of the famous three-diamond symbol, tying it to other Mitsubishi companies.

Mitsubishi Electric faces intense competition from domestic firms such as Hitachi and Toshiba as well as foreign firms such as Schneider and Solectron. Rising raw material prices have also placed a burden on the firm's finances. The company's future lies in its ability to capitalize on its research strengths and diversified product range and expand further into global markets.

Mitsubishi UFJ Financial Group

Mitsubishi UFJ Financial Group is headquartered in Tokyo, Japan; its main business areas are banking and securities. As of September 30, 2007, it included

44 affiliated companies and 525 consolidated subsidiaries with 47,124 employees (BTMU, MUTB, MUS) and 78,300 employees worldwide. It reported gross profits of 3.512 trillion Japanese yen and net income of 636.6 billion Japanese yen as of March 31, 2008.

The Mitsubishi UFJ Financial Group (MUFG) was founded in October 2005 with the merger of two holding groups: Mitsubishi Tokyo Financial Group (MTFG) and UFJ Holdings (UFJH). It is a diversified comprehensive financial services group offering a wide range of services in retail, corporate, and securities. The bank's origins date back to 1870 with the establishment of Mitsubishi by Yataro Iwasaki. Its financial arm, the Mitsubishi Bank, was founded in 1919.

In 2001 the Bank of Tokyo-Mitsubishi Ltd., the Mitsubishi Trust and Banking Corporation, and Nippon Trust Bank Ltd. created MTFG through a share transfer. That same year, Sanwa Bank Ltd., the Tokai Bank Ltd., and the Toyo Trust and Banking Co. Ltd. created UFJH through a share transfer. MUFG is the holding company of three entities: the Bank of Tokyo-Mitsubishi UFJ Ltd. (BTMU, established in 2006); Mitsubishi UFJ Trust and Banking Corporation (MUTB); and Mitsubishi UFJ Securities Co., Ltd. (MUS). In 2007 MUFG created Mitsubishi UFJ Lease & Finance and Mitsubishi UFJ Nicos to manage real estate financing and the like and credit card services, respectively.

BTMU has it origins in the Bank of Tokyo-Mitsubishi (a 1996 merger between the Bank of Tokyo Ltd. (BOT) and the Mitsubishi Bank) and the UFJ Bank Ltd. (a 2002 merger between the Sanwa Bank Ltd. and the Tokai Bank Ltd.). In Japanese, the bank is called Mitsubishi Tokyo UFJ, indicating that Mitsubishi is the strongest entity, although BOT had become Japan's leading foreign exchange bank with 10 times as many foreign branches as domestic. BOT and Mitsubishi Bank both developed strong relationships with what became the Union Bank of California, now part of MUFG.

MUTB was created by a merger between the Mitsubishi Trust and Banking Corporation and the UFJ Trust Bank Ltd. The Mitsubishi Trust and Banking Corporation was formed as a result of a merger between Nippon Trust Bank Ltd. and Tokyo Trust Bank Ltd. The UFJ Trust Bank Ltd. was the name given to the former Toyo Trust and Banking Co. in 2002.

MUS is a result of a merger between Mitsubishi Securities Co., Ltd., and UFJ Tsubasa Securities Co., Ltd., the latter of which had become a wholly-owned subsidiary of UFJH in 2004. In 2002 Mitsubishi Securities Co., Ltd., was created through the merger of Tokyo-Mitsubishi Securities Co., Ltd., Tokyo-Mitsubishi Personal Securities Co., Ltd., Kokusai Securities Co., Ltd., and Issei Securities Co., Ltd.

MUFG positions itself as an integrated group transcending traditional business boundaries in three core business areas: retail, corporate (handled mainly by BTMU), trust assets, i.e., asset management (handled mainly by MUTB), and asset administration (handled mainly by MUS). The group targets expansion especially through the retail side through the provision of a global standard of services, products and advice, and excellence in security and compliance. Retail is essential to building the group's portfolio for sustained growth. In corporate, the group targets include positioning itself as a key financial services provider to large firms while being a lead bank for Japanese small and medium-sized companies. MUFG positions itself globally as one of the world's top five financial institutions. In trust assets, the group's target is to be number one in Japan in both size and quality of service.

Nobuo Kuroyanagi is the current president and chief executive officer of MUFG, beginning his banking career at the Mitsubishi Bank in 1965. Ryosuke Tamakoshi, who became chairman of MUFG at its establishment in 2005, was president and chief executive officer of UFJ Holdings Ltd., the successor of Sanwa Bank Ltd., where he began his career. Haruya Uehara, deputy chairman of MUFG and president of MUTB, began his banking career with the Mitsubishi Trust and Banking Corporation in 1969.

MUFG aims to be a global financial group, and has extended its overseas network to over 40 countries, ranking them first among Japanese banks. Their largest overseas subsidiary is the Union Bank of California. Mitsubishi UFJ Securities International (MUSI) was established in 1983 in England and Wales. In 1990 the BTMU Capital Corporation was created in London and Boston. Other MUFG subsidiaries are in the United States, the Netherlands, the Cayman Islands, and Canada.

Mitsui

Mitsui & Co., Ltd. (Mitsui), is a Japanese company with headquarters in Tokyo. Its main business areas are mineral resources and energy, global marketing, consumer services, and infrastructure; its workforce numbers 42,621 employees worldwide in 161 offices in 68 countries. As of March 31, 2008, it reported gross profits of 988.1 billion Japanese yen and net income of 410.06 billion Japanese yen.

Mitsui & Co., Ltd.'s main business units range from manufacturing and import/export to retail and financial services. Mitsui is currently diversifying in services, exploring for and developing natural resources, and developing new technologies and businesses. Mitsui's global network is organized to access essential strategic information and business engineering capabilities. "Comprehensive business engineering capabilities" as defined by Mitsui are real-time information on customers and markets; know-how and sophisticated specialties; trust among business associates worldwide; and problem-solving capabilities.

Dai-ichi Bussan was established in 1947 with JPY 195,000 in capital and 39 employees. The company took the name Mitsui & Co. (Mitsui Bussan in Japanese) in 1959 when it integrated with other trading companies, thereby returning to its Mitsui origins. Mitsui & Co. was originally the trading company arm of the pre–World War II business group known as the House of Mitsui (established in 1673), which was founded as a dry goods store called Echigoya (now the Mitsukoshi Department Store) in Nihonbashi, Tokyo, by Hachirobei Takatoshi Mitsui. Mitsui & Co. was seen as a model and had a major influence on other trading companies in Japan.

Mitsui & Co. has a long history in mining and mineral extraction and as a source of reputable international business information and services for firms entering new markets. During the 1960s when the Japanese economy was growing rapidly, Mitsui's trading and mining units helped meet the demand for foodstuffs, industrial raw materials, and energy such as oil and coal. The firm also worked to build efficient systems to manage raw materials from extraction to finished product. As Japan's—and the world's—markets have evolved, Mitsui has used its extensive international network to build new businesses in, e.g., training engineers, supplying skills and know-how, and developing high-technology networks and communications services. The firm's major projects are in mineral resources, liquid natural gas, oil, hydroelectric power, wind power, and automotive-related businesses. Mitsui is also actively developing infrastructure projects to access natural resources and/or to provide methods for transportation from source to customer.

Mitsui focuses on four main areas of business: mineral resources and energy; global marketing; consumer services; and infrastructure. The company has 121 major subsidiaries and associated companies worldwide, which serve a range of industries with operations spanning the globe.

Mitsui's subsidiaries and associated companies are distributed as follows: iron and steel products (8 companies); mineral and metal resources (13 companies); infrastructure projects (12 companies); motor vehicles (10 companies); marine and aerospace (3 companies); chemicals (19 companies); food and retail (11 companies); consumer services (18 companies); IT business (7 companies); financial markets (6 companies); transportation logistics (5 companies); and Americas (6 companies). In addition, there are other units working to develop new businesses regionally in the Asia-Pacific and in new industries.

In fiscal year 2007, Mitsui & Co. divested several energy and mineral (i.e., titanium) operations due to unfavorable market conditions. These gains offset the softening residential, energy, and steel products in the Americas units affected by the subprime mortgage crisis.

Led by Shoei Utsuda, president and chief executive officer, Mitsui & Co. issued in 2002 a corporate guideline for its employees called "Mitsui & Co. Aspirations." The aspirations comprise four concepts: serving customers' best interests; placing trust at the foundation of business; working in the spirit of "freedom and open-mindedness"; and being a truly global corporation. Mitsui's corporate mission is to "contribute to a future where the dreams of the inhabitants of our irreplaceable Earth can be fulfilled," and its vision is "to become a global business enabler that can meet the needs of our customers throughout the world."

Mittal Steel

The world's largest steel enterprise, Mittal Steel was established in 1976 by Lakshmi Narayan Mittal (1950–) in Kolkata, India. The richest person in Europe and fourth-richest in the world with net worth of $32 billion, the London-based Indian steel magnate Mittal had brought Mittal Steel to the forefront by his sound judgment and takeovers. A commerce graduate, Mittal joined the family steel business and was put in charge of the international division.

In 1976 he established Ispat Indo in Indonesia. Mittal went on an acquisition spree of steel plants around the world—Iron and Steel Company of Trinidad and Tobago (1989); Sicartsa, Mexico (1992); Sibalsa, Mexico (1992); Sidbec-Dosco, Canada (1994); and Hamburger Stahlwerke, Germany (1995). His business skill was evident in turning losing steel factories into profitable ones. Mittal Steel never hesitated to take risks. The government-owned Iscott steel plant of Trinidad and Tobago, which was incurring a loss of $1 million, doubled its output after Mittal Steel's takeover. Within a year, the state-owned steel plant of Kazakhstan began to produce double in 1996.

Mittal Steel moved its headquarters from Indonesia to London in 1995, and Kensington Palace Gardens became Mittal's residence. The capacity of Mittal Steel group had reached 11.2 million tons by this time. Mittal's Ispat International Ltd. was listed on the Amsterdam and New York stock exchanges in 1997. Before the end of the 20th century, the juggernaut of Mittal Steel marched ahead to acquire Inland Steel Company and Unimetal.

In the 21st century, its international expansion included takeover of Sidex steel plant (2001), Nowa Huta (2003), Polski Huty Stali (2004), and BH Steel (2004). Mittal's relationship with British prime minister Tony Blair (1953–) and the Labour Party came under media scrutiny. It was reported that Blair had interceded on behalf of Mittal Steel for the Sidex steel plant in Romania. Mittal had donated heavily to the Labour Party. Mittal Steel came into being through a merger of Ispat International and LNM (Lakshmi N. Mittal) holdings in 2004. Next year, the International Steel Group, Inc. (ISG), Ohio, merged with Mittal Steel, which made the latter the world's number one steel producer with a net worth of about $22 billion. In 2005 there was the acquisition of Kryvorizhstal steel plant in Ukraine for $4.8 billion. In his home country India, Mittal Steel had invested $9 billion in 2005 for constructing a steel plant in Jharkhand Province and the next year announced a plan to build a 12-million-ton-capacity steel plant in Orissa. The most controversial merger was with the European steel giant Arcelor SA, which dominated newspaper headlines for some time.

In 2006 Mittal Steel purchased Arcelor for $33 billion, which made it the world's largest 100-million-ton steel company with 10 percent of the total world steel output. Mittal became the president and chief executive officer (CEO) with a 43.6 percent stake. Arcelor Mittal's assets were spread among countries in Asia, Africa, Europe, and the Americas. Apart from the mainstream steel industry, Mittal Steel had diversified into shipping, coal, and power. It had also spent $980 million for a 50 percent stake in Caspian Investment Resources, the oil firm of Kazakhstan.

Mittal Steel has become the world's largest steel company with 320,000 employees in more than 60 countries and revenue of about $30 billion. It possesses steelmaking facilities in 27 nations spread over four continents. Mittal and his son, the Wharton-trained

Aditya, have remained the guiding spirits behind Mittal Steel's success, and they have put the company on the world map.

Buying up unprofitable public-sector steel plants and making them profitable has contributed considerably to the growth of Mittal Steel. The successive acquisition of steel enterprises from many parts of the world has made it a highly profitable enterprise. The steel production technique of Mittal Steel has put it far ahead of other steel companies. It has introduced direct reduced iron (DRI) as a source of raw material. The company has not used costly scrap materials for obtaining iron. With emphasis on research and development, Mittal Steel has not remained complacent in spite of its growing success. The future of Mittal Steel seems bright.

Mizuho Financial Group

The Mizuho Financial Group, Inc. (MHFG), established in 2003 with JPY 1.54 trillion in capital, is a bank holding company that engages in managing and operating banks, long-term credit banks, specialized securities companies, and other subsidiaries. As of March 31, 2008, (consolidated) it reported gross profits of JPY 1.661 trillion, net income of JPY 311.2 billion, and a net profit of JPY 511.1. billion. With headquarters in Tokyo, it counts 146 consolidated subsidiaries and 47,449 employees worldwide (2007). The word *mizuho* means a fresh harvest of rice, and when used in the phrase *mizuho country*, it means fruitful country, alluding poetically to Japan.

MHFG is currently organized into three main business groups (corporate, retail, and asset management) as part of the group's strategic plan called "Channel to Discovery." The Global Corporate Group accounts for approximately 51 percent of group profits and is handled by Mizuho Corporate Bank, Ltd. (MHCB), with Mizuho Securities Co., Ltd. (MHSC). The Global Retail Group, handled by Mizuho Bank, Ltd. (MHBK), accounts for approximately 37 percent of profits. The Global Asset and Wealth Management Group, accounting for around 10 percent of profits, is managed by Mizuho Trust and Banking Co., Ltd. (MHTB), Mizuho Private Wealth Management Co., Ltd. (established in 2005), and three other subsidiaries. Additionally, three affiliated firms manage group strategy: Mizuho Financial Strategy Co., Ltd.; Mizuho Research Institute, Ltd.; and Mizuho Information and Research Institute, Inc. In 2007, MHSC and Shinko Securities Co., Ltd., entered into a merger agreement, which will dissolve MHSC, with Shinko being the surviving entity, taking effect on May 7, 2009. The merger has been delayed due to the impact of the subprime mortgage crisis.

MHFG has its origins in Mizuho Holdings, Inc. (established in 2000), which was a result of a merger of Dai-ichi Kangyo Bank (DKB), Fuji Bank, and the Industrial Bank of Japan (IBJ). The trust bank and securities subsidiaries of these three banks were merged to form MHTB and MHSC, and two years later the banking activities were reorganized into MHCB and MHBK, when they became the principal subsidiaries of Mizuho Holdings. A year later, through a stock exchange, Mizuho Holdings became MHFG.

MHFG offers a wide range of financial services such as banking, securities, trust and asset management, credit card services, private banking services, and venture capital. MHBK boasts over 11,000 ATM machines and 515 branches throughout Japan, and offers retail services and support through asset management consulting and personal loans to individual customers. MHBK also offers services such as savings accounts, cash cards, international money transfers, credit cards, and internet banking. In 2004 the Mizuho Mileage Club was created to allow customers to accumulate points via banking transactions and credit card usage. Another new service is a "wallet phone" service with NTT DoCoMo called "iD," in which customers can use their mobile phones as credit cards.

MHCB offers merger and acquisition advisory services, various forms of securitization, pensions, and loan services. MHSC, a wholesale securities company focusing mainly on debt-related and equity-related business, provides financial products and services supporting investment banking, domestic and overseas institutional investors, financial institutions, and corporations. MHTB offers various trust services and banking services of deposits and loans to corporate clients.

MHFG has over 770 offices worldwide operating in banking, derivatives, securities, trust banking, and asset management. MHCB provides products and services to major corporations, financial institutions, and public-sector entities in the Americas, including New York, Chicago, Los Angeles, Houston, Atlanta, Toronto, Mexico City, São Paulo, and the Cayman Islands. In 2006 as part of its new slogan "Channel to Discovery," the MHCB expanded into developing markets in Asia by opening branches in New Delhi, India; Wuxi, China; and Ho Chi Minh City, Vietnam. The Mizuho Corporate Bank (China) was created the following year. Other growth has been in Thailand, South Korea, and Singapore as well as in Milan, Dubai, and Moscow. Mizuho Bank (Switzerland) and Mizuho Trust & Banking (Luxembourg) support the key world financial centers of Tokyo, London, and New York.

Terunobu Maeda, named president and chief executive officer (CEO) of MHFG in 2002, was previously the vice president of Fuji Bank. Other MHFG companies are currently led by Hiroshi Saito, president and CEO of MHCB; Seiji Sugiyama, president and CEO of MHBK; Keisuke Yokoo, president and CEO of MHSC; and Teruhiko Ikeda, chairman of MHTB.

Modernization Theory

Modernization theory refers to the development processes that developing countries—or traditional communities—employ in their adaptation processes to modern technologies, cultural and social change, and adjustment to regional or global economic disequilibrium. Recognizing the far-ranging implications of increasing social and regional inequalities in the wake of colonization and decolonization in the non-European world, developing countries and Western decolonization scholars pondered the practicalities of (1) emulating the European economic growth and modernization model in a bid to successfully improve local conditions, or (2) resisting Western-style modernization attempts in favor of implementing local non-Western-style development policies and practices that aimed to reduce colonial and economic dependencies.

Modernization theory as academic social scientific discourse was popular in the West from the late 1950s until the late 1960s with increasing industrialization describing progressive change in a postcolonial world. In the decades that followed, this approach experienced a backlash as local (or hybrid) approaches gained in popularity and a Western-style modernization model was questioned. However, hints of modernization theory can still be found in the approaches of many development theorists. The notion of modernization appears to have originated in Europe between the 13th and 18th centuries—a period often referred to as the Early Modern Period.

While Max Weber (1864–1920) understood modernization mainly as rationalization, modernization in the views of many also encompasses increasing numbers of participatory citizens, the transformation of societies from agriculture to industrialization, technological change, the relevance of science for progress, and the importance of progress per se. Modernization processes and areas of development also include education (alphabetization), urbanization, and diversity of media. The Modern Era—from the 18th century onward—was marked by industrialization (19th century) and globalization (20th century).

The seemingly desirable aim of the West to ensure societal progress toward modernity often legitimized Western "assistance" (from the "Word" spread by early proselytizing missionaries and the "developing efforts" of the colonizing power/s) and "aid" (financial and credit) programs designed to further the traditional societies' transition from agricultural to industrial nations. Such an approach at the same time implied a so-called backwardness or inferiority of these traditional societies—justifying the Western model as the only possible alternative. These processes of modernization are often understood as a universal development trajectory, starting with colonization and ending with decolonization. To this end, it was often the colonial power that introduced these "modern" or Western advancements.

Foreign aid such as that from the U.S. Agency for International Development has been a cornerstone of modernization efforts.

Due to the challenges these new technologies and knowledge have presented to the power and influence of local elites and the traditions of the local populations, the new ways have not always been enthusiastically welcomed. A further reason for this lack of enthusiasm was that on occasion the Western powers used force to change the traditional ways of the locals in order to (1) set the colonized country on a Western modernization course, and (2) direct (often exploit) the local resources according to the economic and strategic needs of the colonizers. Nonetheless, often in the face of unremitting local resistance, local elites and those interested in advancing in the colonized nations took advantage of these new learning, economic, and social opportunities, not only in the interests of personal development but also to minimize the perceived structural gap between the development level of their homeland and that of the colonizing nation.

One prominent proponent of embracing these new Western ideas and innovations as positive stimulation for his country's own culture and economy was Burma's (today's Myanmar) King Mindon (1808–78). In an attempt to modernize and reform his country, the king introduced and promoted Western technological innovations in this former colony of the British Empire. Similar developments could be observed in other colonized countries that had experienced or were experiencing the technological and military superiority of the foreign powers, the "modern" lifestyle, the enlightenment, the independence, and Western notions of democracy.

Some of the ideas introduced by colonizing powers were more welcome than others, given that they were not necessarily perceived as purely "Western." Prominent persons such as the first president of an independent India, Jawaharlal Nehru, for example, saw education as central to the successful development of a country. As such, these ideas and reforms were on the whole easier to implement in the social reforms of the developing countries. This represented a departure from a colonial mindset: Now there was recognition of the degree of empowerment that would enable the developing countries themselves to effect and control (social) change. Thus the colonizer's role often took the form of change agent in the independence movements of former colonized countries.

Failures and Alternatives

The failure of modernization theory in the late 20th century, palpable in the ongoing and persistent underdevelopment, poverty, and failure of many developing countries to catch up to—or participate in—the world economy, resulted in dependency theorists arguing that disequilibrium still existed. The genesis of the more contemporary disparities, so the argument goes, can be found in the ongoing exploration of developing nations by capitalist nations. Today, this is perpetuated not by military but by financial means, e.g., through credit and development aid. Apart from pernicious macrostructural problems, progress in the postcolonial world was also inhibited by diverse sociopolitical problems and erratic development stages: Africa faced huge economic challenges and debt with the introduction of democracy; in the Islamic world, Samuel Huntington's well-documented perceived "clash" between Eastern and Western values became apparent; east Asia experienced fluctuations of economic boom and financial decline; and Latin America saw the rise of new social movements, military regimes that had their own ideas about the direction and nature of modernization.

Concomitant with the trajectory of decolonization, the number of less developed countries (LDCs) grew. However, these newly independent nations were more heterogeneous than homogenous—economically, culturally, and politically. Some of these countries were resource-rich, others resource-poor. Any concept of presumed unity of these less developed countries, envisaged, for example, in the Bandung Conference (1955), remained utopian. In the decades following decolonization, some of these countries showed significant development, both economically and socially. Nonetheless, many LDCs continued to experience structural disadvantage, continued to be dependent upon their former colonizing power. Furthermore, often within the poorer countries the social and economic disparities continued to exist. In such cases, an economic divide between the rural and urban areas became evident.

Decolonization trends and development strategies are often linked with the term *modernization*, generally understood as a "world-historical transition toward progress." Modernization was first introduced mainly as a Western concept. However, soon the question of alternative models rose. The successful rise of many of Asia's emerging countries, and the role of Confucianism, for example, held great promise. It clearly demonstrated that the developing and developed countries do not necessarily experience the same sequence of modernization.

Monetary Intervention

Monetary intervention is the action of a government, especially outside the course of its ordinary activity, to influence the economy. Typically this involves changes to the interest rate and/or the money supply, in order to manipulate the economy's growth, the strength of the nation's currency, or inflation. Attitudes toward monetary intervention are key to a nation's monetary policy, and different forms of intervention are recommended (not always unanimously) for different economic malaises.

Expansionary intervention increases the money supply or lowers interest rates; contractionary intervention decreases the money supply or raises interest rates. When the goal is to reduce inflation, this is called tight monetary policy; if an interest rate is altered to stimulate economic growth, this is accomodative monetary policy.

Money Supply

Money supply refers to the total amount of money available in the national economy, and there are four different measures used. M0 is the amount of physical currency circulating in the economy—paper money and coins. M1 is M0 plus checking account deposits; M1 is the measure used most often when talking about the money supply with respect to monetary policy and intervention. M2 is M1 plus savings account deposits and time deposits (such as money market mutual funds) under $100,000.

M2 is generally useful as an inflation-forecasting economic indicator. M3 is M2 plus large time deposits (over $100,000), repurchase agreements, and liquid assets—the broadest category, the one that most meaningfully and inclusively measures "how much money there is." Though these definitions seem straightforward, deriving the values is no easy task, and there is often dispute among economists about exactly which methods to use and which money to count for M0–M2.

The money supply is contracted or expanded by manipulating the monetary base and the reserve requirements. Reserve requirements refer to the minimum amount that must be held in each bank's reserves—in the form of physical cash in the bank's vault and the bank's holdings in the central bank. Since banks vary in size, this requirement is expressed as a nonflat amount—for instance, 10 percent of transaction deposits, as in the United States.

In other countries, reserve requirements vary from 2 percent (in the Eurozone) to 80 percent (in Jordan). Reserve requirements affect the amount of money a bank can lend out; in a system with a 10 percent reserve requirement, an initial $10 deposit can be expanded to as much as $100. These days, reserve requirements are not changed frequently, and never without significant advance notice; even a moderate change would cause liquidity problems.

A more common way of impacting the money supply these days is through open market operations—the buying and selling of government-issued financial instruments, precious metals (almost exclusively gold), and foreign currency. There was a time when increasing the money supply required printing more money; these days, in the United States for example, only a twentieth of the money supply exists in the physical form of paper currency or coins. When the government sells bonds, currency, or gold to banks, the money the banks use to make the purchase can be removed from circulation, contracting the money supply; when they buy such instruments, the money supply is increased. These operations have been possible only since the abandonment of the gold standard. Open market operations were a prominent feature of monetary policy under Paul Volcker, the chairman of the Fed from 1979 to 1987, whose policies begun under the Carter administration and continued through the Reagan administration were instrumental in pulling the country out of the economic slump of the 1970s' stagflation.

Since the 1990s, the Fed has become more likely to target interest rates rather than the money supply. Economists like Robert Mundell argue that you cannot target both interest rates and foreign currency exchange rates at the same time, and policy has generally followed this belief, at least in the United States.

Monetary Policy: Rules Versus Discretion

Under a classical gold standard, there is little need for a central bank other than to provide coordination to the payments system. The value of money is determined by the supply of and the demand for gold. Thus the classical gold standard is the ultimate form of a policy rule. By contrast, in a system of fiat money, the value of money in the long run is determined by the rate at which the central bank allows the supply of money to grow. The debate over rules versus discretion is concerned with the question of what constraints should be placed on the central bank when determining monetary policy. Those in favor of policy rules seek to limit the scope of central bank actions and pursue long-run price stability alone. Advocates of discretion argue that central banks must be flexible and respond to short-run fluctuations in both prices and output.

Advocacy for monetary policy rules is rooted in the classical liberal thought of the "Chicago School." Just two decades after the founding of the Federal Reserve System, and just three years after the United States left the gold standard, University of Chicago economist Henry Simons voiced reservations about handing over control of the money supply to a discretionary central bank. Less than three decades later, the advocacy of rules found its strongest proponent, Milton Friedman. Friedman frequently argued for a fixed growth rate for the money supply, contending that policy makers do not have enough knowledge about the way the economy works to be able to fine-tune it effectively. Faced with long and variable lags between the implementation of policy and its final effect, Friedman called for a focus on long-run price stability, which is achieved through stable money growth.

Economic Theory

Theoretical justification for the rules-based approach came from advances in economics in the 1970s when Finn Kydland and Edward Prescott published their seminal work on the "time consistency problem." Kydland and Prescott showed that if the central bank does not have the ability to commit to the optimal long-run policy (low inflation), they will sacrifice price stability for a short-run increase in output. Policy rules give the central bank the ability to commit to a course of action ahead of time and then follow it, even if future policy makers may want to deviate from it. Without rules, future policy makers will deviate from any previously announced path when it suits their short-run objectives. The resulting discretionary outcome is suboptimal. Kydland and Prescott's theoretical work has spawned a vast literature on the time consistency problem as applied to monetary policy and central bank independence. The hypothesis being that central banks that are more independent from the political process are more able to commit to long-run objectives and are more likely to foster low-inflation environments.

In the years that followed, John Taylor developed the notion of "feedback rules." Feedback rules allow for a more activist monetary policy than Friedman's constant money growth rule. The "Taylor Rule," as it is known, allows the policy maker's choice of interest rate to be influenced by the departure of inflation from its target and the departure of output from its natural rate. Though named a rule, it incorporates discretion in the form of the choice of inflation target and sensitivity to output deviations.

Recent Developments

Most central banks recognize the importance of long-run policy objectives, especially under normal circumstances. Yet resistance to explicit policy rules remains, in part due to the perceived need for flexibility in times of crisis. As the international financial markets experienced a large number of institutional failures in 2007 and 2008, the Federal Reserve took a proactive discretionary approach to managing the crisis. This approach was seen by many, though not all, policy makers as necessary to prevent systemic failure and reduce the likelihood of a severe recession. Many academic economists would have favored a less discretionary approach, citing the uncertainty over the short-run effectiveness of the intervention and its long-run cost. The debate over rules versus discretion remains an active topic in both academic and policy discussions.

Monetary Union

A monetary union is defined in general as two or more otherwise independent states joining together to share a common currency. Traditionally, sovereign states have issued their own currencies for both domestic and international exchange. Nevertheless, in the past, countries have elected to join together in some sort of monetary union. There were repeated attempts to establish monetary unions in Europe during the 19th century.

There are two broad classifications of monetary unions. In a "shared" type of union, the members are part of a de facto equal partnership in that each relinquish their own currencies for a single joint currency and they share authority in decisions affecting the union's monetary affairs. In the case of a "surrendered" union, the partnership is fundamentally unequal, with the subordinate partner(s) agreeing to convert their own currencies for that of the dominant member. In this case, the latter country tends to dominate in decisions affecting monetary matters for the group.

It is generally true that realization of a monetary union is a major step in the evolution toward, although it in no way implies the preexistence of, a full political union. Typically, however, states that come into a monetary union have already achieved the status of a common market, although there is no requirement that this be the case.

The most significant advantages of a monetary union include (1) elimination of currency exchange transaction costs, thus reducing the costs of doing business internationally; (2) removal of currency volatility and thus currency exchange risks for companies operating in the member countries because there is a single currency in which to conduct business; (3) greater competition because of the greater transparency in comparing prices of different products and services across the union, and thus greater efficiencies and lower prices; and (4) financial economies of scale due to the creation of a single currency capital pool for members to use in common, thus allowing all members expanded opportunities to access a greater volume of cheaper capital as well as a wider range of investment options.

An important disadvantage of a monetary union is that national governments sacrifice control over monetary policy and thus the leverage to act unilaterally to deal with their particular country's financial crises. This is a particularly critical problem if the members making up the union do not constitute an optimal currency area, i.e., the underlying structure of economic and financial activity within each country is unique and significantly different from one another. In this case, monetary policy conducted by the union's central bank may help one member while damaging the economies of others. Lowering interest rates may help boost a stagnating economy but, at the same time, is just as likely to overheat an already growing country.

Money Laundering

Money laundering is a process whereby one or more financial transactions are carried out in order to disguise or conceal the identity behind, the source of, and/or the destination of money. Usually this is undertaken to obscure connections with crime, and also to prevent payment of taxation, although the latter is generally a lesser objective; much laundering does take place through legitimate companies, and as a result, launderers incur tax bills.

There are many examples of money laundering in history, especially in the Early Modern Period when gold and silver ingots were being replaced in most large transactions by coins. When Elizabeth I was asked for money to pay for the "Northern Lords" who were fighting Mary, Queen of Scots, she ordered Lord Burghley to pay them in coins excepting those that had her head on them to obscure her involvement in an attempt to overthrow her cousin. During the American Civil War, the Confederates often had to disguise the payments being made to agents overseas, especially with payment for the manufacture of the CSS *Alabama*. The decrease in the use of cash and the increase in the amount of banking transactions made money laundering harder to some extent, but it rapidly took the form of "shell companies," many of which were located in tax havens or countries with strict laws against disclosure, such as Switzerland.

During Prohibition in the United States in the 1920s, with vast profits being made from the illegal sale of alcohol, it was necessary to disguise the source of income. Accountants established companies that transferred funds back and forth, working through a number of private shell companies, a number of holding companies, and making heavy use of "offshore" bank accounts. Although Switzerland, Liechtenstein, and Luxembourg became places for money to be stored and/or laundered, a number of legal jurisdictions also encouraged this, with British companies and individuals using the Channel Islands (Jersey and Guernsey) and the emergence of extensive banking industries in a number of Caribbean island groups such as the Bahamas, the British Virgin Islands, and the Cayman Islands.

Gangsters Al Capone and Meyer Lansky became associated with money laundering in the press, but the word was first coined by the British newspaper *The Guardian* when, in the run-up to the 1972 election campaign, U.S. President Richard Nixon's Committee to Re-elect the President (CREEP) was involved in transferring illegal campaign contributions to Mexico and then bringing them back to the United States through a company operating in Miami. The money that is to be laundered became known as "dirty money," and the final money, after it has been laundered, is known as "clean money."

To try to restrict money laundering in the United States, any "significant cash transaction" has to be reported by banks to the Financial Crimes Enforcement Network, along with any suspicious activities. This is done primarily to prevent the evasion of income taxes and other forms of taxation. This involves the authorities then checking on the payment of large amounts of cash into any bank account. To prevent unnecessary investigations into businesses that generate large amounts of coins each week, such as shops, some businesses can obtain a license to allow them to deposit cash. As a result some money laundering involves bringing money from illegal sources and paying it into an account of a legitimate cash business. This, obviously, means that income tax will have to be paid. In fact, one of the main means of money laundering is through using an existing legitimate business.

Other methods of money laundering are using cash obtained from illegal sources to buy gold coins, diamonds, gold, real estate, works of art, expensive postage stamps, and the like that are, at a later stage, sold to realize the money. This can work for a small number of transactions, but is not convenient for regular laundering. Another common method of money laundering involves using a casino—somebody uses the money to be laundered to buy casino chips and then cashes them in for a check from the casino, claiming that the money represents winnings.

More sophisticated forms of money laundering involve establishing companies specifically to launder money and then using them to transfer money back and forth between countries. If a government or tax authority is trying to investigate, the money launderer relies on the fact that one of the links in the chain will remain secret. Gradually, more and more countries have had to provide better regulation for their banking sector, and this has forced people to "park" what is known as "dirty money" or "hot money." With the new homeland security programs introduced after September 11, 2001, the United States and other allied governments have massively increased the requirements for reporting international transactions to allow them to keep track of suspicious transactions.

Money Supply

Money supply is the amount of money available for use in transactions. Money is an asset that is accepted by others as a medium of exchange for goods and services. Today, money in most countries is "fiat" money—money that has no commodity value and is legal tender by government decree. Goods and services are priced in terms of money, and money can be earned and used as a store of purchasing power and wealth. Globally the money supply is measured in a variety of ways, but most central banks consider the liquidity of assets—how easily an asset can be converted and used as money—when defining the money supply for the purpose of conducting policy.

Most central banks define the money supply using aggregates that vary from very narrow measures of the money supply to broad measures. These measures often have a name beginning with "M" and are usually defined based on the liquidity of the assets included. For example, the Bank of England uses M0 as their narrow definition of (most liquid) money. M0 includes notes and coin in circulation plus bank deposits with the Bank of England. In the United States, this narrow definition of money, currency plus bank reserves on deposit at the Federal Reserve Bank, is called the monetary base, or "high-powered money." The next most liquid definition of money in the United States is M1, or currency held by the public plus checkable deposits at banks and travelers' checks. Intermediate measures of money include assets that are less liquid, yet are easily converted to cash, such as various forms of savings and time deposits.

Central banks differ in their assessments of liquidity, based on who issues the asset, who holds the asset, how large the asset is, and how long the asset is held. This makes comparisons of monetary aggregates across countries difficult. For example, M2 in the United States includes all of M1 plus savings deposits, small-denomination time deposits, individually held money market mutual funds, overnight Eurodollars, and repurchase agreements. However, M2 in the European Economic and Monetary Union (EMU) is calculated by including M1 plus short-term savings and time deposits.

The Federal Reserve Bank in the United States no longer tracks M3, an even broader aggregate of the money supply focusing primarily on money held for its store of value; however, forms of M3 are measured in other countries such as the EMU, Canada, Japan, Mexico, and Korea. The Bank of England uses M4, one of the broadest measures of money, as one of its major monetary aggregates on which it bases monetary policy.

Measuring the money supply is important for central banks in the conduct of monetary policy. The money supply and its growth rate are key factors in determining an economy's rate of inflation and short-term economic growth. A central bank influences the money supply when it prints money or increases bank reserves—most commonly through either the purchase of government securities or through low-interest loans to banks, which, in turn, create money by extending loans to consumers. Too much money creation leads to higher levels of inflation; too little can lead to economic recession. This is summarized in the oft-cited equation of exchange:

$$\%\ \textit{change in } M + \%\ \textit{change in } V = \%\ \textit{change in } P + \%\ \textit{change in } Y$$

where the *% change in M* is the growth of the money supply, *% change in V* is the rate of change in the money supply's velocity (number of times a unit of currency is used to conduct transactions), *% change in P* is inflation, and *% change in Y* is economic growth. Many theories of money assume that velocity is relatively stable, such that *% change in V* = 0. If we also assume that economic growth tends toward a specific and stable growth rate, then variations in the growth rate of the money supply above or below that growth rate show up predominantly through changes in inflation. Nobel Prize–winning economist Milton Friedman is often quoted for his assertion that "inflation is always and everywhere a monetary phenomenon."

As reported in *The Economist* (August 11, 2007), it is usually common belief that central banks in the most developed countries control most of the world's money supply growth. However, recent data show that three-fifths of the growth in the world's money supply has come from emerging economies such as China, India, and Russia. Emerging economies have increased the growth rates of their money supplies by an average of 21 percent—almost three times the growth rates in developed economies. While the impact on developed economies of this growth (along with increasing global financial market integration) may not yet be fully understood, it is forcing central banks in developed countries to rethink the conduct of monetary policy.

Monochronic/Polychronic

Monochronic and *polychronic* are terms coined by American anthropologist Edward T. Hall to describe how cultures and societies differ in their perceptions of time.

In polychronic societies, people perform several activities simultaneously and take a fluid approach to scheduling time. To polychrons (or people from polychronic cultures), time is continuous and has no particular structure. It resembles a never-ending river, flowing from the infinite past, through the present, and into the infinite future. According to Raymond Cohen, polychronic cultures have all the time in the world; the clock face has very little importance in societies where perceptions of time are determined by the cycle of the seasons, the unchanging patterns of rural life, and the calendar of religious festivities.

Arabic, African, Latin American, and southeast Asian countries are commonly described as polychronic cultures. The Indonesians, for example, have the expression *jam karet* (or "rubber time"), meaning that deadlines, schedules, and agendas are flexible and stretchable. Many traditional Arabs believe it is impious and irreligious to attempt to see into the future. God, not man, is in charge of what will happen. The Arabic term *Insh'allah* (or "God willing") conveys this belief.

By contrast, monochrons prefer to do one thing at a time. The ideal is to focus their attention solely on one activity, complete that activity, and then move on to the next. In a monochronic culture, time is considered to be discrete rather than continuous. It can be divided up into fixed segments—seconds, minutes, hours, days, weeks, years, and so on—and scheduled, organized, and managed. Monochrons see time as something that is almost tangible: They talk about time as if it were money, as something that can be "spent," "saved," "wasted," or "lost."

The countries of North America and northern Europe are generally considered to have a predominantly monochronic sense of time. In the United Kingdom, monochronic perceptions of time have been described as a legacy of the Industrial Revolution: factory life required the labor force to be on hand and in place at an appointed hour. In the monochronic United States, a great majority of people have grown up in a time system that uses whistles or bells to count off the hours of the day. It is perhaps no surprise that techniques for "time management" were developed in the United States.

Business Implications

The workplace provides a fruitful environment for observing differences in polychronic and monochronic senses of time. Polychrons will typically never arrive at work at the same time every day, preferring instead the flexibility of keeping their daily routines unstructured. Similarly, they do not like to have detailed work schedules or project plans imposed on them, nor do they like to draw up their own schedules. Polychrons shun deadlines in favor of completing projects in their way, and in their own time. They also find dividing their time between a number of ongoing projects to be both stimulating and productive, and thus the most desirable way to work. Since they are capable of easily switching their attention from one activity to another, the polychrons are typically the colleagues seen simultaneously e-mailing, phoning, and eating in important business meetings.

In contrast to polychrons, monochrons prefer to plan and structure their workloads in detail. They tend to start work at the same time each day, and make lists to monitor the tasks that they need to complete on a daily basis in order to meet fixed targets and deadlines. Whenever projects consist of several individual tasks, they prefer to focus on one at a time. Only when one task is complete will they move on to the next. For a monochron, dividing attention back and forth from one activity to another is wasteful use of scarce resources, distracting, and above all else uncomfortable: in the workplace, monochrons are therefore more likely than polychrons to turn down any additional, unanticipated work and may appear uncooperative in crisis situations.

These differences between monochronic and polychronic perceptions of time can and do lead to cultural misunderstandings and conflicts in international business. The scheduling of meetings provides a case in point. If, for example, two American and Brazilian business partners agree to start a meeting at 2 P.M., the American would most likely arrive at the designated meeting place in advance of the agreed meeting time: after all, his time is money. The Brazilian, however, would think nothing of arriving late: he may have to finish off an unplanned business lunch with a colleague, or drop by his office to check his e-mail, before starting the meeting. The American would most likely be extremely frustrated by the Brazilian's late arrival; for his part, the Brazilian would be offended by the American's insistence on punctuality or on getting right down to business.

Similarly, time-management systems do not transfer well between one culture and another. Traditional time-management programs are monochronic insofar as they emphasize to-do lists and careful scheduling. Research shows, however, that businesses in a polychronic society either reject or do not adjust well to such systems. Multinational companies that impose these monochronic systems on their subsidiaries in polychronic societies are often accused of being ethnocentric, which means that they impose their own ethnic or cultural values on others.

Critiques

As much as Hall's concepts of monochronic versus polychronic perceptions of time are relatively easy to understand, they have nonetheless been challenged by some critics. Some detractors claim that, although Hall's concepts are very useful for understanding different attitudes toward time, they are not backed up by empirical data. Others argue that the distinction between monochronic and polychronic perceptions of time is overly generalized. They counter that, within any one cultural group, or within any single country, it is possible to identify people who think differently about time. In China, for example, the inhabitants of the industrialized, southern provinces are said to have a monochronic perception of time while those living in the less industrially developed interior are considered to be more polychronic. Consequently, claim these critics, it is more useful to think of time differences among individuals, not just between cultural groups or countries.

Other critics argue that research based on Hall's dichotomy is value laden, concealing the assumption that there is only one correct way of understanding time. For example, researchers from monochronic cultures have criticized polychronic time systems for "forcing" people to tolerate interruptions and combine tasks that could be performed more effectively if done separately. Conversely, researchers from polychronic cultures have criticized monochronic time systems for their inefficiency, inflexibility, and sluggishness. In reality, argue the critics, there is neither a right nor a wrong way to think about time; there are just different ways of doing so, and each one has its own distinct strengths and weaknesses.

Monopolistic Advantage Theory

Monopolistic advantage theory, first proposed by S. H. Hymer in his doctoral thesis and later expanded by C. P. Kindleberger, explains the reasons multinational corporations (MNCs) are able to compete successfully against local firms. It is a microeconomic theory that makes the firm the center, as well as the cause, of the international movement of capital and goods.

The monopolistic advantage theory elucidates why firms choose to internationalize their operations. Typically, MNCs are at a disadvantage compared to local firms because they have to cope with liabilities of foreignness, lack of local know-how, high cost of acquiring this knowledge in other countries, etc. However, these costs are offset by the existence of certain "monopolistic" advantages possessed by the MNC. Deploying these advantages abroad allows the MNC to glean profits that are not easily accessible to local firms and helps them attain success in international arenas.

Foreign direct investment (FDI) is an equity-based mode of international entry wherein physical investments are made by one company to build a factory in a different country, and also includes the acquisition of lasting interest in firms across national borders. FDI confers ownership rights and control over the foreign affiliate to the multinational firm. Specifically, they choose to enter international markets via FDI in order to capitalize on one or more unique monopolistic advantages that they possess. These advantages may arise from superiority in technological innovation, manufacturing processes, brand names, knowledge, patents, scale economies, or marketing skills in comparison to local firms. The advantages do not arise from location of production, but are specific to the firm. Further, they are owned by the firm and cannot be purchased by local competitors in the open market.

Under conditions of perfect competition, local firms would stand to benefit in two ways. First, they would be able to leverage inherent locational advantages such as physical proximity, favorable consumers, government protection, familiarity with rules, etc. Second, due to the efficient resource allocation situation, they would be able to buy technology or other advantages from the MNC. As a result, possessing these advantages would confer no special benefits or profits to competing multinational firms.

It is important to note that monopolistic advantage theory breaks away from the assumptions of perfect competition that existed in classical economic capital flow theory. Instead, it acknowledges the existence of market imperfections for the factors of production (land, labor, capital, management, proprietary knowledge, etc.) that tend to create barriers to competition from local firms. Due to the existence of these market imperfections, the advantages possessed by multinational firms cannot easily be purchased by local firms, creating quasi-monopolies. Under such conditions, foreign direct investment by MNCs is extremely lucrative, as it provides control over resources in foreign locations and a level of monopoly power vis-à-vis local competitors. Consequently, MNCs are able to acquire monopolistic rents and profits that exceed the costs and disadvantages of competing internationally.

The advantages possessed by foreign firms must satisfy the condition of relatively easy international transferability with minimal incremental cost to the firm. Hence they should be able to be deployed abroad without much adaptation or significant additional expense to the multinational firm. Common examples are the advantages that arise from technological patents, which can be leveraged across borders to recover sunk costs of investment in research and development and to gain profits from such firm-specific knowledge. By exploiting their monopolistic advantages through FDI, multinational firms are able to achieve far superior rents than if they remained in their domestic nation.

Criticisms

Some of the major criticisms of the theory are that it fails to address how the monopolistic advantages occur, that it is static in nature, and that it assumes a large firm going international for the first time. Also, the use of the term *monopolistic* to describe firm advantages may be inaccurate. The advantages can occur from greater efficiencies and hence may be "Ricardian" in nature, as they represent returns that are in excess of the opportunity costs involved.

The theory may not be well suited to explain the activities of entrepreneurial firms or firms in emerging markets as they may not initially possess the monopolistic advantages that allow them to succeed in international markets. New ventures often develop monopolistic advantages after going abroad. The theory also does not explain why FDI will always be the preferred choice of market entry for multinational firms, or why several firms with the same monopolistic advantage may not choose to internationalize identically.

Regardless, the basic logic of monopolistic advantage theory and firm-specific advantages resonates well with later theories such as the resource-based view, and Michael Porter's theory of competitive advantage, and provides explanations for the existence of FDI by multinational corporations.

Morgan Stanley

Morgan Stanley is a U.S. investment banking and global financial services provider. Its clients and customers include corporations, governments, financial institutions, and individuals. The corporation's headquarters is in New York City. Morgan Stanley has about 600 offices in 33 countries and approximately 45,000 employees around the world (2008). The company manages assets worth about US$749 billion (2008).

Morgan Stanley has three main business. First, the institutional securities segment provides services such as capital raising; financial advisory services on mergers and acquisitions, leveraged buyouts, real estate and project finance; corporate lending; sales, trading, financing on securities, and futures exchanges; equity and proprietary trading; benchmark indices and risk management; research; and investment. Second, the global wealth management group provides brokerage and investment advisory services such as financial and wealth planning services; banking and cash management services; retirement services; and trust and fiduciary services. This segment targets high–net worth individuals and hedge funds. Third, the asset management segment provides products and services in equity, fixed income, and alternative investments, such as hedge funds, real estate, private equity, and infrastructure to institutional and retail clients. This segment targets institutional investors.

Morgan Stanley originated from J. P. Morgan & Co. In 1933, according to the Glass-Steagall Act, J. P. Morgan & Co. could not have investment banking and retail banking businesses under a single holding entity. J. P. Morgan & Co. decided to continue its retail banking business. Two former J. P. Morgan & Co. employees—Henry S. Morgan and Harold Stanley—and some others from the Drexel partners founded Morgan Stanley. The firm began its business on September 16, 1935, on Wall Street in New York City. In 1936, Morgan Stanley managed public offerings and private placement with US$1.1 billion—equal to 24 percent market share at that time. In 1942 Morgan Stanley joined the New York Stock Exchange.

During 1951–61, the last founder, Parry Hall, led Morgan Stanley in steady growth. The firm also led the General Motors US$300-million debt issue, US$231-million IBM stock offering, and the US$250-million AT&T debt offering in the 1950s.

In 1962 Morgan Stanley created the first viable computer model for financial analysis. In 1967 it set up Morgan & Cie, International in Paris to enter the European securities market. It acquired Brooks, Harvey & Co., Inc., in 1967 and established a presence in the real estate business.

In 1971, Bob Baldwin helped Morgan Stanley to establish the sales and trading business. In 1970 Morgan Stanley set up its first representative office in Tokyo. Four years later Morgan Stanley International, Inc., was established in London. In 1977 Morgan Stanley added Morgan Stanley Realty, Inc., and the private wealth management department into its business. At the same time, Morgan Stanley merged with Shuman, Agnew & Co. to enter the retail stock brokerage business.

On December 12, 1980, Morgan Stanley led the US$110-million Apple common stock initial public offering (IPO), the largest IPO since 1964. In 1986, Morgan Stanley Group, Inc., became a publicly listed company on the New York Stock Exchange. By the end of 1989, Morgan Stanley not only had set up regional offices in Frankfurt, Hong Kong, Luxembourg, Melbourne, Milan, Sydney, and Zurich but also had regional headquarters in London and Tokyo.

On February 5, 1997, merging with Dean Witter Reynolds and Discover & Co., Morgan Stanley Group, Inc., became Morgan Stanley Dean Witter Discover & Co., which is a global market leader in securities, asset management, and credit services. During the 1990s, Morgan Stanley expanded internationally and had offices in Amsterdam, Beijing, Buenos Aires, Geneva, Glasgow, Johannesburg, Madrid, Mexico City, Moscow, Mumbai, Paris, São Paulo, Seoul, Shanghai, Singapore, Stockholm, and Taipei. In 2001 the firm dropped Dean Witter from its name and became Morgan Stanley again.

In 2004 Morgan Stanley comanaged the US$19-billion Google IPO—the largest internet IPO and largest auction-based IPO in the United States. In 2005 Morgan Stanley advised the largest Chinese IPO—China Construction Bank—with US$9.2 billion. In July 2006 Morgan Stanley helped the largest IPO in the firm's history—Russia's largest oil and gas company OJSC OC Rosneft with US$10.4 billion. To cope with the subprime mortgage crisis, Morgan Stanley announced on December 19, 2007, that China Investment Corporation would infuse US$5 billion capital for exchanging those securities, convertible to 9.9 percent of its shares in 2010.

Morocco

Morocco is one of the fastest-growing emerging markets in Africa. It is rapidly expanding, developing, and opening up opportunities for businesses. Morocco is strategically located in northwest Africa and is less than 15 km. away from Spain. It boasts a range of climates and geographical features from Atlantic and Mediterranean coastal lands on the north and west through the Atlas Mountains and fertile valleys in the heartland and continuing on to the Sahara Desert in the south and east. Arabic is Morocco's official language, but French is widely spoken in business contexts.

Since its independence from France in 1956, political reforms have resulted in the establishment of a bicameral legislature in 1997: the Chamber of Counselors and the Chamber of Representatives. King Mohammad VI has been the king of Morocco since 1999 and has provided a strategic vision for the development of the country—socially and commercially. For example, Morocco is following the social trends of the West, such as equal rights for women. Commercially, government policies and business practices have joined forces to become competitive in the global marketplace.

Current Economic Development

In 2004 Morocco and the United States signed a free trade agreement to develop commercial links between the countries. As a result, an increasing number of businesspeople began to capitalize on the agreement. Soon, Morocco received the attention of tourists. Now the government plans—through the implementation of the strategic plan called Vision 2010—to create jobs and increase tourism to boost the economy. This strategic plan is designed to develop vacation property and to encourage the growth of Morocco's tourism industry, among others. Under the plan, the government hopes to create 600,000 new jobs and reach 10 million visitors in 2010. In fact, since the launch of the plan in 2001, more than 20,000 new hotel beds have already been created and thousands more are to be renovated. It is expected that by 2010, Morocco will have more than 250,000 hotel beds, including 180,000 located in and around the cities.

Similarly, the popularity of the Moroccan property market has increased significantly in the last few years due to its low price and high demand. Property investors, however, need to conduct thorough due diligence on all possible real estate purchases to ensure that they are legitimate before proceeding, because property developers may be so eager to cash in on Morocco's promising market that they may not follow all the necessary regulations or have the required government permissions.

The new favorable political environment has made the climate conducive to conducting businesses, resulting in massive foreign direct investment such as development of hotels, high-rise buildings, offices, and airports, among others. Furthermore, building a tunnel between Spain and Tangiers is also on the horizon. Morocco is poised to become the Dubai of north Africa in the next five years.

A swimming pool at a hotel development in Morocco, which is expected to have more than 250,000 hotel beds by 2010.

Future Economic Development

Morocco's proximity to Spain and relatively high proportion of university graduates who have knowledge of French as a second language gives Morocco the potential for becoming a powerful offshore center for French- and Spanish-speaking countries. Partnering with a leading provider of outsourcing services may help in this regard, as it reduces costs and improves business performance significantly. It is expected that from 2003 to 2018, business process off-shoring in Morocco could add 0.3 percent annually to its GDP growth, reduce its international trade deficit by around 35 percent, and create a total of some 100,000 new jobs. Morocco's unique educated workforce and its geographical position make it an ideal center for services, manufacturing, distribution, call centers, and an array of information technology (IT) services reaching the European Union; west, central, and north Africa; the Middle East; and eastern Europe. However, Morocco's need for industrial development is immediate. Without a proactive industrial-development policy, it is likely that Morocco's employment level will stagnate, its trade deficit will increase, and its economy will grow less than half the expected rate.

Mortgage Credit Crisis of 2008

The mortgage and credit crisis of 2008 is a financial crisis that originated in the United States but contributed to the global economic crisis of 2007–09, and has its most direct origins in the housing bubble and the disastrous consequences of irresponsible subprime lending. Though not solely complicit in the larger economic crisis—which also involves a fuel crisis, the bailout of the American automobile industry, and erratic commodity prices worldwide—the subprime mortgage panic is nearly synonymous with it in the minds and mouths of the public, due to its scope, the clear involvement of human error, and the consequent havoc wreaked on the American finance industry.

The Housing Bubble

The United States housing bubble affected much of the American housing market, especially California, Florida, and the northeast and southwest. Prices peaked in 2005, began to decline in the following year, and as of 2009 were continuing to decline in most markets. As with the dotcom bubble several years earlier, what seems a very obvious inflated peak and inevitable drop in hindsight was not at all clear at the time, and historical perspective has not yet detailed all of the factors or causative nooks and crannies of the event. Though some economists and industry publications had warned of the likelihood of the bubble and of overvaluation of property, former Fed chairman Alan Greenspan, for one, admitted to not recognizing the phenomenon until a year after the peak. In hindsight, what could have seemed like alarmism or overcautiousness at the time—like warnings within Freddie Mac as early as 2003, and at the Federal Reserve in 2001, that subprime mortgages were burdening institutions with too much high-risk debt—seems prophetic now.

It is not clear whether the bubble was fully a national phenomenon or a number of local bubbles, though in Greenspan's words, "all the froth bubbles add up to an aggregate bubble," making the distinction less than critical except perhaps in some discussions of causation. Some areas of the country—the southeast, for instance—certainly saw less growth in housing prices than areas like Tampa, Phoenix, and San Diego, where prices appreciated more than 80 percent from 2001 to 2006. The effects of the bubble's collapse, though, have been more uniform, and foreclosure rates in the low-growth areas have been nearer to those of the high-growth markets. Of the largest metropolitan areas in the United States, only Milwaukee has seen housing prices increase since 2007.

There are a number of contributing causes to the housing bubble, and again, their exact mixture is not yet a matter of historical consensus, but their presence is generally agreed upon. There is, for one, a characteristically American ambition toward home ownership, which is coupled with other accessories in the American Dream, and which tends no longer to involve the multigenerational residence in a family home. Each new generation needs a home of its own, in other words; sons no longer bring wives home, with two or three or even four generations sharing a living space, not even to the limited extent to which that once was true. Many of the subprime borrowers significantly worsened their financial hand with a home purchase, but their perception of their financial health was much the better, because of the cachet of owning one's home. Home ownership remained about the same in the United States from 1980 to 1994, at 64 percent, and then gained more than 5 percent in the next 10 years to peak at 69.2 percent in 2004, shortly before the housing price peak. Mortgage fraud increased by nearly 1,500 percent in that same period. Those two figures alone are sufficient to raise concern.

There is a longstanding belief in the United States that a home is a more stable, risk-free, and responsible investment than nearly any alternative—that housing prices not only won't fall, but will yield greater than average returns. Part of that is based only on the fact that stock prices are tracked in real time, making fluctuations obvious, while houses are valued annually. Part of it is due to the fact, widely spread by realtors, that American housing values as a whole have risen since the 1930s. There is a practical aspect as well. The interest on a mortgage provides a greater tax break than anything available to renters, and the principal paid provides equity in a form renters do not have. But local and regional housing prices have always experienced volatility, and while it is possible to own only a little stock, only a few bonds, or to put only a small portion of one's assets into a mutual fund, a home mortgage is a significant and burdensome long-term debt. Homeowners generally pay much more per month than renters do, even without accounting for possible maintenance and property taxes: the national median mortgage payment ($1,687) is nearly twice the median rent ($868), and the rapid rise of housing values hurt both mortgaged homeowners and landlords, as in many parts of the country, landlords found themselves paying a mortgage that their collected rents did not cover.

Over the long term, home ownership as an investment barely beats the rate of inflation, when you account for the expense of upkeep and property taxes. But the perception of its worth as an investment is so strong that it may have accounted for the difficulty in perceiving the existence of the housing bubble.

Further, the housing bubble and attendant mortgage and credit crisis is the first major economic crisis in which reality TV can be implicated. In 2005 and 2006—during the price peak—there were a number of television shows promoting "real estate flipping." Primarily an American activity, real estate flipping is the purchase and rapid resale of a property for profit, usually with some improvements done on the property before resale. Skillful flipping could involve an understanding of the psychology of buyers, and the ways to maximize the resulting profits of the money put into those improvements. The collapse of a flipping-driven housing bubble in Florida in the 1920s led to the depopulation of new cities and the abandonment of numerous housing developments, which when combined with the effect on the citrus industry of the introduction of the Mediterranean fruit fly devastated Florida's economy until the country's general upswing during World War II.

The TV shows both encouraged and reflected the flipping trend, embarked on as a hobby or part-time job for many of its participants. When a home is purchased with the intent of reselling it quickly, the terms of the mortgage become less important, because it will be paid off in full at the time of sale, long before the consequences of high interest rates have time to come to fruition; many of those advocating flipping as an investment activity promoted low- or no-money-down mortgages, which naturally cost much more in the long run. Flipping was a significant part of the housing bubble: Only 60 percent of homes purchased in 2005–06, that period when a flurry of flipping-centered shows entered the basic cable slate, were purchased as primary residences. While some of the remaining purchases were vacation homes, this is still a startlingly low figure, and flipping of that volume leads to an artificially inflated demand: Because so many houses sell, more houses are built, prices are raised, empty lots are purchased for new developments ... but the demand does not truly exist for that many residences. In 2005 twice as many new single-family homes were built as there had been 10 years earlier. As with the Dutch tulip bubble, such activity only pays off so long as everyone continues to play the game. As soon as the market returns its emphasis to only those tulip bulbs buyers actually mean to plant and grow, a correction must occur.

Such a correction did occur, as by late 2005 many economists were warning it would. Fed chair Benjamin Bernanke confirmed in October 2006 that the housing market was experiencing "a substantial correction," which would put a drag on economic growth. Many placed the blame on Greenspan, who as Fed chair had been responsible for the interest rate on 30-year fixed-rate mortgages reaching a historical low of 5.5 percent, encouraging more mortgagees. But subprime loans would do the most damage. Subprime lending extends loans to borrowers who do not qualify for the usual interest rates because of their risk factors, thus bestowing a greater amount of debt upon those with the least ability to repay it, a practice both ethically and practically questionable. Because the potential profit is high, lenders took many risks, including "ninja" (no income, no job, no assets) loans made to borrowers with no means of repayment except the sale of the house.

The Subprime Industry Collapse

The subprime mortgage industry collapsed in 2007, amid the steepest plunge in home sales since the 1980s. Subprime mortgages represented a disproportionate amount of foreclosures in 2006 as debts came due that the borrowers were unable to repay, and lenders began to face bankruptcy as they were unable to recoup the money they had lent out and were left only with seized assets with rapidly declining values. By the spring of 2008, 10 percent of homeowners had zero or negative equity: their homes had declined in value to such an extent that they were worth less than the mortgage on them, a situation that encourages strapped borrowers to neglect the debt, because that perception of home ownership as equity building and sound investing has been burst.

Subprime lenders began to go into bankruptcy at the start of 2007, including the largest, New Century Financial, which filed for Chapter 11 on April 2, 2007. Because of the practice of securitizing mortgages and other debts, turning them into mortgage-based securities (MBS) and collateralized debt obligations (CDO), far more institutions were put at risk than the lenders themselves. Financial institutions that had made significant investments in MBSs and CDOs began to falter and fail, the value of those securities dropping as housing prices dropped. Profits at FDIC-insured banks fell 31 percent in 2007, most of the damage coming in the fourth quarter. Investors panicked, withdrawing from such securities.

The extent of subprime-backed securities quickly became apparent, as they had insinuated themselves into portfolios worldwide, from American hedge funds to the Bank of China. The global credit crunch began around August 2007, causing the European Central Bank, the Bank of England, and the Federal Reserve to inject capital into the markets to deal with the sudden liquidity crisis. Investor panic, bank runs, and bank failures continued regardless, and even the mild relief offered by the remedy proved temporary. The first of several increasingly sizable bailouts began in the United States, with a limited bailout of mortgage debts announced on August 31. A planned superfund to buy up mortgage-based securities failed within a couple months of its announcement, due to still-falling values and the infeasibility of implementation. Investor panic and bank failures impacted stock markets worldwide, amid fund managers arrested for fraud for misreporting the health of their funds in order to give them time to withdraw their own investments, reported losses of hundreds of billions of dollars at American financial institutions, and the July 11, 2008, failure of Indymac, the fourth-largest bank failure in American history.

All of this transpired in an economic climate already affected by the worldwide commodities crisis. The price of crude oil had skyrocketed after a long period of reasonably cheap energy, reaching an all-time inflation-adjusted high in 2008. The cost of food goods soared worldwide, thanks to the crop diversion of biofuel and the increased demand for more profitable foods that led to shortages of basics like rice and grain. Wheat hit an all-time high, rice a 10-year high, and soy, dairy, meat, and corn all skyrocketed. Foods that had already risen in price due to climate-related shortages, like citrus and chocolate, remained high, and "Big Chocolate" companies like Hershey rejiggered their American-market products to use chocolate-flavored coatings in place of chocolate whenever possible, to avoid exceeding the $1 ceiling on impulse-rack products.

Fall 2008 Global Crisis

In September 2008 the Federal National Mortgage Association (Fannie Mae) and the Federal Home Loan Mortgage Corporation (Freddie Mac) were placed into conservatorship of the federal government, with the Treasury Department making $200 billion available through 2009 to try to keep the enterprises solvent. The collapse of the subprime mortgage industry infected investment banking, as AIG, Bear Stearns, Goldman Sachs, Lehman Brothers, Merrill Lynch, and Morgan Stanley all found themselves in peril because of their MBS investments. Lehman Brothers and Washington Mutual (the country's largest savings and loan) collapsed in September, while Morgan Stanley and Goldman Sachs announced they were divesting themselves of investment banking, the dominant force on Wall Street since the New Deal. The Dow Jones Industrial Average fell repeatedly during that month, nearing 8,000 after a historic high of 14,000 less than a year earlier. No longer revving up or looming, the global economic crisis had entered its acute phase.

In the highly politicized environment of the 2008 presidential election, the Emergency Economic Stabilization Act of 2008 was defeated in the House of Representatives at the end of September, but a version was passed by the Senate on October 1, and President George W. Bush made the unpopular decision to sign it, creating a $700 billion bailout fund called the Troubled Assets Relief Program. The following week was the worst for the American stock market since the Great Depression, prompting the IRS to alter its rules on repatriated currency, encouraging corporations to return money home from overseas investments and foreign subsidiaries, in order to inject liquidity into the stiffening financial market.

The annual G20 meeting, held between 19 countries with the largest economies in the world and a representative of the European Union, was conducted by heads of state instead of ministers of finance, in November. Quickly dubbed "Bretton Woods II," the meeting took on a much broader scope and grander importance than most of its sort, and in essence became a planning session for the 2009 summit planned for April in London. At the core of the meeting was the need for a common approach to the global financial crisis, and a reconsideration of international financial institutions like the International Monetary Fund.

Most Favored Nation Status

Most favored nation (MFN) status, or treatment, is a multilateral trading agreement between member countries. MFN status stipulates that each country extend tariff and regulatory treatment to other member countries that is no less preferential than their existing trade agreements. The agreement ensures that those from one country will not be treated worse that those from any other country. In effect, MNF status simplifies trade agreements since all member countries are extended the best trade conditions automatically without renegotiation. For example, if Mexico reduces tariffs on sugar from Mauritius, it must do so for all countries with whom it has MFN status, unilaterally. MNF status tends to reduce tariffs between all participating nations.

In the late 19th and early 20th centuries, MNF status was included in several bilateral trade agreements. MNF status gained popularity after World War II such that the General Agreement on Tariffs and Trade (GATT) included MFN status as its first article. MFN status is the second article in the General Agreement on Trade in Services (GATS) and article four in the Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS). The World Trade Organization (WTO) superseded these three agreements. All 152 members of the WTO adhere to the MFN status agreement. Although MFN status has its faults, it is seen as the cornerstone of fairness in trade relations.

Political and economic agreements are exceptions to MFN status. Customs unions and free trade zones (usually with strict conditions) can supersede MFN status for those outside the zone. For example, the European Union extends preferential trade conditions to member countries without similar treatment for others. In 1979 the GATT created the Enabling Clause that allows developed nations to extend preferential trade policy to developing nations without unilaterally extending the same treatment to MFN nations. To promote the growth of nascent industries and the standard of living in developing nations, WTO has also implemented escape clauses. These allow special concessions to be made for either case. Other challenges include human rights concerns and environmental policy.

In 1998 U.S. President Bill Clinton renamed the MFN status to Normal Trade Relations (NTR). This agreement allows producers in the country with whom the United States has NTR to benefit from lower tariffs on exports.

Motivation

Motivation is generally defined as the processes that account for an individual's intensity, direction, and persistence of effort toward attaining a goal. The three core concepts when explaining motivation—intensity, direction, and persistence—refer to how hard an individual tries, where the effort is channeled, and how long the effort is maintained. Motivation explains why an individual behaves in certain ways; management can use this concept to guide the practice of encouraging or discouraging certain behaviors of employees and thus improve performance.

What motivates an individual? In general, researchers and managers identified two kinds of motivators: intrinsic and extrinsic. Intrinsic motivators refer to an individual's internal desire to do something, due to such things as interest, challenge, and personal satisfaction. Extrinsic motivators are those that come from outside the person, such as pay, bonuses, and other tangible rewards. According to the Cognitive Evaluation theory, when management gives extrinsic rewards for behavior that had been previously intrinsically rewarded, this can result in a decrease in the overall level of motivation, because the individual experiences a loss of control over his/her own behavior when it is rewarded by external sources.

There are many theories explaining motivation. For example, D. McGregor proposed "Theory X and Theory Y." Theory X assumes that employees dislike work, will attempt to avoid it, and must be coerced, controlled, or threatened with punishment if they are to perform. Theory Y assumes that employees like work, are creative, seek responsibility, and can exercise self-direction and self-control. Managers who believe Theory X will design policies for tight control and coercion, which might cause employee resentment, withdrawal, indolence, lack of interest, or other negative behaviors. Employees' negative behaviors will reinforce belief in Theory X, thus forming a vicious cycle. Although McGregor's theory has been challenged by more recent studies, its basic argument remains valid and central to motivational research.

Motivation theories can be roughly classified into two categories: needs-based theories and process-based theories. Needs-based theories generally argue that individuals have needs that, when unsatisfied, will result in motivation. Maslow's hierarchy of needs, Alderfer's ERG theory, McClelland's theory of needs, and Herzberg's two-factor theory are representative of this type of theory. For example, McClelland argues that people vary in the types of needs they have. Their motivation and how well they perform in a work situation are related to whether they have a need for achievement, affiliation, or power. Needs-based theories are challenged by later researchers regarding the completeness of their categorization schemes (i.e., how many needs are there and which list of needs should we use) and the validity of their explanation (attributing a concrete behavior to a category).

Process-based theories of motivation are inherent in Lewinian intellectual tradition. Lewin believed that specific behaviors (regions of activity) are perceived as paths to a goal and the level of motivation corresponds with resultant psychological force toward the goal. For example, if a goal is important for an individual, the valence of the goal increases the total psychological forces toward the goal. Expectancy theory, Equity theory, and Goal Setting theory are examples of process-based theories of motivation. Specifically, Expectancy theory proposes that Effort (or motivation) = E x I x V. In this equation, E (Expectancy) is the belief that effort could lead to performance; I (Instrumentality) is the belief that performance could lead to reward/outcome; and V (Valence) is the subjective importance/value of reward.

Managers can manipulate employees' motivation by adjusting Expectancies (ability/skill level; training; build self-efficacy, clarify appropriate actions), Instrumentality (measurement of performance, variable rewards for variable performance), and Valences ("Cafeteria style" benefit plans, etc.).

Goal Setting theory proposes that achieving a goal is motivating, and goals clarify expected behavior/performance. When management defines performance goals for employees, they should follow the general principles: specific goals increase performance more than the generalized goal of "do your best"; difficult but attainable goals, when accepted, result in higher performance than do easy goals; and feedback on goal attainment leads to higher performance than does nonfeedback.

Each of the process-based theories has its own issues, but the general principles inherent in these theories have fundamental influences on current management practices. The concept of motivation provides a useful language for understanding what makes people become more productive at work. From the pioneer of management through to the work of contemporary researchers, motivation has and will continue to guide the way we manage people in an organization for productivity and self-actualization.

Motorola

Motorola is an American multinational enterprise specializing in telecommunications and related technologies. The company is headquartered in the Chicago suburb of Schaumburg, Illinois, and has used the name Motorola as its trademark since the 1930s.

Motorola was founded in 1928 by Paul and Joseph Galvin under the name Galvin Manufacturing Corporation. The company started out as a manufacturer and seller of car radios—or motorolas. The name *Motorola* came about as a creative compilation of the words *motor* and *radiola*, and was meant to suggest sound in motion. It became so popular that the corporation changed its name to Motorola, Inc., just a few years after it was established. Currently, the company produces and markets a wide variety of products, including but not limited to mobile phones, laptop computers, computer processors, and radio communication devices. Motorola caters its products and services not only to individual consumers but also to corporations, government entities, developers, and service providers. One of its most recent consumer products, Motorola RAZR, sold over 110 million units by the middle of the first decade of this century, propelling the company to the number two mobile-phone producer slot, behind Finnish multinational giant Nokia.

In general, Motorola positions itself as a company that thrives on "engineering intelligence with style." The company especially emphasizes its customer orientation in the opening statement, which reflects both Motorola's vision and mission, posted on the company's Web site. It reads:

> We're artists. We're scientists. Most of all, we are a global communications leader, powered by, and driving, seamless mobility. Motorola is revolutionizing broadband, embedded systems and wireless networks—bringing cutting-edge technologies into your everyday life, with style.

Throughout its existence, Motorola has experienced numerous ups and downs, related mainly to rapid changes in both the telecommunication industry and the external business environment; in the past several years, the company has been going through rather tough times. For instance, some of Motorola's large projects—like Iridium, a company that was aiming at creating the first truly global communication network—have been derailed due to miscalculated demand. Further declines in the telecommunication industry worldwide in 2001–03 forced Motorola to spin off its U.S. government-related business and its semiconductor product division into separate legal and business entities. The sales of its flagship product, the RAZR, also decreased immensely by the last quarter of 2006. These developments forced the company to begin major cost-cutting and restructuring activities in 2007 that were mainly aimed at closures of various sites worldwide and sell-off of noncore business units. Overall, in 2007 Motorola reported a whopping 84 percent decrease in profits compared to a year before.

Motorola's current financial woes are continuing to worry company's investors. Despite solid sales of about $7.45 billion in the first quarter of 2008, the worldwide operations suffered a loss of $194 million. The company explains such an unfavorable figure by a 39 percent decrease in the sales of mobile devices. Motorola's other divisions, however, are once again showing strong financial results—both Home and Networks Mobility and Enterprise Mobility Solutions businesses continue to expand their solution portfolios and grow internationally. In another development in early spring 2008, Motorola's board of directors announced a split of the company into two separate publicly traded companies: Motorola Mobile Devices and Motorola Broadband & Mobility Solutions. The split is expected to be approved by regulators sometime in 2009.

In spite of financial tribulations, Motorola confirms its strong commitment to both corporate social responsibility and corporate citizenship. In the latest survey conducted by the Corporate Responsibility Officer—aimed to emphasize the corporate responsibility efforts of large, high-impact corporations in eight different categories that include Climate Change, Employee Relations, Environment, Financial, Governance, Human Rights, Lobbying, and Philanthropy—Motorola was named among the top 100 U.S.-based multinationals, a fact the company is taking much pride in. Motorola is also among very few companies in the world that earned a maximum rating of 100 percent in corporate equality, an index that rates employers on a scale from 0 to 100 percent on their treatment of gay, lesbian, bisexual, and transgender employees, consumers, and investors.

Multicultural Work Groups and Teams

Diversity is increasing within organizations at an astronomical rate. Organizations are increasingly operating in multicultural contexts, building strategic alliances, exporting work, and facilitating mergers and acquisitions inside and outside their primary domain of work. Concurrently, organizations are implementing work groups with greater frequency to integrate the knowledge of workers across broad geographic locations and cultural contexts. However, disagreement exists regarding whether a diverse cultural composition of groups leads to positive or negative group outcomes.

On one side, cultural diversity in groups and teams becomes most advantageous when the organization wants to expand its perspective, tactics, strategy, or approach. Diversity can become an advantage in attempting to reposition the organization, reposition a strategy, create a new idea, develop a new marketing plan, or assess emerging trends from a new perspective. If diversity is well managed, with the emphasis on management, it can increase creativity, flexibility, and problem-solving skills, especially for complex problems, improve effectiveness in working with culturally distinct clients, and improve understanding of the dynamics and communication patterns within the organization. The ability to operate more flexibly and to stay open to new ideas is a necessity for the management of the culturally diverse workplace. In fact, managers in this environment need to focus on the multiple perspectives and avoid groupthink.

On the other side of the debate, diversity frequently causes problems in convergent processes, at times when the organization needs employees to think or act in similar ways. Diversity renders communication and integration more difficult. People from different cultures fail to understand each other; they do not work in the same way or at the same pace. The

Multicultural teams can experience a form of culture shock as communication problems and conflicting work styles emerge.

potential for increased ambiguity, complexity, and confusion becomes highest when the organization requires direction and clarity, or in other words, convergence. Diversity causes problems when managers and employees overgeneralize organizational practices and process from one culture to different countries and cultures. It causes problems when a culturally diverse group must reach an agreement, whether this is formal or informal, and increases complexity and difficulty in developing companywide policies and procedures. Finally, cultural diversity might incite intergroup bias leading to negative group outcomes.

Joseph DiStefano and Martha Maznevski, looking at the performance of multinational teams, have noticed that these teams usually fall into one of three performance categories: the destroyers, the equalizers, and the creators. Destroyer teams were categorized as such because their members were observed to mistrust each other—they guarded information jealously and took every opportunity to attack other members of the team. Equalizer teams were observed as suppressing differences and, in turn, suppressing differences in ideas and perspectives. This category resembles what Alfred Adler calls ignoring cultural differences in teams.

Finally, creator teams were found to perform at high levels. In these teams, differences were explicitly recognized and accepted, even nurtured, and their implications were incorporated into every facet of the group's processes. These teams seemed to develop a constantly shifting dynamic that incorporates innovation and cooperation structures. These teams were observed creating value by bringing highly successful products to market in record time, achieving quantum leaps in cost savings in highly competitive industries, inventing new types of alliances with global suppliers and clients, and moving successfully into territory that others have been unable to conquer. The key to this high performance was not in the membership of the teams but in the interaction processes, i.e., how they understood, incorporated, and leveraged these differences. Creator teams interacted according to three principles of mapping, bridging, and integrating.

Models of effective multicultural teamwork have moved away from merely conceptualizing teamwork at the level of behaviors and processes in favor of understanding teamwork at a cognitive level. Indeed, Lynne Millward-Purvis suggests a model of team effectiveness based on shared mental models and meta-cognition. In this model, the authors suggest that for a team to self-regulate, it must have a sound knowledge of itself (its role, goals, strengths, and weaknesses) and be able to reflect upon, review its knowledge and practices, and subsequently refine or correct these. This is essential for the team to be adaptable and flexible in changing circumstances. This process not only requires a shared mental model of the team and its task, but cognitions at a meta-cognitive level in the self-regulatory sense as well as a sense of team motivation.

In this model, two important aspects of team motivation are identified: identity and potency. The identity of the individual is affected by whether the individual is proud to be part of the team such that self-concept and esteem will be related to team success. Potency on the other hand, the authors explain, refers to the collective beliefs that the team can succeed and be effective.

Other models for effectiveness in multicultural teams focus on leadership and social interaction. For a multinational team to be effective, a clear sense of direction must be established at the beginning of a conceptualization phase. After an initial period of euphoria over the internationalism of the project, there is a drop in team morale; communication problems and different styles of working and decision making, leading to culture shock. If the project leader does not succeed in building up trust in the early phases of the project, thereby holding the team together by a common goal, there is a risk that the project will never get off the ground. Especially at the beginning of international projects, it is important to give priority to trust-building measures and team development. For these purposes, social events may be organized and can be more effective than any other sort of social interaction.

Multidomestic Structure

Multidomestic structure is a multinational firm's organizational structure that reflects the philosophy that the world is comprised of many unique markets—usually defined at the national level. By this multidomestic philosophy, for example, many food companies acquire and/or establish business units in as many countries in which they do business, granting these units autonomy to choose products, suppliers, and marketing strategies to suit their local contexts.

To understand multidomestic structure, we first explore the multidomestic concept (or philosophy) and then see how it can be applied to industries, firms, and organizational structures. The core issue is whether one sees the world as one more-or-less monolithic market with similar tastes and preferences or whether one sees the world as made up of many more-or-less unique markets, each with its distinct tastes and preferences. The former may be called a "global" and the latter a "multidomestic" philosophy. Parenthetically, the position between these two extremes is called regionalism, whereby one sees the world as being made up of a small number of regions—for example, Asia, Europe, the Americas, and Africa/Middle-East.

Authors like George Yip (who prefers the term *multilocal*) and Michael Porter show how some industries, by their natures, lend themselves to more multidomestic (as opposed to global) strategies; for example, if competition is independent from country to country as is the case in retail banking, caustic chemicals, and retail groceries. Many competitors in these industries tend to be local, as the benefits of integrating into a global business are necessarily limited. According to Klaus Agthe, the multidomestic business organization may thus actually be a group of "national" subsidiary companies whose ultimate headquarters is structurally separate from each and equally supportive of all of them.

Multidomestic structures are thus the patterns of intraorganizational reporting relationships that enable the multinational firm to manage its operations so that subsidiary (or affiliate) organizations have suitable levels of autonomy to implement a multidomestic strategy. Implementation of this subsidiary autonomy is a key concept. Stuart Paterson and David Brock suggest that autonomy is necessary as a way to improve local responsiveness, and is a prerequisite and a desirable result of subsidiary development. Subsequently, they discern an increasing emphasis on autonomy in research related to multinationals and their subsidiaries.

Multidomestic structures fit well within global area or geographic structures. For example, the Nestlé Group has three global geographic zones (Europe, Americas, and Asia/Oceania/Africa) for most of its food business (with the exceptions of Nestlé Waters and Nestlé Nutrition, which are managed on a global basis). Then each of the geographic zones is divided into individual countries or country groups. For example, the Americas zone contains Latin America and the Caribbean (groups), and the United States and Canada. This structure allows each country (or homogeneous group of countries) to adapt to local tastes and regulations that are relevant to their food and beverage offerings.

Similarly, global product divisions are commonly structured into area and/or country divisions. For example, Nippon Steel Chemical Group has 15 companies structured into three global product divisions, namely Chemicals, Electronic Materials, and Coke & Coal Tar Chemicals. However the Chemicals division has branches in Osaka, Seoul, Taipei, and Shanghai in order to provide country-level customization and support for their products. Further, even the most global firm may have some multidomestic features to their structure. For example, Intel and Microsoft, both of whom are known for their globally integrated processes and standardized offerings, have hundreds of local offices around the world to take care of customer needs and to fine-tune their marketing efforts from location to location.

We thus see that the multidomestic concept is more relative than taxonomical. Just as there is no pure global strategy or structure, so, too, are multidomestic strategies and structures deployed by firms only to limited degrees. As implied by C. A. Bartlett and S. Ghoshal, effective firms in dynamic markets need to find the appropriate balance between the global and multidomestic aspects of their operations. This is how they define the challenge of effective transnational management.

Multi-Fiber Agreement

During the 1960s, the Kennedy administration implemented a quota system to protect domestic cotton producers. In 1962 the Long Term Agreement Regarding International Trade in Cotton Textiles (LTA), a set of bilateral quota agreements, was signed under the General Agreement on Tariffs and Trade (GATT). This agreement was renegotiated several times until finally in 1974 the Multi-Fiber Agreement (MFA) was signed. The MFA was adopted within GATT to essentially protect the industrial nations' textile and clothing industries from the growing competition of developing countries that were able to produce products more cheaply due to lower labor costs. The MFA covered products made of cotton, synthetic fibers, wool, silk, and ramie. Under their jurisdiction all exports were subjected "to quotas when total exports from exporting countries reach[ed] a certain share of total imports in the country of destination."

Initial signators of the textile-and-clothing-protected quotas in the 1950s and 1960s were Japan, Hong Kong, China, India, and Pakistan; however, there was a growth rate on the quotas imposed on the proceeding arrangements so the European Union (EU), Austria, Canada, Finland, Norway, and the United States applied the quota almost exclusively to developing-country exports. Japan and Switzerland were two other signatories that did not impose MFA quotas but instead viewed their act as merely a signal that, if they needed to, they would apply the quota.

The MFA was a complicated system of quotas that acted as an incentive "to large name brands to move their production units to multiple countries and to the developing countries to open their countries to investors." Under the MFA's quotas, and with encouragement of international financial institutions, dozens of poor countries developed apparel industries that created millions of jobs and guaranteed sharing of world clothing.

Significance and Impact

The MFA's original intention of the quotas was to offer protection to the declining textile industries of developing countries. However, with quotas effectively guaranteeing market access, textile manufacturing industries began showing up in countries like Jamaica and Sri Lanka, which before had no significant textile industries. The reason for these textile manufactures in unlikely countries was because the MFA guaranteed market access for them along with neoliberal policies imposed on them by international institutions such as the International Monetary Fund (IMF). In Keith Yearman's article he provides this example of how the MFA created textile access for other countries:

> The elimination of agricultural price-stabilization programs and the removal of tariffs and quotas on food imports in many countries over the past 20 years has forced countless farmers off their lands and into the urban economy, where a formal garment factory job, however low-paid and tedious, can look a lot better than eking out a living in the informal sector. Under the structural adjustment programs many nations adopted as a condition of refinancing their foreign loans, governments privatized public-sector enterprises, often resulting in mass layoffs and further softening labor markets.

In addition, the U.S. textile and apparel companies feared an increase in competition from abroad, but by implementing the quotas established by the MFA, it in fact turned out to benefit larger nations such as the United States with unskilled workforces and acted like an affirmative action program for poorer nations.

Phase-Out

From 1992 to 1994, GATT met at the Uruguay Round, and on January 1, 1995, MFA was replaced by the World Trade Organization's (WTO) Agreement on Textiles and Clothing (ATC). According to Junyuan Tan, it was originally meant for a

> transitory phase between the MFA and the full integration of the textile and clothing industry into the multilateral trading system; Canada, the EU, Norway and the US carried their MFA restrictions into the AFC.

This new agreement inaugurated a 10-year removal of MFA's quota, preference system, and full adoption of textile and clothing products into GATT rules. The transition of ATC is best seen through two processes incorporated in three phases: first, as Tan writes, the "integration of products into the GATT and out of the ATC," and second to "increase in the quota growth rates that remain under the ATC, allowing developing countries to export more goods under restrictions."

At the beginning of each phase, importing countries had to integrate a specific minimum portion of their textiles and apparel imports. The first phase began on January 1, 1995, with a 16 percent integration, followed in 1998 with a specified minimum rate of 17 percent and an increase of the quota growth rate to 25 percent higher than the previous stage rate. The final phase was in 2002 with targets of 18 percent and 27 percent quota growth rate. By January 1, 2005, the Multi-Fiber Agreement officially ended and trade in textiles and clothing was, according to the Interfaith U.S. Trade Justice Campaign, "completely liberalized leaving the future of the industry in less competitive countries in a free fall."

Post-MFA Period

Now, in the period known as the post-MFA period, only members of the WTO can benefit from the textile and apparel quotas that the WTO has implemented. Nonmember countries such as Vietnam and the former Soviet republics are limited by bilateral quotas or other arrangements with the United States and other countries. Ironically, the countries that pushed to end the quotas are now suffering the most. Countries such as Indonesia, Pakistan, Bangladesh, Colombia, and others that were economically heavy on textile exports are now receiving less access than anticipated to the U.S. and European markets for their exports.

The greatest danger, however, in the removal of the MFA's quota system has been with the shifting of textile manufacturing power to China. As MFA's initial purpose was to protect textile manufacturing in rich countries from growing Third World exports, many of these countries thought that with this they would gain even more market share once the MFA's quota was dropped. However, during 1994, China was not a member of the WTO or GATT, thus it was not allocated a quota. In 2001 China joined the WTO and has since dominated the world textile industry so much that instead of opportunity in the industry shifting from rich nations to poor ones, the elimination of the quota has shifted production out of the developing countries and into just a few: China and India. Now countries are inundated with clothing made in China and India, while up to 30 million garment workers worldwide are unemployed.

Also, during this post-MFA period, there has been speculation of lower prices for the consumer; however, this may also lead potentially to a long-term negative impact on the economy. As stated in a document about the MFA,

> The quota system in the past had restricted competition and had allowed less competitive exporters to export more than their competitive share. These less competitive exporters will lose their market share. Export countries previously limited by the MFA will gain from increased market access. However, exporting countries will face lower prices as a result of increased competition, although production and export will be rationalized, with a move to more efficient sectors.

In addition, according to trade observers:

> with a more economically interdependent world the impact is shortsighted to ignore the ill effects on developing nations when the spoils of an open market system go to the most powerful.

Multilateral Investment Guarantee Agency

The Multilateral Investment Guarantee Agency, established in 1988, provides political risk insurance to private companies investing in developing markets. As a member of the World Bank Group, its principal goal is to encourage foreign direct investment in developing markets by augmenting privately and publicly available political risk insurance coverage. Such insurance reduces the risk of investing in developing markets and makes them more attractive hosts for foreign direct investment.

In providing political risk insurance, the Multilateral Investment Guarantee Agency, more commonly known as MIGA, is guided by its principal mission of aiding in the economic development of member countries. This objective is reflected in its insurability criteria, which require insured projects be economically viable, environment-friendly, and contribute to the economic development of their host countries. Consistent with its goals of facilitating economic development, infrastructure projects are a stated priority area for MIGA. This priority reflects the essential nature of infrastructure such as power, telecommunications, transportation, water, and waste management in support of economic development and the inability of many developing country governments to finance its development. A second priority area for MIGA is postconflict countries. These countries, because of their war histories, are often viewed as politically risky. This perception makes it particularly difficult for these economies to attract foreign direct investment and restart the process of rebuilding their economies. This creates a particularly important role of MIGA, which, through the provision of political risk insurance, increases the likelihood of such investment.

The insured, companies that are nationals of MIGA member countries, invest outside their home markets in developing countries that are also members of MIGA. Member countries include both developed and developing countries. Developed country members include Canada, the EU-15, Japan, Switzerland, and the United States, which together account for the vast majority of outward foreign direct outflows. Most developing countries including those in Asia, Africa, the Middle East, and Latin America and the Caribbean are members of MIGA. This extensive membership implies that foreign investment in most developing countries may be eligible for MIGA coverage provided other insurability criteria are met.

MIGA provides four types of political risk insurance: expropriation, war and civil disturbance, breach of contract, and transfer restriction. Both expropriation and war and civil disturbance coverages provide insurance against asset loss. Expropriation coverage protects against actions by the host government that restrict or eliminate the policyholder's ownership rights without compensation. War and civil disturbance coverage, as its name suggests, protects the insured against the loss of physical assets due to acts of war and civil disturbance. Breach of contract coverage protects the investor against the possibility that the host country government fails to fulfill its contractual obligations. The final type of insurance offered, transfer restriction, protects the insured against actions such as the imposition of capital controls that limit their ability to convert local currency to foreign currency for transfer outside the country. Insurance may be purchased individually or in any combination desired by the insured. Insurable projects include equity investments and shareholder loans. Coverage is generally available for a period of no more than 15 years.

While MIGA's political risk coverage is similar to coverage that may be provided by private and individual home country governments, MIGA also coordinates coverage from multiple insurers, both private and public. This works to increase the available coverage for a given investment by having multiple insurers—private, public, and MIGA—that share the project risks. In the first 19 years of its existence, MIGA has facilitated in excess of $28 billion in investment guarantees for infrastructure projects. This is in contrast to the approximately $5.6 billion directly guaranteed by MIGA during this time period. This reflects the insurance expansion effect of MIGA's dual activities.

In addition to providing and facilitating coverage of political risk events, MIGA further manages political risk through its stature as an international institution funded by member country contributions. This stature provides access to member governments that is generally not available to private and public insurers. MIGA uses this access to reduce the likelihood of the political risk events it insures by leveraging its relationship with host country governments. This unique ability confers further advantages to potential investors due to the effective reduction in political risk exposure of their project.

Multinational Competitive Disadvantages

Multinational corporations (MNCs) have multiple sources of advantage that enable them to expand across countries. However, they also suffer from competitive disadvantages, i.e., the condition a firm faces when it creates lower value for its customers and lower profits for itself than its competitors. A competitive disadvantage is always in comparison to a particular competitor or set of competitors. Thus, there are two broad types of multinational competitive disadvantage based on two broad sets of comparisons. The first type is the competitive disadvantage that the subsidiary of an MNC has in comparison to local firms in a host country. The second type is the competitive disadvantage that the whole MNC has against other firms from the home country.

Types

The first type of competitive disadvantage has been analyzed under three related but not identical concepts: cost of doing business abroad, liability of foreignness, and difficulties in internationalization. Initially, building on economics, Stephen Hymer uses the term *cost of doing business abroad* to refer to the additional costs that a subsidiary of an MNC incurs to operate in a host country, which domestic companies do not have to incur. The sources of these additional costs are investments needed to operate at a distance, to deal with unfamiliarity with the economic, political, and social characteristics of the country, or to deal with discrimination by the host government.

Later, building on organization studies, Srilata Zaheer coins the term *liability of foreignness*. Although the liability of foreignness was initially equated with the cost of doing business abroad, later thinking moves away from costs and highlights institutional differences as the hallmark of the liability of foreignness. The sources of liability of foreignness are lack of adaptation to local institutional requirements, lack of legitimacy, and lack of membership of information networks.

Recently, building on strategic management thinking, Alvaro Cuervo-Cazurra and colleagues use the term *difficulties in internationalization* to refer to all sources of competitive disadvantage that subsidiaries of MNCs face. This concept, which includes the cost of doing business abroad and the liability of foreignness, is used to highlight how subsidiaries of MNCs can suffer from multiple competitive disadvantages, most of which are not exclusive to MNCs. The separation of difficulties by their source results in three sets of competitive disadvantage types. First, the subsidiary of an MNC suffers a disadvantage when it is unable to transfer the advantage provided by its existing resources and capabilities to the new host country. Local competitors have imitated or replicated the source of the advantage of the MNC, or customers do not need the firm's products, resulting in a foreign operation that is unable to achieve an advantage over local firms. Second, the subsidiary of an MNC will create a competitive disadvantage when some of the resources and capabilities transferred to the host country become disadvantageous there, because they collide with existing practices and norms.

Alternatively, it is not the specific resources and capabilities but the foreign nature of the subsidiary of the MNC that becomes a source of disadvantage, because the government and/or citizens dislike the country of origin. This latter source of competitive disadvantage, which is termed the *disadvantage of foreignness*, is exclusive to MNCs. Third, the subsidiary of an MNC will face a competitive disadvantage when it lacks complementary resources needed to operate in the new country. It may lack complementary resources to manage at a larger scale, to compete in the new industry, or to operate in a new institutional environment. Only the latter, identified as the liability of foreignness, is exclusive to MNCs.

The empirical literature finds that subsidiaries of MNCs tend to have lower performance, efficiency, and survival than domestic firms, especially at the beginning of operations in the host country. However, some studies caution that this depends on the comparison drawn, and on whether competitive advantages that may compensate for some of the competitive disadvantages are controlled for.

The second type of competitive disadvantage, the competitive disadvantage of an MNC in comparison to other firms from the home country, affects the whole MNC rather than one or some of its subsidiaries. Initial studies, such as those done by Donald Lessard and colleagues, argue that MNCs have an advantage over domestic companies. Later studies focus on comparing not MNCs to domestic firms, but on comparing MNCs with different degrees of international presence. These studies find that MNCs with a limited international presence appear to have a disadvantage in comparison to MNCs with a higher international presence. Lack of experience with international markets reduces performance until the firm develops such experience as it continues expanding abroad. However, at very high levels of international presence, MNCs also appear to suffer from a disadvantage in comparison to those with lower international presence. This reflects the challenge of managing a wide array of operations in multiple and distant places.

Multinational Corporation

Multinational, international, global, or transnational corporations are those that operate in more than one country—not simply exporting goods from one country to another, but offering services in multiple countries or operating production facilities in more than one country. Because the demands of their businesses require them to operate under different conditions within different borders—abiding by local laws and serving different customer bases—their profits and productivity are affected by international matters to a greater degree than those of single-nation companies. Combined with their generally greater wealth, this has tended to involve them in international politics and to make them objects of suspicion. In popular speech, "the corporations" generally implies "the multinational corporations," and especially those that export cultural products from the United States or the West to the rest of the world, or those that control great amounts of natural resources, like the oil companies. These are the companies that have a greater than average impact on world affairs.

The British East India Company is widely considered the first multinational corporation, but it was the advances of the Industrial Revolution—particularly in manufacture and transportation—that paved the way for the modern multinational, just as the internet and the information revolution have led to new forms of multinational operation through online ordering, business process outsourcing, and off-shoring.

Postwar Multinational Corporations

Throughout the 20th century, Americans made great strides in foreign direct investment (FDI), and World War II had a good deal to do with so many of the prominent multinational corporations having American origins. Americans had already made significant progress in reaping overseas profits from domestic innovations, like the Hollywood movies that were shown all over the world. Foreign audiences happily tolerated subtitles or dubbed-in voices in exchange for the much better production values of big-budget Hollywood movies compared to most of the local fare, which is one reason the biggest successes exported from Hollywood were those that made those bigger budgets most obvious: the action movies, thrillers, science fiction movies, and so on. At the same time, the American movie industry specialized from a very early period in the creation and promotion of movie stars, figures whose fame soon outpaced the fame of any one movie.

Other American cultural icons were exported in great numbers as well; having pioneered national advertising in the United States, Coca-Cola began selling its product to the world. Depending on the arrangement (which varied and developed over time), syrup could be manufactured in the United States and shipped elsewhere to be diluted and bottled, or the formula for the syrup could be given to Coca-Cola-owned bottling companies around the world. After World War II, when most of Europe was occupied with recovery, FDI by Americans skyrocketed, accounting for 75 percent of new FDI from the end of the war until 1960. American FDI did not diminish at that point—far from it, it has continued to grow at great rates—but non-American corporations began to engage in it more and more often, such that by the 21st century it had become a worldwide phenomenon.

FDI is the establishing and funding of a commercial enterprise in one country by the citizen of another country, or a corporation from another country—such as an American shoe factory opened in Asia, a Japanese car factory opened in Mexico, or a

Swedish furniture store opened in Detroit. This is the mechanism by which all multinational corporations come into being; the transnational or global descriptor has come into use to imply a way of doing business that transcends national concerns, as opposed to taking an American or Japanese way of doing business and conducting it across the globe. In practice, though, companies are still headquartered in one country or another, and still originate from one culture or another. However, this is arguably analogous to the state-nation relationship in the United States: while a given bank may be chartered in Alabama, or a publisher may be headquartered in New York, its concerns and interests outside of that state clearly outweigh the concerns within that state, and there is likely nothing distinctively Alabaman about a bank with 1,200 branches sprinkled throughout 30 states.

Operating in multiple countries does not mean operating equally in those countries, or divided resources and profits equally among them. From the 1960s on—right after the peak of American dominance of FDI, as the rest of the world started to catch up—labor unions and concerned activists complained that American corporations were using overseas opportunities to move formerly American jobs into countries where wages and other labor costs (benefits, pensions, payroll taxes) were cheaper. In particular, companies were doing this while continuing to rely primarily on American customers, and customers from other wealthy nations, for their income—thus taking American money in, banking greater profits from it, and redistributing their labor costs to other countries. While this began as a labor concern—because companies were not just opening new factories overseas and retaining their existing American factories, they were closing American workplaces and replacing them with cheaper ones elsewhere—it quickly became a national concern, representing a potential drain on American capital and the prospect of the American consumer funding foreign labor with little domestic benefit.

Multinational Corporations Today

Those objections led to the Foreign Trade and Investment Act of 1972, the Burke-Hartke bill, brought before Congress by Representative Burke and Senator Hartke. Protectionist in design, the bill called for greater regulation of the international flow of capital, restricting FDI and creating a Foreign Trade and Investment Commission that would have enforced import quotas by country and category. The bill came right on the heels of the demise of the Bretton Woods monetary policy system, and the same administration that abandoned Bretton Woods—President Nixon's—opposed Burke-Hartke, which came very close to passing. The bill's defeat encouraged multinational activity, even as its near miss encouraged protectionist interests in both political parties. The subsequent 1974 Trade Act preserved some of the import-limiting goals of Burke-Hartke, but little of its sympathy with American workers. It loosened the criteria necessary to petition the International Trade Commission to restrict imports of a good by requiring that the industry in question show that imports are "a substantial cause" of financial troubles that industry faces in the United States. While this protected American companies from foreign ones, nothing was done to protect Americans from the foreign involvements of American multinationals.

Ironically, the automobile industry was at the forefront of both concerns—for every thousand autoworkers complaining that their jobs were in jeopardy because their employer could open a foreign plant with cheap labor, there was an auto executive complaining that Japanese automakers were destroying American industry. The 1980s were the first, and to date only, decade in which more capital was spent on foreigners' FDI on American shores than American companies spent on overseas FDI. Much of this was because of Japanese companies, finally thriving after rebuilding their approach to business and industry in the postwar years, buying out American businesses and opening American factories. For much of the decade, Americans were consumed as much by the economic threat of Japan as the communist-military threat of the Soviet Union. Once associated with cheap, poorly made goods, Japanese industry was now synonymous with efficiency. Images of Japanese workers and executives starting the day with calisthenics, figures comparing the performance of American schoolchildren unfavorably to that of their Japanese counterparts, and cryptoracist descriptions of Japanese rivals as sneaky and ninja-like filled the news, even as American automakers continued to close factories in Michigan in order to move operations to Mexico.

Off-Shoring and Outsourcing

While the original reason to operate in multiple countries was to do business in all of them, over the course of the 20th century the approach developed of exporting labor and other activities in order to maximize profits and efficiency. This quickly became a highly specialized and detailed process. Off-shoring refers specifically to shifting part of a company's operations from one country to another. While this originally was most likely to involve factory labor, where the differences in labor costs would vary considerably from country to country, it applies also to multinational corporations that shift their corporate headquarters (or center of operations for a particular division) from one country to another. While this is still in a sense a shift of labor, it is significantly different from the factory example: executives do not find themselves laid off with new executives hired in the new country, though support, secretarial, and custodial staff very likely will. But because of the high probability of a corporation owning the building in which it is headquartered, moving to a new headquarters likely means using the old building for a new corporate office, retaining the employment of those nonexecutives.

Production off-shoring is sometimes euphemistically called physical restructuring, and involves setting up manufacturing facilities in a country with cheap labor. Many developing countries are destinations for production off-shoring. The job of designing and marketing the product typically remains in the company's home country; once the process of building the product is perfected, it is off-shored, where labor can be had cheaply and needs minimal training. Services off-shoring requires more skilled labor, and is a more recent development. Because India and parts of southeast Asia have a large English-speaking population and low labor costs, they are the destination for most services off-shoring, in which information technology, engineering, customer service, and other tasks are performed by a foreign subsidiary.

Services off-shoring is often used synonymously with business process outsourcing, but outsourcing is different from off-shoring in that it involves hiring a foreign company to do a task, rather than purchasing or building a foreign company for that task. The difference to American labor is not a large one, but outsourcing is available to many more companies—even single-nation ones—than off-shoring is, because a single company can perform outsourced tasks for many client companies. Business process outsourcing (BPO), pioneered in India in the 1990s, involves contracting an outside company to perform customer-service or back office (finance and accounting, or human resources) business processes. This includes customer service and technical support call centers that redirect calls to representatives in India rather than to employees of the company, as well as a wide variety of tasks that do not involve contact with the public and that the public therefore remains largely unaware of. The internet has enabled much of this, allowing sensitive data to be safely communicated instantly to other parts of the world.

BPO has even led to legal process outsourcing and knowledge process outsourcing, BPO subfields in which BPO centers provide legal services or expert knowledge.

International Marketing Research

A number of marketing research companies cater to the special concerns of corporations operating multinationally. Zogby International and SIS International are two of the oldest, both founded in 1984 in New York. Zogby International was founded by political pollster John Zogby, an unsuccessful Democratic candidate for mayor of Utica. Zogby International is still best known for its political polls, and regularly makes headlines as a result of its polling coverage of American presidential campaigns. Zogby International operates in a number of other countries, often as the most reliable or prestigious polling firm, and correctly called major elections in Mexico and Israel, among other places. Like other marketing companies, Zogby is regularly engaged by corporations to manage focus groups and conduct polls to inform decision making such as price-setting, the demographic slant of advertising campaigns, gauging demand of potential products and services or existing products and services in new markets, and so forth. Zogby tends to rely heavily on phone and online polls, which suits some clients better than others.

SIS International was originally founded by Ruth Stanat to provide monthly market research reports to companies expanding into global markets. Beginning in 1990, the company began operating internationally, and has reorganized itself into three divisions: SIS

Intelligence Answering, offering on-demand intelligence services to corporations; SIS International Custom Research, the flagship division, specializing in market entry and market feasibility research to help prepare new enterprises; and SIS Global Research Media, which produces books and other research products, as well as offering custom tracking services. Like Zogby, SIS also offers political polling, but has never been as well-known for it, nor does it make up as significant a portion of its business.

Other major international marketing research firms include Visionagain, a London-based company with American and Indian branches, specializing in the telecommunications and pharmaceutical industries; and SKOPOS Market Insight, founded by psychologists in London, with offices throughout Europe.

Market research of some form is exceptionally important when a company is looking to do business in a new market, whether that means introducing a new line of products or offering their products in a new geographical area. Market research can help find the right angle to attract new customers and establish a brand identity, such as when South Korean auto manufacturer Daewoo expanded into Western countries. It can suggest areas of flexibility and adaptation, such as the plethora of options offered by American food companies throughout Asia: the teriyaki Whoppers, cucumber-flavored Pepsi, and mayonnaise-flavored Doritos in Japan; McDonalds' vegetarian burgers in India, where beef and pork are not served; and Coca-Cola's acquisition of local soft drink brands Limca and Thums-Up in India, in order to avoid direct competition with those well-established products.

International Impact

Multinational corporations often use their resources to attempt to influence change in the world. For instance, Asian countries do not always have—or are not able to enforce—intellectual property law to the same degree as in the West. There is a thriving business in pirated copies of movies and music, with little done about it. Western corporations over the last decade have been trying hard to encourage Asian governments and businesses to crack down on such piracy. Similarly, multinational corporations have pursued international agreements to respect patents and copyright, so that pharmaceutical companies that develop a medicine do not face competition from companies headquartered in countries where the developer's patent is not upheld, and where the medicine could thus be manufactured legally and cheaply by companies that, in the eyes of the developer, do not own it. Other product patents and intellectual property laws protect the interests of apparel companies, software and technology companies, and so on.

Multinational corporations regularly lobby, even in countries where they own no businesses, for favorable industry and environmental regulations and a favorable (or hostile-to-competitors) tariff structure, always seeking to shape the economic environment to their interests. Of course, to an extent lobbying is much like advertising: for every dollar Pepsi spends, Coke spends a dollar to cancel it out, and in the end both stay in the game just to keep the playing field level. In many cases, lobbying works the same way: with tariffs, the importing companies and exporting companies lobby to opposite ends; with regulations, there is quite often a lobbying group that wants the opposite of what the corporation seeks, whether because of labor interests, environmental protection, consumer protection, and so on. For every corporation that markets itself as a producer of enviromentally friendly products in order to attract green dollars, there is another corporation that spent years fighting environmental legislation because of the costs or other consequences—often the very same corporation. Even companies within the same industry can lobby for opposite ends: if Coca-Cola and Pepsi both use vanilla in their formulation but Coca-Cola uses three times as much, it is arguably in Pepsi's interest to see an increased tariff on vanilla beans. This becomes even more true if Pepsi's vanilla beans come from a plantation they own, or if they are pondering a move to vanillin, a vanilla substitute.

Lobbying is not an available tactic in all countries, and sometimes is not effective. In smaller or less developed countries, market withdrawal is sometimes used as a threat: if the country will not adjust its laws or regulations to suit the business, or if it insists on changing them to make them less conducive to the business, then the business will cease operating there. This is most effective when the loss of the corporation's business represents something more than just the loss of jobs—though movie studios have been able to use market withdrawal and tax competition to find the most amenable places to film (leading to Toronto and Vancouver serving as many television shows' New York, for example).

Mundell-Fleming Model

The Mundell-Fleming model is a theoretical model in international macroeconomics. The model demonstrates that the effectiveness of fiscal and monetary policies in the open economy depends on the exchange rate regime. The Mundell-Fleming model was developed in the early 1960s by Robert Mundell (b.1932, 1999 Nobel Laureate in Economics) and Marcus Fleming (1911–76) of the International Monetary Fund.

From 1946–71, the exchange rates of the industrialized nations were fixed to the U.S. dollar, while the dollar was pegged to gold at $35/oz. This was known as the "Bretton Woods system." During 1950–62, Canada experimented with a flexible exchange rate. During the early 1960s, both the United States and Canada had intense internal debates concerning the appropriate mix of fiscal and monetary policies. Working independently, Mundell (a Canadian) and Fleming sought to answer the following question: how effective are monetary and fiscal policies under fixed and flexible exchange rates?

According to Warren Young and William Darity, Jr., Mundell-Fleming is a special case of a more general open economy model. The name *Mundell-Fleming* was coined by Rudiger Dornbusch, who synthesized the work of Mundell and Fleming during 1976–80. Versions of the Mundell-Fleming model can be found in many textbooks.

Two important cases are: (a) flexible exchange rates under perfect capital mobility and (b) fixed exchange rates under perfect capital mobility. The Mundell-Fleming model is based on Keynesian assumptions: output is determined by aggregate demand, and prices are sticky (inflexible). Individuals hold domestic money, domestic bonds, and foreign bonds. The country under analysis is a small country, which means that it cannot influence the world interest rate. Under perfect capital mobility, there are no restrictions on movements of financial capital. If the domestic interest rate is above the world interest rate, a massive amount of financial capital flows into the country instantaneously, as foreign and domestic residents shift their financial holdings to domestic bonds. This causes a massive increase in the demand for domestic currency. Conversely, if the domestic interest rate is below the world interest rate, a massive amount of financial capital flows out of the country instantaneously, as foreign and domestic residents shift their financial holdings to foreign bonds. This causes a massive increase in the demand for foreign currency. For these examples, we assume that initially, the domestic and world interest rates are equal.

Exchange Rate Regimes

With a flexible exchange rate regime, the exchange rate is set by market forces. An exchange rate appreciation reduces exports and increases imports, and leads to a decrease in the interest rate. An exchange rate depreciation increases exports and reduces imports, and leads to an increase in the interest rate.

For fixed exchange rate regimes, the central bank keeps the exchange rate fixed. If there is excess demand for domestic currency (the domestic currency is undervalued), the central bank sells domestic currency and buys foreign currency. This action expands the money supply, since the public receives new domestic currency (money) in exchange for foreign currency (a nonmoney asset). If there is excess supply of domestic currency (the domestic currency is overvalued), the central bank buys domestic currency and sells foreign currency. The money supply contracts, since the public receives foreign currency (a nonmoney asset), and the central bank receives domestic currency (currency is defined as money only if held by the public). To successfully defend an overvalued currency, the central bank must have large foreign currency reserves; otherwise, it runs out of reserves and is forced to devalue or float the currency (adopt a flexible exchange rate).

Predictions

For case "a" above, under fixed exchange rates and perfect capital mobility, monetary policy is completely ineffective. An increase in the money supply lowers the interest rate below the world interest rate and induces a massive capital outflow. The central bank maintains the exchange rate by selling foreign currency, which leads to a contraction in the money supply. This reverses the original monetary expansion and increases the interest rate. The process continues until domestic and foreign interest rates return to equality, and output returns to its original level.

Under fixed exchange rates and perfect capital mobility, fiscal policy is very effective. Expansionary fiscal policy (lower taxes and/or higher government spending) leads to an increase in the interest rate above the world interest rate, and induces a massive capital inflow. The central bank maintains the exchange rate by buying foreign currency, which generates an expansion of the money supply and a decrease in the interest rate. The process continues until domestic and foreign interest rates return to equality. Thus, the original fiscal expansion leads to a subsequent monetary expansion, which reinforces the original positive effect on output.

For case "b" above, under flexible exchange rates and perfect capital mobility, monetary policy is very effective. An increase in the money supply lowers the interest rate below the world interest rate and induces an exchange rate depreciation. The depreciation leads to an increase in exports. The interest rate increases; this process continues until domestic and foreign interest rates return to equality. Output rises as a result of monetary expansion and the increase in exports.

Under flexible exchange rates and perfect capital mobility, fiscal policy is completely ineffective. Expansionary fiscal policy raises the interest rate above the world interest rate and induces an exchange rate appreciation. The appreciation leads to a reduction in exports, thus reversing the effects on output of the original fiscal expansion. The interest rate declines. This process continues until domestic and foreign interest rates return to equality, and output returns to its original level.

Munich Re Group

Known in English as Munich Re, the Münchener Rückversicherung-Gesellschaft (Munich Reinsurance

Company) is the second-largest reinsurance company in the world. It has its headquarters in Munich, Germany, and currently has some 5,000 customers located in 160 countries.

The company was founded on April 19, 1880, by Carl Thieme, the businessman who was also responsible for the establishment of the Allianz insurance company. With the Cologne Re established in 1846 as the first reinsurance company in the world, and another started in Thuringia in 1853, under Carl's father Julius Thieme, Carl Thieme saw an opportunity to establish a business that comes from reinsurance—essentially an insurance company for insurance companies. This allows insurance companies to "spread the risk." The main guiding principle of the company from its foundation was that it had to be totally independent of any risks taken by insurers. This has meant that it only deals with insurance companies, not with the general public. It also refused to be connected with any insurance company. In 1886 Munich Re established an office in Paris, and later, offices in St. Petersburg, Copenhagen, and Stockholm, and eventually London in 1890, opening a branch in the United States in 1899.

Initially many insurance companies did not see it as necessary to be involved in reinsurance; they felt that this would erode some of their profits. However the claims that followed the San Francisco earthquake in 1906 changed this. With massive losses in the earthquake, spread over many companies, only six of them—four U.S. and two English—actually paid their liabilities in full; when they were asked to pay their obligations, four German insurance companies stopped trading in the United States to avoid meeting their obligations, and the Hamburg-Bremen Fire Insurance Company discounted all payments by 25 percent.

Many of the German companies had not recognized the risks from such large exposures, and this led many of them to become involved in reinsurance, with Munich Re picking up much business (as well as having to pay out 11 million marks). It soon began insuring luggage on travels, and in 1910 wrote reinsurance for aviation.

In 1914 Munich Re had annual premiums of some 204 million marks, making it the world leader in reinsurance, with Allianz contributing about a tenth of all its premiums and some 40 percent of its profits. The war, however, badly affected business, with many non-German companies not able to deal with them during the war and not wanting to deal with them afterward. By the early 1920s, the premium for Munich Re had fallen to 65 million marks, with Allianz having managed to take over rivals and double its size. It was not until 1930 that Munich Re was, once again, the leading reinsurance business in the world, with Allianz providing upward of 40 percent of its premiums and a substantial amount of its profits. During World War II, much of the foreign business of the company was transacted by Union Zurich.

After World War II, Munich Re once again faced a slump in business but steadily built it up again, and is now the second largest reinsurance company in the world. This involved work on reinsurance of installations of the petroleum industry, which led to their booklet *Oil at Sea: Hazards, Liability, Insurance* (1980). The company has 43,000 employees (2008) working in more than 50 locations, and has gross revenue of €37.4 billion (2006). It covers reinsurance for 5,000 insurance companies in 150 countries. Nikolaus von Bomhard is the chairman of the board of management. Munich Re was the largest reinsurer for the World Trade Center in New York City when it was destroyed on September 11, 2001. For this, it set aside $500 million to help pay for the loss. In 2005 Gerhard Berz, who had worked for 30 years on geo risks with Munich Re, wrote *Weather Catastrophes and Climate Change: Is There Still Hope for Us?*, published by the Munich Re Group to much acclaim.

National Accounts

Science advances through the interaction between theory and measurement. Without appropriate measurement, there is no way to assess the accuracy of theory quantitatively. Thus, it is no surprise that efforts to measure economic activity date back centuries. Among the early attempts to gauge national income were those of William Petty in the 17th century. By today's standards, Petty's statistics were extremely simplified, but the genesis of the idea was there. Nearly a century later, François Quesnay developed his Tableau Économique, which analyzed intersectoral flows. Quesnay's Tableau was a forerunner of modern day input-output analysis of the type pioneered by Wassily Leontief and is still practiced to this day.

The next major advances in national income accounting came in the early 20th century. Economists on both sides of the Atlantic began to break down systematically the income and expenditures of the national economy into categories such as consumption, saving, investment, government, and trade. Motivation for the development of the national accounts during this period was the desire among policy makers for accurate, timely information about the performance of the economy during the Great Depression and World War II.

A. L. Bowley and Colin Clark performed some of the early work in this area in the United Kingdom, but British efforts to create a system of national accounts took a giant step forward with the work of Richard Stone. Working with Clark and others in the British government during the World War II years, Stone helped create the major definitions used in national income accounting and set up the basic balance sheet concepts. The basic categories of spending and income were quickly incorporated into the growing body of macroeconomic theory research.

In the United States in 1913, the first director of research at the National Bureau of Economic Research, Wesley C. Mitchell, created one of the first definitive treatises on the business cycle. Though it was not actually national income accounting as we know it today, Mitchell's work aimed to quantify cyclical behavior in different sectors. Mitchell's student Simon Kuznets would carry the work further and complete a system of national accounts that resembles the system currently in use.

Both Kuznets and Stone received the Sveriges Riksbank Prize in Economic Sciences in Memory of Alfred Nobel (Kuznets in 1971 and Stone in 1984). Stone's Nobel citation specifically singles out his work on national accounts. Kuznets received the prize for his empirical research on economic growth—research that was informed and shaped by his work on national accounts.

Methodology

The crucial measure for any system of national accounts is gross domestic product (GDP), the value of final goods and services produced in a country in a year. GDP has replaced gross national product (GNP) as the primary indicator for countries in the United Nations (UN) National Accounts Main Aggregates Database. The difference between GDP and GNP is simply the net factor flows into or out of the country. Wages paid to foreign workers in the country, for example, are counted in GDP, not in GNP. Another way to look at it is that GNP measures the value of output produced, using domestic factors of production regardless of where they reside. With factor flows making up a significant component of economic activity, the difference between GDP and GNP is no longer trivial, and GDP is a better measure of the economic activity taking place within the country's borders.

In the systems of national accounts used by most nations as well as by the UN, GDP is calculated by three methods: the expenditure approach, the income approach, and the production (or value added) approach. All three methods must sum to the same amount. Each method has several categories of income, production, or expenditure. The precise headings of each of these categories vary among nations. The UN System of National Accounts, for example, lists government expenditures as a subcategory of final consumption expenditures. In the United States, the National Income and Product Accounts (NIPA) system lists government expenditures as a major category heading. When making international comparisons, one must take care to reconcile these minor differences. Sources of international data such as the UN and the Penn World Tables make those adjustments for consistency.

In the expenditure approach for the NIPA in the United States, total spending is broken down according to the type of spending. Consumption refers to spending by households to purchase goods and services for immediate consumption. Gross private domestic investment is the term given to spending by nongovernment entities (generally, businesses) to purchase capital goods. Real estate investment, both commercial and residential, is also included in this measure. The trade account—net exports—refers to the country's external trade balance, generally computed by using data from customs and from the country's balance-of-payments accounts. Government consumption and investment is a top-level category in the NIPA, including all transactions involving purchases of goods and services by any level of government but not including transfer payments such as Social Security payments.

The income approach adds compensation of employees, proprietors' income, rent, corporate profits, net interest, and other sources to arrive at national income. Adding depreciation of capital yields GNP; finally, adding net factor payments yields GDP. The production approach, less commonly cited in the literature, adds the value added by sector. All methods must yield the same result. Because the data come from different sources, some disagreement is inevitable. In the NIPA, a line item called statistical discrepancy, which usually is very small relative to GDP, is included to reconcile the difference between the expenditure and income approaches.

Along with the problem of classifying spending and income, the construction of price indexes often accompanies the task of national income accounting. Additionally, one must recognize that national income accounting and the calculation of GDP are imperfect measures of national welfare. GDP by definition does not count home production, illegal transactions, or the value of leisure time. National income accounting deals only in market transactions and values the goods and services at market prices without offering any normative judgment as to the social value of the activity.

Nationalization

Government ownership of an industry or a formerly private company is known as nationalization. By far the more frequent of the two phenomena is government ownership of an industry. Although some authors, such as Lars Bengtsson, have argued that choice of industries is random, nationalized industries typically are those that government considers to be fundamental to national security (from oil to media) or national income (based on a natural resource that may also be a wasting resource), as well as those that are particularly attractive to foreign direct investment. According to Bengtsson, a nationalized industry can be viewed as a governmental hierarchy, whereas an industry with a strong governmental organization that buys, sells, and/or competes with private actors is called a governmental market system. The government can also govern a market with only private actors through regulations, via a regulated market system.

Amy Chua discussed a different class of nationalization in developing economies, wherein the purpose is discrimination against an economically dominant ethnic minority. Here, market processes of competition and rule of law are manipulated to benefit certain ethnic constituents and to disadvantage others; little or no attempt is made to justify this action in terms of socialist or communist ideology. She cited the ethnically targeted nationalizations and confiscations in postcolonial Burma, Indonesia, Kenya, Malaysia, Pakistan, the Philippines, Sri Lanka, Thailand, Uganda, South Africa, and Zimbabwe.

Although the primary focus of this entry is government nationalization of industry for issues of security, income, state building, or public policy, not nationalization to disadvantage an ethnic minority, the expropriation of private property is very often a consequence.

Precedents in International Law

In his study of nationalization in Latin America, David Schneiderman noted that constitutional rules once expressly enabled state intervention in the market to redistribute wealth through rules permitting the expropriation or nationalization of property, subject, for example, to the provision of "appropriate" compensation, which protected host country governments from the external pressures generated by foreign economic power. In the 1990s, this type of state capitalism fell into disfavor, and the countries of Latin America mostly abandoned the constitutional design mandating public control of the economy or enabling nationalization of key economic sectors.

Today, both expropriation of property and nationalization are prohibited unless they are for a public purpose, nondiscriminatory, and accompanied by the payment of "prompt, adequate, and effective compensation" that is fully realizable and transferable. This perspective is embodied in international law. In a famous case, the Iran–United States Claims Tribunal—created to resolve the crisis between the Islamic Republic of Iran and the United States arising out of the detention of 52 U.S. nationals at the U.S. Embassy in Tehran and the subsequent freeze of Iranian assets by the United States—it was found that property rights must be respected and that compensation must be paid when the alien owner of those rights is deprived of them by acts attributable to a state. Although a revolution does not by itself create liability, neither a revolution nor any other changed political, economic, or social circumstances can be invoked to avoid liability for deprivation of an alien's property that is attributable to the state.

Government's Role in Economic Growth

Despite the ubiquity of government, government as an actor in national economic growth and development has been largely ignored by international business theorists. Government's importance to economic growth was addressed by Bengtsson, who argued that even in many traditionally capitalist countries, the public sector (involving both national and local governments) accounts for one-third to one-half of GNP. Hence, government is an actor in the economy as a whole, having a substantial influence over the governance structures employed through its right of enacting laws. In fact, the government is a more powerful agent of economic activity than any other single agent in most countries, whether their economies are capitalist, mixed, or planned.

In *Storm over the Multinationals,* Raymond Vernon viewed the activities of companies expanding into multiple international jurisdictions as a source of new complications for national policies and programs affecting job creation, inequitable income distribution among classes and regions, the availability of scarce supplies, the functioning of local markets, tax revenue, consumer safety, environmental protection, and national security. Writing at the same time as Vernon and Maurice Bye, George Stigler saw the government regulator as an ineffective functionary, held hostage by the more-moneyed, far more strategic regulated firm. Although international business theorists have largely ignored the role of government, a few—such as Vernon, Bye, and Edith Penrose—have examined the public policy implications of government action, including the decision to nationalize.

Dynamics of Sharing Oil Revenue

In her article "In Profit Sharing Between Producing Countries and Oil Companies in the Middle East," Penrose explored the economic questions involved in the sharing of oil revenue between the oil companies and the producing countries—two interested parties that stand to gain from bargaining. One of the parties invests capital to start the industry and runs it; the other supplies the raw material, which is a wasting asset. Both parties are interested in promoting the most profitable long-run expansion of the industry, but the producing countries' governments are concerned with their own oil production, and the oil companies are concerned with investing in the countries from which they can expect the highest returns. Looking at Penrose's indices of profitability and dividend payout for the oil majors from 1954 to 1966, one can see an increasing loss of profits paid out to foreign investors through dividends. While profits continued to grow, benefiting the majors, the loss of income to the producing countries made the case for government action to ensure profit sharing.

Penrose argued that the proportion of its profit that a company is willing to give up depends on its estimate of the cost of meeting the government's final demands compared with the cost of resisting them, up to the point where the loss in either case makes the business unprofitable. Conversely, a government's demands depend on the loss that it believes it can inflict on the company by not giving or by canceling the concession under negotiation—that is, on its estimate of the value of the concession to the company—or on the amount that it thinks the company is prepared to give up to avert political disturbances and maintain political goodwill. The latter alternative applies in the case of negotiations with a company that is already established in a monopolistic position in the country and in circumstances in which the government cannot run the industry.

For an established oil company, the cost of acquiescing to the government's demands is the additional profit lost in one form or another and the future profits expected. But the cost of resistance is not necessarily the loss of the concession (as it might be in the case of new concession agreements), for the company is in a strong position to precipitate an economic crisis, which may drive the negotiating government out of office. In fact, the company itself need take no positive action, which would force the government to risk political action, arousing the populace against the oil companies, condoning or inciting political harassment, or threatening nationalization on terms unacceptable to the company—steps that, once taken, are not easy to retreat from.

Granting Concessions Versus Nationalizing

If the economy of a country has become heavily dependent on the continuance of oil revenue, and the government cannot run the industry, an existing oil company, if it has a virtual monopoly or acts in concert with other companies, is in an extremely strong position vis-à-vis any single government. The progressive economic deterioration following the cessation of oil revenue is likely to cause greater political difficulties for the government, its eventual repudiation, and the substitution of a government pledged to reestablish the flow of oil revenue.

If the oil companies compete for a concession, the share of profits offered to the government rises to the point where the company obtaining the concession retains only normal profit—the amount of anticipated profit that would just induce the company to enter or continue to invest in the oil industry of the country. In this circumstance, the government would be able to extract nearly the full value of the concession from each company.

If the government can run the industry and obtain revenue not significantly below the revenue it previously obtained from the companies, it is in a good position to nationalize. Forcing the foreign companies out completely would not be to the country's economic advantage, because the country would lose the indirect advantages of increased rate of innovation; freer flow of technical information, leading to the more rapid application of advanced technology; and a greater supply of technical and managerial personnel. In calculating the advantages of nationalization, the government should take into consideration the alternative product that could have been produced by its resources, had they not been directed into oil production, including lost productivity, foreign exchange, and tax revenue.

Impact of Nongovernment Forces

Bye, the French structural economist, investigated the impact on the world economy of the interplay of flows and forces depending neither entirely on government nor on firms. Like Penrose, he focused on wasting assets (oil and mines). Bye warned that given the differential planning horizons of foreign investing firms and national governments, the latter cannot delay public welfare for long-term growth gains that might materialize only after the resource is depleted; it must fund social programs in the short term via taxes, tariffs, and other actions directed at what he called the "large multi-territorial unit." Governments, therefore, have an incentive to drive up extraction revenue to the point where the company obtaining the concession retains only normal profit, which is the amount of anticipated profit just sufficient to induce the company to enter or continue to invest in the country's oil industry. In these circumstances, the government can extract nearly the full value of the concession from each company.

Alternatively, if the government can run the industry itself (nationalize it) and obtain revenue not significantly below the revenue it previously obtained from the companies, it is in an extremely strong position with respect to established oil companies.

It should be noted that nationalization could be done without inhibiting technological progress if the government-owned firm were able to do technology licensing deals or call in consultants. Indeed, given that rival firms stand to make money from technology licensing or consulting services, there is scope for playing them off against one another.

Subsidizing Small Firms

In her introduction to *The Large International Firm in Developing Countries* Penrose quoted Bye:

> The mutual relations of large firms within one and the same industry ... have an impact on the world economy which is at least as important as that which the theory of the market assigns to factor proportion

and observed that his remark "applies with full force to [the oil] this industry ... " The international petroleum industry is dominated by a few large sellers, but operating in the interstices of the oil market are a group of smaller independents, whose activities have a significant influence on the industry. These smaller firms exist largely because of government action. Exploration is expensive, and small firms naturally operate at a cost disadvantage in this area; government subsidies and regulations, however, can create artificial but effective barriers to monopoly by making it impossible for foreign firms to operate without a domestic partner.

Investment in Developing Countries

Thomas Andersson's study of multinational investment in developing countries suggested that the endeavors of many developing countries to obtain benefits such as direct investment, reduced tax rates, and free profit repatriation further reduce their foreign exchange earnings from direct investment, particularly because multinational enterprises tend to repatriate funds rather than reinvest in troubled economies. This situation increases the attractiveness of nationalization, the risk of which again hampers direct investment and other benefits. Since the 1970s, however, nationalization has been in decline.

Andersson's investigation cited access to inexpensive borrowing, a fall in commodity prices, and the increasingly negative impact on direct investment from continuing the practice of nationalization after most other countries had stopped. Nevertheless, the developing countries' need for foreign exchange remains critical, as those countries have accumulated multibillion-dollar debts, and exports to the industrialized economies have been squeezed by import quotas and other kinds of protectionism.

Direct investment is increasingly viewed as a favorable source of foreign capital, employment opportunities, and an increase in output and exports. Hence, host country policies have become more benevolent than ever, and the recent investment revival in developing countries is expected to continue over the next decade. Increasing wealth, privatization, and government openness to foreign direct investment (FDI) have led to increased private investment in previously nationalized businesses.

Economies in Transition

According to UNCTAD, FDI inflows to developing countries and economies in transition (the latter comprising southeastern Europe and CIS) rose by 16 percent and 41 percent, respectively, in 2007 to a new record of $98 billion. Whereas resource-rich countries such as Kazakhstan received more than in 2006, the privatization of formerly state-owned enterprises drove FDI toward southeastern Europe.

FDI inflows to Africa, an estimated $36 billion, were supported by a continuing boom in global commodity markets, but new inbound FDI took place in the banking industry. Egypt, Morocco, and South Africa were the main beneficiaries of FDI inflows.

In Nigeria, the government divested 51 percent of its stake in NITEL, the country's telecom operator in 2006, to Transcorp for $500 million in the hope that privatization would turn around its performance and improve services. Now the government is seeking a new investor to acquire 27 percent of Transcorp's share in NITEL and to buy another 24 percent of the state's remaining 41 percent share and take control of the company.

Women weaving silk cloth in a private enterprise that was once a state-owned workshop in Uzbekistan in 2002.

Since its establishment in 2002, the Kosovo Trust Agency (KTA) has sold a significant share of the country's state-owned enterprises through spin-off and liquidation methods. As of November 2007, KTA administered about 650 state-owned enterprises; about 320 companies were privatized and about 110 firms placed in liquidation.

National Regulatory Agencies

Anyone doing business in countries outside the United States can safely assume that they will encounter government agencies regulating every direct and indirect aspect of commerce. Just as is the case in the United States, these agencies enforce regulations governing establishing a business, taxes, costs, prices, financial transactions, pollution, wages, workplace safety, and import and export duties. What the business person cannot assume is that working with regulatory agencies overseas will be the same as it is in the United States. Nor can the person assume that regulations and regulatory agencies will be similar even when nations have a common membership in an organization such as the European Union (EU), Southern Common Market (Mercado Común del Sur [Mercosur/Mercosul]), or Association of Southeast Asian Nations (ASEAN). Each nation's regulations are a product of its history, culture, and politics as well as attitudes toward the conduct of business.

The nation's openness or hostility toward business, and foreigners, its current economic situation, and even the nature of its civil service all have a bearing. A European nation with a long history of equal trade will have regulatory agencies that operate differently from those with a colonial background. In the latter case, an assumption of exploitation by more highly developed nations may create a basic distrust of outside business interests. A nation that, until recently, possessed a state-run, centralized economy may also present challenges to Western business interests. In addition to these factors, one may find regulatory bodies that may require special handling in either intangible or concrete ways to ensure their cooperation. Another factor, one that will apply mostly to nations with a long history of commercial law and regulation, is deregulation. The decrease in regulations governing business can also affect the attitudes of regulatory agencies and their representatives in the interpretation of the remaining rules.

While businesspeople have always had to contend with the regulatory agencies of their own country as well as the nation with which they are doing business, it will not be unusual in the future to incorporate planning for how the business enterprise will contend with international regulatory agencies. Organizations such as the EU, International Monetary Fund (IMF), World Trade Organization (WTO), or the World Bank will increasingly affect international business in the future. One example of national regulation moving to an international basis has been the European Aviation Safety Agency, an EU agency that came into being in 2003 with the aim of replacing the national aviation safety agencies in Europe that have functioned similarly to the U.S. Federal Aviation Administration (FAA). In the gap between national rules and agencies and those international rules and agencies that supplant them, U.S. businesses will have to become familiar with the rules and workings of both levels of agency.

International treaties, the Kyoto Protocols governing emissions is but one example, while not binding on U.S. companies in the United States, can affect overseas subsidiaries. These agreements would be enforced by the regulating agencies in the country where the American concern will do business.

Globalization has accelerated this factor in some part because it creates new situations that were never covered by law and that were never dealt with by regulatory agencies. There can be a regulatory vacuum in these instances, an area where businesses must tread cautiously. The result of new legislation, especially where there appears to be a sacrifice of either national self-interest or an unfair or illegal advantage, can create a backlash. A possibility of that kind of reaction can arise in situations such as occurred in Germany in 2005. In that year, the *Wall Street Journal* reported that lobbying members of Germany's parliament by commercial interests was growing. Along with the growing awareness of this activity was the awareness that it was not adequately regulated. Legislation was subsequently introduced to begin to prevent potential abuse. In a different country with a different set of assumptions and tradition, the effect on regulation and the government agencies charged with carrying them out could have been different, introducing a new complexity for international businesses working in that country.

Regulation does more than impose restrictions and rules on foreign investors and businesses that enter a country to do business. It should also provide the guarantee that the foreign investments will be safeguarded, that investors will receive their returns in a fair way, and that the intellectual property, financial, and other rights will be protected. However, the regulating agencies themselves and the way they function are also important. While regulations may seem clear, how regulatory agencies enforce them may be less clear. The transparency of the process and what is required by the business, what the agency does and how long and complicated its process are critical. In addition to wide latitude given to regulatory agencies in some nations, other organizations that are independent of financial or commercial agencies will also come into play. For example, in Brazil, which is hardly a unique case, there is the law and the regulating agency, but there are also courts at several levels that may provide a third, and often binding, interpretation of the regulations.

Another factor that business people must be aware of is that agencies in various countries will have changing sets of responsibilities and reporting relationships. Unlike the U.S. government in which organizations are relatively stable, a minister's portfolio (that is, his or her set of responsibilities) can change with some frequency. An example of this has been recent changes in the responsibilities of the finance minister in Germany and France. In many instances, there will be a title change accompanied by a shifting of subordinate departments (e.g., workplace safety or ensuring a percentage of native employees). Thus, with a new organizational identity, new reporting relationships, and perhaps new agendas set by the new minister, the manner in which the regulating agency can change can be dramatic. Of course, certain areas such as environmental regulation would be outside the purview of finance ministers and must also be considered.

Prior to contacting and working with regulatory agencies, the businesspeople must have done their homework. Success depends on exhaustive research with legal and business experts, especially when both the regulations and the character of the agencies can change. Illustrative examples, however, can provide an idea of the complexity as well as an idea of the general attitude toward business, especially U.S. business.

France

As an example, many regulatory agencies in France report to the minister of the economy, industry, and employment, who answers directly to the prime minister. While not directing all agencies, this ministry governs most aspects of employment, business, consumer issues, and industry. The U.S. businessperson coming to France must remember that while a great deal of direction comes from agencies at the federal level (i.e., national-level agencies), there are other entities. There are regulatory agencies that function on the state, provincial, or geographical department level. Localized agencies will be encountered not only in France but everywhere. The differences in complexity will vary. The manner in which a company conducts business with all of the agencies in France differs greatly from Germany or, more especially, nations such as China or Russia.

In France, and once again this will be the case in several countries, regulatory agencies have a great deal of leeway in how they enforce the regulations. In France, whether the agency will administer regulations in the spirit or the letter of the law may depend on the ministry or agency policy. In other countries, this will be true as well. Further, in some countries such as Russia or China, an individual government employee can and may choose to exercise a very personal reading of a regulation.

Another consideration for those working with French agencies (as well as those conducting business in other countries) is the degree to which the business person can understand and see the processes the agency conducts. That means understanding process and having the ability to petition when there are differences of opinion. In France, the degree of transparency for international business operations has improved from where it was a few years ago. Further, the standards by which the French will allow U.S. products to enter the country has become more defined and clear. However, and this is common throughout the EU, EU-level standards are in force. In France, as is the case throughout the EU, where there are no EU standards, the national standards as enforced by the nation's appropriate regulatory agency will apply.

Germany

Regulation in Germany can also be quite complicated. As is the case in France, the minister of finance will manage several regulatory agencies. In this case, however, there are several German ministries, all of whom report to the federal chancellor, that contain regulatory agencies. These would include the federal ministries for environment, nature conservation, and nuclear safety; economics and technology; food, agriculture, and consumer protection; labor and social affairs; and economic cooperation and development.

The German business regulatory context is complex. The basis for Germany's economy for a long time has been the export of its products and so the nation has a highly developed sense of international business. Admittedly, this outlook and its history are more developed in what was West Germany than in the former German Democratic Republic, but the gap has decreased. In addition, especially since the arrival of Angela Merkel as chancellor, there has been a movement in Germany to reduce regulations, and as a consequence, the effects of regulatory agencies on international business.

Germany's economy and international commerce, however, are still highly regulated. The number of regulatory agencies is not small and dealing with the extensive bureaucracy that administers what many consider to be an excessive set of regulations can be a complex experience. In Germany, as in other countries, regulatory agencies exist at the federal, state, and local levels, so a U.S. business concern must interact with a wide variety of agencies. Non-German businesses do have opportunities to petition to have grievances resolved and German regulatory agencies have been effective in handling these procedures fairly. Foremost among these has been the Cartel Office, which oversees many aspects of international business.

Despite the heavy degree of regulation and existence of a large number of agencies in these and other Western countries, they are relatively minor compared to the complexity of regulation and its implementation that businesses encounter in Russia.

Russia

In 1991 the Union of the Soviet Socialist Republics (USSR) ceased to exist. Constituent republics such as Latvia, Lithuania, Estonia, Belarus, Ukraine, and others became independent nations. The center of the old USSR, Russia, became what was supposed to be a free-market state. Initially, it appeared to be an excellent place for international companies to establish businesses. What these companies have encountered, however, is a complex system of regulation and bureaucracy. A major contributing factor has been Russia's regulating agencies. There is an increasing body of laws and regulations that are coming into being that are increasingly consistent with international standards such as those required by the WTO. There is still a substantial gap between what the law says and how it is implemented and enforced by the agencies.

The Russian business regulatory bureaucracy can be characterized as having a high degree of capriciousness, obtuseness, and corruption. Any businessperson going to Russia could do worse than to read short stories of Gogol in the Tsarist times, stories of Bulgakov in Stalinist Russia, and some historical research to understand what could be best described as the care and feeding of apparatchiks (the operators within government agencies).

The U.S. government reports that incidences of these difficulties have decreased in recent years, but they still do exist. In 2002 Transparency International placed Russia 21st in a list of 21 nations in what it called its Bribe Payers Index. Placing the country last on the list indicated that it was where a business was most susceptible to paying bribes. The Transparency International 2007 corruption index placed Russia at 146 out of 180 nations. One year before, it had ranked 121 on the list, the recent survey indicating that corruption is becoming substantially worse.

There have been government initiatives to reduce corruption in these agencies. It was declared by President Vladimir Putin in 2006 to be a priority and it is assumed that his successor, Dmitry Medvedev, will continue the effort; the results have not yet shown any substantial improvement.

It ought to be noted that while Russian regulatory agencies have one of the worst reputations in this regard and are presented here as an example, they are not unique. The degree and effects of corruption within regulatory agencies is a factor that must be researched by any company wishing to engage in business in another country.

In the background of Russian regulatory agencies, however, is the body of regulations and laws and how they were introduced as well as the nation's experience with free commerce and its regulations. The Russian Federation in the few years of its existence has undergone dramatic changes. The change from an entirely state-directed central economy to one in which perhaps 75 percent has been privatized has been rapid and uneven. There have been no real precedents in Russian history that could be followed. Additionally, much that underlies Western assumptions of regulation and how it is applied do not exist. Combined with the high degree of politicization that exists in Russia on all levels, from the federal to the local, and a higher degree of local autonomy than one might expect, the application of regulations can vary widely. In addition, there can be what would be illegal or extralegal actions performed by the regulatory agencies themselves, such as expropriations of property or enterprises on the local level.

China

In many ways, the regulatory agency situation in China is similar. There is much confusion in the body of laws and regulations. China's evolutionary path has, like Russia's, been one of transition from a totally state-dominated economy to an international economy where transparent regulations are supposed to be applied uniformly.

Chinese regulatory agencies all ultimately report to the executive branch of the government of the Peoples' Republic of China. The main executive organization, under the premier, is the State Council. It comprises vice premiers and ministers who direct the nation's affairs. Within the State Council, there is the Ministry of Commerce, which contains several departments (both specialized and general) that regulate international trade. Its departments are responsible for areas such as foreign investment, importing and exporting, and WTO affairs. Specialized departments include those dedicated to working in the areas of West Asian and African affairs, international trade and economic affairs, and foreign trade. There is one department that handles only issues relating to Hong Kong, Macao, and Taiwan.

Additionally, the State Administration for Industry and Commerce governs many aspects of market regulation. According to the Chinese government, its current (2008) functions include developing and implementing the laws and regulations for industry and commerce, registration and licensing of businesses, quality of goods, intellectual property, contracts, and investigating illegal activities such as pirating goods.

While the degree of corruption existing in Chinese regulatory agencies may not be as great as is the case in Russia, there is a great deal of variation in how agencies can interpret laws and regulations. This last factor has become a serious matter to some companies looking to do business in China. In addition, the Chinese business environment is so large that the Chinese government cannot enforce all regulations to include those regarding intellectual property rights. The recall of Chinese toys in 2007 because of lead paint is another example of regulations not being enforced by China's regulatory agencies.

Finally, there is the complexity of dealing with many agencies that further complicates the process of working with regulatory agencies. In a situation that exists in some other nations as well, not only do these agencies govern companies coming into China but also domestic Chinese companies looking for international investors. As an example, in 2000, the Chinese government decreed that any Chinese Internet company that wished to sell its shares abroad had to receive approval from three different agencies: the China Securities Regulatory Commission, the Ministry of Information Industries, and direct approval from the State Council itself.

In addition to government regulatory agencies, there are trade associations that either have a voice in regulation and its enforcement or at least some degree of influence. Government regulatory agencies can be assumed to govern every aspect of commerce to include banking and securities as well as manufacturing, providing services, or export and import.

States may claim that they are governed by laws and not people, but the fact will remain for businesspeople that a body of laws and regulations can be interpreted quite differently at different levels and locations. Assuming that business and commercial laws and regulations are enforced uniformly within a country or that all agencies at the federal level will have the same amount of scope for interpretation will be a serious mistake. To understand the nature of these organizations requires extensive research, but there is assistance on a number of different fronts. Organizations such as Transparency International regularly report on the degree of corruption that exists in a nation's governmental agencies that regulate business. Both the U.S. State Department and Commercial Service provide information not only on a nation's commercial laws, but also its regulatory agencies. The World Bank provides an extensive collection of documentation from the perspective of ease of doing business in a country, an index that can provide background on the ease of dealing with a particular nation's regulatory agencies.

Near-Shoring

Near-shoring (also nearshoring) means moving jobs to a nearby foreign country. It is part of the "X-shoring" constellation of terms that include off-shoring (sending work to an overseas location), multishoring (sending outsourced work to several overseas locations based on the job to be done and the relevant skills available), and two-shoring (using both an offshore location and a domestic one).

Near-shoring should be part of a company's global strategic considerations because it can generate many direct material benefits, depending on market conditions:

- It allows a firm to upsize or downsize and to spread risk to other parts of the production chain.
- Wage and costs differentials in near-shore countries make the company more competitive in the home market.
- Nearby countries may have higher-quality workers with multilingual capability.
- Rather than extend operations to a country around the world, a company that employs near-shoring can reduce costs and time to market because of the closer proximity to the home market.
- Time-zone advantages mean easier synchronous communication.
- Nearby markets open new consumer markets.

The question facing owners and managers is how to select a near-shore location. This selection usually is usually made through a high-medium-low market selection matrix for making comparisons. Considerations include size and composition of the near-shore market; economic conditions such as growth rate, tariffs, and trading blocs that the country is part of; labor-market factors, such as skilled employees, wage costs, and employee protection regulation; infrastructure issues such as transportation, electricity, and telecommunications; risk factors such as susceptibility to natural disasters; political stability and corruption; and intellectual property protection.

Especially important for near-shoring decisions are wage costs in important labor sectors. Using the rankings of the top near-shoring destinations from *BusinessWeek* and comparative salaries from *Over-*

seas Digest, an owner/manager of an IT company may want to consider the following near-shoring options:

	Rank	Data Entry	Programmer	Help Desk
Argentina	5.5	$11,397	$26,966	$18,826
Brazil	5.9	$7,809	$18,246	$12,790
Bulgaria	5.8	$11,397	$42,524	$29,791
Chile	5.8	$24,105	$45,389	$31,971
China	6.6	$24,501	$58,007	$40,489
Czech Rep.	5.6	$12,104	$28,558	$19,957
Egypt	5.6	$24,559	$47,931	$33,632
Estonia	5.6	$9,034	$21,252	$14,863
Hungary	5.5	$6,011	$15,428	$11,363
India	6.9	$40,050	$45,208	$31,561
Indonesia	5.9	$25,463	$49,471	$34,703
Mexico	5.7	$12,555	$29,725	$20,748
Philippines	5.8	$12,038	$28,432	$19,863
Poland	5.6	$12,822	$30,341	$21,182
Slovakia	5.6	$35,965	$71,545	$50,257
Thailand	6	$18,843	$35,050	$25,179

NEC

NEC, formally known in Japan as Nippon Denki Kabushiki Gaisha, is a multinational company, headquartered in Tokyo. Employing 152,922 people, it describes itself as "one of the world's leading providers of Internet, broadband network and enterprise business solutions dedicated to meeting the specialized needs of a diversified global base of customers." To achieve that goal it provides a variety of electronics products and services to include personal computers and peripherals, computer storage, networking equipment and services, and semiconductors. It also manufactures and sells consumer goods such as refrigerators, air conditioners, microwave ovens, and washers. In the year ending March 2008, it announced that its revenues totaled $46.172 billion and its profits totaled $227 million. According to iSuppli Applied Marketing Intelligence, NEC Semiconductors ranked number 13 in the world with 2.1 percent world market share.

The company is organized into three major sections: IT Solutions, Network Solutions, and Electronic Devices. IT Solutions provides both computer hardware and software as well as services. Network Solutions designs and implements network systems to include mobile and wireless systems. Electronic Devices provides semiconductors, displays, and other electronic equipment.

NEC (an abbreviation for Nippon Electric Company) is a very old company. It came into existence in 1898 and was initially a joint partnership with the American Western Electric Company. NEC was the first Japanese company formed with foreign capital; it made and maintained telephone equipment, first phones and switches, and then switchboards. While NEC provided equipment for domestic consumption, it also made equipment for export, starting in 1904, sending equipment to China and then to Korea. The company did not expand in a smooth fashion but rather in fits and starts in direct response to the Japanese government's timetable for providing telephone service to the islands. When the government decided upon expansion, NEC expanded as well. Whenever the government called a temporary halt to installing services, NEC had to pause as well. It was during these pauses that NEC began the practice of importing electric appliances for sale in Japan.

Starting in the mid-1920s, NEC began developing a radio communications business, first broadcasting with imported U.S. equipment in 1925. NEC expanded into developing radio transmitters that were sold in both Japan and China. NEC also developed a method for transmitting photographs by radio, first accomplishing this in 1928.

As was the case with many industries, NEC was taken over by the government during World War II and was run directly by the Army. The NEC factories were severely damaged during U.S. bombing raids and were not able to reopen until 1946. As the 1950s opened, NEC began developments in several areas commencing with research, development, and manufacture of transistors. The company also made radio broadcasting equipment for export, began developing computers (a transistorized model appeared in 1959), and underwater communications cable.

NEC appeared in the United States and Switzerland. In 1978 the first NEC factory in the United States opened. In the 1980s, NEC entered semiconductor chip production, personal computers (entering this market in 1982) while continuing to manufacture telephone systems, and also made consumer goods such as videocassette recorders, televisions, and printers. In this period, NEC was also heavily engaged in the design, development, and manufacture of supercomputers. It was this last area that not only brought a great deal of favorable attention, but also unfavorable notice, namely from the U.S. government.

In 1997 NEC was cited by the U.S. Commerce Department for attempting to dump supercomputers on the U.S. market. The dumping was to be accomplished by underbidding U.S. supercomputer manufacturer Cray on a contract for the American National Center for Atmospheric Research. NEC had bid to provide four 32-processor SX-4 supercomputers in May 1996 for $35 million. Finally, in February 2001, NEC announced a distributorship arrangement with Cray for NEC's SX-Series supercomputers, the same machines that had been at the center of the suit four years before. NEC granted Cray exclusive rights to distribute the SX supercomputers in North America. Further nonexclusive rights for sales in Europe were also granted to Cray. The entire agreement was predicated on the dumping fines levied on NEC to be dropped.

NEC supercomputer development has continued to make substantial gains. NEC created the Earth Simulator (ES), designed to perform global climate modeling. It was at the time (2002–04) the fastest computer in the world. In May 2008 NEC announced that it had been awarded a contract to build a new version for the Japan Agency for Marine-Earth Science and Technology (JAMSTEC). NEC is expanding into other business areas as well. Also in May 2008, it announced that it was going to work with Nissan to produce lithium ion batteries for electric and plug-in hybrid vehicles. The plan calls for an investment of $115 million with the stated goal of producing 65,000 batteries a year by 2011.

In common with its rival Fujitsu, as well as some other Japanese companies, NEC has been plagued with accounting difficulties and accused of fraud. In 2006 the company was forced to admit that as the result of an internal investigation it had discovered that one of its subsidiary companies (NEC Engineering) had recorded nonexistent business deals and had done so for four years.

Negotiation and Negotiating Styles

Negotiation is a long-standing art that has developed into a major mode of decision making in all aspects of social, political, and business life. Negotiation may be defined as a process of potentially opportunistic interaction by which two or more parties, with some apparent conflict, seek to do better through jointly decided action than they could otherwise. Negotiation then becomes a structured set of interactions in which parties weigh alternative courses of action, each of which may have different consequences, both for the parties themselves and for others in their social, political, or commercial constituency.

Negotiations do not always lead to decisions or agreements. Other outcomes can include softening or hardening of position, personal understanding between negotiators, and symbolic messages sent to the rest of the stakeholder community.

Distributive and Integrative Negotiation

The two main types of negotiation are distributive and integrative. A distributive negotiation usually involves a single issue in which one person gains at the expense of the other operating under zero-sum conditions. Distributive negotiation involves traditional win-lose thinking. In distributive negotiation, each party has a target point that defines what it would like to achieve. Each also has a resistance point, which marks the lowest outcome that is acceptable. The arc between these two points makes up each one's aspiration range. As long as some overlap exists between each party's aspiration ranges, there exists a settlement range in which each one's aspirations can be met.

Examples of tactics used in distributive negotiation are persuading your opponent of the impossibility of getting to his or her target point and the advisability of accepting a settlement near yours; arguing that your target is fair, whereas your opponent's is not; and attempting to get your opponent to feel emotionally generous toward you and, thus, accept an outcome close to your target point.

In more conflicts, however, more than one issue is at stake, and each party values the issues differently. The outcomes available are no longer a fixed pie divided among all parties. An agreement can be found that is better for both parties than what they would have reached through distributive negotiation. This situation calls for integrative negotiation, which involves a progressive win-win strategy.

Added-Value Negotiation

One practical application of the integrative approach is added-value negotiation, during which the negotiating parties cooperatively develop multiple deal packages while building a productive long-term relationship. It consists of five steps:

1. Clarify interest, with each party identifying each tangible and intangible need. The two parties discuss their respective needs and find common ground for negotiation.
2. Identify options, which involves creating a marketplace of value when the parties discuss desired elements of value.
3. Design alternative deal packages. Each party mixes and matches elements of value from both parties in workable combinations.
4. Select a deal. The parties jointly discuss and select feasible deal packages with a spirit of creative agreement.
5. Perfect the deal. The parties discuss unresolved issues and build relationships for future negotiations.

Strategies for Dealing With Conflict

Individuals in organizations adopt various strategies to deal with conflict, such as:

- Avoidance—based on the assumption that conflict can be handled by avoiding it. Opposing views cannot be heard unless apparatus for their expression exists. There is always the danger, however, that a conflict will be harder to deal with when it does erupt.
- Smoothing—based on the effort to resolve conflict by putting the emphasis on the value of teamwork; the assurance that "we all agree, really"; and an overt, honest attempt to get past the divergence of opinion.
- Forcing—the opposite of smoothing. A party attacks expressions of dissent and deals with conflict by stamping it out.
- Compromise—in which divergence of views is acknowledged and confronted. One possibility is to split the difference. The major drawback of this strategy is that both parties fail to win.
- Confrontation—involves accepting the conflict of opinions or interests, exploring the scale and nature of the conflict, and then working toward an accommodation of the differences that will provide a greater degree of satisfaction of the objectives of both parties than can be achieved by simple compromise. This strategy may be the most productive one in many cases; it offers the opportunity for both parties to win.

Among other things, the benefits of having conflict out in the open appear to derive from (a) full exploration of the issues that the negotiation is intended to address; (b) identification of parties' real concerns (information that is needed if integrative solutions are to be developed later); (c) consideration of more options; (d) a lack of false optimism; and (e) enhanced feelings of empowerment and procedural justice.

The Five Steps of Negotiation

The process of negotiation can be viewed as being made up of five steps:

- Preparation and planning. Before the start of the negotiation, both parties need to do their homework. What are the nature of the conflict and the history leading up to this negotiation? Who is involved? What do the parties want from the negotiation, and what are their goals? Each party's assessment of the other party's goals is very useful, because each party can anticipate its opponent's position and therefore is better equipped to counter the opponent's arguments with the information that supports its own position. When this type of information is gathered, it should be used for the development of a strategy.

  As part of the strategy, each party needs to determine both parties' Best Alternative to a Negotiated Agreement (BATNA). The BATNA determines the lowest value acceptable by the party for a negotiated agreement. Any offer the party receives that is higher than its BATNA is better than an impasse. Conversely, each party should not expect success in the negotiation effort unless it is able to make the other party an offer it finds more attractive than its BATNA.
- Definition of ground rules. When the development of the strategy is complete, each party should define the ground rules and procedures with the other party over the negotiation itself. Who will do the negotiating? Where will it take place? When will it take place, and what time constraints, if any, will apply? To what issues will the negotiation be limited?
- Clarification and justification. When initial positions have been exchanged, both parties will explain, amplify, clarify, and justify their demands. This exchange provides each party an opportunity for educating and informing the other on the issues, why they are important, and how the party arrived at its initial demands.
- Bargaining and problem-solving. The essence of the negotiation process is the actual bargaining in trying to reach an agreement.
- Closure and implementation. The final step in the negotiation process is formalizing the agreement and developing any procedures that are necessary for implementation and monitoring.

Negotiating Styles

One obvious method for achieving an integrative solution is to suggest that this solution will be a product of the personalities or management style of the individuals involved in negotiation. Along these lines, a range of individual differences have been used as a basis for predicting which style a particular negotiator's behavior will fall into. Most notably, one scholar distinguished among four types of motivational orientation toward a particular conflict: individualistic, altruistic, competitive, and cooperative. These orientations differ in the degree to which individuals are assumed to show concern for their own and others' outcomes. Individualists are assumed to be concerned primarily with maximizing their own gain with no regard to others, altruists with maximizing others' gain with no regard to themselves, competitors with

Some cultures are more willing to make concessions than others, including Norwegian, North American, and Arab groups.

maximizing their own gain at the expense of others, and cooperators with maximizing their own gain as well as that of others. Accordingly, individuals with a cooperative orientation are viewed as holding the key to the discovery of integrative solutions, provided that their opponents also have the same orientation.

Along very similar lines, other scholars developed a dual-concern model that differentiates among individuals on the basis of their conflict style. This style is viewed as being the product of two independent personality variables: concern for self and concern for others. Concern for neither the self nor for others is associated with inaction, concern for others but not the self with concession making, concern for self but not others with contending, and concern for both the self and others with problemsolving.

Third-Party Negotiations

Occasionally, individuals or group representatives reach a statement and are unable to resolve their differences through direct negotiations. In such cases, they may turn to a third party to help them find a solution. Four basic third-party roles exist:

- A *mediator* is a neutral third party who facilitates a negotiated solution by using reasoning and persuasion, suggesting alternatives, and the like. Mediation is effective when the conflicting parties are motivated to bargain and resolve their conflict, when conflict intensity is not too high, and when the mediator is perceived as being neutral and noncoercive.
- An *arbitrator* is a third party with the authority to dictate an agreement. Arbitration can be voluntary or compulsory. The big advantage of arbitration is that it always results in a settlement.
- A *conciliator* is a trusted third party who provides an informal communication link between the negotiator and the opponent. In practice, conciliators typically act as more than mere communication conduits. They also engage in fact-finding, interpreting messages, and persuading disputants to develop agreements.
- A *consultant* is a skilled and impartial third party who attempts to facilitate problem solving through communication and analysis. The consultant's role is not to settle the issues but to improve relations between the conflicting parties so that they can reach a settlement themselves. This approach has a longer-term focus, as it tries to build new and positive perceptions and attitudes between the conflicting parties.

Cross-Cultural Issues in Negotiation

Researchers generally agree that significant cross-cultural differences occur in several negotiation behaviors. Some scholars categorize these differences as follows:

- Persuasion styles, such as rational argument (North Americans) or affective, based on feelings (Arabs)
- Confrontation versus avoidance, such as confrontation in France and the United States, and avoidance in Japan
- Initial positions, which are extreme for Russians, Arabs, Chinese, and Japanese, and moderate for North Americans
- Concession patterns, in which some cultures are reluctant to make concessions (Russians) compared with those that are likely to do so (Norwegians, North Americans, Arabs, and Malays)
- Nonverbal behavior, such as silence (used most by the Japanese and least by Brazilians) and touching (used most by Brazilians and least by the Japanese)

These extensive and significant differences in negotiation behavior create cultural barriers that can make cross-cultural negotiation very difficult. Thus, negotiators who are unfamiliar with these barriers are likely to leave the bargaining table confused and frustrated, and escalation of conflict may follow. Negotiators, therefore, must be trained in cross-cultural negotiation to reduce the impact of barriers, such as prejudice, stereotypes, misunderstanding, and communication breakdown.

Neocolonialism

The study of neocolonialism involves the exploration of aspects of strategic and economic dominance of former colonial dependencies. Neocolonialism highlights the fact that colonialism and imperialism do not simply have a historical dimension. Rather, the political economy of power and economic relations in some cases takes the form of a continuation of colonial and imperialist interdependencies. Postcolonial dependencies could include activities such as the nomination of puppet governments, control of the development pace and direction of the developing nation, and exploration of exclusive trade relationships.

Neocolonialist discourses argue that dominance over legal, military, cultural, and political issues did not stop with the formal European abandonment of their colonies and/or the independence movements that found voice in many foreign-ruled countries. In some cases, the forms of dominance simply became more informal and indirect.

History of Neocolonialism

In 1955 an Asian-African conference was held in Bandung, Indonesia, at which representatives of formerly colonized nations collectively denounced their former Western imperialist/colonial domination. Predominant objectives were decolonization, national sovereignty, and independence; a voice in their respective nations' development; and a strategic role on the world stage.

By the 1960s many former colonies had become independent, both politically and legally. It was then that use of the term *neocolonialism* became widespread. A famous proponent was Kwame Nkrumah, the first prime minister and later president of Ghana, who, while leading his country to independence, recognized that in spite of a country's formal independence and sovereignty, its economic and political system frequently continued to be directed from the outside. Often it was no longer military but monetary power that determined the continued imperialist dominance of the former colonial states—economic power exercised by pressuring the formerly colonized state to purchase products from its former colonial power.

Within an almost exclusive trade relationship such as this, neoliberalism, free market mechanisms, and competition are invalidated at the expense of the local economy in the formerly colonized state. Moreover, developing countries may be unable to set prices for their natural resources that may be in high demand in the colonial nations, perhaps resulting in a divergence of local markets' needs, production, and low labor costs.

Third World Development

Following the Bretton Woods agreement, the introduction of an international monetary system, and the oil crisis of the 1970s, many Third World countries had to postpone their development strategies; the creation of a global capitalist market favored the hegemony of developed countries. Small developing countries were not yet able to compete with the bigger and richer countries, which determined the rules of this international system. World capital and world economies came under the control of the International Monetary Fund (IMF), the World Bank, and the General Agreement on Tariffs and Trade (GATT). The United Nations entered world politics. Through these multiple institutions, many developed nations, foremost of which was the United States, were able to exercise control of world capital.

As later studies would reveal, the import substitution strategy regularly prescribed for developing countries as a means of improving their underdeveloped economies resulted in (a) developing countries focusing on the production of finished goods, with accompanying high import duties to protect the local industries, and (b) multinational companies (MNCs) subsequently exporting lower-import-duty machinery and technologies. Increasing foreign direct investments (FDI) created new debt and technological and structural dependencies of neocolonized countries on foreign capital. It also resulted in the neocolonization of developing countries by international economic powers.

The Neocolonial State

When it comes to strategic dominance in the neocolonial state, proimperial civil servants can control state issues such as exchange rates, fiscal policy, allocation of resources, foreign investment, and a pluralism of legal environments in favor of the colonial powers. Regarding foreign-policy issues, a danger exists that the country will be incorporated into the imperial power's geopolitical and imperialist aims instead of addressing its own economic, political, and developmental needs. Development goals, including the improvement of living standards, increasing access to education, and the creation of more jobs might become secondary considerations if the neocolonial state is not left to establish its priorities.

Voices from outside the neocolonial states insist that the former colonies should focus first on their agricultural sectors and second on industrialization, to ensure that their people have enough to eat. Such a view is often rejected by the leaders of developing countries, who argue that it would take them forever to feed and to increase the living standards of all their citizens. Industrialization and foreign trade, however, cannot be postponed; otherwise, the gap between the developing and the developed countries will increase, with dependencies on manufactured products growing exponentially.

Outside Cultural Influences

Certain development aid or loan programs have been criticized for forcing former colonial territories to agree to financially or ideologically unfavorable conditions. The neocolonial dependencies of Africa, Asia, the Caribbean, and Latin America do not stop there. Cultural influences, such as access to news, information, and media, can promote imperialist popular cultures and zeitgeist, subsequently increasing the sale of said media and cultural products at the expense of the creation and promotion of local or regional cultures and tastes. This particular notion of cultural imperialism, which became popular in the 1970s, embodies domination by international media corporations and the introduction of specific cultural values by a dominating foreign force. Clearly, cultural imperialism has vital social and economic consequences for the local cultures.

Academic discussion and analysis of the continuation of colonial dependencies revolves around theories of development and dependency. The prevalence of rich developed countries' self-interests in international politics and the rise of free-trade imperialism are discussed in World Systems Theory. Modernization theorists argue that the development of developing nations will occur gradually, similar to the development processes that many of the developed countries experienced in the past.

Colonialism Defined

Understanding the political economy of neocolonialism requires understanding its antecedent. The term *colonialism* often refers to European colonialism, both classical and modern. In classical Greek, *colonialism* means "people settling down away from home and the administration and governing of such settlements." Greek colonization had a regional character, with new settlements spread around the Mediterranean and Black seas. In contrast to the more economic-oriented Greek colonization, the Roman Empire pursued foreign settlements more on the basis of strategic and political control of conquered territory and the expansion of its empire.

The Golden Age of the 15th and 16th centuries heralded a period of European overseas expeditions undertaken in search of spices, slaves, food, and territories. Asia and Latin America saw a rapid increase in the number of foreign settlers, tradesmen, adventurers, missionaries, and diplomats, each group employing economic or military power in its attempt to exploit and fleece the native population. In later years, some of these settlements were controlled and administered by new immigrants, who in some cases sought independence of their own. In the United States, for example, former colonizers Britain and France strongly opposed such a move but, as history shows, unsuccessfully.

In contrast, modern colonialism refers to colonial domination not mainly through economic or military power settlements, but through expansionist imperial control from the outside—from the colonizing country. The positions of many high-ranking civil servants and senior administrative roles of the colonized territory are filled by representatives or delegates of the colonizing nation. In Latin America and Asia, many of these colonies remained under colonial rule and administration until the 20th century.

Imperialism Defined

Colonialism is often associated with imperialism. Whereas the former addresses one specific form of foreign domination (i.e., colonial control), imperialism encompasses a wide range of commands by a foreign power, including military, economic, and political. The concept of imperialism, which appears to have originated during the times of Napoleon I (1769–1821) and Napoleon III (1808–73) of France, soon found its way into the vocabulary of the expansionary empire of Great Britain. Whereas imperialism originally was characterized as political control over a foreign territory, later it extended to include economic and technological control.

The economic causes of imperialism had their genesis in (a) the economic problems that beset Europe in the 19th century and the need to safeguard the import flows of agricultural products from overseas territories, and (b) the protection of the selling markets for Europe's own industrial products. The *dependentistas* (Latin American dependency theorists in the 1960s and 1970s) not only recognized the significant role that economic dependency was playing, but also highlighted the fact that Western capitalism actually increased underdevelopment in formerly colonized countries. Later research expanded the concept of imperialism to cultural imperialism and the ecological aspects of imperialism.

Neomercantilism

Deriving its name from mercantilism, the political economic philosophy characterized by the desire of nations to enrich themselves through the control of trade, neomercantilism is a similar philosophy modified to fit the modern world. Whereas mercantilism generally refers to the 16th through 18th centuries, neomercantilism usually is considered to span the 19th century through the present, especially the post–World War II period. In that long span of time, the precise character of what might be called neomercantilism has changed. One common thread, however, is that neomercantilism deals with an industrial world as opposed to the pre–Industrial Revolution version of mercantilism.

Modern neomercantilism is diametrically opposed to the philosophy of neoliberalism. The neoliberal political economic philosophy is one of free markets, deregulation, and unfettered trade. The policies of the Washington Consensus, as outlined by John Williamson, are a fairly comprehensive statement of the basic neoliberal philosophy. Modern neomercantilism, like its intellectual predecessor, has at its core a belief that active direction of international economic relations yields superior outcomes relative to the more laissez-faire neoliberal approach.

Neomercantilism in American History

In his study of the American Revolution, John Crowley places the early United States in the context of global trade. His thesis is that the early United States valued its trade relations with Britain that had been forged in the colonial era. He describes the colonists as neomercantilists, not yet ready to face the harsh environment of free trade. It should be pointed out that Crowley's view is not without controversy, as it overturns the conventional view that the early United States was born out of resistance to the trade practices of the British (e.g., the Navigation Acts) and a commitment to the classical liberal ideas of Adam Smith. Nonetheless, the fledgling American republic had reason to be concerned about being cut loose from the relative protection of the British Empire and its important trade connections. Meanwhile, as the 19th century began and the Industrial Revolution got under way, the British enjoyed the benefits of their hegemony, which allowed them more freedom to trade.

By the late 19th and early 20th century, the United States was getting set to surpass Britain at the top of the economic ladder. In this rapidly changing economic environment, the United States was quite successful at consolidating its power and hegemony both as an economic and military power. It did not accomplish this success solely through unfettered markets and commitment to neoliberal ideals, however. The trade negotiations with and foreign investment in the Kingdom of Hawaii are examples of what could be considered neomercantilist policy that helped the United States obtain economic and military power and influence in the South Pacific.

U.S. Hegemony After World War II

After World War II, U.S. hegemony was assured, and the nation took the central role in the Bretton Woods system of fixed exchange rates. It was at this point that the U.S. dollar became the world's reserve currency. Bretton Woods tied the world currency system to the dollar, and the United States took on the responsibility of maintaining that reserve currency and therefore ensuring the stability of the system as a whole.

Being the provider of the world's reserve currency had certain advantages. Like Britain before it, however, the United States found itself limited by its role as the world economic leader. It could not run persistent trade or budget deficits without putting serious strain on the dollar, and it was coming under pressure from neomercantilist policies in Europe and Japan. Ultimately, this pressure proved to be too much, and the dollar peg had to give way. As Bretton Woods broke up, however, new economic powers were rising and were giving credit to neomercantilist policies for their success.

The Rise of Asian Economies

Japan, Korea, and Singapore were among the Asian countries with the most active industrial policy. In their period of fast growth in the 1960s through the 1980s, government and business worked together to increase national welfare. A heavy dose of central planning was involved, but it was informed by market prices and executed in the context of global markets and participation in bilateral and regional trade agreements. In a world in which international institutions limit a country's ability to use outright trade protection, the use of subsidies, industrial policy, and managed trade characterize modern neomercantilism.

More recently, China, with its evolving market economy and firmly controlled central government, has been cited as an example of a neomercantilist country. China is accumulating reserve currencies, attracting foreign capital, and experiencing fast growth in its export sector. Currency policy, rather than outright trade protection, becomes the dominant policy tool in this modern form of mercantilism.

Neomercantilism in Economic Literature

Although the term *neomercantilism* is often used in international relations, it is seldom used in economic literature, likely because of the negative connotation associated with the mercantilism of the 16th through 18th centuries. Opposition to neoliberalism and the Washington Consensus in economic literature shares some of the features of neomercantilism (e.g., advocating national industrial policies, capital controls, and managed trade) as described in the international relations literature without necessarily using the neomercantilist term. Advocacy of such policies in the economic literature tends to be more benign—that is, focused on bringing stability and poverty relief to the Third World—rather than focused on gaining international military might, as under traditional mercantilism.

Nepotism

Nepotism is the favoring of an employer's relatives and friends in the workplace. The relative or friend is hired solely on the basis of kinship, regardless of any regard for the ability to do the job. The word *nepotism* is derived from the Latin word *nepos,* which means "nephew" or "grandchild." The term came into use in the late Middle Ages from a practice of popes and bishops. Since they had taken a vow of chastity they normally had no children of their own, but they often had nephews to whom preferment was given in ecclesiastical employment. Some nephews preferred became cardinals. At least one, Rodrigo Borgia (1431–1503) became a pope (Pope Alexander VI). The general practice was outlawed in canon law by the papal bull, *Romanun decet Pontificem* (1692), issued by Pope Innocent XII.

Hiring family members is an expected aspect of many cultures around the world. The ties of blood create responsibilities for the welfare of family members, and giving them a job becomes very important to the solidarity of kinship relations. In societies where extended families, which may be clans or tribal, are the primary social structure, the practice of nepotism is either common or an expected practice. The practice in the Third World by locals can have a negative effect because it creates a dead weight of incompetence among job holders who have demonstrated no merit. Globally it is a not unusual for smaller companies and many nonprofit organizations to hire family members. Children may learn the family business by doing paid jobs.

Managers from Western countries where nepotism is not the standard practice have at times had to yield to local practices and hire numerous family members. When commercial employers hire people who are related to each other, though not to the employer, it can have the benefit of making leading family members responsible for other family members. The steel industry in the United States long practiced hiring members of families recruited from eastern and southern Europe because these families had close ties and would discipline their relatives if their jobs were put in jeopardy by the misbehavior of junior family members.

The opposite of nepotism is the creation of a meritocracy, where those with the most abilities are hired because it can be demonstrated by examinations or by their performance records. It is often the case that talent in high-performing individuals is found in their offspring, so that the practice of hiring the children of high achievers is sometimes simply allowing merit to have an opportunity. Among Protestant ministers there have been families that have produced excellent ministers for generations.

Nepotism in Government

In the United States some states and some federal practices limit nepotism. It is commonly denounced for political reasons, as happened when President John F. Kennedy appointed his brother Robert Kennedy to be Attorney General. Elsewhere in the world there has always been a tendency toward dynastic succession. The succession in North Korea, Syria, Azerbaijan, and elsewhere has been that of father following son as his successor.

Wives have also followed husbands even in situations where they were elected by the people. In Trinidad and Tobago Patrick Manning simply appointed his wife Hazel Manning to the Cabinet for two terms. And nearby in Cuba Fidel Castro was succeeded by his brother Raul Castro. These and many other examples around the world create monarchial dynasties in what are nominally republics. Business hiring is often expected to follow the example of the political leadership. Nepotism often is accompanied by negative effects such as bribery, favors or delays in bureaucratic decision-making by those whose jobs depend upon kinship.

Business hiring is usually viewed as purely an economic decision, unlike some governmental hiring even in the United States. However, business hiring in the Third World may be unintentionally very political if it involves hiring members of different ethnic groups. The income and prestige of these jobs can change the balance of power between the groups involved and threaten to stimulate more ethnic conflict.

Nestlé

Nestlé, which specializes in sales of processed food, traces its origins to the Farine Lactée Henri Nestlé, founded in 1866. Heinrich Nestle (1814–90), the company's founder, was born in 1814 in Frankfurt-au-Main, Germany; he was apprenticed to a pharmacist, learning how to produce chemicals and make up prescriptions. He moved to Vevey, Switzerland, and there changed his name to Henri Nestlé, changing his Christian name to a French one and adding the acute accent to his surname. He became very interested in rapeseed oil, which he manufactured and used for oil lamps, and in the manufacture of liqueurs and absinthe.

During the 1840s, Nestlé established a business making and selling carbonated mineral water and lemonade. In 1847 he was forced to stop selling mineral water, and 10 years later, he was focusing on sales of fertilizers and gas lighting equipment. During this time, he became interested in the development of infant formula due to the high infant mortality rate at the time. Half of his own siblings had died when they were young.

When some mothers were unable to breastfeed children, they generally used a mixture of cow's milk, sugar, and wheat flour. Nestlé decided to manufacture his own milk formula, removing acid and starch to make it easier for babies to digest. To sell it, he made it in a powdered form as Farine Lactée Henri Nestlé (Henri Nestlé's Milk Flour), which became the name of the company. By the mid-1870s, the product was being sold throughout the United States as Nestlé's Infant Food. Soon afterward, Henri Nestlé-Ehmant, as he was then called, retired to Montreux and then to Glion, where he lived in what became known as Villa Nestlé until his death in 1890.

Processed Foods

In 1905 Farine Lactée Henri Nestlé merged with a rival, the Anglo-Swiss Milk Co., which was established in 1866 by Charles A. Page and George Page, brothers from the United States, at Cham, Switzerland. Together, the two companies had competed in the manufacture of milk formula; together, they formed Nestlé, which built on the strengths of both businesses to manufacture milk products, confectionary items, bottled water, ice cream, coffee, food seasonings, and pet foods. The companies also had the rights to manufacture chocolates as Peter, Kohler, Nestlé, and Cailler. In 1927 the firms bought from Gerber & Company AG the right to make cheese. Then they moved into the making of instant coffee, which was sold under the name Nescafé

Through acquisitions, Nestlé has grown to offer a vast number of brands and products tailored to markets around the world.

and is now one of the most profitable and best-known lines in the company.

The company later grew larger with the purchase of Fabrique de Produits Maggi SA in 1947. In 1960 it took over Crosse & Blackwell (established 1830) and its affiliated companies, which operated in Great Britain, Australia, South Africa, the United States, and many other parts of the world. Gradually, Nestlé started buying up other European brands, including Vittel in 1990 and Perrier in 1992. In 1998 it bought Sanpellegrino, Rowntree Mackintosh, and Spillers Petfoods. In addition, it bought several U.S. companies, including Carnation Co. After the purchase of Ralston Purina in 2002, a new division of Nestlé was established, called Nestlé Purina PetCare. Then Nestlé expanded into frozen food with Chef America, Inc.

Nestlé, which maintains its headquarters in Vevey, currently employs 276,000 people (2007) and has assets of $129 billion, with operating income of nearly $17 billion and profit of $12 billion.

Net Capital Outflow

Net capital outflow is a situation wherein the amount of money country A invests in other countries exceeds the amount these countries invest in country A. When this happens, the net capital outflow is positive. If the opposite is the case—when the investment by other countries in country A exceeds A's investment in other countries—the net capital outflow is negative. These investments include foreign direct investment (when, for example, Ford Motor Group acquires a plant in Britain) and portfolio investment (for example, the purchase of British company shares by American residents).

Positive net capital outflows mean that the funds owned by a country exceed its domestic investment requirements and this surplus is invested abroad. Net capital outflows are determined by net exports (the surplus of exports over imports). If a country's net exports are positive, its trading partners have a corresponding trade deficit; they are demanding more goods than they produce. To finance this deficit, they borrow money from a country with a positive trade surplus. Consequently, the country with the surplus acquires assets in the countries with the deficit.

The relationship between capital outflows and net exports is important for the balance of payments on capital account. The capital account records transactions involving international movements of ownership of financial assets and includes, for example, ownership of company shares, bank loans, and government securities. When a country has a deficit on its capital account, its investment in foreign assets exceeds foreign investment in its own assets; the opposite applies when a country has a surplus on its capital account. Consequently, a country that has a positive net capital outflow (deficit on its capital account) will have a surplus on its trade account; conversely, a country with a negative net capital outflow (surplus on its capital account) will have a deficit on its trade account.

In addition to these capital flows, significant and unpredictable flows of funds often occur between countries that may not be directly related to net exports. These are sometimes referred to as "hot money." Hot money is money that moves at very short notice from one financial center to another to take advantage of higher short-term interest rates for the purposes of arbitrage or because its owners are concerned about future political intervention in the money market. As a result of greater integration of world capital markets and greater access to, and dissemination of, financial information, significant and destabilizing flows of hot money can occur. For example, George Soros, the global financier, is reputed to have made a $1-billion profit by speculating that the Great Britain pound (GBP) would be devalued in 1992.

The key determinant of the speed and volume with which capital flows between financial centers depends on the degree of capital mobility. Perfect capital mobility occurs when domestic and foreign assets are perfect substitutes and when adjustment to interest rate differentials is instantaneous. In other words, a slight difference in interest rates between two centers is eliminated immediately. This process works because the inflow of money reduces interest rates, whereas the outflow of money from other centers increases interest rates. Imperfect capital mobility means that interest rate differentials between centers may persist for longer periods of time. This can occur when assets are not perceived to be perfect substitutes, for example, when there are differences in risk associated with each asset. Imperfect capital mobility can also occur when governments impose restrictions on capital inflows and outflows, for example, via exchange controls.

Net capital flows do not occur for the same reasons as "capital flight." Capital flight is frequently associated with developing countries and occurs when domestic capital is exported in response to largely political risks, for example, fears that a government will be overthrown or that civil war is likely. When capital is exported for these reasons, the outflow has no relation to the trade balance but occurs because the owners wish to avoid sequestration of their assets.

Netherlands

The Kingdom of the Netherlands is a commonwealth of three countries, formed by charter between the Netherlands, the Netherlands Antilles, and Aruba, the latter two of which originated as part of the Netherlands' colonial empire. The Netherlands Antilles (309 sq. mi., population 225,000, gross domestic product [GDP] $2.4 billion in 2004) is also known as the Dutch Antilles (sometimes still referred to in texts as the Dutch West Indies, the Colonial-era term) and includes the islands of Bonaire, Curacao, Saba, Saint Eustatius, and Saint Maarten. The political union of these five islands was scheduled to be dissolved in December 2008, with each island becoming a sovereign nation within the federacy of the Kingdom of the Netherlands, but the dissolution has been postponed (though no date is set, plans for dissolution proceed). Aruba (74 sq. mi., population 104,000, GDP $2.4 billion in 2008) was once part of the Netherlands Antilles but seceded in 1986 after years of struggle and debate.

The Kingdom of the Netherlands is often referred to as "the Kingdom," both to disambiguate because foreigners so often use "the Netherlands" to refer to both the country and the commonwealth, and in order to avoid the appearance that the European nation is superior to the New World entities in the commonwealth's estimation. The current form of the Kingdom was formed in 1954, though an entity of the same name persisted from 1830 (when Belgium declared independence) to 1954. The Kingdom came about as a result of a radio address by the Dutch Queen Wilhelmina on New Year's Day, 1942, when the Dutch royals were in London, in exile from the Nazi-occupied Netherlands. In this speech, Wilhelmina declared that the government wished to reexamine its relationship with its colonial holdings, and that after the Nazis were expelled from the Netherlands, the government would raise the colonies up to a position of equal participation in the kingdom. Although the primary purpose of the speech was to drum up support for the Dutch in democracies like the United States, where many Americans had a natural distrust of monarchies and colonial powers, the government made good on its promise, negotiating the practicalities over the nine years between the end of World War II and the institution of the Kingdom in 1954.

The administration of the Kingdom falls to the monarch—currently Queen Beatrix (b. January 31, 1938), who took power in 1980 when her mother Queen Juliana (daughter of Wilhelmina) abdicated because of her failing health—working in conjuction with the Council of Ministers of the Kingdom. The Council in turn is made up of the Council of Ministers of the Netherlands—the country's executive cabinet—along with a plenipotentiary minister from both Aruba and the Netherlands Antilles. The prime minister of the Netherlands acts as chair of the Council. Because the Kingdom does not have an economy or laws separate from its member nations, administration is a periodic rather than ongoing task. Upon dissolution of the Netherlands Antilles as a political union, the constituent islands will have plenipotentiary ministers of their own.

Government and Economy

The Netherlands (16,033 sq. mi., population 16,440,000) includes most of the Kingdom by any measure. The densely populated country, though associated in the Western imagination with windmills, wooden shoes, and Sinterklaas, is also the oldest capitalist country in the world, with the first stock exchange. Amsterdam, famous now as the laboratory where the country's experiments with progressive legal reforms play out, was the wealthiest trading center of the early modern world, and the country's early success with free market economics—a century before Adam Smith—paved the way for the Colonial era, funding fleets of trading ships to plot spice routes and slave routes. Much of the shape of the modern economy was first traced in Amsterdam, from boom and bust cycles to the phenomenon of speculator-investor mania to the insurance industry and retirement funds—with much of that in place years before the free market Patriots expelled the British from the American colonies in the interest of capitalist democracy.

The modern day Netherlands is an industrialized and cosmopolitan country. With Belgium and Luxembourg, the country is part of the Benelux economic union (the name coming from the first letters of each of the three countries) and was instrumental in the European communities that led to the formation of the European Union. In the late Middle Ages and early modern eras, the Benelux countries were called the Low Countries, known for their wars, their music, and their art. The unofficial "capital city" of Western law is The Hague, the Netherlands' third-largest city, home to the International Court of Justice, the International Criminal Court, Europol (the EU's criminal intelligence agency), the International Criminal Tribunal for the Former Yugoslavia, and the Special Tribunal for Lebanon. Though the capital of the Netherlands is Amsterdam, the government operates principally from The Hague, where the Supreme Court is located, along with the Queen's offices and domicile, and all foreign embassies.

The Netherlands is a parliamentary constitutional monarchy, and rated as the fourth most democratic country in the world by *The Economist*, as of the end of 2008. The general tendency in Dutch politics is to move toward consensus and synergy. The monarch arbitrates between political parties during the formation of the Council of Ministers, which consists of 13 to 16 members. The prime minister has no official power greater than that of other ministers, and is almost always the leader of the political party with the greatest representation in government. The States-General, a bicameral parliament, consists of the 150 members of the Lower House (or Second Chamber) elected in direct elections every four years or upon the dissolution of a cabinet, and the 75 members of the Upper House (First Chamber) who are elected by the provincial assemblies (themselves elected by direct election every four years). Legislators of the Upper House have the power to reject legislation, but not to amend or originate it.

The Social-Economic Council, a body of regional regulatory agencies, consults with the government on all major decisions, and in turn meets with trade and economic unions as part of the Dutch tendency toward consensus-seeking. The Social-Economic Council is charged with providing advice to form an economic policy that is fair to labor, fair in its distribution of income, and promotes healthy sustainable economic growth in the nation.

A prosperous country, the Netherlands has the 16th largest economy in the world, with economic growth considerably above the European average. Inflation is low, and unemployment is the lowest in the European Union. Industry centers around chemicals, petroleum, and food processing, and Dutch investors are among the five largest groups of foreign investors in American companies. Amsterdam continues to be a hub of stock trading activity, while Rotterdam is the continent's largest port, and the busiest port outside Asia. The recently built Betuweroute railway is a high-speed freight railway bringing goods from Rotterdam to Germany.

Neuroeconomics

In 2008, students at 31 New York City high schools were offered up to $1,000 for scoring well on Advanced Placement (AP) exams. The good news is that the number of AP exams taken rose from 4,275 in 2007 to 4,620, an increase of 345. In addition, a greater number of 5s (the highest score) were posted. On the other hand, the overall number of students who passed the AP exams declined slightly, from 1,481 to 1,476.

By contrast, in Tucson, Arizona, School Superintendent Vicki Balentine announced results of the first year of a three-year plan to give 75 sophomores $100 per month for maintaining perfect attendance and at least a C minus average. Those offered the money seemed to show up more for classes and school activities than a control group that received no cash reward.

Why, despite a significant economic reward, did students perform slightly worse on the AP tests in New York? Why does the Tucson experiment appear to be yielding better results? Those are questions that the new field of neuroeconomics seeks to answer.

Neuroeconomics is the study of what happens when people make decisions about money, such as why people save, buy stocks, steal, and overspend. As Colin Camerer, George Lowenstein and Drazen Prelec note, in spite of years of a significant volume of research data, economists lack a reliable theory that explains "why stock prices fluctuate, why people trade, and why there are so many actively managed mutual funds despite poor fund performance." These and other authors argue that one fruitful area for discovering the reasons for people's economic decision making is neuroscience. It is possible that the brain mechanisms that underlie the psychological processes of attention and perception have direct application to economics.

Neuroeconomics is a branch of the field of "behavioral economics." Behavioral economics uses research from such social sciences as anthropology, psychology, sociology, and biology to demonstrate how factors in these fields influence economic behavior. Neuroeconomics expands behavioral economics by using facts about brain activity.

Neuroeconomics examines specific elements of choice in decision making. These elements include risk, wishful thinking, ambiguity, expectation, time preference, and learning. In addition to exploring these elements of choice, neuroeconomics seeks to discover the neural correlates of those elements of choice. By examining those relationships between brain functioning and decision making, neuroeconomists can better understand sound financial judgments as well as what processes might impair those judgments.

Neuroeconomists are challenging standard economic assumptions that decision making is a simple matter of integrated and coherent utility maximization. Peter Politser argues, however, that despite the promise of neuroeconomics for understanding economics decision making, the field currently suffers from inconsistent and contradictory findings across studies. Part of the reason for the lack of clarity in these findings is that because neuroeconomics is a new field, it lacks clear methodological guidelines for studying and interpreting neuroeconomic phenomena.

Recent developments bode well for seeing those guidelines develop. For example, George Mason University hosts the Center for the Study of Neuroeconomics (CSN). CSN is a research center and laboratory dedicated to "the experimental study of how emergent mental computations in the brain interact with the emergent computations of institutions to produce legal, political, and economic order." The Camerer Lab at the California Institute of Technology is also doing significant research in neuroeconomics. In addition, the first handbook of the field, *Neuroeconomics: Decision Making and the Brain,* was recently published in association with the Society for Neuroeconomics.

In the meantime, Whitney Tilson, who helped create the New York City incentive program, expects improvement in 2009, and hoped more students would sign up as word spread about the financial incentive to take AP tests. Program organizers noted the cash incentive program would be tweaked for next year; the rewards for 4s and 3s would most likely be lowered to $500 and $250 (scores of 5 will still net $1,000), a move that most neuroeconomists would likely approve.

Neutral/Affective

There are several different frameworks by which to study the phenomenon of culture. One such framework is that developed by the research of Fons Trompenaars and Charles Hampden-Turner, who developed a model examining cultures along seven different dimensions. One dimension that the two authors identified was the neutral/affective dimension. In neutral cultures, people tend not to show their emotions in public or in business dealings. In affective cultures, open expression of natural emotions are both accepted and encouraged. This neutral/affective dimension is explored in more detail below, with specific attention given to managerial implications of the concept.

The neutral versus affective dimension concerns the acceptance of expressing emotions in a culture. In cultures with a more neutral orientation, people expect that interactions are objective and detached. People act stoically and maintain their composure. As such, the focus is placed more on the task and less on the emotional nature of the interaction. Such cultures see it as important not to let emotion influence objectivity and reason in decision making.

Conversely, cultures with a more affective orientation consider expressions of emotions, such as anger and laughter, to be normal. People are encouraged to express their emotions because it is considered to be a more natural way of being. They smile a great deal, talk loudly when they are excited, and are enthusiastic when greeting other people.

Thus, in organizations from cultures that are more neutral, members are reluctant to reveal their thoughts or feelings. In addition, controlling one's emotions is considered to be an admirable managerial quality. Physical contact and expressive gestures are generally avoided. Thus, a good manager in a neutral culture will keep emotions in control as an act of power and status, and also will keep communication directed to the task at hand. The reluctance to reveal emotions is apparent in different cultural expressions, such as the Japanese notion that "Only a dead fish has an open mouth" or the English maxim "Empty vessels make the most noise."

By contrast, feelings and thoughts are revealed in both verbal and nonverbal ways in an organization from an affective culture. Managers often express emotion and touching is much more common than in neutral cultures. Organizational members are free to express strong commitment to positions, and emotional outbursts are tolerated. Controlling one's emotions is not seen as an example of power and status, but rather a suggestion of distance from other organizational members.

Businesspeople from neutral cultures do not always express precisely and directly what they are really thinking. This playing of "the cards close to the vest" orientation can lead to misunderstandings, especially when dealing with businesspeople from affective cultures. Members of neutral cultures often feel discomfort with physical contact in public and communicate in a more subtle way. This method of communication makes it difficult for members of other cultures to read between the lines and get the message.

Trompenaars and Hampden-Turner have a number of suggestions about how to best overcome differences along the neutral/affective dimension when conducting international business. For businesspeople from neutral cultures doing business in affective cultures, they should (1) not be put off by emotions that are expressed by their cultural counterparts; (2) ask for "time-outs" in meetings and negotiations to regroup; (3) when the affective counterparts are expressing goodwill, respond in an open and warm manner; (4) not misinterpret either expressions of enthusiasm or strong disagreement as an indication that the affective counterparts have made a final decision; and (5) realize that the negotiation involves the people as much as the proposal being discussed.

For businesspeople from affective cultures doing business in neutral cultures, they should also (1) ask for "time-outs" in meetings and negotiations to regroup; (2) put as much down on paper beforehand so as not to get off track in an emotionally charged atmosphere; (3) not mistake lack of emotion as disinterest but merely a tactic of not revealing their position; and (4) realize that neutrals will focus on the proposal, not on the people involved.

Countries that rank high on being a neutral culture include Austria, Hong Kong, Indonesia, Japan, and the United Kingdom. Affective cultures include Argentina, China, Cuba, Italy, Mexico, the Philippines, Russia, and Spain. However, there are some interesting nuances concerning the neutral/affective dimension. Chinese culture is generally affective, so organizational members will be more likely to express their emotions naturally. However, if they feel that expressing their emotions will cause them to "lose face," they will refrain from showing their true feelings or intentions. In addition, people from affective cultures usually do not avoid physical contact, but many Chinese often do not like to be touched by strangers.

In addition, Trompenaars and Hampden-Turner note that emotional display in intercultural business communication involves two questions. First, "Should the emotion be exhibited in business relations?" The second question is, "Should it be separated from reasoning processes lest it corrupt them?" In the United States, for example, emotions are exhibited, but treated separately from rational decision making. By contrast, Italians exhibit and do not separate emotions from the decision-making process. Finally, the Dutch will not exhibit emotions and separate them from the decision-making process.

Newly Industrialized Countries

The term *newly industrialized countries* (NICs) refers to a group of once-developing economies that industrialized—or are still industrializing—with an emphasis on the production and export of manufactured goods; *newly industrializing economies* is often taken as a synonym. The term generally applies to those countries that industrialized after World War II. Comparability between different studies of these countries is not always straightforward, not least because there is no precise definition of an NIC. Moreover, each study regards a different range of countries as NICs depending on their level of industrialization at the moment of analysis. Through the 1980s and 1990s, the NIC category gained prominence in economic and policy analysis, especially in regard to the economies of east Asia, but popular use of the term has waned since then in favor of the broader concept of "emerging economies." As a unique category, however, the term *NIC* retains some distinction in classifying some of the economies achieving industrialization during the latter part of the 20th century.

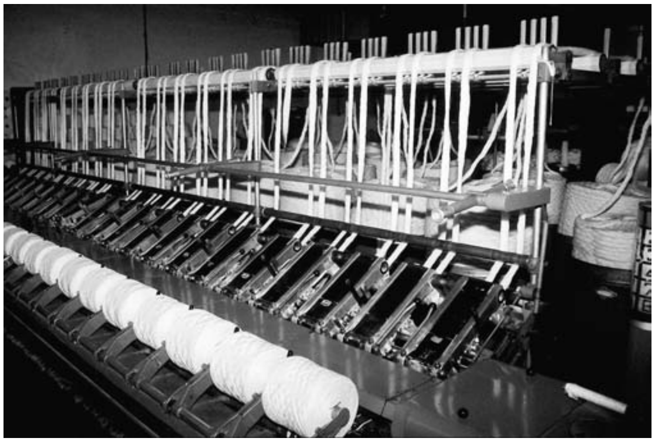
In 1979 the Organisation for Economic Co-operation and Development (OECD) published a report called *The Impact of the Newly-Industrialising Countries*, which along with a conference on NICs hosted by the OECD, brought the term to prominence. This initial usage was quickly reinforced by the adoption of the term by researchers at the World Bank, the Royal Institute of International Affairs, and by academia in general. Yet from the start, there was no common definition of an NIC or a universal method of quantifying NIC status.

For the OECD, an NIC exhibited the following characteristics: (1) fast growth in both the absolute level of industrial employment and its share of total employment; (2) a rising share of the world exports of manufactured products; (3) fast growth in real per capita gross national product (GNP) such that the country was successful in narrowing the gap with the advanced industrial countries. Using these criteria, 10 countries were generally considered to exhibit NIC characteristics from the early 1960s: Hong Kong, Singapore, South Korea, Taiwan, Brazil, Mexico, and from Europe, Spain, Greece, Portugal, and Yugoslavia. With a slightly wider interpretation, a range of other countries were also mooted as NICs, which would have doubled the original list.

While the OECD criteria were somewhat vague, other definitions were more specific. Working for the World Bank, Bela Balassa thought that to qualify for NIC status countries needed per capita income greater than $1,100 and for manufacturing to account for at least 20 percent of gross domestic product (GDP). Inevitably, this resulted in a variation on the OECD listing, indicating the somewhat arbitrary nature of specifying a quantitative economic threshold in determining what constitutes an NIC.

A further limitation of this economic approach was identified by Anis Chowdhury and Iyanatul Islam. They argued that identifying NICs purely in terms of manufacturing and trade was too limiting because it failed to consider the sustainability of the industrialization or the improvement in the standard of living or quality of life. Hence, in reaching a definition of an NIC, they broadly accepted the OECD/Balassa approach and added that a savings ratio of 15 percent was required, along with a Human Development Index of 0.75 (above average performance in purchasing power, life expectancy, and literacy). In their analysis, 22 countries could be classified as NICs in 1988, with a further 10 on the cusp of reaching the thresholds, including India and China.

The underlying problems of definition and measurement serve to underline the dynamic nature of the NIC concept, and that one needs to recognize that by any quantitative measures the set of NICs is going to change over time. Equally, the underlying concept of an NIC is very much focused on industrialization through manufacturing and especially the export of manufactured products, and hence may be regarded as fixed to a period of economic development witnessed in a number of countries from the 1960s through to the 1990s. Since then, much attention in studies of economic, and specifically business, development has shifted to focus on rapid economic growth coupled with the opening of domestic markets, financial transfers, and reform of governance and market mechanisms, all embodied in the concept of the "emerging market." Hence, the age of the NIC may have passed, or it may yet endure both as a contemporary economic reality and as a historical lens of analysis for economic development.



A textile mill in Portugal, which was stifled by a dictatorship 1926–74. Just 9 percent of its 2005 exports were high-tech.

Irrespective of the precise definition employed, the four east Asian NICs of Hong Kong, Singapore, South Korea, and Taiwan have undoubtedly achieved remarkable economic gains since the 1960s, their performance earning them the name of Asian Tigers. By the mid-1990s, their GDP per capita was approaching that of developed economies, and they were all considered by the World Bank to be comfortably high-income countries. But it is in trade that the success of the four, along with later NICs Indonesia, Malaysia, Philippines, and Thailand, has been most stark. Absolute levels of manufacturing and especially their share of world exports of manufactured goods have soared. Taken together, these eight Asian NICs accounted for just over 1.5 percent of manufactured goods exported worldwide in 1963, and reached 14.6 percent in 2000, although their share dipped to 12.1 percent in 2006. The inclusion of China in this group would elevate the 2006 figure to 22.8 percent.

The success of the first and second waves of NICs from east Asia tends to eclipse the performance of some of the other originally identified NICs. The experience of Brazil and Mexico has been mixed, with economic growth hit by financial crises and policy turmoil. In 2006 they remained in the World Bank's estimation to be upper-middle-income countries, but their growth rates do not appear to indicate an imminent change in this position. As trading nations, Brazil and Mexico have made significant progress since the 1960s. In the case of Mexico, its share of manufactured goods exported has changed from 0.4 percent in 1980 to 2.3 percent in 2006, making it one of the world's major exporting nations, with much of its now £189 billion trade stemming from export processing zones. Of the European NICs identified, the industrialization of Greece, Portugal, and Spain is often overlooked. Today, they are all high-income countries, albeit with Spain's income per capita noticeably higher than that of the others.

The goods most commonly associated with the early phase of NIC trading expansion were low-cost manufactures produced by unskilled or low-skilled labor. NIC exports to developed economies became particularly significant in textiles and garments, leather and footwear, children's toys, and in a range of other smaller sectors. Some of the NICs, such as South Korea, did become noted for the production of more intermediate technology goods that were often considered an essential element of earlier industrialization, such as iron and steel production and shipbuilding. Overall, through the 1960s and 1970s, the exports of the first NICs moved steadily away from the lower technology levels, and the makeup of exported goods further shifted as they sought and attracted investments from multinational firms seeking low-cost manufacturing sites from which to export.

For some of the initial NICs, higher technology goods eventually became a mainstay of their manufactured exports. According to the World Bank, in 2005 approximately 34 percent of Hong Kong's and 32 percent of South Korea's exports of manufactures were categorized as high technology, this being where there is a high research and development intensity in the product, such as in computers, pharmaceuticals, or electrical machinery. Further generations of NICs have grown their exports on the basis of a comparative advantage in low-cost labor, although there is nothing to suggest that their exported goods will also move away from low-technology products; in 2005, the share of high-technology goods in the manufactures exports of Greece reached only 10 percent, in Portugal 9 percent, and in Spain 7 percent.

Explanations of the rise of many NICs often revolve around industrialization strategies. The popular approach until the 1950s was of import-substituting industrialization (ISI) in which industrialization was promoted using tariff barriers and other protectionist measures to enable domestic enterprise to prosper. By the 1960s, this method was increasingly recognized as too limiting, and there was a move by some developing countries to adopt a more outward-looking industrialization policy in which exports were encouraged. In parallel to this move, a set of external changes made export-based industrialization more viable: the liberalization of the world trading regime, new transport and communication technologies, and the increasing presence of multinational enterprises establishing low-cost manufacturing bases through foreign direct investment.

The experiences of the individual NICs indicate that there is no single pathway of later industrialization, but rather each country has applied different policy mixes that have involved ISI and export-led aspects. Ultimately, for many of the first wave of NICs, the gap between them and the advanced industrial economies has been reduced, and they are clearly now industrialized economies themselves, although there remains a gap in terms of per capita income between these and the advanced industrial economies such as the United States, Japan, Germany, and the United Kingdom.

New Trade Theory

Associated with economists Paul Krugman and Elhanan Helpman, new trade theory makes two major points: (1) through economies of scale, trade can increase the variety of goods available to consumers and decrease the average costs of those goods, and (2) in those industries in which the output required to attain economies of scale represents a significant proportion of world demand, the global market may be able to support only a small number of enterprises.

New trade theory predicts that when nations trade with one another, individual national markets are combined into a far larger world market in which better economies of scale are available to individual firms. Further, each nation may be able to specialize in producing a narrower range of products than it would in the absence of trade, thus affecting both absolute advantage and comparative advantage. By buying goods from other countries, each nation can simultaneously increase the variety of goods available to consumers and lower the costs of those goods, offering an opportunity for mutual gain even when countries do not differ in their resource endowments or technology, irrespective of absolute or comparative advantage.

Developed in the late 1970s and 1980s, new trade theory was motivated by the failure of more traditional theories to explain why, since World War II, the ratio of trade to gross domestic product (GDP) has increased, why trade has become more concentrated among industrialized countries, and why trade among industrialized countries is largely intraindustry trade.

In the early post–World War II period, the United States accounted for much of the world's income and consumption. As the distribution of national income becomes more equal, new trade theory predicts that trade volumes should rise. The ability to capture scale economies ahead of later entrants, and thus benefit from a lower cost structure, may explain the pattern of trade observed since World War II. Countries may dominate in the export of certain goods because economies of scale are important in their production and because firms located in those countries were the first to capture scale economies, giving them a first-mover advantage. Hence, new trade theory identifies first-mover advantage as an important source of comparative advantage.

Variances With Other Theories

By extension, new trade theory suggests that the economies of scale produced by trade can change comparative advantages for trading nations. New trade theory, however, is at variance with the Heckscher-Ohlin theory, which suggests that a country will predominate in the export of a product when it is particularly well endowed with those factors used extensively in its manufacture.

By stressing the influence of first-mover advantage, rather than labor/price advantage or location advantage, on comparative advantage, new trade theory has triggered a reaction from proponents of both neoclassical trade theory and the ownership-location-internalization (OLI) paradigm of international business growth associated with John Dunning.

Geography and Economic Activity

In Krugman's model, the location of economic activity is not an issue. Trade costs are zero, so firms are indifferent about the location of their production sites. Initial conditions play a pivotal role in determining the allocation of production.

In new trade theory, as in neoclassical trade theory, this role for geography is determined outside the model. Where geography does matter is in the incursion of transport costs in trade among nations and in consumer demand, which influences market size. The combination of transportation costs and market size causes countries to produce those goods and services for which local demand is relatively high.

Government Intervention in Trade

New trade theory has also stimulated renewed interest in the merits of government intervention in international trade. Most neoclassical economists regard the optimum tariff argument as the only theoretically sound argument for limited government intervention, subject to a large number of constraints. If a country is large enough in the world markets, for example, a tariff will improve the country's terms of trade to the extent that favorable terms outweigh loss of volume and higher production costs. This argument is the so-called optimum tariff argument.

New trade theorists argue that government intervention in trade may be more beneficial than previously thought, because the normal assumptions of perfect competition do not apply and because the market is dominated by a comparatively small number of large firms. Here, increasing national welfare by improving the terms of trade is a justifiable motive for export subsidies or tariff protection, among other instruments that effectively shift monopoly profits from the foreign to the domestic producer.

Problems in Government Intervention

The problem for government is how to persuade the foreign firm to cut its output while the home producer increases its output without provoking a price war. As Nigel Grimwade argued, if the foreign producer does reduce his output, he loses at the expense of the home producer; if he leaves output unchanged and cuts price, he can hope that the home producer will change his mind when he sees that the decision to increase output has served merely to disadvantage himself.

If the government of the home country intervenes by granting an export subsidy to the home producer, reduced marginal cost will prompt the home producer to raise output, even if the foreign producer takes no immediate action. To ensure that the price is not forced down, the foreign producer will reduce his output. As a result of the government subsidy, the profits of the home producer have increased at the expense of the foreign producer, allowing the home-country producer to enjoy a welfare advantage that is passed on to its trading partners and consumers.

New York Convention

The New York Convention, or to give its full title, the Convention on the Recognition and Enforcement of Foreign Arbitral Awards, was a series of measures adopted on June 10, 1958, during a diplomatic conference organized by the United Nations (UN). They required that the courts in the countries that sign the convention agree to recognize arbitration agreements in each of these countries. This, therefore, set the standard for international arbitration and cross-border enforcement of arbitration awards. The name *New York Convention* came from the fact that it was drawn up and signed in New York, at the headquarters of the UN.

The idea of the New York Convention came from the International Chamber of Commerce when they were meeting in 1952. They produced what became the first draft of the Convention on the Recognition and Enforcement of International Arbitral Awards to the UN Economic and Social Council. This had support from many countries, and Kohei Teraoka, the secretary of the Japanese Ministry of Foreign Affairs, signed this on February 4—it was the first official act performed by the Japanese in the UN headquarters. The 1952 meeting led to the International Conference in 1958, which was chaired by Willem Schurmann, the permanent representative of the Netherlands to the UN, and Oscar Schachter, who worked at the UN and later became president of the American Society of International Law, after many years of teaching at Columbia Law School.

The system of international arbitration through the New York Convention has made it much easier for alternative dispute resolutions for cross-border commercial transactions. This is because of the reduced costs—the arbitrations are final and not ordinarily subject to appeal. They can also be done confidentially. And last, the arbitration is immediately enforceable in another jurisdiction provided that that country has signed the convention. It is also possible, for some complicated political disputes, to have the arbitration take place in a neutral country.

As with UN conventions, representatives of countries signed the agreement, but it did not come into force until it was ratified by that country's legislature or cabinet, or whatever process chosen by the country. At that point, the country is then bound to the convention. The first country to accede to the New York Convention was Israel on January 5, 1959, followed by Morocco on February 12; Egypt and Syria (as constituent members of the United Arab Republic) on March 9; France on June 26; and Thailand on December 21. In 1960 Cambodia, India, and the Soviet Union joined, with Norway, Austria, Japan, West Germany, Romania, Poland, and Bulgaria in the following year; and Ecuador, Finland, Hungary, Sri Lanka, Greece, Madagascar, and the Central African Republic in 1962.

After the initial impetus, a few more countries joined each year—the United States on September 30, 1970; the United Kingdom on September 24, 1975; Canada on May 12, 1986; and the People's Republic of China on January 22, 1987. The reason for the delay in the United States acceding to the convention was that the enforcement of arbitral awards was under the jurisdiction of the various states, not the federal government—although there were many business interests who wanted the U.S. government to accede to the convention. The most recent country to join was the United Arab Emirates on August 21, 2006. There are 51 member states of the UN and the Republic of China that have not signed the convention. The only European countries that have not signed are Andorra and Vatican City.

Altogether, the convention consists of 16 articles. Because of the problems over enforcing decisions made in arbitration, there are seven defenses that can be used against contesting enforcement. These are that a party in the arbitration dispute was under some incapacity; that the arbitration agreement was invalid; that a party to the arbitration was not notified with enough time to defend himself/herself; that there was a dispute over the members of the arbitral tribunal; that the award is not binding; that the matter cannot be resolved by arbitration; and that enforcement would be against what a country's government deeded to its "public policy."

New Zealand

New Zealand is a country situated in the southwestern Pacific Ocean, about 2,000 km southeast of its largest neighbor, Australia, separated by the Tasman Sea. Recognized for its geographic isolation, the country's two major islands—North and South—and numerous smaller islands, most notably Stewart Island and the Chatham Islands, are home to a population of about 4.2 million people. New Zealand's territorial domain also includes the Cook Islands, Niue, Tokelau, and the Ross Dependency in Antarctica.

To the north, the country's neighboring island nations include Tonga, Samoa, Fiji, and New Caledonia. *Aotearoa* (translated as "the Land of the Long White Cloud") was originally used by the indigenous Maori to describe the North Island. The term is used in a modern sense to refer to the entire North Island—Auckland, Hamilton, and Wellington (capital city)—and the South Island's largest city, Christchurch. Other large cities include Dunedin and Tauranga. Like other countries with Western economies, New Zealand is a relatively urbanized country, with about 72.2 percent of residents living in 16 main urban areas. More than half of the population lives in the three largest cities.

Reflecting the country's colonial history, New Zealand's people are predominantly of British and Irish ancestry. An estimated 78 percent of New Zealanders identify themselves as being of European descent. According to the 2006 census, indigenous Maori (14.6 percent) are the largest minority in New Zealand, followed by Asian (9.2 percent) and non-Maori Polynesians (6.9 percent).

New Zealand is a constitutional country, a monarchy with a parliamentary democracy. As the symbolic head of state, Queen Elizabeth II is represented by the governor-general of New Zealand, appointed on advice by the political leader, the prime minister, as the nation's head of government. The House of Representatives is the single chamber of the New Zealand parliament. General elections are held every three years under a form of proportional representation called Mixed Member Proportional (MMP).

A unique feature of leadership is the role of women; New Zealand is the only country in which women have simultaneously occupied the highest offices in the land. From March 2005 to August 2006, Queen Elizabeth II, Governor-General Dame Silvia Cartwright, Prime Minister Helen Clark, Speaker of the House of Representatives Margaret Wilson, and Chief Justice Dame Sian Elias were all in office. Also worthy of note is the fact that at the time, New Zealand's largest listed company, Telecom New Zealand, had a female chief executive officer, Theresa Gattung.

Recent Economic History

New Zealand's economic growth and prosperity have been built on primary product exports, principally wool, meat, and dairy products, mainly to the United Kingdom. Up until the 1970s, the country's relatively high standard of living depended on its strong trade relationship with Britain. The country's prosperity eroded over the next two decades due to several events, including the world oil crisis and the end of a guaranteed market for commodity exports in 1973, when Britain joined the European Community. Consequently, the nation entered a prolonged economic crisis such that by 1982, per capita income was reported by the World Bank to be the lowest of all developed nations surveyed.

Efforts to restructure the highly protectionist and regulated economy to a liberalized, free trade market began in 1984. *Rogereconomics* and *Ruthanasia* are names commonly used to describe the program of macroeconomic restructuring implemented during this period, after Finance Ministers Roger Douglas and Ruth Richardson. Despite these changes, the global share-market crash in 1987 triggered recession, and unemployment rose to 10 percent in the early 1990s.

New Zealand's economy gradually recovered, and the country regained its status as a prosperous nation with a gross domestic product (GDP) of NZ$155.672 billion in 2006. In addition, the nation once again enjoys a relatively high standard of living, with GDP per capita in 2006 of NZ$37,873 and life satisfaction ranking 20th on the 2006 Human Development Index. Quality of life in New Zealand cities is also ranked relatively highly, with Auckland placing 5th and Wellington 12th in the 2008 Mercer Quality of Living Survey.

Services play an important role in the economy, particularly the tourism industry, which contributes around 9 percent of the country's GDP. Even though the primary sector contributes just 4.3 percent of GDP, agricultural and other primary products make up a disproportionate share of exports, and almost a quarter are exported. As a result of this imbalance, the economy is susceptible to fluctuations in commodity markets. In particular, dairy products accounted for 21 percent ($7.5 billion) of total merchandise exports in the year to June 2007. The dairy cooperative Fonterra, the largest company in the country, controls almost one-third of the international dairy trade.

In 2006 Australia was New Zealand's leading export partner (20.5 percent), followed by the United States (13.1 percent), Japan (10.3 percent), China (5.4 percent), and the United Kingdom (4.9 percent).

One of the biggest challenges facing New Zealand's economy is a series of brain drains, beginning in the 1970s, in which many well-educated New Zealanders migrated to Australia, Britain, and the United States. To counteract this outflow, New Zealand has a relatively open immigration policy, especially in relation to attracting skilled and talented professionals. Due in part to this policy, New Zealand has one of the highest proportions in the world of residents born overseas, at around 23 percent, and has drawn educated professionals from around the world.

Nigeria

The west African country of Nigeria was a major economic power when the British invaded and occupied parts of the country from 1861. Nigeria gained its independence in 1960. With a population of 135 million and covering 923,700 sq. km, it still dominates—politically and economically—much of west Africa.

In the early 17th century, European powers started to establish trading posts along the coast of what is now Nigeria. Initially, some of these posts were for trading with the local people, but soon the English and other Europeans started the slave trade. The Company of the Royal Adventurers was chartered in 1660, succeeded 12 years later by the Royal Africa Company. Along the coast, trading posts were replaced by English and Dutch forts where slaves were held before being transported to the Americas.

During the Napoleonic Wars, following the French invasion of the Netherlands, the British broke the hold of the Dutch. By the middle of the 19th century, most of the British trade was focused on the area around Lagos and the delta of the River Niger. This trade coincided with many wars in the region among different tribes. With the abolition of the slave trade, the British started expanding into plantation agriculture, dealing in palm oil, and also attempting to secure sources of oil and ivory.

A fishmonger arranging her wares in a Nigerian market. The country's oil industry employs just 10 percent of the workforce.

The British started ruling Nigeria in 1861, with Lagos becoming a crown colony. Ostensibly, the aim was to prevent illegal slave trading and also involvement in the Yoruba civil wars. In 1900 the Protectorate of Northern Nigeria was established. By 1906 the whole of Nigeria was under British control, with the colony of Lagos being incorporated into the Protectorate of Southern Nigeria. In 1914 the Northern and Southern protectorates were merged. The economic focus of the country was on growing cash crops and exploiting raw materials and minerals to help industrial development in Europe.

In the 1890s a railway was built, and in the late 1920s, roads were improved, thereby helping create a wealthy elite in Nigeria that started consuming British manufactured exports. The pound sterling became the medium of exchange. As a result, many British companies and some local firms started mining tin; growing cotton, cocoa, and groundnuts; and continuing palm oil plantations. As a result of increasing wealth in Nigeria, many British and other agency houses operated in the country, and many Nigerians enlisted in the British armed forces during World War I and World War II. During the latter conflict, agitation for independence increased, and in 1945, a large 40-day strike crippled the country's economy. The British made many concessions, and Nigeria started preparing for independence. After experiments in federalism, independence was granted in 1960.

Political problems started in 1962 along tribal lines. In 1966 the military staged a coup d'état, which was followed by countercoups. In May 1967 Lt. Col. Odemegwu Ojukwa urged autonomy for eastern Nigeria, which then formally seceded as the Republic of Biafra. This secession led to a civil war from May 1967 to January 1970, in which tens of thousands of people were killed or died of starvation or lack of medical supplies. It ended with defeat for Biafra.

Oil and Natural Gas

The oil crisis of 1973 and 1974 led to a financial windfall for Nigeria—so much so that in 1975, about 90 percent of the export revenue of the country came from oil. Soon afterward, deposits of natural gas were found. At the same time, coal production fell; it had been 940,000 tons a year in 1958 but was only 73,000 tons in 1986, when it made up less than 1 percent of the country's energy.

The wealth in Nigerian oil led to more disputes and military coups, which in turn led to a succession of military leaders, some of whom were involved in widespread corruption and graft. Although Western companies were eager to do business with Nigeria owing to the wealth there, many were nervous about the government's poor human rights records.

Despite the oil deposits, some 70 percent of the workforce is still involved in agriculture, although it accounts for only 27 percent of the nation's gross domestic product (GDP). Industry, especially oil, employs 10 percent of the workforce and generates 49 percent of Nigeria's GDP. The service sector accounts for 20 percent of the workforce and produces 24 percent of the GDP.

Oil and petroleum products make up 95 percent of the country's exports, with most of the remainder coming from cocoa and rubber. Some 46 percent of the exports go to the United States, with India and Spain being other major importers of Nigerian oil. Imports—especially of manufactured goods, machinery, transportation equipment, food, and live animals—come from many countries, with 9 percent from the United States and 8 percent from both China and the United Kingdom.

Nikkei Index

The Nikkei Index reflects a number that expresses the market-value-weighted average of a group of stocks. There are five Nikkei indices: the Nikkei 225, Nikkei 500, Nikkei 300, Nikkei JASDAQ, and Nikkei All Stock Index. The Nikkei 225 is the most widely tracked Japanese stock market index in world. Other popular Japanese stock market indices are the Tokyo Stock Price Index (TOPIX) and Nomura 400. Similar to broad-based stock market indices in other countries, the Nikkei 225 is an indicator of future economic performance of the overall economy. It is composed of the most liquid 225 stocks on the Tokyo Stock Exchange (TSE) First Section. These 225 companies represent about 69 percent of the total current profits and 68 percent of total assets of all TSE First Section companies. At the end of 2007, there were 2,976 publicly traded companies in Japan. The number of public companies listed are TSE (2,389), TSE First Section (1,727), TSE Second Section (467), and TSE Mothers (195).

Nikkei 225 is calculated and published by the privately held Nikkei Inc. (Nikkei). Nikkei was established in 1876 and is the parent company of Japan's largest daily business newspaper, Nihon Keizai Shimbun. Occasionally, Nikkei removes stock issues from the index and replaces them with other issues because of bankruptcies, mergers, and annual reviews in consideration of changes in each stock's liquidity and Japan's industrial structure. Nikkei uses industry sector r ebalancing rules to assure that the index reflects possible changes in Japan's industrial structure. The 225 stocks that compose the index are grouped into six sectors: Technology, Financial, Consumer Goods, Materials, Capital Goods/Others, and Transportation/Utilities. The six sectors are composed of 36 industries: (1) Technology: pharmaceuticals, electrical machinery, automobiles, precision machinery, telecommunications; (2) Financial: banks, securities, insurance, miscellaneous finance; (3) Consumer Goods: marine products, food, retail, services; (4) Materials: mining, textiles, paper and pulp, chemicals, oil, rubber, ceramics, steel, nonferrous metals, trading companies; (5) Capital Goods/Others: construction, machinery, shipbuilding, transportation equipment, miscellaneous manufacturing, real estate; and (6) Transportation/Utilities: railroads and buses, trucking, shipping, airlines, warehousing, electric power, gas.

The Nikkei 225 is modeled after the Dow Jones Industrial Average (DJIA). As with the DJIA, it is a price-weighted average of stocks in the index. The DJIA consists of just 30 stocks and is much older. DJIA was first published in May 1896 by Charles Dow, former editor of the *Wall Street Journal*. The Nikkei 225 was created in 1950. Since its beginning, the Nikkei 225 has been calculated using the Dow Jones method. Ex-rights-adjusted prices of 225 stocks are summed and divided by a "divisor," which on July 28, 2008, was 24.424. The divisor is occasionally adjusted to maintain consistency as firms enter and exit the index.

The Bubble Economy

Nikkei 225 peaked at 38,916 Japanese yen on December 29, 1989, its highest level ever. At the peak, market capitalization of TSE-listed shares accounted for 97 percent of the market capitalization of all Japanese equity markets combined and was roughly equivalent to the collective market capitalizations of the New York Stock Exchange, London Stock Exchange, Deutsche Borse, Swiss Exchange, Borsa Italiana, and BME Spanish Exchanges. From 9,703 yen in 1984, the index soared 300 percent over five years, creating one of two colossal "asset price bubbles" experienced by Japan during the latter half of the 1980s—reminiscent of the manias recounted in Charles Mackay's *Extraordinary Popular Delusions and the Madness of Crowds*: Tulipomania, the South Sea Bubble, and the Mississippi Scheme of the 17th and 18th centuries. In addition to the stock market bubble, another bubble appeared in Japan's real estate market. The market value of one square meter of land in Tokyo's Ginza district rose to US$1.5 million. According to some estimates, the market value of the Imperial Palace grounds in central Tokyo was higher than all of the land in California.

The Nikkei 225 descent from the peak was nearly as steep as the climb had been. Between 1990 and 1991, the index descended rapidly, falling to as low as 14,309 yen—a loss of 63 percent of market value in just over two years. By 2003 it sank further to as low as 7,608 yen, equal to only 20 percent of value at the December 1989 peak. On October 20, 1987, as the bubble was forming, the Nikkei 225 experienced the largest percentage decline in its history, falling 14.9 percent in a single day—so-called Black Tuesday, coming on the heels of Wall Street's Black Monday, when on October 19, 1987, the DJIA fell 22.6 percent, its largest, single-day decline in history. On October 2, 1990, during one of the worst long-term market declines in Japanese stock market history, the index experienced its largest percentage gain in a single day of 13.2 percent.

Other Nikkei Indices

The Nikkei 500 was created in January 1972 and comprises 500 First Section–listed companies. In other important respects, it is similar to the Nikkei 225. The index is reconstituted each year according to changes in trading volume, trading value, and market capitalization. The last reconstitution took place on July 22, 2008. Nikkei introduced the Nikkei 300 in October 1982. The base year of the Nikkei 300 is 1982, with October 1, 1982, equal to 100. As with most other Nikkei indices, component stocks are selected from the TSE First Section. The index is periodically rebalanced in consideration of liquidity, stability, and sector coverage. The Nikkei JASDAQ Average contains all stocks listed on the JASDAQ Securities Exchange.

There are six securities exchange markets in Japan: the Tokyo Stock Exchange (TSE), Osaka Stock Exchange (OSE), Nagoya Stock Exchange (NSE), Sapporo Stock Exchange (SSE), Fukuoka Stock Exchange (FSE), and JASDAQ. JASDAQ is the only one specialized solely in venture firms and small capitalization stocks. Other Japanese exchanges created "sections" that specialize in "small cap" stocks—TSE's Mothers exchange, OSE's Hercules exchange, NSE's Centrex exchange, SSE's Ambitious exchange, and FSE's Q-Board exchange. In terms of market capitalization, the top four JASDAQ-listed firms are Yahoo Japan Corporation, Rakuten, Jupiter Telecommunications, and McDonald's Holdings Japan.

Of the 700 IPOs in Japan between 1998 and 2007, 48 percent were listed on JASDAQ. The other 52 percent were listed on Mothers, Hercules, TSE, and other markets. At the end of 2007, the number of listed companies on the following Japanese securities exchanges were: TSE1 (1,727), TSE2 (467), OSE1 (641), OSE2 (249), Hercules (172), Mothers (195), and JASDAQ (976). Note that some companies are listed on more than one exchange. At the end of 2007, the total market capitalization, in trillions of Japanese yen, for each, was: TSE1 (475.6), TSE2 (5.4), OSE1 (322.1), OSE2 (2.1), Hercules (1.7), Mothers (2.8), and JASDAQ (13.4). Total trading value for each, in trillions of Japanese yen was: TSE1 (688.5), TSE2 (3.4), OSE1 (22.9), OSE2 (0.8), Hercules (6.2), Mothers (13.3), and JASDAQ (10.8). The last of the Nikkei indices, the Nikkei All Stock Index, is comprised of all stocks on Japan's five stock exchanges: Tokyo, Osaka, Nagoya, Sapporo, and Fukuoka. Only JASDAQ is excluded.

Nippon Life Insurance

Nippon Life Insurance Co. (Nihon Seimei Hoken Sōgo-gaisha or Nissay in Japanese) provides life insurance products to individual and corporate customers. In addition to providing life insurance and annuity products, the company engages in real estate development and management and in a variety of educational and philanthropic projects.

Nippon Life employs around 62,000 people (as of January 1, 2008). Its headquarters is located in Osaka, Japan. Although the company primarily operates in Japan, where it has 130 branch offices, it also has operations in North America, Europe, and Asia, including a New York representative office. Nippon Life's principal overseas subsidiaries have also offices in the United Kingdom, Germany, and China.

While Nippon Life engages in the life insurance business, its subsidiaries and affiliates conduct nonlife insurance and other life insurance operations. Its business includes underwriting whole life, whole life medical treatment, long-term care, term life, retirement, and reinsurance policies. Nippon Life provides insurance accounts that allow customers to combine death, medical treatment, long-term care, retirement, and nonlife coverages. Moreover, the company provides asset management; serves as proxy for other insurance companies and other financial institutions; and engages in credit guarantees, counter sales, private placement of securities, transaction of trading securities, and sales of investment securities and investment trust beneficiary securities.

Nippon Life's underwriting insurance is a product of its life insurance business licenses. Its asset management contains financial assets invested in loans, securities, and real estate. Nippon Life underwrites bonds and then offers them to the public.

History

Historically, the company has been successful. It was established as a limited company in 1889. In 1891, the company was renamed Nippon Life Assurance Co. The company then faced a major restructuring and reformed as a mutual company in 1947. Nippon Life continued its operations by choosing to grow either by acquiring other companies or by forming joint ventures.

Major events in Nippon Life's history include the 1991 foundation of a U.S. insurance subsidiary, Nippon Life Insurance Company of America, which enabled Nippon Life to offer products and services under its own brand. In 1997, the company established a joint venture called Nippon Life Insurance Company of the Philippines. Also in 1997, Nippon Life acquired shares of a Thailand insurer, Bangkok Life Assurance. The company later increased its stake in Bangkok Life Assurance. In 2003 the company established China-based Nissay-SVA Life Insurance in a joint financing agreement with a consumer electronics manufacturer in China. Beginning in 2007, this joint venture offered insurance products related to stock investment. In 2008 Nippon Life became the largest shareholder of the U.S.-based Principal Financial Group.

Key executives of Nippon Life include Ikuo Uno (chairman), Kunie Okamoto (president), Mitsuhiro Ishibashi (vice chairman). Members of the board of directors include Eitaro Waki, Takashi Minagawa, Tetsuro Taki, Keizo Tsutsui, Kiyoshi Ujihara, Chiaki Hamaguchi, Yoichi Fujita, Yoshikazu Takeda, Kenichi Kobayashi, Yoshinobu Tsutsui, Takeshi Furuichi, Yoshihisa Akiyama, Akito Arima, and Shin Ushijima.

Market Position

Nippon Life is successful for many reasons. First, it is the foremost figure in the Japanese insurance market. Thanks to its long history and leading market position, the company enjoys strong brand awareness and brand loyalty. Also, supported by its massive financial resources, the company dominates the Japanese market with greater bargaining power than its rivals. Nippon Life has managed increasing profitability in its operations. Through strong profitability, the company attracts investors and provides a strong base for future growth plans.

Probably the best way to assess the power of Nippon Life is to review its strong solvency margin. The solvency margin ratio is one of the indicators that determine whether a company has the leeway to pay benefits in the event of a catastrophe or a stock market collapse. This ratio not only proves that Nippon Life is a strong insurance company, but also shows its ability to threaten its competitors.

Nippon Oil

Nippon Oil Corp. (Shin Nihon Sekiyu Kabushiki-gaisha in Japanese) is engaged in the refining and marketing of oil and gas. As a group of companies, it is also engaged in exploration, production, and importation of oil and gas; infrastructure construction; fuel cells; and other energy-related activities.

Nippon Oil operates primarily in Japan. The company was incorporated in 1888 and now employs around 13,000 people (as of January 1, 2008). Its headquarters is located in Tokyo. Although its domestic facilities—such as oil refineries, oil stocks, and plants—are scattered throughout Japan, the company's principal subsidiaries maintain overseas facilities, such as in Liberia and Canada.

Japan is the company's largest geographic market (95.7 percent of its total revenue in 2007). Other geographical areas of operation are Asia and Oceania (3 percent of total revenue in 2007), North America (0.8 percent of total revenue in 2007), and Europe (0.5 percent of total revenue in 2007).

The company generates revenue from four of its business divisions. These divisions include refining and marketing (89.9 percent of total revenue in 2007), construction (6.2 percent of total revenue in 2007), oil and natural gas exploration and production (3.1 percent of total revenue in 2007), and other (0.9 percent of total revenue in 2007).

One of the flagship businesses of Nippon Oil is the distribution of petroleum products. Principal products include fuel oils (such as automotive gasoline and aviation fuels), automobile lubricants (such as gasoline- and diesel-engine oils), marine lubricants (such as cylinder oils for high-speed engines), industrial lubricants (such as turbine oils, compressor oils, and vacuum-pump oils), metalworking fluids (such as heat-treatment oils, rust-preventive oils, electric insulation oils, and asphalt), and petrochemicals (such as ethylene, propylene, benzene, and carbon fiber products). Nippon Oil markets its products with the brand name ENEOS.

Also, especially throughout its subsidiaries, the company stores and transports petroleum products; manufactures and sells liquefied gas and petrochemical products; explores and develops crude oil and natural gas; manufactures, sells, and purchases crude oil and petrochemical products overseas; and designs, constructs, and engineers oil-related facilities. Major subsidiaries of Nippon Oil that conduct these operations include Japan Canada Oil Co., Nippon Oil Exploration USA, Nippon Oil Exploration and Production UK, Japan Vietnam Petroleum Co., Mitsubishi Oil Company Exploration UK, and Mizushima LNG Co.

History

Nippon Oil was formed in the late 1880s as Nippon Oil Ltd. and changed its name to Nippon Oil Co. in 1894. The company established strong exploration projects in 1960s and further developed these activities throughout the 1990s. In 1999 the company merged with Mitsubishi Oil Co. to become Japan's largest oil importer and distributor. This merged company was initially called Nippon Mitsubishi Oil Corp. and was renamed Nippon Oil Corp. in 2002. Today, it continues its operations with the help of numerous overseas subsidiaries.

The key people of Nippon Oil include Fumiaki Watari (chairman) and Shinji Nishio (president). Its board of directors consists of Naokazu Tsuda, Makoto Satani, Toshikazu Kobayashi, Yukihiro Matsuyama, Masahito Nakamura, Shigeo Hirai, Kan Ueno, Seiichi Isshiki, Yasushi Kimura, Yasuo Kamino, Junichi Kohashi, Naoaki Tsuchiya, Makoto Kuramochi, Akira Kitamura, Hideo Tabuchi, Michio Ikeda, Hiroshi Ono, Teruo Omori, Hideaki Kobashi, Yukihiro Tabata, Jun Matsuzawa, and Hajime Okazaki.

Market Position

One of the reasons for Nippon Oil's success may be its strong market position in the Japanese oil industry. As the largest refiner in Japan, Nippon Oil is responsible for 22.5 percent of total petroleum-products sales in Japan (as of 2007). Also, Nippon Oil has the largest service-station network in Japan, with more than 10,000 facilities, constituting more than one-fifth of the total stations in Japan. Another reason is Nippon Oil's broad product portfolio, which gives it a steady cash inflow and increases its customer base. Finally, strong research and development capabilities help the company modernize and improve its products. The company spent more than $100 million in 2007 for research and development, supporting exploration, production, and refining activities.

Nippon Steel

Nippon Steel Corp. (Shin Nippon Seitetsu Kabushikigaisha in Japanese) is one of the principal iron and integrated steelmakers in the world. The company is also Japan's largest steelmaker, with production capacity of more than 30 million tons annually. As a group of companies, it is also engaged in various engineering and construction activities, production of chemicals, and development of new materials.

Nippon Steel operates primarily in Japan. Its subsidiary companies include Nippon Styrene Monomer Co. Ltd., Nippon Micrometal Corp., Nippon Steel Chemical Korea Co. Ltd., NSCC Asia Ltd. (Hong Kong), Nippon Technoresearch Corporation and Nippon Steel Chemical Carbon Co. Ltd. The company's global strategic alliances and joint business activities vary from different levels of core-steel production to logistics and technical issues. The company employs around 47,000 people (as of January 1, 2008). Its headquarters is located in Tokyo.

The company generates revenue from six business divisions: steelmaking and steel fabrication (80 percent of total revenue in 2007), engineering and construction (7 percent of total revenue in 2007), urban development (2 percent of total revenue in 2007), chemicals (6 percent of total revenue in 2007), new materials (2 percent of total revenue in 2007), and system solutions (3 percent of total revenue in 2007).

The steelmaking segment produces multipurpose and multiservice products such as electric power supply and services, fabricated and processed steels, titanium, and flat-rolled products. In addition, this segment designs and provides maintenance for equipment, transportation, facility management, and related analysis and testing.

Among the other segments, the engineering and construction segment provides civil engineering and marine construction, which includes natural gas platforms and undersea pipeline infrastructure. The urban development segment is responsible for effective use of idle land owned by the company. This segment also provides housing and large-scale urban development operations, including real estate and rental of buildings. The chemicals segment provides industrial chemicals as raw materials for other products, such as materials for liquid crystal displays (LCDs). This segment is well known for its large share of the global market for advanced electronic materials. The new materials segment provides advanced composite materials for industrial use, including fine ceramics, bonding wires for semiconductors, and carbon fibers. Finally, the system solutions segment provides engineering consultation services on computer systems related to industrial use.

History and Market Position

Nippon Steel was formed in 1970 as a result of the merger of Yawata Iron and Steel and Fuji Iron and Steel, both of which were established in 1950. During the 1980s, the company expanded its operations into other segments, such as new materials (1984) and electronics (1986). Throughout the 1990s and 2000s, Nippon Steel progressed its business operations by conducting joint ventures and strategic alliances in different geographical markets.

Key employees of Nippon Steel include Akio Mimura (president), Akira Chihaya (chairman), Hideaki Sekizawa, Shoji Muneoka, Hiroshi Shima, Kiichiroh Masuda, and Bun'yuu Futamura.

The company is the dominant power in the Japanese market, not only in crude-steel production, but also in nonferrous materials. Some of its unique chemical products that are used in consumer electronics, such as plasma displays and cellular phones, hold about half of the market share. This share is meaningful considering the constantly growing household-appliances market, especially in countries such as China and India. Its prevailing market position gives the firm the advantage of economy of scale and increases its bargaining power.

Nippon Steel is known for technological innovations. The company's research and development achievements result in low production costs, making the company competitive in the worldwide steel industry.

Nippon Telegraph and Telephone

Nippon Telegraph and Telephone (NTT) began its existence in 1953 as a government-owned corporation. It has since changed into a privatized firm after a 20-year conversion program with the Japanese government holding one-third of the company's stock. NTT is the largest provider of telecommunications in Japan and the largest telecommunications company in Asia.

Based in Tokyo, NTT has more than 193,000 employees. Revenue in the year ending March 2008 was $91,192,000, with profits of $4,042,000. NTT provides the entire range of telecommunications services: mobile phones, land lines, and data communications. In addition, the company sells telecommunications equipment and operates Japan's telecommunications networks. In 2008 NTT provided service to 46 million customers.

Through the years, NTT has been recognized as a leader and innovator in telecommunications. It has, however, encountered the problems plaguing other telecommunications companies in recent years: competing for market share in an environment of increasingly fierce competition and small profit margins. As a result, NTT has looked at ways of going beyond its core capabilities to widen its customer base.

NTT is currently divided into five operational components: Regional Communications, Long Distance and International Communications, Mobile Communications, Data Communications, and Other. Regional Communications provides telephone and related services within the prefects (provinces) of Japan. Long Distance and International Communications provides communications services between the prefects. Mobile Communications provides mobile telephone services, while Data Communications supports system and network services. Finally, the Other component provides a wide range of miscellaneous support service for the company ranging from building maintenance to research and development.

As a result of legislation passed in 1984, NTT's status as a government-owned and -operated monopoly began to change. From 1985 to 2005, the Japanese government privatized the company. In 2005 the last optional shares were sold with the government in possession of only the mandated one-third ownership (actually, 33.7 percent).

The process of privatization and removal of the monopoly apparatus included not only government divestiture of shares, but it also entailed reorganization of NTT as well as other actions. In 1985 NTT was incorporated as a private company. Two years later, it was listed on the Tokyo Stock Exchange. In the 1990s various branches of NTT came into being, began operations, and were subsequently listed on the Tokyo Exchange. In 1999 NTT was reorganized. There were now three subsidiaries: NTT East, NTT West, and NTT Communications. NTT East and West were given the responsibility for providing telephone service for Japan.

With the removal of the monopoly came competition, and as the 21st century began, competitors very quickly started to crowd NTT, cutting into its customer base. In 2001 the telecommunications company Softbank offered broadband internet services. With that success, Softbank began to expand, buying Japan Telecom and beginning to offer the basic fixed-line service that NTT had been offering. With the acquisition of Cable & Wireless PLC, Softbank placed itself as the second-largest provider of fixed-line telecommunications in Japan.

In 2002, the year after Softbank entered the scene as an internet provider, NTT announced that it had suffered losses of $6.5 billion. NTT's response, as shown the next year, was to decrease losses by providing a wider range of services, even though to keep customers, it had reduced the costs for phone service within Japan. In June 2003 NTT announced that it had developed significant improvements in fiber optics that would allow it to transmit at speeds 10 times faster than had previously been the case. The technical innovation was seen as a means of allowing NTT to expand into Japan's broadband market to make up for the losses occurring that would continue as fixed-line services were not expanding and the mobile phone market appeared to reach saturation and gains could only be made by lowering the price for service. NTT was also looking for the number of customers it served through fiber optics to increase.

In May 2006 NTT reported that it had a 30-percent decline in full-year profits based on losses in both its mobile phone and fixed-line businesses. The president of the company had to acknowledge that the trend was not good and there were no grounds for optimism in the near-term future, although it was hoped that internet and computer services would at least partially offset the decline. The following year, NTT announced that it would maintain its strategy of looking beyond fixed-line communications as a way to counter losses.

Two years later, in March 2008, NTT had recovered and reported that profits were up by 32 percent based on the performance of long distance and international operations. Later in the year, NTT announced that net profit had increased in the April/June quarter by 17 percent mostly because of sales of mobile phone handsets.

Nissan Motor

Nissan Motor Co. Ltd. is a multinational enterprise headquartered in Ginza, Tokyo, Japan. With 3.5 million cars sold worldwide in 2006, Nissan is one of the top 10 car producers in the world and is number two in Japan. Of these 3.5 million cars, only 740,000 cars (21 percent) were sold in Japan; the remaining 2.8 million cars were sold overseas, mainly in the United States and Asia. Although Nissan has increasingly shifted its production abroad, it still produces significantly more cars (1.2 million) than it sells in its domestic market. The main plants in Japan are located in Kanagawa-ken and Tochigi-ken, both in the Kanto region not far from Tokyo. Both plants are open for public visits. In addition, Nissan produces in North America, southeast Asia, China, Europe, and Africa.

From 2004 to 2006, Nissan steadily increased its sales from 8,576 billion yen ($83 billion) to 10,468 billion yen ($102 billion) while keeping its net income relatively constant at around 800 billion yen ($7.8 billion, outperforming all major American car producers but still falling behind Toyota.

History

Compared with other Asian carmakers, Nissan has a long history dating back to 1914. At that time, the company produced mainly trucks under the Datsun brand and only later started to produce cars under the Nissan brand. The company raised capital in 1933 and was formally acknowledged as Nissan Motor Co. Ltd. in 1934.

In the 1960s Nissan started to export small cars to the United States and Australia. By 1970, Nissan had established itself as one of the major carmakers in the world. The oil crisis in 1973 gave Nissan, as well as other Japanese carmakers, a major boost in sales abroad, because consumers became aware of fuel prices and appreciated the small Japanese economy cars.

To overcome trade barriers in the 1980s, Nissan set up plants in Australia, Mexico, Taiwan, South Africa, the United Kingdom, and the United States. As a result of this aggressive international expansion, the company had to scale back some of its operations, closing its plant in Australia, among others. In the late 1990s, Nissan had suffered consecutive losses to such an extent that it needed a partner to survive; in 1999 Nissan was virtually bankrupt.

Through outlets such as this dealership in the United States, Nissan sold 2.8 million cars overseas in 2006. Despite a serious downturn in the 1990s, it rose to become one of the world's top 10 car manufacturers.

After other Japanese carmakers and Daimler-Chrysler rejected an alliance, Renault was the only remaining bidder for the ailing Nissan. In March 1999, Renault acquired a 36.8 percent stake of Nissan for $5.4 billion. Renault later increased its investment in Nissan to 44.3 percent, and also invested 15 percent in Renault. At that time, the financial press was extremely skeptical that medium-size Renault would be able to turn Nissan around. Limited financial resources, cultural differences, and the complicated Japanese bureaucracy posed serious challenges. On the positive side, the companies brought complementary assets into the alliance. Nissan had a strong presence in Asia and North America, as well as advanced engineering skills. Renault offered a presence in Europe and a more marketing- and sales-focused approach.

Soon after his arrival in Japan, Carlos Ghosn, a charismatic Renault manager, implemented the Nissan Revival Plan. Even before the targeted timeline, Ghosn achieved his ambitious goals and turned Nissan into a profitable carmaker. This successful turnaround of a Japanese company through a foreign investor attracted worldwide attention, resulting in various publications ranging from books to academic case studies, and made Ghosn one of the most famous executives in Japan.

Not immune to the cutthroat competition in the global automobile industry, Nissan has failed to increase profitability during recent years. That Ghosn has become chief executive officer of both Nissan and Renault has not made the situation any better. To compete, Nissan has increased its investment in research and development and is expanding into Russia and India.

Nokia

The giant mobile phone company Nokia had its origin in 1865, when mining engineer Knut Fredrik Idestam (1838–1916) set up a paper mill at Tampere, Finland. After six years, he shifted to the town of Nokia on the banks of the Nokianvirta River in Finland. Nokia went into the rubber business in 1898. Its cable and electronics venture began in 1912 with the setting up of Finnish Rubber Works. Finally, Nokia Corp. emerged after a merger between Finnish Rubber Works and Finnish Cable Works in 1967. The corporation manufactured varied products, including personal computers, television sets, capacitors, cables, cycles, tires, and even the well-known Wellington boots. Its major focus, however, was mobile communications, in which it became a pioneer.

The Mobira Cityman 200 was the earliest communications model used for military and commercial purposes. In 1979 a merger with Salora Oy resulted in new Mobira Oy–produced mobile phones. After three years, the company introduced the Mobira Senator, an automobile phone. In the same year, Nokia's DX200 switch became the world's first operational digital telephone. Nokia launched the world's first transportable phone, the Mobira Talkman, in 1984. Three years later, it manufactured the Mobira Cityman 900, the first handheld phone. In 1989 the company changed its name from Nokia Mobira Oy to Nokia Mobile Phones. Nokia produced GSM (Global System for Mobile Communications) phones in 1991, making international roaming feasible. International calls through mobile phones ushered a new era of globalization: it was through Nokia's network that the premier of Finland made the first GSM call in 1991.

The computer and television divisions were not profitable, and beginning in 1992, the company focused on telecommunications only. This important strategic decision was made mainly due to the initiative of Chief Executive Officer Jorma Jaakko Ollila. Ollila's tenure as CEO from 1992 to 2006 was an eventful period during which Nokia became the world leader in the mobile telephone industry.

In 1992 the company launched Nokia 1011, the first GSM handset. Two years later, it introduced the Nokia tune in its Nokia 2100 model. The first satellite call was made in the same year with the help of a Nokia GSM handset.

The company introduced the snake game in the Nokia 6110 in 1997. It also launched a Wireless Application Protocol (WAP) handset, the Nokia 7110. In the new millennium, Nokia continued to improve mobile technology, and mobiles with sophisticated features flooded the world market. The 3G Nokia 6650 was launched in 2002, and the next year, multiplayer gaming was introduced. The Nseries of 2005 was another improved multimedia version. Nokia had now sold one billion phones to its customers. Olli-Pekka Kallasvuo became CEO of Nokia in 2006, and Ollila remained as nonexecutive chairperson.

Recent Developments

In April 2007 Nokia and Siemens formed the Nokia Siemens Networks. In the internet era, Nokia realized the value of connectivity, which had transformed the communication industry, and introduced the new internet services brand, Ovi. By this time, Nokia was the fifth-most-valued brand in the world. In 2007 and 2008, Nokia acquired companies such as Twango, Enpocket, and Navteq, which operated in video, personal media, and data-sector mapping. Nokia and Microsoft cooperated on network security and e-mail services.

The Comes with Music plan, launched in December 2007, helped Nokia regain its position as the world's leading manufacturer of mobile phones. Under this plan, customers could download music from Universal Music Group and Sony BMG for one year free of cost.

Nonfinancial Information Reporting

The complexity of modern business requires a company to disclose various information, formatted in numerous reports. Financial reporting traditionally has been regarded as the backbone of business reporting, which was more or less enough when an enterprise was primarily, if not exclusively, assessed on its crude financial performance. On the other hand, financial reports have been statutory driven and therefore compulsory, and companies have had little choice but to comply with the requirements set in the Accounting Law (Act) and/or a set of financial standards.

With the introduction and worldwide promotion of International Accounting Standards (IAS), nowadays the International Financial Reporting Standards (IFRS), the process of harmonization of accounting rules and principles has been accelerated. A set of annual financial statements prepared by a business entity, although reporting primarily and numerically the results achieved in the past financial year, includes a narrative statement by the chairperson or president, giving his or her views on the position and performance of the company in the past year. Often, this statement is an additional important source of information for financial and business analysts studying the performance of the company.

Growth of Nonfinancial Reporting

The growth in nonfinancial information reporting has had exponential growth with the rise in the importance of social reporting, corporate social responsibility (CSR), environmental reporting, and sustainable development and growth. The nature of investors may not have changed, but their perception of socially related information certainly changed in the last decade of the 20th century and the first decade the of 21st century. A famine for information exists, going beyond classical financial reporting. A good report by today's standards encompasses not only detailed financial information but also information on the market; the human resources function; the potential and problems of the company; the legal, political, and economic environments in which the company operates; and the view of management on all the major issues that may influence the company's position and market performance.

Financial performance as a prime descriptor of the company's success has been replaced by market performance. Business/financial analysts, investors, executives, and business and management scholars would agree that the very concept of market performance is more complex today and that making an appropriate assessment requires extensive use of information of a nonfinancial nature, more future oriented than a mere report on the past.

Motivation

Motivation for nonfinancial reporting usually is strategy driven, ensuring that the reputation and brand of the company are taken care of. Managers perceive that nonfinancial reporting practices are increasingly important due to competitor pressure. Fewer than 50 companies used nonfinancial reporting as late as 1992, but in 2006, more than 2,000 companies regularly reported nonfinancial information.

Nonfinancial reporting is perceived to be driven by the clear interest of various stakeholders in receiving information beyond mere financial reports, regardless of how detailed those reports are. Stakeholder/shareholder activism directly influences trends in company reporting. The most recent empirical research, however, has shown that pressure from nongovernmental organizations (NGOs) is declining and that direct shareholder activism is exerting further pressure for nonfinancial information reporting.

Financial and business analysts are the driving force behind the increasing thirst for nonfinancial information. Financial analysts testified to the Jenkins Committee in the United States that nonfinancial information reporting is of ultimate importance for analyzing financial markets and understanding future development.

Although the pressure from analysts is present at the macro level, the perception of companies is that financial markets, per se, are not the key driver in defining the need for nonfinancial information reporting. The investment community is focusing increasingly on social information reporting, and the top (Forbes 500) companies realize that they must comply with the expectations of current and potential investors.

Future Reporting

It is difficult to foresee how nonfinancial information reporting will develop in the future, because the very nature of nonfinancial information reporting may change. At present, it is largely voluntary; whether some information will be disclosed is a decision of the firm, based on management's assessments of costs and benefits. Empirical research has not as yet corroborated the belief that voluntary disclosures have a direct positive influence on the movement of share prices. In contrast, some researchers have suggested that it may have an adverse effect.

Overall, nonfinancial information reporting may remain a dominant practice primarily in large Western companies, most likely those that are on the Forbes 500 list. Leading firms in emerging and developing markets may also endorse the practice, but it is not clear what benefits they will draw. The investment community will also have to learn how to deal with the increasingly important inflow of indirect information voluntarily given by companies, well above the level prescribed by law.

Nongovernmental Organizations

A nongovernmental organization (NGO) is a specific type of voluntary organization characterized by its involvement in international relief and development activities. As part of the voluntary sector, NGOs are distinct from government and commercial organizations and are characterized by being formal, private, non-profit-distributing, self-governing, and possessing a degree of voluntarism.

It is possible to distinguish between NGOs based in developed countries (Northern NGOs) and those based in developing countries (Southern NGOs). Northern NGOs can be further divided according to their principal method of operation: operational NGOs, which pursue international development by working directly with beneficiaries; advocacy NGOs, which seek to facilitate change through lobbying and awareness-raising activity; and fund-raising NGOs, which gather resources that are subsequently delivered to beneficiaries through partner organizations.

These methods of operation are not mutually exclusive. Some NGOs have very broad mission statements; others restrict themselves to specific geographic areas or types of activity. In a broader sense, NGOs make a distinctive contribution to international development as a result of their independence. In particular, they are credited with an ability to reach the poorest and most marginalized groups while retaining the flexibility to respond quickly to changing environments. Conversely, they are criticized for their lack of global impact, as they often focus on community-level projects, although working alongside other types of organizations in the international development community serves to enable impact at multiple levels.

The Voluntary Sector

In simple terms, it is possible to divide organizations into three categories, or sectors: private (commercial), governmental (public), and voluntary (third). The scale and importance of the voluntary sector is vast. In the United Kingdom (UK), 2008 data on civil society showed that the sector had a workforce of 1.3 million people (around 4.5 percent of the country's working population), comprised 865,000 organizations, and had a combined income of £109 billion.

The boundaries among these sectors are becoming progressively blurred, however, with governments funding the voluntary sector to deliver public services and to pursue government objectives, and businesses entering relationships with voluntary organizations to demonstrate their social responsibility. Volvic, for example, is currently working with World Vision to develop water and sanitation resources in Africa. In its "1L for 10L" campaign, Volvic, through World Vision, will provide 10 liters of drinkable water for every one liter it sells. The project will take place in Zambia, Ghana, Malawi, and Mali through the building of wells and associated infrastructure. The UK government provides competitive grants to fund the delivery of a wide range of services, including schemes for urban regeneration; youth projects; and the refurbishment of community facilities through the Big Lottery, the Voluntary Sector Support Unit, and other funding schemes.

Voluntary Organizations

An NGO is a specific type of voluntary organization, so before focusing on NGOs, it is useful to define voluntary organizations in general. The voluntary sector is sometimes defined as comprising organizations that are neither commercial nor governmental—a so-called residual approach. By contrast, structural-operational definitions identify voluntary organizations according to key characteristics of voluntariness.

One such definition identifies five key features of voluntary organizations. They must be *formal* (with some degree of institutionalization), *private* (institutionally separate from government), *non-profit-distributing* (not returning profits to owners or directors), *self-governing* (equipped to control their own activities), and *voluntary* (involving some meaningful degree of voluntary participation). Although few people would disagree with the principles behind these criteria, in practice they do have limitations.

The suggestion that a voluntary organization must exhibit a degree of formality or institutionalization is useful in distinguishing between ad hoc and organized action. In making this distinction, however, informal associations are effectively excluded from the voluntary sector. This exclusion may not be desirable, as the vast majority of voluntary action takes place through small, informal, and ad hoc associations.

A further concern is that research suggests that as an organization becomes more formal, the level of voluntary participation falls. Consequently, two of the defining features of voluntary organizations inherently conflict.

Although the requirement to be institutionally separate from government is sound, it can be difficult to achieve in practice. Since the late 1980s, a gradual shift toward a contract culture has occurred, with voluntary organizations entering into contracts with governments to undertake specific projects or to provide particular services. Governments often attach strict planning and reporting requirements to their funding, with the result that some voluntary organizations end up operating in a manner similar to public-sector bodies. Overreliance on funding of this kind can have an adverse effect on the image of the voluntary organization, as well as on its freedom and operational efficiency. Data from the United Kingdom indicate that the proportion of voluntary-sector income being received from the public sector continues to increase.

Several definitions include the requirement that voluntary organizations should not distribute profits, but different perspectives exist on what this requirement means in practice. One view is that an organization should not distribute net earnings to anyone who exercises control of it. The reference to net profits suggests that it is acceptable to pay staff. Some observers question this practice on the basis that it can be difficult to determine the point at which fair compensation becomes profit distribution.

The issue of self-governance is inextricably linked to the concept of an organization. For an organization to be recognized as an entity, it must be in a position to influence its own actions. It is widely acknowledged, however, that voluntary organizations have complex stakeholder groups. The emphasis placed on accountability to stakeholders suggests that it may be difficult for voluntary organizations to truly determine their own actions.

The issue of voluntary participation is also problematic in the sense that no reference is made to the level at which the volunteers should work. In some larger voluntary organizations, volunteers are active in fund-raising, whereas decision making is undertaken by paid professionals. This arrangement raises the question of whether such volunteers have a suitably significant role to justify calling the organization a voluntary one.

Despite the problems with structural-operational definitions, they are nevertheless more positive than the residual approach outlined earlier, in that they provide criteria for inclusion in the voluntary sector. NGOs are a specific type of voluntary organization that meet this structural-operational definition.

Terms

Any consideration of the voluntary sector and the organizations that reside within it invariably becomes engaged in a debate about terminology. There appears to be a lack of consensus on the use of specific terms and the meanings associated with them. The result is that it can be difficult to interpret research studies, as it is not always clear what type of organization is being examined. Therefore, no treatment of this subject area would be complete without considering some of the terms that are in use and the ways in which they may be interpreted.

In addition to *nonprofit,* terms that are in widespread use include *charity, nongovernmental organization (NGO), private voluntary organization (PVO), not-for-profit, nonprofit,* and *third-sector organizations.* Similarly, these organizations are collectively labeled as the *third sector;* the *nonprofit sector;* the *voluntary sector;* and, more recently, *civil society.* What might these terms mean, and are they really just different labels for the same type of organization?

Charity is the easiest term to define as a result of its legal standing. In the United Kingdom, a charity is a legally recognized entity. To become a registered charity, an organization must have aims consistent with the current interpretation of the principle of charitable purposes, which sets out acceptable types of activity. After being awarded charitable status, an organization must fulfill strict criteria that dictate how and for what purpose it operates.

Registered charities are strictly regulated by Charity Law, and the Charity Commission has a range of powers to intervene if this law is contravened. One of the challenges with this approach, however, is that the definition of acceptable activity changes over time. Consequently, some registered charities would not be given charitable status under the current interpretation of the criteria.

At first sight, the terms *nonprofit* and *not-for-profit* (NFP) appear to be very similar, implying that they may be interchangeable. Indeed, there is no discernible difference in the way these terms are used by the literature. It is possible, however, to make a subtle but important distinction between nonprofit and not-for-profit organizations. It can be argued that although not-for-profit organizations do not have the generation and distribution of profits as a primary goal, they may still make profits without jeopardizing their status. By contrast, it may be argued that nonprofit organizations must not make a profit, whether or not it is their intention to do so.

The term *third-sector organization* differs from the others in that it doesn't describe organizations themselves. Instead, it is a generic term used to refer to the set of organizations that have been placed within the third sector. Therefore, the definition of this term relies on the definition of the third sector and perhaps on the structural-operational definition outlined earlier. It seems that these two terms are simply alternative inert labels adopted by some to avoid using terms that have the potential to carry deeper meanings.

The term *nongovernmental organization* is meaningless if taken literally; after all, businesses are also nongovernmental. The term is in widespread use, however, and was officially recognized in 1950 through a United Nations resolution. It has gained a meaningful definition through historical association, being traditionally used to describe voluntary organizations that are specifically involved in international relief and development activities. Thus, general support exists for the suggestion that NGOs represent a specific type of voluntary organization defined by principal purpose.

Some literature uses the term *private voluntary organization* to refer to organizations engaged in this kind of activity. There is some debate as to whether the terms *NGO* and *PVO* are interchangeable, although recent use exhibits convergence of the terms. The only apparent difference seems to be that these organizations tend to be called NGOs in Europe and PVOs in North America—a distinction echoed by some intergovernmental bodies.

Methods of Operation

One problem that does arise is the current trend toward using the term *NGO* to refer to organizations that carry out development work in their own countries (so-called grassroots or indigenous NGOs). This use is inconsistent with the idea that NGOs carry out international development work, and it would be logical to argue that organizations operating solely in their own countries are really examples of voluntary organizations. The term is used this way, however, which leads to an initial categorization of NGOs that distinguishes between those based in developed countries and those based in developing countries. These are often referred to as Northern NGOs and Southern NGOs, respectively. The use of the terms *Northern* and *Southern* reflects prevailing terminology, which refers to the developed world as the global North and the developing world as the global South.

Northern NGOs can be divided according to their principal method of operation, distinguishing among operational, advocacy, and fund-raising. Operational NGOs make a distinctive contribution to international development, providing practical help, support, and expertise to host communities. They are credited with an ability to work at the level of individual communities and to reach the poorest, most marginalized groups. These NGOs may be involved in campaigning and fund-raising too, but their focus is on delivering resources directly, taking a practical and hands-on approach to international development.

Debate exists about the continued role of operational NGOs as Southern NGOs grow in number and power. The role of operational NGOs perhaps grew out of the traditional view of international development as being based on technology transfer from developed to developing countries. Over time, however, this view has changed, and an argument has been made that Northern NGOs should focus on advocacy and fund-raising, leaving operational work to their Southern counterparts.

Advocacy NGOs make their contribution to international development by raising awareness of specific issues at individual and governmental levels. It has been argued that advocacy in developed countries is an alternative approach to NGO operation, which reflects a focus on the root causes of poverty and inequity. Indeed, some NGOs focus entirely on this approach and consequently have no overseas activity. In this way, international development is pursued by raising awareness of issues to mobilize public support and to lobby governments to take action to address development and humanitarian issues.

Advocacy as an approach is argued to be beneficial, as many of the causes of poverty can be linked to inequities in political and economic structures, and as such, these issues cannot be addressed effectively by simply providing resources to local communities. Instead, it is argued that it is necessary to pursue changes at political and economic levels to enable developing countries to help themselves out of poverty. Such approaches are consistent with the criticism of NGO activity for being too small-scale and failing to recognize the wider structures within which their work takes place. Advocacy can be achieved through direct lobbying of key individuals, collaborative work, research and publication, attendance at conferences, and participation of NGOs in working groups.

Although all NGOs arguably engage in fund-raising to finance their activity, for some, fund-raising is their principal purpose. Fund-raising NGOs focus on raising money and other material resources for distribution to organizations in developing countries. Many smaller NGOs operate in this way and may combine fund-raising with advocacy work. NGOs of this type tend to work in partnership with one or more Southern NGOs to distribute the resources to beneficiaries, viewing this practice as a more sustainable method of development, as it enables developing countries to build their own support mechanisms and make use of local resources and expertise.

Activities

In addition to the method of operation, it is possible to identify NGOs according to their type and location of activity. International development can be pursued through various types of activity, including projects relating to children and education, HIV/AIDS and other health issues, water and sanitation, community and personal development, advocacy and human rights, natural resources and agriculture, business and economic development, and emergency relief.

Large international NGOs such as Oxfam, Save the Children, and Christian Aid have broad mission statements. Consequently, they operate in several countries and are involved in a wide range of project types. Some large NGOs, such as WaterAid and FARM-Africa, focus on specific types of activity; many smaller NGOs, such as Pumpaid, Book Aid International, and Children in Crisis, have a similar focus. Also, numerous small NGOs focus on specific countries or regions, including the Bihar Foundation, India Development Group, and Friends of Northern Uganda.

Contributions to International Development

NGOs make a distinctive contribution to international development. Governments are often criticized for focusing on economic development, commercial benefit, and the creation of export opportunities for their own firms yet being ineffective at the grassroots level. Intergovernmental bodies such as the International Monetary Fund (IMF) and World Bank are similarly criticized for emphasizing economic development.

Although economic inequity is undoubtedly a root cause of poverty, some argue that changes at this level alone are ineffective in improving people's lives at a grassroots level. By contrast, it is argued that NGOs should pay more attention to the lives of individuals, families, and communities by focusing on social, economic, and environmental welfare. This argument is consistent with the view that NGOs are proponents of community-based (participative) approaches to international development. As such, NGOs are considered to be particularly effective in reaching the poorest and most marginalized communities. Their size and agility enable them to act quickly, and their closeness to communities allows them to readily identify and respond to local needs. NGOs attempt to use local skills, expertise, and resources as much as possible, which serves to empower communities and is consistent with the goal of achieving sustainable development.

It has been argued that NGOs are more efficient and effective than governmental organizations in tackling poverty as they are less bureaucratic. Further, it is frequently suggested that beneficiaries trust NGOs as a result of their perceived impartiality. This trust is especially important, as an increasing number of humanitarian crises are linked to conflict, which makes it difficult for governmental organizations to become involved. These qualities characterize the distinctive contribution of NGOs to international development.

Criticisms

Concurrently, however, NGOs are criticized for the lack of global impact that their small-scale projects are able to achieve. Thus, NGOs and governmental organizations appear to have complementary strengths, suggesting that a development community in which these types of organizations work together would be effective at both micro and macro levels. Indeed, this appears to be happening, with increased cooperation among NGOs, intergovernmental bodies, and governmental agencies. Cooperation has been noted by several UN agencies, including the United Nations Development Programme and the United Nations Children's Fund, as well as the UK government's Department for International Development.

Such cooperation has resource benefits for NGOs, enabling them to reach more beneficiaries than they otherwise would. It also presents potential problems, as official donors have specific reporting requirements. Additionally, acting as a subcontractor can have an impact on the very modus operandi that makes NGOs so important to international development. The relationship with official donors, therefore, is an important one that can affect the way in which NGOs work.

The International Development Community

The international development community is large and complex. The guiding principle of international development—working toward global equity in areas such as health, education, and opportunity—naturally attracts a range of organizations. Large humanitarian operations such as those in the Great Lakes region of Africa in the mid-1990s and the Balkans in the late 1990s, for example, are reported to have involved up to 300 organizations of various types.

Different models of the flow of aid exist, illustrating the movement of resources and the range of organizations that are involved in this process. The basic model consists of three major components: the constituency from which resources enter the system, intermediaries through which resources are channeled, and beneficiaries that receive the resources. NGOs are one type of intermediary facilitating the movement of aid resources from developed to developing countries.

Movement of Resources

Resources enter the system principally, although not exclusively, from developed countries. These resources ultimately derive from a combination of private donations and taxation. Private donations are made to Northern NGOs, whether advocacy, fund-raising, or operational. Advocacy NGOs use these donations to finance their lobbying work. Fund-raising NGOs act as a conduit through which the donations will be channeled. They may direct the donations through Northern operational NGOs, through Southern NGOs, or through community-based organizations in developing countries.

Operational NGOs by definition use donations to directly finance their work with beneficiaries in developing countries. Simultaneously, governments in developed countries receive income through taxation, which enables governments to finance their contribution to the international community. This contribution is made in several ways. Many governments operate their own development programs through dedicated departments that enable them to give direct support to beneficiaries. Such activities are invariably connected with the pursuit of the Millennium Development Goals, which were initiated through the United Nations in 2000 to guide development action. The UK government's Department for International Development (DfID), for example, is active in pursuing these goals, which include eradicating extreme poverty and hunger, achieving universal primary education, promoting gender equality and the empowerment of women, reducing child mortality, improving maternal health, combating HIV/AIDS and other diseases, ensuring environmental sustainability, and developing a global partnership for development.

Resources can also be directed to beneficiaries through the governments of developing countries in what is referred to as bilateral aid. Another approach is for resources to be directed through intergovernmental bodies such as the UN or World Bank in what can be labeled multilateral aid. In addition, Northern governments channel development resources through Northern operational NGOs to benefit from the distinctive characteristics that NGOs can offer.

Oxfam

Oxfam is a well-known example of an international NGO. Oxfam receives its income from several sources, including private donations, trading through its retail operations, and government and other pub-

lic authorities. Oxfam has a broad mission statement that commits to tackling poverty and suffering. Such a broad purpose requires a range of approaches. Consequently, Oxfam seeks to tackle poverty and suffering through initiatives relating to education, health, debt and aid, climate change, HIV/AIDS, gender equality, and trade and livelihoods.

As well as performing operational work, Oxfam carries out research to support its lobbying and advocacy. It operates in more than 70 countries and engages in both emergency relief and long-term development activities.

Nontariff Barrier

One of the few things on which most economists agree is that in the long run, countries will be better off with a free trade regime—that is, unrestricted flow of goods and services among countries. For a variety of reasons, however, many countries choose to discourage unrestricted imports or exports of goods and services. The main tools used to achieve this goal are tariffs and quotas. Countries may impose a tariff on foreign goods entering the country. Countries may also specify that only a certain quantity of a particular product (or service), called a *quota,* may enter the country. In addition, countries may impose other conditions or restrictions on the flow of goods among countries. These conditions are known as *nontariff barriers.* Whereas sometimes these restrictions are motivated by objectives other than restriction of trade, they are classified as nontariff barriers as long as one of their consequences is restriction of trade flows.

Examples of nontariff barriers include subsidies for producers; national procurement policies that give preference to domestic producers; health, safety, and customs procedures when they discriminate against foreign goods; and voluntary or legislated export restrictions. Subsidies for producers include all programs that artificially lower domestic production costs or increase prices, subsidized prices for inputs to manufacturers or tax rebates, export financing subsidies, or tax rebates on exports. Continuing disputes between the United States and Canada regarding lumber rests on the U.S. claim that Canadian provincial governments unfairly subsidize saplings needed by lumber firms. The U.S. government encourages U.S. farm exports through its Export Enhancement Program and its Dairy Export Incentive Program. The European Union (EU) had created notorious "butter mountains" and has followed "common agricultural policy" to support EU farmers.

National procurement policies, now illegal under World Trade Organization (WTO) rules, take the shape of restricting a certain percentage of government purchases to domestic producers or giving domestic producers a specified price advantage.

Health-related nontariff barriers are the most difficult to assess as to whether they are justified. In 2003, concerned that EU-style restrictions on genetically modified foods would spread around the world, the United States, Canada, and Argentina launched a case with the WTO against the EU, demanding that the EU lift its restriction on the imports of genetically modified beef and other products. In 2006 the WTO ruled against the EU, finding no scientific justification for Europe's failure to allow use of new varieties of corn, soybeans, and cotton. The ruling, however, was criticized by environmental and consumer groups for failing to protect consumer health and safety.

Similarly, in the spring of 2008, the EU appeared to be close to removing health-related restrictions on the imports of U.S. poultry. The EU had banned imports of U.S. poultry on the grounds of health effects in 1997 because of the U.S. practice of washing chicken carcasses with chlorinated water. U.S. policy makers have challenged the health effects and demanded an end to the ban. An agreement seems likely that will require the imports to be washed with potable water and to label the product as having been cleaned earlier with chlorine.

Export restrictions may be imposed in a bilateral or a multilateral arrangement. In the 1980s auto producers in Japan agreed to voluntarily limit the number of automobiles they would export to the United States and Canada. This arrangement was in response to threats that U.S. automakers faced in view of the oil crisis and the resulting demand for fuel-efficient cars.

Although the restriction gave American automakers room to breathe, it had some unanticipated side effects. First, Japanese producers upgraded the quality of cars they exported while maintaining the quantitative limits to which they had agreed. Second, these restrictions resulted in increased exports of knocked-down autos and auto parts that were then assembled within the United States. The net consequences of these restrictions were to allow Japanese automakers to entrench themselves deeply in the North American market.

In the 1950s, U.S. textile producers managed to place voluntary restrictions on cotton textiles from Japan. As new producers and new materials came into the market, these restrictions were replaced by a multilateral Multi-Fiber Agreement, which placed quotas on the exports of all major exporting countries to all the major importing countries of textiles.

Effects

The economic effects of nontariff barriers on imports are similar to those of tariffs and quotas in some ways. Nontariff barriers against imports raise the profits of the domestic producers of competing goods by reducing competition within the industry. Consumers generally are worse off when the restrictions are motivated by the desire to protect domestic producers and better off as a result of the imposition of health-related barriers imposed in view of valid and verifiable risks associated with imported products.

Export subsidies almost always result in the fall of national welfare, even though they bring some benefits to the producers who receive the subsidies. Unlike the case with tariffs, however, governments do not earn any revenue from the imposition of nontariff barriers.

North American Free Trade Agreement

Linking more than 400 million citizens in a single economic unit producing more than $12 trillion worth of goods and services, the 1993 North American Free Trade Agreement (NAFTA) is among the most pivotal agreements in the social, political, and economic evolution of an integrated North America. NAFTA's goals are to eliminate barriers to trade; promote conditions of fair competition; increase investment opportunities; provide adequate protection for intellectual property rights; establish effective procedures for the implementation and application of the agreement and for the resolution of disputes; and further trilateral, regional, and multilateral cooperation. Since its inception, NAFTA has been credited with boosting economic productivity, creating greater employment opportunities, and reducing the costs of business, as well as for privatization, deregulation, environmental concerns, and the erosion of the sovereignty of national governments in favor of corporations.

Impetus for NAFTA

U.S. President Ronald Reagan (1981–89) was a prominent advocate of North American free trade, part of an ideology that espoused loosening governmental regulation of businesses and the primacy of the free market in society. Nonetheless, increased American protectionism, a result of massive trade deficits with Japan and a restructuring economy, prompted fears in Canada that it would be shut out of its most important market (by the mid-1980s, the United States was taking more than 70 percent of Canada's exports), and convinced traditionally protectionist Conservative Canadian Prime Minister Brian Mulroney (1984–93) that free trade was Canada's best bet. After years of often-acrimonious negotiations (and a spirited 1988 Canadian election), the Canada-U.S. Free Trade Agreement came into force in 1989.

Reagan's successor, George H. W. Bush (1989–93), was also an advocate of free trade. Keen to build on the Canada-U.S. agreement, the United States sought an identical deal with Mexico. President Carlos Salinas (1988–94) of the Institutional Revolutionary Party (PRI) had, like Mulroney, turned his back on decades of PRI policy. Mexican industry had been heavily protected, but advocates of free trade argued that Mexico would benefit immensely from access to the U.S. market. Salinas believed that Mexico could use its low-cost-labor advantage to lure American business, particularly to specially created industrial zones called *maquiladoras.* Not wanting to be left out, Canada joined in the U.S.-Mexico negotiations, and in 1992 an agreement was reached that largely echoed the earlier Canada-U.S. Free Trade Agreement. On January 1, 1993, the North American Free Trade Agreement became reality.

Key Components

The reduction of tariff barriers was the main goal of NAFTA. Under the agreement, almost all tariffs among the three countries were eliminated by January 1, 2003, covering a host of sectors including energy, agriculture, and manufactured goods. Mexican tariffs on U.S. goods, which averaged 10 percent, were phased out over 10 years, allowing the Mexican economy time to adjust to the new competitive reality. Several tariff

Spinning cotton by traditional methods in Mexico in 1994. Wages increased after NAFTA, but poverty still plagues Mexico.

exceptions remain, however. Canada's dairy and poultry industries are exempted. Similarly, the sugar, dairy, peanut, and cotton sectors are exempted in the United States. In Mexico, tariffs remained on corn, beans, and powdered milk until 2008.

Rules of origin establish whether products are made in a NAFTA country and, thus, can enter into member countries duty free. Each NAFTA partner maintains its own external tariffs governing goods from non-NAFTA countries. These rules of origin are particularly important in certain sectors, including the auto industry, in which cars and parts must have 62.5 percent North American content (that is, must be made in one of the three countries) before they enter the other two NAFTA partner countries duty free. Nonetheless, more than 90 percent of trade among the three countries is duty free.

Investment is a second key component of NAFTA. The agreement's Chapter 11, which governs investment, makes rules on how investors should be protected by the NAFTA member governments. These rules state that NAFTA countries cannot treat companies that set up or invest in any of the NAFTA countries any differently.

In 1997, for example, Canada banned the importation of MMT, a fuel additive produced by American Ethyl Corp., which the government felt might be environmentally damaging (the product was not banned in the United States). American Ethyl sued Canada based on Chapter 11 rules and won, forcing Canada to pay $20 million in damages. This outcome led to some severe criticism that Chapter 11 creates a bill of rights for corporations, allowing them to conduct business at the expense of environmental or health standards.

Dispute settlement is another central element of NAFTA. Although most trade among Canada, the United States, and Mexico is problem free, in some instances governments disagreed and imposed penalties, such as countervailing duties, that applied tariffs on products coming from one of their NAFTA partners. The dispute-settlement mechanism also governs antidumping, in which one country claims that another is selling its goods for a price that is below its actual value—dumping goods into a country. In cases of countervailing duties or dumping, the countries go to an arbitration panel made up of representatives of the two disputing countries and a chairperson who is picked by both countries to decide whether penalties should apply or whether they should be lifted and restitution should be paid.

NAFTA dispute resolution is not always effective. In 2002 the United States attached a 27-percent duty on softwood lumber from Canada. Canada claimed that this duty was unfair and sought recourse under NAFTA. When the panel found in Canada's favor, the United States ignored the decision. This long-running lumber dispute illustrates the fact that NAFTA's dispute-resolution decisions are not necessarily binding.

Other Issues

NAFTA allows the citizens of each country to move across borders for work outside the regular immigration channels, through special visas for specialized workers and intracompany transfers. This arrangement facilitates the flow of cross-border professionals and businesspeople to meet economic needs in member countries and also expands the pool of labor and job opportunities. These measures have been criticized by some labor groups as allowing employers to lower labor costs, hurting workers in all three countries.

NAFTA contains special side agreements on the environment and labor. These agreements were added during the negotiations to ensure that each country enforced proper labor laws and environmental standards in an effort to maintain a certain level of consistency from country to country, and to ensure that none of the countries would weaken these areas to attract investment.

Some observers have criticized these agreements as not being effective in maintaining proper standards in either the environment or in the workplace. Many critics point to the Mexican maquiladoras as examples of situations in which lower wages and poorer working conditions have hurt workers and their communities.

Impact

The economic impact of NAFTA on the economies of the three countries since 1993 has been significant. Trade growth is by far the most telling statistic. In 1994, total trade among Canada, the United States, and Mexico amounted to $297 billion. By 2002 that figure was $676 billion, an increase of 128 percent. Every day, NAFTA partners trade $1.8 billion worth of goods. By 2001, Mexico had overtaken Japan as the United States's second-largest trading partner (12.4 percent of U.S. trade), after Canada (20.4 percent). The key sectors for trade in the NAFTA region include transportation equipment, electronics and communications equipment, and textiles.

The impact of free trade on each of the three countries has been impressive. Canada attributes 40 percent of its gross domestic product to external trade. Every day, more than $1 billion worth of goods crosses the Canada-U.S. border. Canada's merchandise trade with the United States and Mexico rose from $112 billion in 1993 to $235 billion in 2000. Canadian trade with NAFTA countries has more than doubled, whereas its trade with the rest of the world has grown by only 29 percent. Along with the auto trade, lumber, agricultural products, and energy (oil and gas) exports constitute the primary trade for Canada.

The United States, by far the largest economy of the three partners, has also witnessed a significant growth in its NAFTA trade. Between 1993 and 2000, U.S. merchandise exports to its NAFTA partners more than doubled and was well ahead of the 52 percent growth in exports to the rest of the world. In 1993 total U.S.-Mexico trade amounted to $150 billion. By 1999 that figure had grown to $320 billion, as exports to Mexico from the United States increased by 133 percent, primarily in electronic and electrical equipment, industrial machinery, transportation equipment, and chemical and metal products. U.S. trade with Canada has also increased significantly, although Canada-U.S. trade had been increasing since the 1989 agreement. U.S. exports northward increased 35 percent between 1993 and 2001, whereas imports from Canada increased 69 percent. Overall employment in the United States increased by 12 percent, or 15 million jobs, during that period.

The growth in trade in Mexico since that country joined NAFTA has been equally significant. By 1996, Mexico's third year in the NAFTA agreement, Mexico-U.S. trade reached $148 billion, a 65 percent increase from the 1993 pre-NAFTA level. Canada-Mexico trade increased 43 percent by 1996 over pre-NAFTA levels and positioned Canada as Mexico's third-largest trading partner, whereas Mexico is now Canada's sixth-largest trading partner.

Although all these statistics point to a massive growth in trade and investment among the three countries, the human benefits of NAFTA are more difficult to ascertain. Unemployment rates in some parts of Canada and the United States have remained relatively stable since 1993, and deindustrialization has increased, particularly in the American Midwest. Poverty remains significant in Mexico, and although wages and employment may have increased in some areas, much of Mexico retains the status of a developing country. Many have argued that the true benefits of freer trade have been unevenly distributed to corporations that have taken advantage of the new regime.

Political Aspects

Politically, free trade in North America has not been without its challenges. In Canada, free trade has historically been linked to national identity and sovereignty, and opposition to the 1989 FTA was particularly intense. During the 1992 U.S. presidential campaign, free trade was a divisive issue, most visibly exhibited by the stunning electoral story of H. Ross Perot, the anti–free trade Texan famous for his warning that Americans would inevitably hear the "giant sucking sound" of U.S. jobs being drained southward by Mexico.

Mexico, however, has experienced the most pointed challenges. On January 1, 1994, the Zapatista National Liberation Army (EZLN), led by Subcomandante Marcos, took over villages in the Mexican province of Chiapas. The Zapitistas declared NAFTA a "death sentence" for the indigenous peoples of Mexico and proclaimed a state of war against the federal government. Although the Zapatista uprising was eventually quelled, the Zapatista legacy is strong, and a consistent anti-NAFTA organization remains in Mexico, uniting labor, academic, aboriginal, and nationalist groups.

Since the initial outburst of protest against the agreement in the early 1990s, opposition to NAFTA and free trade has remained significant. Civil-society groups believe that governments have ceded too much sovereignty to corporations and to pro-trade bodies such as NAFTA and the World Trade Organization (WTO), and that the globalization represented by free trade has given anti–free trade forces significant traction. The high-profile protests against the WTO and the proposed Free Trade Area of the Americas (FTAA) have given anti–free trade groups significant publicity. But civil-society groups are not the only ones that have continued to challenge free trade. Mainstream opposition to NAFTA continued in the 2008 presidential election, in which Democratic candidates Barack Obama and Hillary Clinton called for the agreement's renegotiation. Nonetheless, NAFTA remains a central aspect of an emerging North American polity.

Norway

With its long coastline and mountainous geography, Norway has long traditions of natural resources extraction. The Organisation for Economic Co-operation and Development (OECD) has characterized Norway as a paradox, because it ranks low in terms of average innovation outcome but it performs well regarding the economy and standard of living, including extensive public funding of welfare services. The country's population was 4.7 million as of 2008.

Norway's geography facilitated an industrialization process that relied on natural resources such as timber, fisheries, and shipping in the late 19th century. After having been a part of first Denmark (1536–1814) and then Sweden (1814–1905), Norway's 1905–20 period showed several initiatives for colocating heavy industry and power plants at large waterfalls. During the German occupation in World War II, numerous projects related to railways, energy, and heavy industry were started, and many of these projects were completed after the war. The postwar government furthermore initiated extensive public programs for regional planning and industrial development. From 1974 to 1992, the service sector experienced considerable growth.

Within manufacturing and mining, the most important natural resources sectors besides fisheries and aquaculture are the sectors centered on oil and gas extraction, which developed from the early 1970s onward. By the beginning of the 21st century, oil and gas extraction accounted for approximately a quarter of gross domestic product, and in terms of all export revenues, it accounted for 42.5 percent. Oil and gas extraction has increasingly been supported by adjoining sectors specializing in high-technology supply ships, finance engineering, and other supplies, where several specialized Norwegian firms are at the international forefront. After the discovery of oil resources in 1969, Norway ran a countercyclical financial policy during the 1970s. Thus, economic growth was higher and unemployment lower than for most other Western countries. In the early 2000s, much of the policy debate in Norway has focused on how the economy should be turned in other directions than the heavy emphasis on oil and gas extraction. The historian Ola Grytten, for example, claims that Norway, despite its wealth, has lost competitive power because past policy focused on subsidies and Norwegian firms adapted to domestic policies rather than to market trends.

Norway is also known as one of the prime examples of social policies for wealth distribution and intergender equality. Social insurance was gradually implemented, starting with accident insurance for factory workers (1895) and later expanding into also covering other occupational groups and types of insurance, including old age pensions (1936), unemployment insurance (1939), disability insurance (1960), and welfare benefits for widows and single mothers (1964). Postwar reforms focusing on families and the labor force participation of females include maternity leave (1956), separate taxation for married couples (1959), a day care act (1975), working environment act (1977), parental leave act (1978), and equal status act (1978). In the early 2000s, the governing parties initiated reform measures aimed at extending optimal participation in the labor market to previously marginalized persons by integrating labor market and welfare-related programs, including an abolition of strict cognitive and organizational division between these two areas of social security policy.

Norwegian politics has maintained a balance between overall taxation levels and implementation of social security programs and instability, especially in recent years when it comes from gaining a left vs. conservative majority in the parliament. Main political issues include concrete funding of the welfare state and the relationship to the European Union (EU). The Labor Party and its allies strive to uphold a high level of public funding and responsibility of welfare programs and hence argue for continued high levels of income and corporate taxes, supplemented with a modest consumption of the state Petroleum Fund created from oil revenues. The conservative parties agree on the basic principles of the welfare state, but argue for lower taxation levels supplemented with selective privatization programs. In addition, the liberal Progress Party has a competing view in arguing for more drastic privatization and consumption of Petroleum Fund assets. It achieved about 25–30 percent of the votes in popular polls as of 2008, that is, about the same level as the Labor Party, albeit hitherto failing to achieve sole or coalition government formation. Norway continues to be a nonmember of the EU following public referendums in 1972 and 1994. The issue continues to be a focus for political debate; however, the actual EU linkages are to a certain degree upheld through the country's membership in the European Economic Area, which permits Norway to participate in the EU internal market.

Novartis

Novartis is the outcome of the consolidation of three Basel-based firms—Sandoz, Ciba, and Geigy—that in 1996 created the second-largest pharmaceutical firm in Switzerland and the third-largest in the world at that time. Talks of a possible merger began in the early 20th century (between Ciba and Geigy), and by 1918, the three firms came together to form Basler Interssengemeinshaft (also known as Swiss IG) to face competition from the large international cartels based in Germany, France, and England. Swiss IG was dismantled in 1950. In 1970 Ciba merged again with Geigy to form Ciba-Geigy, and 26 years later, a merger with Sandoz created Novartis.

All three firms started operations in the 19th century with the production and commercial exploitation of a newly discovered process to create synthetic (aniline) dyes and technological complementarities to the textile industry cluster.

History of Sandoz

Sandoz was founded in 1885 by businessman Edward Sandoz and chemist Alfred Kern under the name Chemische Fabrik Kern und Sandoz. In 1893, after the death of Kern, Sandoz transformed the firm into a public limited company under the name Chemische Fabrik vormals Sandoz. The firm changed its name again in 1939 to Sandoz Ltd. In the early days, the firm produced mainly dyestuffs and textile chemicals; saccharine, a sugar substitute; and some basic pharmaceuticals. Sandoz's early attempts to diversify further in pharmaceuticals did not meet with success. Only the soaring prices of pharmaceuticals during World War I and the favorable conditions of the Swiss environment persuaded the board to commit to research and development in drugs.

The new laboratory was headed by Arthur Stoll, who elevated research quality; introduced new processes to achieve more accurate dosing of drugs; set the foundations of calcium therapy; and developed ergot, the first successful home-developed product and one from which many other drugs were subsequently developed, notably lysergic acid diethylamide (LSD).

History of Geigy and Ciba

Geigy traces its origins to Johann Rudolf Geigy-Gemuseus, who commenced his import business in 1758 in Basel. His descendants built the first dyestuffs production facility in 1833 and, in 1859, began production of the synthetic dye fuchsin. Commercial success led to the development of an extensive network of sales representatives. In 1911 the firm became a limited company, and at about the same time, the production of the first pharmaceutical products started. During the interwar period, Geigy diversified into chemicals used for the protection of textiles and subsequently into the development of pesticides, notably dichlorodiphenyltrichloroethane (DDT).

In 1859 Alexandre Clavel, who had run a silk dyeworks since 1838, obtained the license of the Venguin process to produce fuchsin and became the first producer of aniline paints in Basel. In 1864, due to environmental complaints, production moved outside Basel, and in 1873, the company was sold to Bindschedler und Busch.

Under chemist Dr. Robert Bindschedler and businessman Albert Busch, the company grew rapidly. In 1884 the owners transformed it into a limited company and renamed it Gesellschaft für Chemische Industrie in Basel. The abbreviated form of the company name, Ciba, became widely known and in 1945 was adopted as the official name of the company.

In the 1960s Geigy surpassed Ciba in terms of sales due to the worldwide success of the pesticide DDT. The benefits of a merger in terms of international expansion and economies of scale and scope became apparent. The two firms, which were already running joint international operations, started negotiations for a joint research center that led in 1970 to an "absorption fusion" of J. R. Geigy Ltd. into Ciba Ltd. under the name Ciba-Geigy. The new firm expanded further in genetic engineering with the acquisition of Chiron Corp.

Market Position

Today, Novartis is the fourth-largest pharmaceutical firm in the world and represents 8 percent of world sales of drugs. The firm is highly internationalized, with 99 percent of its sales and 53 percent of its assets in 2004 outside Switzerland.

Although Sandoz expanded abroad as late as 1964, Ciba and Geigy internationalized much earlier. In the late 19th century, J. R. Geigy built a plant at Maromme, and in 1899, Ciba acquired the French branch of the Basel firm L. Durand & Huguenin, established in 1882 in St. Fons to avoid rising duties on imported dyes. Today, Novartis has 253 of its 280 affiliates outside Switzerland.

NZSE 50 (New Zealand Stock Index)

The NZSE 50 (also known as NZX 50) is the group of 50 top companies measured by free-float adjusted market capitalization listed on New Zealand's stock exchange. According to New Zealand Exchange (NZX) guidelines, the free float is determined by excluding blocks of shares greater than 20 percent and blocks between 5 and 20 percent, which are considered strategic. The weights of corresponding stocks are determined on the basis of the resulting free-float market capitalization. This adjustment is considered to provide an index that closely reflects the main index because it is designed to represent the composition of stocks traded.

The NZX 50 is available as a total return and as a gross index indicator. Companies included in this headline index are among the nation's premium brands, long-established heritage companies, and several foreign firms. These companies—which include Telecom, Air New Zealand, Fisher & Paykel, and ING—are part of more than 200 companies that form NZX's premier equities market, formerly known informally as the Main Board. Aspects of the old system of indices are still present in the new system and specifically the NZX 50. Thus, it is important to consider the major changes in New Zealand's stock exchange in general and development of the major indices in particular.

History of NZX

Before 2002, NZX's predecessor, the New Zealand Stock Exchange (NZSE), was a mutual organization owned by its member broking firms. This organization was the successor of the Stock Exchange Association of New Zealand and the Auckland, Wellington, Christchurch-Invercargill, and Dunedin Stock Exchanges, established under the Sharebrokers Amendment Act of 1981. New Zealand's Stock Exchange became a public company, following its demutalization at the end of 2002 to a limited liability structure: NZSE Ltd. Former members of NZSE were each issued 10,000 shares in the new company. This transition became official when the company changed its name to New Zealand Exchange Ltd. (NSX). In turn, the NSX's markets were renamed the NZSX Market (stock market), the NZAX Market (alternative market), and the NZDX Market (debt market). NZX began to trade and list securities on its main equity market, the NZSX, in June 2003. These changes placed the NZX in the dual position of being a listed company on its own exchange and regulating the conduct of the exchange.

Since the middle of 2005, the NZX Centre has been located in the nation's capital city of Wellington, housed in the renovated Odlins Building on the waterfront. Other important developments that have shaped New Zealand's stock exchange include the move to a national computerized screen trading system in June 1991, ending the open cry pit. Eight years later, this system was updated by the FASTER trading system, and in 2001, the internet-based eFaster facility was introduced, allowing direct online access to the market.

Before its introduction in November, the stock exchange's trading hours were extended on September

1, 2001, to be in line with market trading in Australia and the United States.

Index System

Developments in the old index system influenced the new system, which still exhibits many of the features of the previous one. Until 2003, the NZSE 40, with a base value of 1,000 (as of July 1, 1986) was the most widely quoted index of New Zealand stock market prices. Stocks included in this index were chosen based on their market capitalization, and the index's composition was reviewed quarterly. A capital and a gross index were calculated for this index, but the capital index was generally referred to as the NZSE 40 index. From March 3, 2003, the NZSE 50 replaced the NZSE 40 and was later renamed the NZX 50 and NZX 40, reflecting changes in the name of the stock exchange company and its equities board.

Due to the high proportional representation of single companies in the index, Telecom in particular, the NZX 50 Portfolio Index was introduced. This index caps the weights for large companies in the NZX 50 to 5 percent of the index market capitalization. Both the NZX 50 and NZX 50 Portfolio indices' base value were set at the NZSE 40 closing value on February 28, 2003.

In addition to these indices, the NZSX 15 (now the NZX 15) was launched on February 9, 2004; it comprises the 15 largest and most liquid domestic securities listed on the NZSX market. Constituent companies are weighted by free-float market capitalization, but the weighting of any security in the index is capped at 30 percent. This index has a base value of 3,000 as of October 1, 2001, and its composition is reviewed every six months.

Focused Indices

The exchange has several focused indices, including the NZX SciTech Index, which highlights the performance of companies with significant business interests in the development and commercialization of new technologies, and the NZX 10 Index, which provides a measure of the price trends of New Zealand's top 10 listed companies, excluding overseas stocks.

Other indices—the NZX MidCap Index, the NZX SmallCap Index, and the NZX All Index—are also monitored to evaluate the performance of New Zealand's stock exchange market and constituent companies.

Off-Shoring

Off-shoring is the migration of jobs rather than people between countries and regions. Firms ship at least part of their production and jobs abroad and then reimport the products and services into their home country. Examples include the relocation of call center and medical transcription jobs from the United States to India. In a sense, off-shoring is simply a different manifestation of the principle of comparative advantage. India has a well-educated, English-fluent labor force willing to work for less than comparably educated Americans.

Jobs can be off-shored from a rich country to a poorer one, as in the call center example. But jobs can also be moved in the opposite direction. Legal services, computer programming, engineering, and management services are all examples of jobs off-shored from other countries to the United States. (The United States has a substantial surplus in services trade—more than $50 billion in 2003.) What makes off-shoring a controversial topic is the qualitative difference between traditional trade in goods and services (paired with labor mobility between countries and regions) and the actual shift of the jobs.

When taking advantage of the lower labor costs in another country required either moving an entire factory or encouraging the low-wage workers to emigrate, trade in services was limited by the high cost of relocation. As communication costs fall, however, off-shoring makes possible trade in specific service jobs that previously was not cost-effective. In particular, low communications costs make it possible to outsource many high-skill jobs as well as low-skill ones. Thus, medical radiographs taken in the United States are routinely transmitted digitally to radiologists in India to be read for U.S. hospitals.

Candidate Jobs

Recent estimates are that as many as 11 percent of U.S. jobs are at risk of off-shoring, based solely on industries in which some off-shoring is already taking place. Which jobs can be off-shored depends on a wide range of factors. India shares both English and a common law legal heritage with the United States. As a result, some routine legal work is also already being off-shored from the United States to India, highlighting the importance of cultural factors in making off-shoring possible. Some jobs, of course, require a physical presence, and these jobs are less vulnerable to off-shoring. But even jobs traditionally performed in person sometimes can be performed virtually. Security firms are already off-shoring the monitoring of security cameras, for example.

On the other hand, the ability to off-shore jobs has important limits. Although some countries offer significantly lower wages for particular occupations, labor costs must be compared on a productivity-adjusted basis. (Unit labor costs statistics provide productivity-adjusted wages.) When these adjustments are made, the cost advantage of the low-wage country often is significantly less than it initially appeared. Moreover, off-shoring is driving up labor costs in the low-wage economies. Wages in the computer programming industry in India have been rising at a rate of almost 15 percent per year recently, reflecting the high demand for skilled labor due to off-shoring. Such rapid increases erode the cost advantage of the off-shoring operation.

Policy Issues

Off-shoring raises three important policy issues. First, if off-shoring continues to expand, groups that previously did not view themselves as vulnerable to international competition will experience disruption and insecurity. If the gains from trade are worth these costs, an important policy question is whether and how to compensate individuals and firms that suffer dislocation costs as a result of off-shoring through transition assistance, retraining, and other programs.

Second, the expansion of economic vulnerability due to off-shoring threatens the political coalition supporting free trade in some rich countries. Although the consensus among economists is that the gains from increasing the scope of trade to include service sector jobs are large enough to outweigh, in the aggregate, the costs of the resulting disruptions, this situation could lead to a change in the post–World War II worldwide trend toward trade liberalization.

Third, some people argue that particular jobs produce benefits for the countries where they are located. In particular, research and development work is widely thought to produce significant benefits through the creation of innovation clusters like Silicon Valley in California.

Old Mutual

Old Mutual is an international insurance, savings, and wealth management company, headquartered in London, with recognized brands in South Africa, the United States, the United Kingdom (UK), Europe, Latin America, India, China, and Australia.

Old Mutual was founded as the Mutual Life Assurance Society of the Cape of Good Hope in South Africa in the British Cape Colony in 1845, and demutualized on July 12, 1999. Old Mutual's stock is listed (with percentage of shares in parentheses) on the London Stock Exchange [LSE] (64.69), the Johannesburg Stock Exchange [JSE] (31.52), the Zimbabwe Stock Exchange [ZSE] (1.64), the Namibian Stock Exchange [NSE] (0.29), and the Malawi Stock Exchange [MSE] (0.1). The company has American Depository Receipts (ADRs) available through the Bank of New York. The company is organized around four customer-centered global regions: North America, Europe and Latin America, South Africa, and Asia Pacific.

The company follows a philosophy of decentralization to allow each of its units to react quickly to local economic market conditions and regulation. Recognizing changes in demographics, lifestyles, and wealth management, the company has positioned itself to shift from life products to open-architecture (investment funds run by third-party fund managers) unit trusts and mutual funds with lower front-end charges.

Old Mutual's North American operations are in the United States, Canada, and Bermuda. In the United States, Old Mutual's asset-management brands and boutique affiliates include Old Mutual Asset Managers; Old Mutual Capital; Acadian Asset Management; Barrow, Hanley, Mewhinney & Strauss, Inc.; Dwight Asset Management Co.; Rogge Global Partners; The Campbell Group; Ashfield Capital Partners; Analytic Investors; Clay Findlay; 2100 Capital Group; Copper Rock Capital Partners; Heitman; ICM; Larch Lane Advisors; Liberty Ridge Capital; Lincluden; Provident Investment Counsel; Thompson Horstmann & Bryant; and Thompson, Siegel & Walmsley Investment Management. In North America, the company's life insurance brands are Old Mutual Financial Network and Old Mutual Bermuda. Old Mutual Bermuda alone accounts for 25 percent of all funds managed by Old Mutual. The North American region accounts for £170.1 billion of funds under management by Old Mutual.

In 2006 Old Mutual acquired Skandia, an insurance (Skandia Life), internet banking (SkandiaBanken), and financial services (Selestia Investment Solutions) firm based in Sweden that expanded its scope of operations by 20 countries. Old Mutual's UK, Nordic, European, and Latin American operations are in the UK, Sweden, Norway, Finland, Denmark, Switzerland, Austria, Poland, the Czech Republic, the Netherlands, France, Germany, Hungary, Italy, Portugal, Spain, Colombia, Mexico, and Chile. In Europe, Old Mutual's asset management brands include Old Mutual and Palladyne. The Europe and Latin America region accounts for £60.6 billion in funds under management by Old Mutual.

Old Mutual's operations in southern Africa are in South Africa, Botswana, Kenya, Malawi, Namibia, and Zimbabwe. The operations in southern Africa include asset management, life insurance, banking, and general insurance. The company's asset management brands in this region include Old Mutual Investment Group, Marriott Income Specialists, SYmmETRY, and Umbono Fund Managers.

Old Mutual's banking group, Nedbank Group Ltd. (Nedbank Retail, Nedbank Capital, Nedbank Corporate, and a 50.1 percent interest in Imperial Bank), has assets of some 489 billion Rand and operates branches in South Africa, Lesotho, Malawi, Namibia, Swaziland, and Zimbabwe. Old Mutual has a 75 percent interest in a general insurance company, Mutual & Federal (M&F), which provides automobile, fire, property, and casualty insurance in South Africa, Namibia, Botswana, and Zimbabwe. Old Mutual plans to sell its interest in M&F to Royal Bafokeng Holdings. The South Africa region accounts for 41.7 billion Rand of funds under management by Old Mutual.

Old Mutual's Asia Pacific operations are in Australia, India, Hong Kong, and China. In India, Kotak Mahindra Old Mutual Life Insurance Ltd. (KMOM) is part of a joint venture (26 percent interest) with the Kotak Mahindra Group. KMOM currently operates 106 branches in 74 cities throughout India. In China, Skandia BSAM is part of a joint venture (50 percent interest) with the Beijing State-owned Asset Management Co. (BSAM). Skandia BSAM is authorized to operate in Beijing, Shanghai, Jiangsu Province, and Guangdong Province. The Asia Pacific region accounts for £6.5 billion in funds under management by Old Mutual (£6.4 billion in Australia alone).

Total assets under management in fiscal 2007 were approximately £279 billion. Total assets under management were derived from the United States (61 percent), Europe (22 percent), southern Africa (15 percent), and the rest of the world (2 percent). In fiscal 2007, Old Mutual delivered a European Embedded Value (EEV) adjusted operating profit from its long-term business of about £1,621 million and an International Financial Reporting Standards (IFRS) adjusted operating profit about £1,624 million.

Operating profits by region for 2007 were as follows: 70 percent from southern Africa operations (£1,254 million), 15 percent from Europe and Latin America operations (£268 million), and 15 percent from operations in the United States (£260 million).

Oman

Oman's history stretches back to 3000 B.C.E., when Sumerian traders imported copper from the people of this region. The region also was a key supplier of frankincense, highly desired in the Middle East and Mediterranean Europe. Arabs arrived from present-day Yemen in the 2nd century, and there were settlers also from Persia. Islam arrived in Oman in 630 C.E., during Prophet Muhammad's lifetime, in the form of a letter carried by the Prophet's emissary Amr Ibn al-As to the brothers Abd and Jaifar al-Julanda, who ruled Oman. Having embraced Islam, Oman's leaders unified the Arabs and drove the Persians out. Maritime trade flourished. Sohar became the largest seaport in the Islamic world. Omani merchants and delegates spread the message of Islam and Arab culture as far as China.

After Vasco da Gama's voyage, the Portuguese projected imperial power briefly in the area but were expelled in 1650. Although never considered a foreign occupational power, the British declared Oman a protectorate and assumed control of the Omani military. Oman flourished as a major trade link between Europe and Asia.

In 1970, with the assistance of the British, Qaboos bin Said al-Said overthrew his father, declared Omani independence, and became the sultan of Oman. The sultan appoints a cabinet with ministers known as the Diwans. Remaining quietly in the background of regional politics, Oman housed British and American troops during the Iraq wars of 1991 and 2003 as well as the 2002 Afghanistan war.

Nearly 50 percent of Oman's 3.3 million residents live in the capital Muscat. Of Oman's population, 75 percent are Ibadhi Muslim. Indian merchants, the majority of whom are Hindu, have traded in Muscat for over 200 years. Some people of Persian and Baluchi ancestry live in the north. The official language is Arabic. English is quickly becoming a second language. Hindi is also growing due to the influx of Indian migrants.

Commercial petroleum exports from Oman commenced in 1967. With over 740,000 barrels of oil produced per day, petroleum revenues are crucial to the economy. Oman's main petroleum buyers are China, South Korea, Japan, and Thailand. To reduce dependence on oil, al-Said has implemented plans to open Oman to the outside world and to diversify and transform the economy. Tourism and natural gas exports are being developed.

With globalization, education has become increasingly important. Sultan Qaboos University, Oman's first, opened in 1986. Nine other private institutions specialize in study-abroad programs and international education. Education reforms led by al-Said are vital to the country's social and economic progress. Women are being brought into the social and economic mainstream. Women have training and career opportunities equal to men, traditional culture and Muslim religious practices are honored, and international differences are respected. The sultan appointed a woman to head the new Ministry of Tourism.

Oman's natural attractions include beaches, mountains, deserts, and wadis. Multinational companies are opening luxury hotels. Resorts surrounding Muscat offer tropical marine excursions and tours of the country's most breathtaking sights. The booming tourist hotspot of the Musandam Peninsula is not connected to Oman's mainland, but juts out into the Strait of Hormuz at the tip of the United Arab Emir-

A telecommunications tower in Muscat, the Omani capital, which is home to half the country's population.

ates. Musandam Peninsula is easily accessible by road from Dubai, and attracts visitors seeking a relaxed interlude from the high-energy bustle of Dubai. The Muscat Festival, held annually from January to February, offers a traditional cultural experience. Tony shopping malls are springing up such as the Muscat City Centre, financed by the United Arab Emirates.

Open Economy Macroeconomics

Much of the influential research in macroeconomics in the post–Great Depression era has focused on domestic economic fluctuations. For a large country such as the United States, the assumption that foreign interest rates had little effect on domestic economic variables was accepted. Foreign investment and net factor flows were small relative to the domestic economy. Furthermore, the Bretton Woods system of fixed exchange rates ensured that little reason to model currency fluctuations existed. Today, however, understanding linkages between national economies is of critical importance.

The first step toward a serious modeling of open economy macroeconomics came with the introduction of the Mundell-Fleming model, which was an improvement on the basic Keynesian IS-LM structure. Recently, scholars have developed more advanced models based on microeconomic foundations. Some of these models are based on closed economy versions of equilibrium models of the business cycle. Other scholars have attempted to incorporate "sticky prices" into their models in the tradition of New Keynesian macroeconomics.

Whatever the approach, it is crucial to realize that the basic challenges of open economy macroeconomics are that linkages exist between markets and must be respected, and that there are limits to what government policy can accomplish because they cannot control all the variables simultaneously—a problem sometimes referred to as the trilemma.

Models

One possible reason that progress in open economy macroeconomics began rather slowly is that the United States, as the dominant economy, was largely assumed to be able to pursue its own domestic policy objectives without regard for interest rates and other prices in the rest of the world. Hence, research in macroeconomics focused mainly on domestic prices and interest rates. In the Keynesian paradigm, the overriding objective was to understand how active intervention with fiscal and monetary policy could promote economic stabilization.

One basic approach simply adds net exports to the Keynesian model. Domestic spending (absorption) depends positively on domestic income and negatively on the domestic interest rate. Net exports depend positively on foreign income and negatively on domestic income. Real exchange-rate depreciation at home causes domestic goods to become cheaper on the world market and, thus, improves the trade balance. Putting these statements together yields an open economy IS curve.

As a result, for example, an increase in foreign income will increase domestic aggregate demand, causing both domestic output and interest rates to increase. The amount that output and interest rates increase depends on the money market and whether the economy is near full employment.

The Mundell-Fleming model builds on this approach by further specifying that in a world of perfect capital mobility and fixed exchange rates, the situation described above would result in an increase in domestic interest rates relative to world rates and lead to increased capital inflows. The result is a balance-of-payments surplus. As foreign capital rushes in, upward pressure is put on the value of domestic currency. If the economy is small (by definition, an economy that cannot affect world prices or interest rates), this pressure would require the central bank to sell the domestic currency (buy foreign reserves). This action takes the pressure off, discouraging capital inflows and bringing the balance of payments back into balance. As a result, of course, the domestic interest rate would fall back toward the world rate. In the case of perfect capital mobility and fixed exchange rates, the monetary authority of a small open economy is completely at the mercy of external factors.

The monetarist approach takes a somewhat different view. Whereas the Keynesian approach to macroeconomic stabilization policy puts more emphasis on fiscal policy, the monetarist school of thought (associated with Milton Friedman and the University of Chicago) asserts that the supply of money is an important determinant of the balance of payments. Key features of the monetarist approach are that a stable money demand function depends on domestic prices and income. The money supply consists of both the supply circulating in the economy and foreign reserves. Finally, purchasing power parity holds, and money supply equals money demand.

The consequence of the monetarist setup of the model is that given foreign prices and domestic income, money demand remains constant. Therefore, in a fixed-exchange-rate regime, a change in the domestic money supply leads to an equal and opposite change in foreign reserves. As a result, the monetary authority need not intervene in the exchange market but can restore balance-of-payments equilibrium through monetary policy alone.

Both the Keynesian and monetarist approaches can be extended to models of exchange-rate determination under floating exchange-rate regimes. Although these models did much to increase understanding of how international variables (e.g., exchange rates and balance of payments) respond to changes in global economic conditions, they are not based on microeconomic principles. Recent research has focused on modeling international economic relationships, giving special attention to the microeconomic foundations.

Recent Developments

Numerous puzzles in open economy macroeconomics cannot be resolved in the older Keynesian and monetarist frameworks. Among those puzzles is why a home bias tends to exist in both trade in goods and in asset holdings. Another question is why consumption growth across countries is less correlated than standard macroeconomic theory would predict. These puzzles exist because economic models based on perfectly competitive markets and rational optimizing behavior by consumers and firms predict more trade and economic integration than scholars observe. One branch of open economy macroeconomic research has tried to explain these anomalies through the use of dynamic macroeconomic models similar to those that have been employed to analyze domestic macroeconomic issues such as business cycles.

Some of these puzzles can be solved without resorting to the assumption of price stickiness. The home-bias problem can be partially explained by adding transaction costs. The cost adds a friction that prevents consumers and firms from fully optimizing. Models based on microeconomic foundations can often be constructed to enough precision so that they can be calibrated to empirical data and tested quantitatively.

Price anomalies such as the failure of purchasing power parity and the failure of the exchange rate to correlate systematically with other variables require more than just transaction costs to explain. Nominal price rigidity (or sticky prices) may also be necessary.

Research in the new open economy macroeconomics builds on previous work by incorporating price rigidities. The Mundell-Fleming model, like other models in the Keynesian tradition, assumed an extreme form of price rigidity: prices were assumed to be fixed. In the new open economy macroeconomics, prices are not fixed by assumption but are allowed to be somewhat fixed in the short run. Often, the mechanism by which the price rigidity occurs is based on microeconomic foundations. Imperfect competition and price discrimination are common features of such models. Menu costs and other mechanisms for allowing prices to update slowly ensure that the model does not go immediately to the long-run equilibrium. As a result, pricing anomalies arise endogenously; as a result, government intervention in currency and money markets may have real economic effects.

Unanswered Questions

Many unanswered questions remain, and many important recent economic phenomena present an ambitious agenda for open economy macroeconomic research. There is fundamental agreement among the many models that an economy cannot simultaneously achieve price stability, exchange rate stability, and perfect capital mobility—a situation known as the trilemma.

Until recently, China achieved the first two conditions by controlling capital flows. As the Chinese economy loosens the capital controls, China will lose its grip on either domestic prices (higher inflation) or the exchange rate (revaluation). What remains uncertain is the precise mechanism by which internal and external prices will be affected.

Other economies face decisions about whether to abandon fixed exchange rate regimes to regain control of their domestic money supply. Fixed exchange rates offer stability but are subject to speculative attack. Understanding the nature of nominal price rigidity in international markets is crucial to evaluating the various policy options available to governments. Researchers in open economy macroeconomics continue to grapple with these critical issues.

Operations Management

Operations management (OM) is the synergetic group of business activities responsible for developing, implementing, operating, managing, and improving business processes aiming at transforming resources (i.e., inputs) into products and services (outputs). OM is closely related to the process of value creation within a company; therefore, it is essential to success in business. Inputs cover designs, specifications, energy, materials, shop floor workers, management, and more. The transformation is intrinsically related to the nature of the business and can be physical (e.g., manufacturing), the result of an exchange of monetary value (e.g., retail), informational (e.g., an Internet Service Provider), a change in location (e.g., delivery system), and even psychophysiologic (e.g., a movie or healthcare). Naturally, outputs depend on the type of transformation and can vary from goods (e.g., a car) to sensations (e.g., listening to a live concert). Ultimately, OM is about assuring optimum value creation through efficient and effective use of resources to deliver the best products and services.

The roots of OM go as far back as the Industrial Revolution (i.e., the 17th century), when our capacity to produce goods was multiplied by many times, mostly through the introduction of machines. Later, the same machines enabled the so-called scientific management era in the early 20th century to develop. Careful analysis, in-depth study, and precise design made possible the mass production of goods. The large amount of quantitative methods developed to support decision making and problem solving generated a new scientific field—management science. The World War II effort helped make many of these methods more sophisticated and, more importantly, helped create another foundation of modern operations management—computational methods.

The 1980s increased pressure for quality, productivity, and efficiency. Hence, there were large investments in Just-in-Time, Total Quality systems, and reengineering. Environmental issues, globalization of the supply chain and competition, process integration (e.g., enterprise resource planning [ERP]), mass customization, the Basic Research in Computer Science system, and the internet have made OM even more challenging and sophisticated in recent years.

OM covers the core of a firm's whole value chain from developing products and services to delivering products and services. More specifically, OM incorporates development, production, and delivery of products and services. Operations strategy, forecasting, development of products and services, process management, location and layout, supply chain management, and aggregate planning are all examples of activities under the OM umbrella.

Opportunistic Behavior

Opportunism is one transactional partner's execution of such devious plans that others cannot help blaming him or her for injustice unless they blame themselves for inattentiveness, complacency, or timidity. Stockholders, suppliers, buyers, insurers, employers, and citizens must always be vigilant: never expecting deviousness is utopian.

Contracts usually involve consideration. Each party provides benefit to another, planning his or her own net benefit. No given distributive ratio of fair outcomes exists. Candidly using others instrumentally is a fair procedure. If one-sided outcomes arise consensually, such fair procedure counts as fairness of substantive outcome. Hence, procedural injustice counts as substantive injustice. Undisclosed plans are devious. Impromptu ploys, too, deviate from consensus, if any partner, farsighted enough, would have required them to be forsworn. Schemes are very devious if, having been forsworn, they are executed anyway. Predictable outcomes, however, cannot be blamed on deviousness.

A Contested Example

In 1926 General Motors bought its body supplier, Fisher Body, outright. Sixty percent owned by GM since 1919, Fisher Body supplied GM at cost plus 17.6 percent. From 1923 to 1925, Fisher doubled its return on assets to 17.3 percent as transport costs burgeoned. GM was used to colocation by Fisher. As demand for GM cars boomed, however, colocation no longer suited Fisher: from 1924, no new Fisher plant was sited near GM. Such unhelpfulness was predictable, given on-cost profits. By conceding 17.6 percent on-cost, probably overestimating its power to persuade Fisher not to take advantage, GM consented to potential injury. An untoward share of profit looks substantively unjust, but no procedural injustice was done. Only a loyal steward might be expected disinterestedly to undo what GM wittingly accepted. According to Oliver Williamson, the General Motors/Fisher Body case, though factually disputed, illustrates contractual friction.

Evidence

Opportunism is not evident unless one partner misleads the other. Calculated opportunism exists if facts or intentions, knowledge of which would disquiet a trading partner, are deliberately misrepresented. Otherwise, a sufficient sign of opportunism is that, impromptu and postcontract, a crafty inclination emerges: relying on facts not known previously to redistribute net benefit or forming redistributive intentions not at first contemplated. This state of mind is dispositional, not intentional.

Williamson defines opportunism as guileful self-seeking. Instrumental self-interest is open. Candid deals victimize no one. Misrepresentation lulls dupes into devious deals. The spirit of markets is, doubtless, not unequivocally caveat emptor (vendor). Goodwill and courtesy subsist. Yet trade is risky if gains from breaking solemn pledges outweigh self-enforced fairness. Opportunism need be neither feral nor pervasive, but as tricksters occur randomly, distrust abounds and must be mitigated. Arrangements such as vertical integration, not necessarily anticompetitive by intent, often are designed primarily for private dispute resolution, whereas sovereign dispute resolution is impracticable.

Mitigation

Opportunists thrive on "impacted" information: conditions that make it costly to scrutinize the state of the world, including a partner's state of mind. Vertical integration facilitates scrutiny. Otherwise, beneficial deals are deterred, efficient trades frustrated, and costly precautions induced for fear of opportunism. Sellers eschew price discrimination, suspicious of cunning buyers pleading poverty or of arbitrageurs. Though scale economies are available, industry rivals may not outsource research to one another because a sly supplier of knowledge might distort it. Market failure also explains integration of research and development: afraid to be gulled, independent researchers hide the slightest clues to their ideas in case they complement alternative ideas already partly formed by others.

Insurers cannot guess whether clients will be negligent after they are insured; neither can they easily uncover deceit. Experience rating (familiarization with partners' characteristics) ranks partners by their probity. Insurers offer counteropportunist incentives, such as discounts for proven clients that eschew petty or dishonest claims, and abate risk. Because insurers pool information, risky clients struggle to get better deals elsewhere when their charges rise with each claim.

Penalized like flighty insurance claimants, job quitters encounter rules mandating entry-level pay when they flit from job to job. Employers using cumulative audits of overall performance eventually pay premiums to highly rated employees, just as insurers eventually grant discounts.

Some firms need distinctively skilled workers who are adaptable to vagaries in technological, trade, and product life cycles. They need people who, without haggling, helpfully share tricks of the trade with apprentices. Codified ideas accessible to employers can be told to recruits, but even if they are similarly qualified, they cannot be told the ropes; someone must show them. Incumbents gain over time a monopoly grasp of idiosyncratic processes: they may, unhelpfully, interact inscrutably with recruits and perform so perfunctorily as to squander a firm's uniqueness.

Internal labor-market rules sweeten a firm's atmosphere; bonds of "citizenship" unlock impacted information. Upstarts from outside, faking eligibility, are thwarted by port-of-entry rules. Not paid specifically on the basis of performance (quid pro quo) but rewarded after tactful, cumulative experience rating and upon achieving seniority, incumbents are protected from opportunistic queue jumpers.

Antitrust authorities may compel release of complete know-how. Operational kinks are ironed out by sharing insight into makeshift solutions with customers. Not disclosing intuitive know-how embedded within a supplier's experience may suggest caginess in relations with customers, in whose work such inscrutability begets inefficiency; uses of supplies may be shown unhelpfully. Unhelpful showing and selective disclosure of know-how, or its distortion, betokens a more begrudging disposition than customers expect. It is understandable that customers are so treated—they are potential rivals, after all—but unfair if an artful dodger led them to expect openness.

Symmetrical Information, Asymmetrical Audacity

Trading partners necessarily omit to plan for all unforeseen contingencies. Starting with symmetrical information, sometimes they are not symmetrically creative concerning what is to come. Not designedly contrived by one partner, emergent gray areas prompt anyone so disposed to improvise impromptu. A maintenance firm, for example, stipulated payment by a rail track owner after workers were on site. It bought motorcycles so its employees were punctual. Supplies were delayed by congested traffic.

Opportunism sometimes involves gall: Traders are not symmetrically bold. Partners may hold symmetrical information, but knowing his state of mind full well, the confident opportunist often challenges timid victims to act on that knowledge.

A hotelier boasted of his skill, years earlier, in "stringing creditors along." His checks bore inconsistent words and numbers; and although he needed an associate's signature, he signed solo. Paying "as late as possible" was a "question of nerve," he said. Cunningly, not impromptu, he shifted costs to suppliers without consensus. In commercial dealing, governments, too, are disposed—or intend—to pay late. As to the social contract, it is stealthily breached in numerous sovereign abuses of the rule of law.

Conditions

Two conditions must exist to constitute opportunism. The first is bounded rationality. This term means that only a little of what needs to be known can be known. What little is known, moreover, is complex and subject to change. Anyone who is boundlessly rational would not be prey to opportunism, unless he were timid, but would know everything about the state of mind of potential and current trading partners, and about all possible states of the world bearing on all plans.

The second condition is small numbers. Victims of opportunism would not be its prey if large-numbers bargaining were not, as is common, subject to fundamental transformation into small-numbers situations. A supplier or employee initially interchangeable with others grows with experience and by embedding himself becomes virtually irreplaceable. In large-numbers situations, one can turn away from one to many other partners. Often, though, victims sink by degrees into small-numbers situations with partners to whom, for the time being, they are inextricably wedded.

Functionaries (and Predators)

According to Oliver Williamson, in large U-form and corrupted M-form organizations, functionaries entrenched in enclaves of private power enjoy various discretionary abuses: uncompetitive supply, persistent cross-subsidy of pet projects, and empire building, among others. Given stockholders' inhibited propensity to displace them, their irreducible opportunism is abetted by diffuse accountability, partisan misrepresentations, and weak auditors, lost in byways of impacted information.

Using qualified majority voting, concert parties, poison pills, stock dilution (or support), vexatious litigation, and so on, miscreant functionaries defy stockholders' displacement efforts. Predators too, quite opportunistically, discredit incumbent managers, who need deep pockets to restore stockholder confidence.

Oligopolists are secretive mines of impacted information, inscrutable to one another. Therefore, collusion sufficiently concerted to mimic market dominance or monopoly is problematical. Accordingly, natural (and patented) monopoly aside, dissolving monopolies into oligopolies is not quite fruitless.

Optimization

Optimization is the study of organizational problems in which one seeks to minimize or maximize a real function by systematically choosing the values of real or integer variables from within an allowed set. In mathematics, optimization is called mathematical programming. This type of programming is not computer programming, though computers are used extensively to solve complex optimization problems.

Practically, optimization is a process, technique, or methodology to make a decision, system, or design as perfect, functional, and effective as possible under the given circumstances.

Over time, optimization has developed into a field of study in recognition of the fact that several disparate disciplines present situations in which commonalities in terms of mathematical elements can be identified. Based on these commonalities, optimization problems can be formulated and resolved by the use of a unified set of ideas available in the field of optimization.

Optimization forms part of a larger repertoire of techniques in the field of operations research or management science that includes probability theory, queuing theory, games theory, decision analysis, and simulation. Operations research (in the United States) or operational research (in the United Kingdom) is an interdisciplinary branch of applied mathematics that deals with optimization of the performance of a system.

A typical situation requiring the application of optimization involves the manager of a business call center who faces a problem such as the following. A client service group has 50 call center staff members. On an average, each executive handles 800 calls per work session. For each staff member added to the group, the call-handling capacity per executive drops by 10 calls. The manager wonders how many staff members should be added to the existing group so that the total call-handling capacity of the group is maximized. The solution to this problem requires the technique of optimization. (The solution is to add 15 staff members to have a call-handling capacity of 42,250 calls per session. Adding fewer or more than 15 staff members would reduce the total number of calls handled.)

The optimization problem involves three elements: the objective function, a set of variables, and a set of constraints. The objective function is the variable that is to be optimized. The set of variables affects the value of the objective function. The set of constraints prevents the variables from taking on certain values that are not admissible. In the problem above, the objective function is the total call-handling capacity of the client group at the business call center. The set of variables is the number of staff members and the number of calls per session. The set of constraints is the limitations set on the variables—the number of staff members or calls cannot be negative, for example.

Applications

Optimization finds applications in a wide range of disciplines that include biology, business, economics, engineering, and information technology. The basic idea of optimization applications is that situations have common elements that could be expressed mathematically in terms of a model. This model brings together several variables that can be used to solve optimization problems. The complexity of the model depends on the number and variety of variables involved in the problem being resolved. Thus, linear programming could be used to solve simple optimization problems.

A simple problem in linear programming is one in which it is necessary to find the maximum (or minimum) value of a simple function subject to certain constraints, as illustrated in the call center example earlier in this article. More complex techniques include nonlinear programming, integer programming, and stochastic programming.

Applications of optimization in organizations have increased greatly after the availability of computers to solve optimization problems with several variables. Optimization can be applied in many situations in business organizations. Application areas include airline optimization, finance and economics, marketing, production and logistics, scheduling, supply-chain management, telecommunications, transportation, and yield management.

International Applications

Myriad areas are available for application of optimization in international business, too. Optimization methods enable international businesses to increase their responsiveness to changing global market forces while minimizing their cost. Areas of applications in the international context include material allocation; transportation logistics; workforce and production planning; and efficient management of inventories, customers, risk, compliance, pricing, and marketing.

A multinational corporation could face a situation in human resource management in which it needs to match highly skilled and multicultural employees to available job positions, using a method that is scalable so that it can handle large pools of jobs and resources in a dynamic market. The approach could use constraint programming, for example, to manage the complex constraints encountered in the field and reach near-optimal assignments that take into account all resources and positions in the job pool. The constraints, which are applied at both the individual and team levels, concern job role, skill level, geographical location, languages, and many other factors.

In international organizations, marketing optimization can deal with the typical problem of multichannel marketing event optimization. An increasing number of firms use multiple channels—such as e-mail, call centers, and direct mail—to contact customers with marketing events. The determination of an optimal set of marketing events to present to an individual customer, given a set of marketing events by channel, a set of individuals, some additional constraints, and the concepts of saturation and cannibalization can be a useful application of optimization.

Optimization has certain limitations, such as facing difficulties with the specification of the objective function, unrealistic linearity, lack of feedback, and lack of dynamics. Often, organizations that want to deploy optimization tools face the challenge of the relatively high cost of such tools.

Option

In the finance world, an option is a contract between two parties when one party grants the other the right to buy/purchase a specific asset at a particular price within a particular time period. Alternatively, the contract may grant the other party the right to sell a specific asset at a particular price within a particular time period. The party who has received the right but has no obligation and instead has the right of decision to make (buy/sell in the case of a call or put option) is known as an option buyer or option holder. The party who has sold the right and is under the obligation to respond to the buyer's decision is known as the option writer or option issuer. The price at which options are exercised is known as the strike price or exercise price. The option buyer pays an option price to the option seller known as an option premium. An option premium is not refundable even when an option is not exercised. Options can take many forms, such as the following:

- Call Option: A call option gives the option buyer the right to buy a specific asset on a specific date for a specific price. The option seller is under an obligation to fulfill the contract, that is, to sell, and he/she is paid for an option premium by the option buyer. A call option can be long call or short call. A long call is when the trader who believes that the stock price will increase might buy the call option rather than buy the stock. If the stock price increases over the exercise price of the call option by more than the premium paid, he/she will get a profit. On the contrary, if the stock price decreases, he/she will not use the call option and buy the stock from the market and lose the amount of premium. A short call is when the trader who believes that the stock price will decrease might short sell the stock instead of selling a call option.
- Put Option: A put option gives its holder, that is, the option buyer, the privilege or right to sell a specific asset by a specific date for a specific price. The option seller is under an obligation to fulfill the contract, that is, to buy, if the option buyer is ready to sell. The option writer charges the option premium initially for the same. The put option can be long put or short put. A long put is when the trader who hopes that the stock price will decrease can buy the put option. If the stock price decreases below the exercise price by more than the option premium paid,

then the trader would get a profit. If the stock price increases, he/she will not exercise the put option and lose the option premium being paid by him/her. A short put is when the trader who hopes that the stock price will increase can buy the stock instead of buying the put option. If the stock price increases, a short put would give him/her profit, and vice versa.

- American Option: An option, either call or put, that can be exercised even before maturity/expiration date is called an American option.
- European Option: An option, either call or put, that can be exercised only on the maturity/expiration date is called a European option.
- Bermuda Option: An option that can be exercised only on few specific dates prior to maturity is known as a Bermuda option.
- Preference Option: In this option, the option buyer gets a privilege to designate the option either as a call option or put option.
- Average Rate Option: This is the arithmetic average of the spot rate during the life of the option. It is the rate that is considered at the time of maturity instead of the spot rate. This rate can be applied to call as well as put options.
- Compound Option: This is the option on an option. It can be a call on a call or a call on a put or a put on a put or a put on a call.

An option is a derivative instrument that is used to hedge risk. Both the option buyer and option writer can protect themselves from an uncertain situation. Hedging is being done by resorting to the purchase or sale of options. Speculators use options for speculative purposes. Normally, the speculator enters into vertical spread on call combinations, horizontal spread on call combinations, or diagonal spread on call combinations, or straddles and strangles. Basically, there are three situations in option exercises. The first is at-the-money: this is the situation in which the strike price is equal to the spot rate on the expiration date. The second is in-the-money: in the case of a call option, an in-the-money situation is confronted when the strike price is lower than the spot price. Conversely, in the case of a put option, an in-the-money situation occurs when the spot price is lower than the strike price. The third situation is out-of-the-money: this is the opposite of the in-the-money situation. In the case of a call option, an out-of-the-money situation is confronted when the spot price is lower than the strike price. Conversely, in the case of a put option, an out-of-the-money situation occurs when the strike price is lower than the spot price.

Option prices depend on a number of factors such as degree of volatility, interest rate differential, expiration date, change in forward rate, change in spot price, and so forth. It is said that an option is "a double-edged sword to hedge against risk."

Organisation for Economic Co-operation and Development

With headquarters in Paris, the Organisation for Economic Co-operation and Development (OECD) began in 1948 as the Organization for European Economic Co-operation (OEEC), to promote the Marshall Plan for the reconstruction of Europe after World War II. Membership of the OEEC was gradually extended to non-European states, and in 1961, 20 countries joined to reform the international organization into the OECD by authority of the Convention on the Organisation for Economic Co-operation and Development.

In mid-2008, the OECD comprised 30 member states. As members, these nations share the principles of representative democracy and free market economy. Member nations meet in committees to exchange ideas; review their efforts to improve national economic performance; and advance policies on trade, science, employment, education, and financial markets. The scope of the OECD agenda, therefore, is broad, covering economic, environmental, and social policy.

Through exchange of information, the organization aims to provide a forum where members can identify best practices, design solutions to common problems, and coordinate domestic and international policies, often by adopting nonbinding agreements that can develop into binding treaties and other legal instruments.

Structure and Mission

Together, the council, secretariat, and committees form the OECD's structure. The council is comprised of member countries, each with an ambassador leading its delegation. The secretary-general heads the secretariat, which in turn is made up of 14 directorates and about 2,500 staff members. Finally, around 200 committees, working groups, and expert groups comprised of experts from member and nonmember countries are dedicated to a specific theme of the OECD's agenda.

The OECD engages nonmembers through its Centre for Cooperation with Non-Members (CCNM). About 25 nonmember countries participate at varying levels in OECD committees, and about 50 nonmembers contribute to OECD working parties, schemes, or programs. The organization also provides policy-dialogue and capacity-building activities—country programs, regional approaches, and global forums—in which participants can share best-policy practices and obtain input into the OECD's policy debate. Dialogue has also been established with several countries on the possibility of accession, enhanced engagement, and cooperation with nonmembers, particularly those of strategic importance to the OECD.

The OECD functions primarily as a forum for the exchange of experiences, ideas, and information between national governments on a range of contemporary policy issues. As part of this role, the secretariat's statistical agency, based in Paris, collects and analyzes data on a broad range of subjects, including patterns in society, trade, the environment, agriculture, taxation, technology, and economic development forecasts. Statistics on these topics are published in a variety of formats and are viewed as being reliable sources of comparable statistics.

Each year, the organization releases several hundred books as well as working papers and reference materials. Flagship titles include *OECD Economic Outlook, Main Economic Indicators, OECD Factbook, OECD in Figures,* and *OECD Observer.*

Toward the goal of achieving transparency in international tax affairs, the agency periodically publishes a list of uncooperative tax havens. It also produces and regularly updates the Model Tax Convention and a set of guidelines for the testing of chemicals, both of which have become de facto standards.

International Policy Activities

Apart from providing information, the OECD takes an active role in shaping international policy and treaties by engaging with business, trade unions, and other groups in civil society on topics such as bilateral taxation, investment, and transfer pricing. In the mid-1990s, for example, the OECD created the OECD Anti-Bribery Convention, which came into effect in February 1999 and led the design of a proposed Multilateral Agreement on Investment (MAI), which was later rejected.

Other recent initiatives include a task force on spam and suggested best practices for internet service providers and e-mail marketers, a review and forecast of environmental problems and solutions, and policy direction and guidance on the future of the internet economy.

Partner Organizations

As an international organization, the OECD works closely with governmental and nongovernmental organization (NGO) bodies and agencies, including the Business and Industry Advisory Committee (BIAC), Development Centre, International Transport Forum, International Energy Agency, and Trade Union Advisory Committee (TUAC). In addition to participation by individual member states of the European Union, the European Commission is involved in the OECD's work.

Like similarly structured organizations, the OECD participates as an independent organization in the system of coordinated European organizations, whose other members include the North Atlantic Treaty

Organization, the Western European Union, and the European Patent Organisation to maintain similar employment conditions for its staff.

OSE All Share Index (Oslo)

The Oslo Stock Exchange is a medium-sized stock exchange based in Oslo, Norway. Domestic market capitalization, or the number of issued shares of domestic companies, including their several classes, multiplied by their respective prices at a given time, is $353,353 million (2007)—an increase of 26.2 percent from 2006, making the Oslo Stock Exchange 24th in the world in terms of domestic market capitalization. It is also ranked 28th in the world in terms of growth. Market capitalization over gross domestic product, an indicator of the relative importance of stock exchange in local markets, has been increasing sharply, from 43 percent in 1997 to 81 percent in 2007.

As of 2007, 241 companies were listed on the Oslo Stock Exchange, 40 of which were foreign. Also in 2007, 30 new companies were listed, six of which were foreign. Concurrently, a relatively large number of firms—18, all domestic—was delisted.

The origin of the Oslo Stock Exchange is commonly traced to the Exchange Act of 1818 and the April 1819 opening of the Christiania Exchange. Originally, the stock exchange facilitated exchanges of foreign currencies, specific goods (e.g., ships), and a limited number of commodities. The exchange started listing prices for stocks and shares on March 1, 1881. The level of activity in stock and shares trade was very modest before World War I. The postwar era was characterized by a shift from trading commodities and foreign currencies to trading stocks and shares. The Norwegian economy was strictly regulated following World War II. Deregulation in the 1980s and the revival of the Norwegian economy after the discovery of commercially viable oil fields off the west coast of Norway were largely responsible for the steady growth of the exchange ever since.

It should be noted, however, that like many other exchanges around the world, the level of activity in the Oslo Stock Exchange has been affected by global economic shocks (e.g., the Great Depression, the oil crisis of the 1970s, and Black Monday in 1987) and speculative booms (e.g., the period after World War I and the dotcom era).

The Oslo Stock Exchange was one of the first movers into the age of electronic trading. As early as 1988, the exchange put an electronic trading support system in place. As of 1999, a new electronic system both eliminated brokers' need to have any physical connection to the exchange and, more important, allowed trading to take place from anywhere in the world. The exchange was very late in introducing option trading, however. It was not until 1990—some 20 years after option trading had begun in the United States—that an option market was opened at the Oslo Stock Exchange.

The OBX index is a weighted summary of the value of the 25 most liquid stocks traded on the Oslo Stock Exchange. The index is adjusted for divided payments and is revised every June and December. The index is tradable in its own right, and futures and options services are available. It is heavily dependent on the energy sector generally and on the performance of StatoilHydro ASA in particular. The weight of this company in the index varies at around 25 percent, and its market capitalization is approximately 40 percent of the market cap of all 25 firms in the OBX index.

The exchange is fully owned by Oslo Børs VPS Holding ASA. The largest shareholder is the largest financial institution in Norway, DnB NOR ASA, which holds approximately 19 percent of the shares. The top management team of the exchange is very homogeneous, with few international team members. The board of directors exhibits the same tendency with regard to lack of international representation but exhibits gender diversity, as required by Norwegian law.

The exploitation of newly discovered oil fields off the west coast of Norway helped revive the Norwegian economy and contributed much to the steady growth of the Oslo Stock Exchange. Above, a Norwegian-owned oil rig in operation off shore.

Trade in stocks is done by 57 brokers who trade on behalf of customers and multiple relatively small brokers. The largest two brokers, SEB Enskilda ASA (plc) and DnB NOR Bank ASA (plc), control merely 15.6 percent of stock turnover (2008). The broker market for other market instruments, such as derivatives, is highly concentrated.

The Oslo Stock Exchange is renowned not only for its early use of electronic means of communication but also for its information transparency. Information on specific exchanges, prices, and turnover can be found as early as 1881 in *Kierulfs Håndbok* (handbook). A related unique source of information, the shareholder registry, contains multiple shareholder characteristics. The book and the shareholder data registry have been used repeatedly for research purposes.

The stock exchange is open for trade between 9:00 A.M. and 4:30 P.M. Central European Time. Currently, like other stock exchanges, the Oslo Stock Exchange provides real-time and delayed trading data, as well as a range of trade-related statistics distributed through a wide range of communication platforms.

Outsourcing

Outsourcing, also known as blind off-shoring, is a process by which companies hire other companies, usually located in other countries, to perform lower-level work. The main motivation behind the practice of outsourcing is for a company to minimize its costs while at the same time increase its revenue and productivity and thus gain advantage over other firms.

The 1970s saw a change in the outsourcing trend where global outsourcing shifted from comprising solely manufacturing services to including information technology outsourcing (ITO), and later, business process outsourcing (BPO). As the name suggests, the former involves the provision of some or all information systems by one or more providers, which might include data conversions, database administration, help desk, and network management, among many others. BPO, on the other hand, takes place when a firm turns over its management to a third party by outsourcing call centers, human resources administration, finance, as well as accounting functions. ITO and BPO are currently two of the fastest-growing sectors in outsourcing.

Today, India in particular has become the leading destination for ITO and BPO because its cheap and skilled labor makes it a very affordable destination for foreign companies. Although the IT industry in India has been present since the 1980s, it was not until the following decade that Indian firms became the outsourcing destinations for companies around the world, which included firms such as American Express, GE Capital, and British Airways. In comparison, the BPO industry has been in existence for little more than five years, making it a fairly new, yet rapidly developing, sector today. Presently, India is characterized by being home to numerous IT "giants" such as Infosys or Wipro, which are the leaders in this particular field. Moreover, trying to stay on top, India is actually beginning to outsource its outsourcing services, hoping that such a step will place it ahead of other outsourcing nations such as China. Indian companies are hiring representatives all over the world so as to ensure a broader range of language skills along with other abilities to offer companies who outsource their services to this nation.

As the number of companies outsourcing to India increases, what has to be taken into account is that not all of these transactions end up being a success. In the case of the insurance and financial firm Conseco, the decision to outsource has definitely done more harm than help, and it experienced numerous problems. On the other end of the spectrum, however, is the air industry giant Boeing, which has experienced tremendous gains as a result of transferring manufacturing offshore.

Benefits and Risks

A company that decides to delegate some of its operations to a foreign country like India is able to focus on its core competency, which is yet another benefit to outsourcing as core competencies are where the success and the profit of the firm lie. After all, having all the responsibility of finishing the mundane and everyday tasks transferred to a foreign company enables the firm to dedicate more of its at-home personnel and resources to doing what truly distinguishes the company from its competition. The improved communication system makes this process even easier as companies in India can collaborate daily with their customer companies so as to make sure that everything is being done according to the predetermined standards. In addition, time differences mean that a U.S. company can shut down for the day while the partner in India is continuing on with the work, making the home company more efficient.

Yet another important benefit that companies can enjoy when outsourcing is having no overhead costs. Seeing that the offshore companies provide their own facilities and personnel, a U.S. firm does not have to deal with all of the logistics associated with building its own plant overseas, such as is the case with greenfield investments. Specifically, there is no need to recruit, hire, or train new employees in addition to other expenses such as insurance, worker's compensation, social security, and company benefits, as all are put on the shoulders of the outsourcing company. The U.S. business reaps the benefits of having another firm provide them with a ready service or product.

The most controversial issue with outsourcing is whether this business method is a boon to workers and employees of particular firms and society in general. Namely, to many workers the word *outsourcing* is feared and despised, as they automatically assume that it goes together with job termination. The truth is, however, that although outsourcing does

A young man undergoing computer training in 2008 in preparation for work in India's growing high-tech industry.

involve delegating jobs to people in other countries, it does not mean that workers in a home country are left jobless. After all, in some cases outsourcing may create services not previously available, which means that new positions will be created and workers acquired to fill those job openings. In addition, hiring cheaper labor overseas enables companies to hire more "higher-end" skilled workers or dedicate funds to further train current workers. Moreover, the common mistake is to believe that every job can be outsourced; the truth is that jobs, especially in the service sector, which may require face-to-face interaction, can be very difficult to transfer overseas.

Despite the benefits described above, outsourcing does have its faults and shortcomings. Many of the companies that decide to engage in this business method share the common fear of losing their intellectual property or trade secrets. Joining in with a firm in a foreign country requires the home company to share some of its strategy and strengths, making both easy targets for the outsourcing firms to steal and incorporate into their own operations. As part of learning operations, offshore workers can gain knowledge that can be applied to other projects down the road. Seeing as most offshore workers act as contractors, there is the possibility that they might use the information they gain to help competitors. In other words, outsourcing threatens the safety of the know-how of the home company.

Language and cultural differences can pose yet another disadvantage for a firm that plans to engage in offshore outsourcing. Customers may find it difficult to communicate with customer service representatives when they are located in another country. As a result, companies might find that they have many customers who, dissatisfied with the service, are looking for a different company. The need to study cultural differences is, therefore, a crucial step that every company should consider before entering into an outsourcing contract.

Outsourcing is closely related to the concept of foreign direct investment (FDI). Much like FDI, outsourcing involves investing in a foreign country, only on slightly different terms. The main difference between the two concepts is that through FDI, the home company is looking to sell the goods on the foreign market whereas in outsourcing, the services and the products are brought back to be sold or implemented in the company's home facilities.

Because outsourcing is becoming a dominant trend in today's world, it should not be forgotten that the business strategy carries both benefits and disadvantages, meaning that not every company is set to gain from applying outsourcing. It is a fault of many firms to not take into account the risks of this business decision and instead focus solely on the good that it can provide. It is imperative that a company do thorough research on the country before plunging in. To make the process of outsourcing more efficient, studies should be conducted illustrating the necessary steps a company should take to successfully implement outsourcing strategy in a particular country. Such research can help eliminate some of the risks associated with outsourcing. In all, patience and careful planning seem to be the determinants of any successful business decision, especially one as complicated as investing overseas.

Overseas Private Investment Corporation

The Overseas Private Investment Corporation (OPIC) has played a vital role in advancing globalization for over three and a half decades. It does so by encouraging outward foreign investment by U.S. businesses to developing countries. Established in 1971, OPIC is an agency of the U.S. government that advances the economic development of new and emerging markets. To this end, OPIC has the responsibility of aiding U.S. companies to invest in a wide variety of overseas development projects.

OPIC performs its central responsibility by: (1) financing U.S. companies through direct loans and loan guarantees to eligible investment projects in developing countries and emerging markets; and (2) providing political risk insurance to U.S. development companies against the uncertainties of political instability, currency conversion issues, and expropriation possibilities (i.e., the risk that a host government will confiscate the assets—such as a factory, inventory, bank accounts—of foreign businesses). Funding for OPIC operations and services comes from market-based fees it charges for its products and services. Consequently, OPIC is a self-sustaining agency. OPIC provides funding and insurance to U.S. investors, contractors, exporters, and financial institutions. To assess appropriate countries, industries, and companies in which to invest, OPIC undertakes economic and market analyses of products, firms, and nations; these studies are done either in-house or are subcontracted on a competitive basis to outside consulting firms.

OPIC spreads its investment activity over a wide geographical area, including (but not limited to) sub-Saharan and northern Africa, eastern Europe and Russia, Latin America and the Caribbean, the Middle East, and Asia and the Pacific. As of 2008, OPIC invested in U.S. companies undertaking development work in over 150 countries dispersed throughout these (and other) regions. OPIC's mission in its financing function is to complement the private sector and provide financing in countries where conventional financial institutions are unable to finance on the required scale.

OPIC divides its financing role into two categories, depending on the size of the U.S. company looking to undertake international development projects. On one end of the size spectrum are the small and medium-sized enterprises with annual revenues of less than $250 million, and at the other end of the scale are the larger companies with annual revenues over $250 million. In this latter case, the investment is generally for projects that require large amounts of capital, such as infrastructure, telecommunications, power, water, housing, airports, hotels, high-tech industries, financial services, and the natural resource extraction industry. If projects require capital in excess of what OPIC itself can support because of resource limitations and regulatory restrictions, OPIC will work with colenders to extend its resource base for certain projects.

In general, OPIC provides support for the creation of privately owned and managed investment funds that make direct equity and equity-related investments in companies—often small and medium enterprises (SMEs)—within newly emerging market economies. As part of its financing function, OPIC facilitates the transfer of information, skills, and expertise from U.S. companies and their management team to their counterparts in the developing countries, and thus aids the latter in achieving self-sufficiency that extends beyond the life of the particular project.

OPIC sources indicate that, from 1991 through 2007, the corporation has committed close to $3 billion in funding to approximately 40 private equity funds. These funds, in turn, have invested approximately $3.5 billion in over 400 privately owned and managed companies operating in over 50 developing countries worldwide. OPIC's credit-based support of such funds that invest in companies creates a multiplier effect in attracting additional foreign direct investment in, and international financing of, companies in the developing and newly emerging countries.

OPIC's function in reducing the risk of doing business abroad is an important part of its mission in facilitating American companies to invest in international development projects. Many companies shy away from foreign direct investment in the face of perceived political (and other types of) risk. This reticence is in large part the result of the difficulty in constructing a business model for undertaking foreign investments when the possibility of political problems that can arise and threaten project success is a real concern and, moreover, is generally unpredictable over a number of dimensions. OPIC thus encourages private investment in developing countries through its political risk insurance.

As an agency of the U.S. government, OPIC operates through funding provided by Congress. In 2008 OPIC's authorization was extended in the Consolidations Appropriations Act of 2008 (P.L. 110–161). This Act provides $47.5 million for OPIC's 2008 administrative expenses and allows a transfer of $20 million from OPIC's noncredit account to fund its credit program.

Overtime

Overtime occurs when an employer requires or permits an employee to work extra hours over and above their normal working hours for the day or week. Where overtime is worked, this can take the form of paid overtime (normally at a premium rate), unpaid overtime, or the hours worked in overtime are recompensed by time off in lieu from normal working hours, either on a like-for-like basis or at a 1.5 rate.

In the United States the Fair Labor Standards Act (FLSA) requires employers to pay nonexempt employees time and a half the regular rate for all hours worked over 40 in each work week. The regular rate of pay can be the hourly rate or it can be calculated on a piece rate, salary, commission, or other basis, but the overtime compensation due to employees must be computed on an hourly basis. Discretionary bonuses, however, are excluded from such calculations. Hours cannot be averaged over two or more weeks, except in certain prescribed cases such as hospitals and nursing homes, when employers can use an 80-hour standard over a two-week period. Otherwise, even though overlapping work weeks may cause computational problems, the statutory 40 hours in a single work week prevails.

Employees classified as executive, administrative, professional, computer, or outside sales staff, however, are exempt from the overtime provisions of the FLSA and these form a growing proportion of the workforce in the United States.

The FLSA, which provides a base on which individual states are free to build, has no limitation on the number of hours an employee may work in a given work week. In contrast, the European Union's (EU's) Working Time directive sets a 48-hour limit to the working week (although certain exemptions and averaging are permitted by national laws). This is because the EU wishes to discourage overtime: It considers that workers are more likely to suffer adverse health problems and/or be more prone to accidents if they work long hours. Accordingly, unlike the United States, the EU does not prescribe any payments for working beyond normal hours and practice in member states varies. In the United Kingdom, for instance, manual workers traditionally receive premia for working beyond 40 hours per week.

Arguably, the provision of overtime pay has perverse consequences. It encourages workers to carry out their work slowly, as they will be rewarded at a premium rate if they are required/permitted to work over and above their normal hours. Also, absence procedures can be abused where employees deliberately take "sick leave" so that their colleagues can cover for them and earn overtime payments. Furthermore, researchers have found that manufacturing plants that use paid overtime are not more efficient than those that do not.

Conversely, overtime pay gives the employer flexibility to deal with peaks and troughs in the demand for goods and/or services; it enables the employer to increase the number of hours worked of permanent employees quickly and easily, without resorting to temporary employees. Furthermore, overtime payments at a premium deter the employer from using overtime unnecessarily and at the same time prevent employees from being exploited. The employer will, however, need accurate management information systems to ensure that overtime is awarded equitably. If some employees perceive they are not being given the opportunity to earn overtime pay unlike their colleagues, grievances can result.

There is a gender issue to overtime payments. Statistics show that men are more likely to receive overtime payments than women. Also, both in the United States and the United Kingdom, it is usually implicit, if not explicit, that managers will work whatever hours are required to ensure the fulfilment of their responsibilities, and in some sectors, such as the financial services, there is a long hours culture. The British Trade Union Congress calculated that over a fifth of all employees put in an average of seven hours overtime a week in 2007. As the issue of work/life balance creeps up the agenda, the emphasis is shifting from debates about rewarding overtime to debates about curtailing overtime.

In 2007, over a fifth of workers in the United Kingdom put in an estimated average of seven hours overtime every week.

Pacific Rim

The Pacific Rim is the name given to the countries located on the edges of the Pacific Ocean, and is a term generally associated with economic interaction among these countries. Together, they account for some 42 percent of the world's population, and about 56 percent of the world's gross domestic product (GDP), as well as about half of the trade in the entire world. The term *Pacific Rim* was coined in the early 1980s and used by Anthony H. Chisholm and Rodney Tyers in their book, *Food Security: Theory, Policy, and Perspectives From Asia and the Pacific Rim*. Four years later, David Aikman followed up on the theme with *Pacific Rim: Area of Change, Area of Opportunity*.

Since ancient times, there were clearly interactions between the different parts of the Pacific as the Norwegian adventurer Thor Heyerdahl was able to show in his *Kon-Tiki* expedition of 1947. Gavin Menzies in his book *1421: The Year China Discovered the World* (2002) has also argued that the Chinese had managed to voyage to the Americas, an argument first propounded at length by John Ranking in *Historical Researches on the Conquest of Peru, Mexico, Bogota, Natchez and Talameco in the Thirteenth Century by the Mongols* (1827), although Ranking dates the contact as a century or so earlier than Menzies. From the 16th century, with the Spanish taking the Philippines and being involved in some of the Pacific islands, there were trade links across the Pacific with the Manila galleons and other ships regularly traversing the Pacific. Valparaiso in Chile was a port much concerned with this trans-Pacific trade for centuries. In World War II, there was much fighting in the Pacific, with the Southwest Pacific area being designated by the Allies. The mutual defense treaties, the Southeast Asia Treaty Organization (SEATO) and the Australia–New Zealand–United States Treaty (ANZUS), both encompassed the Pacific, with the Association of Southeast Asian Nations (ASEAN) being founded in 1967 and coming to represent first a political and then a largely trade organization.

It was in the 1970s, when some of the countries around the Pacific started booming economically, that moves were made to increase trade across the Pacific to allow other countries to benefit from the new Asian "tiger" economies of Hong Kong, Singapore, South Korea, and Taiwan (Republic of China). The emergence of China as a major economic power seeking close involvement in the Pacific and the end of communism in the Soviet Union (and indeed the end of the Soviet Union in 1991) helped encourage this sense of community in the Pacific Rim, which led to the formation of the Asia-Pacific Economic Cooperation (APEC) in 1989.

The idea of bringing together the countries of the Pacific Rim was that there were vast natural resources in some of the countries: Australia, Canada, Chile, Colombia, Mexico, Peru, the Pacific parts of Russia, and the United States. Australia, Chile, and the United States are also centers of agricultural production, as are New Zealand and Thailand; and the Philippines, South Korea, and Japan have great technological expertise, and China, Indonesia, and Mexico have vast human resources. Singapore, Taiwan, and Hong Kong (since 1997 a part of China) are centers of great entrepreneurial skills, and Japan and the United States have an aggressive capitalist outlook. Together, it was felt that these countries can contribute to their own prosperity and also the prosperity of other countries in the region.

Mention should also be made of the other countries in the region: Brunei and Malaysia, which have always been prosperous; the Central American countries of Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua, and Panama; and Cambodia, Vietnam, and North Korea, which have gone through periods of isolation. By nature of the definition, the Pacific islands are generally excluded from the Pacific Rim, although Papua New Guinea has been a member of APEC since 1993. India has also requested membership of APEC although it is not "on" the Pacific Rim.

There have been a number of studies of the Pacific Rim and how trade alliances have helped cement business relationships in these countries. Many of these countries are heavily involved in export trade, and curiously, most—even those in Latin America—have significant Chinese communities that have fostered contact for over a century. Indeed, that became the subject of the book *Lords of the Rim: The Invisible Empire of the Overseas Chinese* by the well-known U.S. writer Sterling Seagrave.

U.S. businesses also proliferate in the Pacific Rim, with the major cities in the Pacific Rim being seen as Auckland (New Zealand), Busan (formerly Pusan, South Korea), Brisbane (Australia), Ho Chi Minh City (Vietnam), Lima (Peru), Los Angeles, Manila (the Philippines), Melbourne (Australia), Panama City (Panama), Portland, San Diego, San Francisco, Santiago (Chile), Seattle, Seoul (South Korea), Shanghai (China), Singapore, Sydney (Australia), Taipei (Taiwan), Tokyo (Japan), Vancouver (Canada), and Yokohama (Japan). Most of these cities are ports and shipping remains the key to the Pacific Rim. Honolulu, Hawaii, has become the headquarters of some trans-Pacific operations such as the East-West Center and the Institute of Asian Research, with the regular Rim of the Pacific Exercise (RIMPAC) controlled by the U.S. Pacific Command, also coming from there. Manila, the former headquarters of SEATO, has been the headquarters of the Asian Development Bank; and Singapore is the location of the headquarters of APEC. The headquarters of the ASEAN secretariat is currently in Jakarta, Indonesia.

Pakistan

Pakistan is on the northwest border of India and also shares borders with Iran, Afghanistan, and China.

The country emerged in 1947 from the partition of India when the British left. Pakistan is an active member of the United Nations. With a population of 169.3 million, it is the sixth-most-populous country and the second-most-populous Muslim country in the world.

The coastal region of modern-day Pakistan has been a center of extensive trade since ancient times, as archaeological work on the Indus Valley civilization has revealed. Goods from around the Indian Ocean, and even farther afield, were brought in and traded for many centuries. Following the collapse of the civilization, northern Pakistan found itself astride the Silk Road, which facilitated trade between Europe and China. As a result, that region enjoyed increased wealth, and its people developed close familial ties with people in Afghanistan.

During the period of British colonial rule, from the mid-19th century to 1947, Britain stationed many soldiers in the region, with Quetta emerging as a major garrison town. Many Pakistanis also enlisted in the British Indian Army during the World War I and World War II periods; as a result, many villages survived on army remittances. After independence in 1947, Pakistan found itself in a difficult position both politically and economically. Its first aim was ensuring a stronger economic position, which it achieved by developing Karachi into a major port. Karachi remains the largest city in the country, with a population of 9.34 million (2007), which is nearly twice that of the next-largest city, Lahore. The Pakistani government was eager to encourage a sense of national identity, however, so it moved the capital first to Rawalpindi and then to Islamabad.

Some 42 percent of the workforce is employed in the agricultural sector, which provides some 22 percent of Pakistan's gross domestic product (GDP); services make up 38 percent of the workforce and 53 percent of the GDP. In industry—coal, iron, steel production, scrap metal, and oil—some 20 percent of the workforce accounts for 25 percent of the GDP.

In terms of international trade, the country runs up a large balance-of-payments deficit, exporting textiles, rice, and some other agricultural produce, and importing machinery, petroleum, petroleum

Schoolchildren throng a fruit vendor in Karachi, Pakistan's largest city, which is home to more than 9 million people. Per capita GDP in Pakistan is only $830, though its cities fare better economically than rural areas.

products, transport equipment, chemicals, edible oils, grains, and flour. Some 21 percent of the nation's exports go to the United States, and 11 percent of its imports are from China.

Pakistan experienced rapid economic growth in the 1960s, with West Pakistan becoming the powerhouse of the country's economy. East Pakistan (modern-day Bangladesh) continued to have a largely agricultural economy. To protect Pakistan's new industries, the government introduced several exchange rates to make it harder for imports to compete with locally produced products.

The country has had a variety of governments, with a military coup d'état overthrowing the elected government of Zulfikar Ali Bhutto in 1977; Bhutto was executed two years later. Great political instability followed. General Pervez Musharraf staged a coup in 1999 and ruled the country until his resignation in August 2008 and replacement by President Asif Ali Zardari, who was elected the next month. This instability has led to many foreign companies being nervous about investing in the country.

After the attacks on the World Trade Center and the Pentagon on September 11, 2001, the U.S. military took a great deal of interest in the radical Muslim movements in Pakistan, leading to tensions between the pro-Western Musharraf government and many Pakistanis on both the left and the right, leading to further instability and frightening many would-be investors. Despite Pakistan's political problems, the economy of the cities generally has held up, with inflation reaching 7.9 percent in 2006. By contrast, poverty is widespread in the countryside. The country's per capita GDP is $830 (128th in the world).

Panama

This Central American country was occupied by the Spanish from the 1510s and gained its independence as part of Gran Colombia in 1821, becoming an independent republic in 1903. The move to independence centered on Panama's position, which eventually led to the building of the Panama Canal.

Under the Spanish, Panama was ruled initially by a violent conquistador, Pedro Arias de Avila. Panama City was established in 1519 on the Pacific Ocean. Because all goods from Europe going to South America had to be routed through Peru, and because many traders did not want to go past Cape Horn, goods were unloaded in Panama at the port of Colon in the Caribbean and then taken by land to Panama City. Trade to Europe also went through Panama, with much gold from Peru transported in Panama. Consequently, the Welsh pirate and buccaneer Sir Henry Morgan arrived from the Caribbean, sailing up the Chagres River and then going by land to attack and sack Panama City in 1671. In 1739, in the War of Jenkins' Ear, British admiral Edward Vernon also attacked Panama. As a result of this newfound vulnerability, it was regarded as safer to send goods via Cape Horn.

In 1821 Gran Colombia, of which modern-day Panama was the northern part, became independent. The economy of the region was transformed in 1849 by the California gold rush; many people sought to go from Europe to the West Coast of America by crossing Panama. This traffic led to the building of the Trans-Panama Railway, which rapidly became, mile for mile, the most expensive railway in the world for passengers, with the overwhelming majority of passengers and goods going from the east coast to the west coast.

In 1883, following the French success with the Suez Canal, Ferdinand de Lesseps drew up plans to build the Panama Canal. Despite raising large amounts of money from investors and speculators, he ran into many problems; parts of the building work were delayed, and the plan collapsed. It was left to George Washington Goethals (1858–1928) to use U.S. funds to build the canal, which finally opened in 1914. During both the French and the U.S. construction work, many migrant laborers were brought to Panama from Barbados, Trinidad, and other parts of the Caribbean. The canal became U.S. territory (and remained such until 1979), and the United States purchased the Danish West Indies from Denmark in 1917 to help control and supply the canal.

When the United States started its interest in the Panama Canal, independence movements arose, with the elite in Panama City agitating for full independence. A civil war in Colombia in 1903 provided the opportunity for a revolutionary junta to declare independence on November 3, 1903. Under the 1903 Panama Canal treaty, the United States was able to maintain its rights; initially, it had "sovereign rights in perpetuity over the Canal Zone." But after several interventions, in 1936 the United States revoked its right to intervene militarily, and in 1955 it signed a new treaty providing a higher payment to the Panamanian government for continued use of the canal.

After a 1968 coup d'état, a military dictatorship under Gen. Omar Torrijos (1929–81) was established in Panama, leading to a renegotiation of the canal treaty. In 1979 Torrijos and U.S. president Jimmy Carter signed a new treaty that phased out all U.S. ownership and control by 1999. In return, the Panamanians, in another treaty, undertook that the canal would remain open and neutral during times of peace and war.

A U.S. government dispute with Panamanian general Manuel Noriega led to the U.S. invasion of Panama in December 1989, after more than a year of economic sanctions. The U.S. government claimed that the country was being heavily used by drug syndicates, and the invasion led to the deaths of some 1,000 people. The U.S.-installed Endara government rapidly collapsed. In 1999, however, the United States relinquished control of the Panama Canal.

During some periods of its history, Panama has used the U.S. dollar, and its currency, the balboa (named after the Spanish explorer who was the first European to see the Pacific Ocean), is heavily tied to the U.S. dollar.

Panama's main exports are bananas (heavily controlled in the past by United Fruit Co.), shrimp, sugar, coffee, and clothing—the Panama hat becoming famous around the world. Imports include capital items, oil, food, and consumer goods. Some 20 percent of exports go to the United States, and Japan provides 37 percent of the country's imports.

Parent Country National

Parent country nationals (PCNs) are employees who are citizens of and are hired from the nation where an organization has its original and current headquarters (the parent country). PCNs are distinct from host country nationals (HCNs), who are staff hired from the country where the international subsidiary is operating (the host country). Third country nationals (TCNs) are citizens of neither the parent nor the host country. The role and function of a PCN depends on the organization's approach to international human resource management and the needs of the overseas subsidiary where the PCN is assigned. PCNs use different adaptation strategies to cope with their overseas assignments, and there are both advantages and disadvantages in using PCNs to staff international subsidiaries.

The term *parent country national* usually is used only to identify an employee who is posted to an overseas country as an expatriate (overseas assignment of more than one year), as a worker on a short-term assignment (less than one year), or as a flexpatriate (several short-term overseas postings, sometimes referred to as commuter assignments). The term became widespread in the business world in the 1960s and 1970s, when it became apparent that the traditional employment dichotomy of expatriates and nationals could not accommodate employees who were citizens of neither the host nor the parent country (TCNs). Researchers and organizations replaced the dichotomy by distinguishing employees by parent, host, and third country citizenship.

Global businesses now categorize employees by using frameworks that include length of assignment (expatriate, short-term, and flexpatriate), direction of assignment (expatriate vs. inpatriate), and nature of assignment (expatriation vs. virtual assignment). Virtual assignments are job assignments focused on projects within a particular country that rely on electronic communications such as videoconferencing rather than require the assignee to travel to the country itself. Inpatriates are transfers of HCNs or TCNs to corporate headquarters for developmental purposes.

The role of PCNs in an international organization depends on the organization's approach to international human resource management. Those management approaches can be categorized as (1) exportive/ethnocentric, (2) integrative/regiocentric and geocentric, and (3) adaptive/polycentric. In the exportive/ethnocentric approach, PCN expatriates function in a control position, as this approach is characterized by a transfer of the parent company's human resource management system to the host country. PCNs also benefit from international developmental experience while they are on expatriate assignment. The integrative approach also allows for the employment of PCN expatriates; however, human resource management policies and managerial practices are transfused and adapted from host country to parent country, and vice versa. PCNs are learners in the adaptive approach, in which organizations focus on adopting and localizing the practices and policies of the international organization to the host country.

PCNs are used for overseas assignments for several other reasons, including filling an existing overseas position, developing managers in terms of global awareness and experience, fulfilling the role of organizational development, and problem solving. Researchers have found differences in the importance of the reasons for employing PCNs in subsidiaries, depending on the organization's headquarters country, demonstrating that national culture can influence organizational reasons for expatriation. Japanese and European companies are more likely to use PCNs, whereas U.S. companies are more likely to use HCNs.

PCNs tend to use different adaptation strategies when on overseas assignment. Researchers have categorized PCN expatriates according to their degree of allegiance to the parent or host country as being outcomes of adaptation. The categories are (1) free agents, who have low allegiance to both home and host countries; (2) "going native" expatriates, who have high allegiance to the host country and little to the home country; (3) "hearts at the parent" expatriates, who have high allegiance to the home country and little to the host country; and (4) dual citizens, who have high allegiance to both countries. The choice of adaptation strategy appears to be linked to the personality of the PCN.

Advantages and Disadvantages

Several advantages result from employing PCNs who have experience in the organization rather than HCNs or TCNs. PCNs usually are considered by headquarters as being familiar with the organization's goals, products, services, technology, policies, and procedures. This familiarity may help facilitate coordination, control, and development of organizational strategy.

The use of PCNs also has several disadvantages. Among them: (1) PCNs may impose a culturally inappropriate management style on the host country subsidiary; (2) using PCNs may limit the promotional opportunities of HCNs; and (3) the compensation for PCNs usually is greater than that received by HCN staff, which may cause a degree of resentment among HCN staff. PCNs also may take a long time to adapt to the host country, which is likely to affect their work performance.

Some researchers have questioned whether HCNs, TCNs, and inpatriates may be better equipped to deal with the cultural challenges of international management than are PCN expatriates. The use of PCNs in global organizations appears to continue to develop rather than diminish, however.

Patents

A patent is a contract between society as a whole and an individual inventor. The objective of a patent is to provide the holder a temporary monopoly on his or her innovation and thus to encourage the creation and disclosure of new ideas and innovations in the marketplace. A patent provides the owner exclusive rights to hold, transfer, and license the production and sale of the product or process. Patents are part of the area of intellectual property law that covers copyright and related rights, trademarks and service marks, appellations of origin, industrial designs, layout designs of integrated circuits, and undisclosed information such as trade secrets.

Patents are provided for products or processes that are new and/or involve new steps and that can have industrial application. A patent is the result of a unique discovery, and patent holders are provided protection against infringement by others. In general, machines, products, plants, compositions of elements (chemical compounds), and improvements on existing items can qualify for patent protection.

Patents go back as far as ancient Greece and Rome. Pliny wrote that one day, an inventor came before Emperor Tiberius to show him his invention of unbreakable window glass and to beseech him for an inventor's fee. Tiberius asked whether anyone else knew the formula. The man assured him that the invention was absolutely secret, whereupon the emperor immediately cut his head off "lest gold be reduced to the value of mud."

In 1623 England enacted the Statute of Monopolies under King James I, which declared that patents could be granted only for "projects of new invention." In the 18th century, the English judicial systems developed the prerequisite that a written description of the invention must be submitted. These developments led to modern United Kingdom and U.S. patent law. Now all member countries of the World Trade Organization (WTO) are duty bound to enforce minimum standards of patent protection. Any noncompliance is liable to attract legal action.

International and National Provisions

The WTO's Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPs) provides the international standards for patents. TRIPs requires country signatories to allow the patenting of product or process inventions subject to the normal tests of novelty and inventiveness. Three exceptions to patentability exist: (1) inventions contrary to morality; (2) innovations dangerous to life, health, or the environment, or to treatment of humans or animals; and (3) plants and animals (other than microorganisms) used for the production of plants or animals.

TRIPs confers an exclusive patent on making, using, offering for sale, selling, and importing for these purposes. Process patent protection must give rights not only over use of the process, but also over products obtained directly by the process. Patent owners also have the right to assign, or transfer by succession, the patent and to conclude licensing contracts. The term of protection is 20 years, counted from the filing date. Under all patent systems, after this period has expired, people are free to use the invention as they wish.

Although all WTO members are subject to the patent provisions in the TRIPs agreement, patents are actually granted under national laws, so the rights are also national in scope. An Australian patent, for example, can be defended only against infringements in Australia. But the Patent Cooperation Treaty (PCT), concluded in 1970, allows inventors to patent an innovation simultaneously in other countries. A patent application filed under PCT is called a PCT application. After an inventor makes an application under PCT, the International Searching Authority (ISA) carries out a thorough search and provides a written opinion on the patentability of the invention. Again, granting procedures are handled by the relevant national authorities. No such thing as an international patent exists.

One new form of patent deserves special mention. Business method patents claim new methods of doing business. This type of patent emerged in the late 1990s, with Amazon.com's famous one-click-shopping patent. IBM owns a patent on a process for paying software developers. Such business process patents may actually hold back innovation.

As important as patent protection is, numerous controversies have arisen, such as the excessive prices of patented human immunodeficiency virus/acquired immune deficiency syndrome (HIV/AIDS) medicines in South Africa. TRIPs unwittingly has caused a problem in that pharmaceutical companies can charge excessive prices for patented antiretroviral medicines. In this case, U.S.-patented triple therapies for HIV/AIDS could cost more than $10,000 per person per year—far beyond the ability of sick South Africans to pay. Meanwhile, competitors launched generic equivalents of these patented drugs, forcing large pharmaceutical companies to cut their prices to around $1,000 per person per year. As dramatic as this cut was, the cost was still three times higher than the cheapest offer from the Indian generic company, Aurobindo: $295 per person per year. The pressure from generic-drug firms has played a pivotal role in decreasing the prices of patented drugs.

Planning, Application, and Use

Because quite often the patent process is complex, typically taking three years, careful planning is required. Experts recommend the following basic rules:

1. Pursue patents that are broad, are commercially significant, and offer a strong position.
2. Prepare a patent plan in detail.
3. Have your actions relate to your original patent plan.
4. Establish an infringement budget.
5. Evaluate the patent plan strategically.

Patent applications must include detailed specifications of the innovation that any skilled person in the specific area can understand. A patent application has two parts: specification and claims. The specification is the text of a patent and may include any accompanying illustrations. Its purpose is to teach those fluent in this area of technology all they need to understand, duplicate, and use the invention. The specification may be quite long. Claims are a series of short paragraphs, each of which identifies a particular feature or combination of features that is protected by the patent. The entire claims section, at the end of the patent, typically is one page long or less. After the application is filed, an examiner will determine whether the innovation qualifies for patentability by researching technical data in journals as well as previously issued patents. Based on those findings, the application will be rejected or accepted.

Although intellectual property may represent a significant share of some firms' market value, only a small percentage of issued patents is commercially valuable. Also, many patents go unimplemented, and so firms may want to sell unused or underused patents to monetize intellectual property assets for other purposes.

A survey of 150 technology firms and research universities in the United States, western Europe, and Japan found that only 15 percent had no unused patents. Although patent holders may have many legitimate reasons not to exploit their patented inventions, the situation led to the creation of patent exchanges or patent licensing markets, which set a fair market value on a patent and facilitate its sale.

Value of Innovation Versus Cost of Patent

Any inventor must weigh the value of the innovation against the time and money spent to obtain the patent. Also, it is important to remember that many patents are declared invalid after being challenged in court. One reason is that the patent holder waited an unreasonable length of time before asserting his or her rights. A second reason is that those bringing suit against the patent holder are able to prove that the individual misused the patent rights. A third reason is that other parties are able to prove that the patent fails to meet tests of patentability and therefore is invalid.

Truth be told, the entrepreneur might waste a lot of money on protecting intellectual property that could have funded marketing and product development. Another factor is whether the invention will be obsolete before the patent is issued, especially in a fast-moving market. Neither is there any guarantee that a patent is valid. Many cases have been lost by showing that the patent examiner was mistaken and missed an important precedent. A good example is the Toyota RAV4, which was copied perfectly as the Chinese-built Jonway UFO. Toyota has not been able to stop UFO sales because it did not get proper patent protection for the car's design in Europe. The UFO is identical to the RAV4 down to the body panels and doors, which are interchangeable with the original Toyota model parts. BMW and Daimler have started lawsuits to try to prevent the launch of Chinese clones of their own cars. The brands argue that the look-alikes could hurt their brand images.

If, after careful review, an entrepreneur concludes that the innovation will withstand any legal challenge and is commercially worthwhile, a patent should be pursued. If a challenge is mounted, legal fees may be sizable, but a successful defense can result in damages sufficient to compensate for the infringement plus court costs and interest. In fact, the court may award damages of up to three times the actual amount. In addition, a patent infringer can be liable for all profits resulting from the infringement as well as for legal fees.

Payroll Taxes

Payroll taxes are of two types: they are either taxes that must be paid by an employer (employer payroll taxes) or they are taxes employees must pay (employee payroll taxes). The requirement to withhold taxes from the wages or salaries paid to employees forces employers to deduct the taxes that are owed by each employee before wages or salaries are paid. This practice makes the employer the government's tax collector. Both employer and employee payroll taxes are usually simply lumped together and called payroll taxes because they are all handled as a part of the calculations needed by an employer to meet payday obligations.

United States

Employer payroll tax obligations are usually generated with a formula directly related to the amount of money an employee has earned. For example, employer payroll taxes in the United States require paying a matching portion of the employee's Social Security taxes (6.2 percent up to the annual maximum), Medicare taxes (1.45 percent of wages or salary), federal unemployment taxes (FUTA), and state unemployment taxes (SUTA).

The FUTA tax rate for employers is 6.2 percent of gross compensation for all employees on the first $7,000 of income. However, because a business must also pay SUTA taxes, it is allowed to take a 5.4-percent SUTA credit on its FUTA obligation. This reduces the net tax owed for FUTA to 0.8 percent; however, because SUTA rates vary between states, the amount owed as an employer payroll tax varies. In addition, employers usually have to pay an unemployment compensation tax.

Employers may also be liable for local taxes calculated on the basis of their employment activities. Sometimes, employers may have taxes levied upon them based on the number of workers they employ on a fixed or variable formula. Additional tax burdens such as business income taxes, inventory taxes, or property taxes may be owed, but these are not payroll taxes.

Taxes that are withheld from wages (hourly earnings) or salaries (payments on a nonhourly basis) are paid on either a pay-as-you-earn (PAYE) or pay-as-you-go (PAYG) basis. Employers in the United States are usually responsible for withholding the following taxes: federal income taxes, Social Security taxes (6.2 percent up to the annual maximum), Medicare taxes (1.45 percent), state income taxes (if applicable), and local taxes (such as city, county, school district, state disability, or unemployment insurance), if applicable.

Payroll taxes on the wages or salaries of individual workers or employees are calculated on their gross earnings unless there are tax provisions that allow for pretax exclusions. Contributions to 401(k) and 403(b) plans may be paid with pretax dollars. These exclusions are part of a policy goal that seeks to promote personal savings for retirement. Employers may allow employees to deduct a wide variety of deductions for union dues, stock plans, life insurance premiums, health plans, uniforms, meals, and other items. These last deductions are voluntary payroll deductions and are not payroll taxes.

Generally, an employer reports total payroll taxes by calculating the gross earnings and then deducting the various payroll deductions to arrive at the employee's net pay. The biggest portion of payroll taxes are the Federal Insurance Contributions Act (FICA) taxes. The FICA tax is a combination of Social Security taxes and Medicare taxes. Both the employer and the employee pay these taxes with each paying half of the amount due. The total for both combined is 15.3 percent.

Other Countries

Payroll taxes vary across the world. In Australia, the employer payroll tax is a specific tax paid by the employer for each worker. The tax is paid to the states and territories. The only employee payroll tax deduction is for Australian medical care. Mexico also has a similar state focus for its payroll tax collections. Canada has both Canadian federal payroll employee tax deductions as well as provincial deductions. A common Canadian payroll employer tax is for health insurance for employees.

In Great Britain the HM Revenue & Customs (HMRC) system is a PAYE system that requires employers to deduct income taxes and National Health Insurance contributions (NIC) from employees' wages. In addition, employers pay taxes as contribution to NIC for sick leave, maternity leave, and other types of family leave. Historically, payroll taxes in Europe have been much higher than in the United States. While producing a successful social safety net, high tax rates have interfered with job creation. Since 2000, payroll tax rates in Europe have declined, allowing payroll taxes to be invested in new enterprises.

The new Russian civil code mandates a number of payroll taxes. Employer payroll taxes must be paid to the Pension Fund, the Social Insurance Fund, the State Employment Fund, and the Compulsory Medical Insurance Fund, plus a transportation tax and an education tax that are also based on wages. Unlike in the United States where individual taxpayers are responsible for taxes on dividends paid to stockholders, in Russia employers are required to withhold taxes on dividends and on other forms of compensation.

Payroll taxes are relatively new and relatively low in Africa. They are often called an enterprise tax, which is levied to fund training of workers. South Africa collects a uniform levy for employee training activities. However, its payroll tax burden is greater in its six metro areas than elsewhere because the system is still in development. In Latin America the social insurance program is paid for with payroll taxes. In addition, other taxes such as income taxes may be collected. In Brazil, a payroll tax is collected to finance education with a tax burden for employers of about 40 percent and only 15 percent for employees. In Asia, social security programs are financed with payroll taxes. In addition, unemployment insurance and injury compensation payroll taxes are collected.

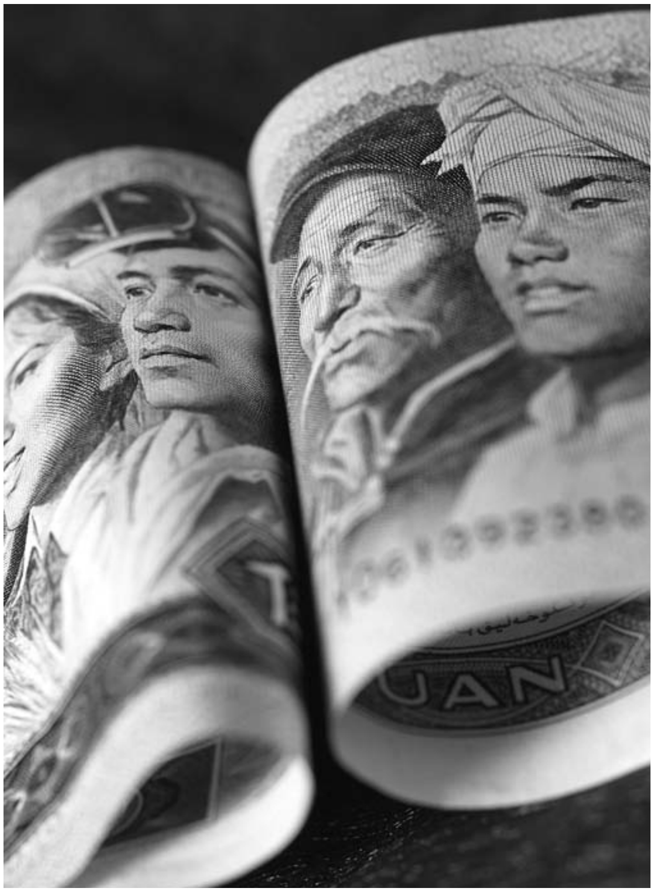
Pegged Exchange Rate

A pegged exchange rate exists when a government fixes the value of its country's currency to that of another country or group of countries (the reference currency/currencies). As a result, when the value of the reference currency/currencies rises, so does the value of the pegged currency, and when the value of the reference currency/currencies falls, so does that of the pegged currency. Pegged exchange rates can be seen as an attempt to create a fixed exchange rate zone in the midst of a floating exchange rate system and are most often implemented by developing country governments as a way of creating currency stability and reducing inflationary pressures.

A recent example of a successful currency peg is that of the Chinese yuan. From 1994 to 2005, the Chinese government pegged the value of the yuan to the U.S. dollar at a rate of $1 = 8.28 yuan. In essence, this created a fixed exchange rate zone between the U.S. dollar and Chinese yuan, reducing currency exposure for companies doing business between the two countries. However, many outside China, including some members of the U.S. government, suggested the peg



With its foreign currency reserves and controls on convertibility, China successfully pegged the yuan to the dollar 1994–2005.

was increasingly keeping the yuan at an artificially low exchange rate and was fueling a boom of Chinese exports that was hurting not only producers in China's export markets (like the United States) but also those in countries attempting to compete with Chinese exports (like other Asian producer nations).

To keep the yuan from rising above its pegged value, the Chinese government was forced to buy U.S. dollars (increasing the demand for them, and therefore supporting their value) through issuing more yuan (increasing the supply of them, and therefore suppressing a rise in their value, but risking inflationary pressure as the domestic money supply expands). Amid much international discussion, the Chinese government announced, in July 2005, that they were releasing the peg to the U.S. dollar in favor of a more flexible link to multiple currencies, including the euro, the yen, and the U.S. dollar. They also announced an immediate increase in the value of the yuan against the U.S. dollar of 2.1 percent, as well as greater day-to-day flexibility of the yuan rate versus the dollar and other currencies. As of August 2008, three years after this announcement, the yuan/dollar exchange rate had moved from 8.28 yuan/dollar to 6.86 yuan/dollar.

The unpegging of an exchange rate is not always so orderly. In 1978 the Thai government pegged that country's currency to the U.S. dollar at a rate of $1 = 25 baht. Through several decades of rapid economic growth, the peg provided reassurance to foreign investors in Thailand, who felt confident in pursuing the higher returns available there, because the peg allowed them to convert both their profits and, if desired, their capital, back into U.S. dollars at the "fixed" exchange rate. Thus, if an investment in the United States yielded a 5 percent return, and one in Thailand a 10 percent return, there seemed to be no risk in accepting the 10 percent return, because, as long as the peg held, there was no potential for the return to be eroded by a dropping Thai baht.

This dynamic of high returns and no perceived currency exposure drew increasing investment into Thailand. Despite concerns that growth was overheated and, in some cases, misdirected, the Thai government maintained its commitment to the peg. On June 30, 1997, the Thai prime minister announced that the Thai baht would not be devalued, but two days later, after intense speculative attack, the peg was released, and the baht became a floating currency. The Thai economy was in distress, and six months later, the Thai baht traded at 56 to the U.S. dollar.

What makes one currency peg succeed and another fail? For one thing, the Chinese government had huge foreign currency reserves and was accumulating more every day because of its large trade surpluses, while the Thai government had more limited reserves to address the problem. Second, the Chinese government maintained controls on the convertibility of its currency, therefore controlling the amounts investors or currency speculators could buy or sell, while Thailand did not have these controls. Finally, the widely held perception was that the Chinese yuan was undervalued and should rise, while the perception with regard to the Thai baht was the opposite, spurring speculative action and withdrawals of invested funds. However, even successful currency pegs, like China's, can lead to negative consequences, such as domestic inflation and international pressure, as they are seen as thwarting market forces in a world of floating exchange rates.

Pemex

Pemex is a Mexican state-owned oil company that operates throughout Mexico. The company is so large that its revenues account for as much as one-third of the Mexican government's entire revenue, and for about 7 percent of Mexico's export earnings. The company is involved in exploration, production, refining, petrochemicals, and more. Pemex has estimated reserves of 15.5 billion barrels of oil equivalent.

In the early years of the Mexican oil industry, the Mexican engineer Ezekiel Ordóñez discovered an oil reserve in San Luis Potosí, Mexico, in 1901. In the same year, President Porfirio Díaz issued the Petroleum Act to boost oil activity, giving advantages to foreign investors and foreign companies. Later, with the fall of Porfirio Díaz, the revolutionary government of President Francisco I. Madero issued on June 3, 1912, a decree to establish a special tax stamp on the production of oil, and subsequently, he ordered a register of companies operating in the country. Three years later President Venustiano Carranza established the Petroleum Technical Commission. By 1917 the Constitution of Mexico had dictated national control of all the riches of the subsoil, and the Carranza government soon imposed a tax on land and oil contracts to exert control over the industry.

In 1920 there were 80 oil companies in Mexico producing and exporting; 17 of these companies received 90 percent of their capital from Anglo-Americans. The company Petroleos de Mexico, A. C., was founded later, in 1934, and was responsible for encouraging more domestic investment in the oil industry.

Other important events in the history of the Mexican oil industry include the establishment of a union of Petroleum Workers in Mexico in 1935. Just two years later, following a series of events that damaged the relationship between employees and employers, a strike broke out against foreign oil companies and paralyzed the country. The Conciliation and Arbitration Board ruled in favor of the workers, but oil companies sought protection before the Supreme Court of Justice. In 1938, President Lázaro Cárdenas sided with oil workers striking against foreign-owned oil companies for an increase in pay and social services. On March 18, citing the 27th article of the 1917 constitution, President Cárdenas embarked on the state's expropriation of all oil resources and facilities, nationalizing the U.S. and Anglo-Dutch operating oil companies and creating Pemex.

In 1992 the Mexican government issued a new Organic Law of Petroleos Mexicanos (Pemex) and subsidiary bodies where the government set up basic guidelines to define the powers of Pemex as a decentralized body of the Federal Public Administration, and as a company responsible for leading the national oil production. This new law establishes the creation of a corporate body and four subsidiary bodies for Pemex and its future operations. These subsidiary bodies are Pemex Exploration and Production (PEP), Pemex Refining (PXR), Pemex Gas and Basic Petrochemical (PGPB), and Pemex Petrochemical (PPQ).

Despite its current $77 billion in revenue, Pemex pays high taxes to contribute to the federal budget. In recent years the company has only been able to meet its demands through massive borrowing, so that it owes a staggering $42.5 billion, including $24 billion in off-balance-sheet debt because the Mexican government treats the company as a major source of revenue. The state-run company pays out over 60 percent of its revenue in royalties and taxes, with those funds paying for about a third of the federal government's budget.

In 2005, with record-breaking oil prices (due to the Iraq war, economic expansion of the United States and the People's Republic of China) the company saw an unexpected excess of funds. This tendency continued in 2006 and 2007. However, the excess funds were used to pay salaries of bureaucrats and current government expenses, instead of being invested in projects for exploration and production. During President Vicente Fox's administration, these funds amounted to about $70 billion, yet the administration said that there was not enough money to pay debts. To help capitalize the company, President Felipe Calderón then made clear at the beginning of his presidency that he would respect the constitutional mandate to keep Pemex in the government's hands, but that he would try his best to open up the sector to private investment.

Pension Systems

A pension is an income given to an individual after retirement. Different systems exist to provide and fund this pension, both private (generally employer-provided) and public (provided by the government). In the United States, Social Security is the closest analogue to a public pension system, though it is not traditionally referred to that way (notably, Social Security pays out at a given age instead of upon retirement, and as a social welfare program, it includes disability benefits).

Pensions typically work like annuities, in that money is paid in during the deferral phase and paid out in periodic checks during the annuity phase. In the United States, employer-provided pension plans became more common during World War II, when scarcity of funds led to wage freezes and an increase in benefits such as pensions became the alternative to giving an employee a raise. Pension plans also encourage employee loyalty, since the eventual benefits increase the longer the employee works for the company, such that career moves that are lateral in salary and current benefits will generally be a step down in terms of overall benefits. The longer an employee has worked for a company, the more he or she has to lose by leaving for another position, which thus gives the greatest motivation to the most experienced workers.

Defined Benefit and Defined Contribution

In addition to the question of whether they are private or public, pension plans can be defined benefit or defined contribution, or a hybrid of the two. In the United States, it is typical to refer only to the defined benefit plan as a pension, but defined contribution plans have become the most common type of privately funded retirement plan in the country.

Defined contribution plans accrue from contributions paid into the plan over time, which are invested in stocks or mutual funds, with the returns of those investments affecting the individual's account balance. When the market as a whole takes a significant dip, part of the resulting panic is because of the number of people whose retirement plans are thus so influenced by market performance. Common defined contribution plans include the 401(k) and the Individual Retirement Account (IRA). The 401(k) is an employer-sponsored salary reduction plan: employees define a percentage of their paycheck to be diverted into the 401(k) account instead of disbursed to them, and any such earnings are tax deferred (taxed not in the year they were earned, but in the year they are disbursed as benefits, further down the line). Some employers will match the employee's contribution, in whole or in part, the specifics of which are agreed-upon when the plan is set up and signed. Defined contribution plans have the benefit of protecting employees from employer bankruptcy, a protection not offered by employer-sponsored defined benefit plans, which may be used to pay off an employer's debts in case of bankruptcy; while the Pension Benefit Guaranty Corporation, a federal agency created by the 1974 Employee Retirement Income Security Act (ERISA), ensures defined benefit pension plans, it does so with a cap on the maximum benefits, especially for benefits paid to early retirees (a great number of which can be expected when an employer goes bankrupt) and benefits paid to survivors of deceased employees.

A 401(k) plan remains active for the rest of the employee's life, but must begin paying out by April 1 of the calendar year after the employee turns 70 1/2, unless the employee is still working. Similar plans are the 403(b) for employees of public schools, self-employed ministers, and employees of 501(c)(3) non-profits; and the 457 plan, for government employees.

IRAs are another creation of ERISA and come in various types. The most common are the traditional IRA, which is funded by "before-tax" money like the 401(k), and the Roth IRA, which is funded with after-tax money and is therefore tax-exempt when it pays out. IRAs are protected from bankruptcy by both state and federal laws; some states protect IRAs from seizure to satisfy lawsuits, but they are usually not protected from IRS fines for failure to pay taxes, or divorce settlements.

Defined benefit plans are what most Americans mean by pension plans. Instead of paying out according to investment earnings, like a defined contribution plan, a defined benefit pays out a specific monthly amount determined by a particular formula. Sometimes this is a flat amount multiplied by the employee's length of employment with the company (another demotivator for changing jobs later in life). Other times, the benefit is determined according to the employee's salary in the years leading up to retirement, without consideration of the length of his employment; because this approach benefits recently hired executives more than it does lower-wage workers of lengthy service, it is not favored by labor unions.

Retiring early leads to a reduced payment from the defined benefit plan, on the assumption that it will be paid out for a long period of time. Despite this, because companies can hire young employees for less money, there are often incentives built into the pension plan to encourage early retirement. Unlike defined contribution plans, defined benefit plans are bound to an employer—if you leave the job before you are old enough to draw on your pension fund, you do not receive the pension. This is one reason defined contribution plans have risen in popularity in the last 30 years.

Social Security

Social Security is essentially a defined benefit plan. All workers and self-employed individuals pay into the Social Security system; employers further pay a payroll tax. These taxes are paid into the Social Security Trust Fund maintained by the U.S. Treasury. Unlike individual plans, current Social Security outgo is paid out by current Social Security income; the current generations of employees are funding the benefits of the current generation of retirees. The money that is left over is then invested in government bonds, funding the federal government's deficit spending. Congress grants the trust fund the authority to pay out Social Security payments only to the extent of the revenue collected and its holdings in bonds—in other words, should the total of payments owed exceed the total of revenues collected, the trust fund would be unable to issue its payments in full, rather than borrowing from some other source in the federal government. (Depending on the circumstance, a bailout seems likely, followed by a longer-term legislative solution.)

Social Security comes under criticism for a number of reasons. It was introduced as part of President Franklin Roosevelt's New Deal legislation, and the circumstance in which it was introduced—an economic crisis coupled with a rarity of employer-provided retirement benefits—no longer obtains, though it is true that a new economic crisis has arisen in the 21st century, and that not every American's employer provides a pension. Social Security is also criticized for being inefficient; excess revenue is stored in bonds instead of enjoying greater growth through low-risk investments. Social Security is not guaranteed to the degree that private plans are, insofar as the trust fund is limited. Further, the Social Security number has been adopted as a sort of identification number by many public and private agencies, though this is frowned upon by the Social Security Administration and theoretically restricted by the 1974 Privacy Act. Perhaps the biggest problem is that the tax to fund Social Security is regressive—only wages below $102,000 are taxed, such that upper-class earners pay a substantially lower percentage of their wages.

PepsiCo

One of the major manufacturers in the world of carbonated and noncarbonated drinks, and also many other foods, the Pepsi-Cola Company was established in 1898 and only became PepsiCo after its merger with Frito-Lay in 1965.

The original founder of Pepsi-Cola was Caleb Bradham (1867–1934), who lived in New Bern, North Carolina. A pharmacist, he operated a soda fountain in his drugstore and made a variety of drinks including what was originally known as Brad's Drink, first created in the summer of 1893, and five years later named Pepsi-Cola, probably because of the use of pepsin and cola nuts, although there are a number of other theories including the purchase by Bradham of the trade name Pep Kola, and also Pepsi-Cola was an anagram for Episcopal, Bradham's drugstore being located opposite a large church.

Bradham gained the trademark in 1903 and ran the company successfully, expanding it greatly. In 1903 Bradham had to rent a nearby warehouse to produce the 7,968 gallons of syrup he sold that year. However, he had expected that after World War I, the price of sugar would rise. Instead, it fell and Bradham was forced out of business in 1923. The trademark was sold to Roy C. Megargel, but in 1931, it was again approaching bankruptcy. In that year, the company was bought by the Loft Candy Company. Its president, Charles G. Guth, was unable to make much of a success of it and offered to sell the company to Coca-Cola, but they turned him down. Gradually, the company was turned around and started to sell well, especially during the latter period of the Great Depression, with its price cut to $0.05. In 1938 the profits were double those only two years earlier.

In the 1940s, Pepsi expanded, but there were complaints that it had ignored the African American market in its advertising. The company responded by hiring an African American sales team and it was able to criticize Coca-Cola for its company chairman's support for segregationist politicians. Gradually, Pepsi expanded and in 1963, the company used the slogan "Come Alive—You're in the Pepsi Generation." Richard Nixon was a supporter of Pepsi's expansion, and during his presidency, Pepsi started marketing in the Soviet Union. However, it remained banned in India from 1970 for refusing to hand over a list of the ingredients. Pepsi was also involved in a major sales campaign against Coca-Cola and in 2004 the market share for Pepsi was 31.7 percent, as against 43.1 percent for Coca-Cola. Around the world, Coca-Cola outsells Pepsi. During the 1980s and early 1990s, with major marketing campaigns launched by Coca-Cola and PepsiCo, the "Cola Wars" were waged, with Pepsi promoting itself as "The Choice of a New Generation" and featuring the "Pepsi Challenge."

As well as producing Pepsi-Cola, its most well-known product, PepsiCo also produced Diet Pepsi, some flavored Pepsi drinks, Mountain Dew, 7UP, and a range of other carbonated drinks. It also produces products under the Quaker Oats brand (especially breakfast cereals), having bought that brand in 2001; the Frito-Lay brand (potato chips and other snack foods); and is involved in partnerships with many other brands such as Lipton Iced Tea, which it markets. In 1977 PepsiCo bought Pizza Hut, followed by Taco Bell the following year, and a number of other restaurant chains. However, it sold all of these, most between May and October 1997—Pizza Hut and Taco Bell becoming a part of Tricon Global Restaurants. The company now has 185,000 employees, and it has net assets of $34.6 billion, with revenue of $29.5 billion, and net income of $5.7 billion (2007 figures). It has a market capitalization of $107 billion

(2008). Its CEO is Indra Nooyi from India, who was ranked as fifth in *Forbes Magazine*'s 100 Most Powerful Women in 2007. There is also a separate company, the Pepsi Bottling Group, which handles bottling and distribution.

Periphery

The term *periphery* refers, collectively, to the poor, unindustrialized, and underdeveloped nations of the world that are not heavily involved in global economic activity. Prime examples of peripheral countries include poor, largely inwardly focused, agrarian African nations such as Burundi, the Democratic Republic of the Congo, Ethiopia, Mozambique, Niger, Rwanda, Tanzania, and Zambia. Understanding the nature of the periphery and how it interfaces with nonperipheral areas is a critical step in understanding economic development and the global economic system, particularly from the perspective of dependency theory.

From a practical standpoint, the notion of the periphery arose from a need to account for the fact that great heterogeneity exists among nations in terms of developmental status and the nature and level of involvement in the global economic system. Some countries are heavily and aggressively involved in global economic activity. Other nations are far more domestically/inwardly focused. In this regard, a peripheral nation's involvement in the global economic system may entail nothing more than relatively small-scale exportation of basic commodity goods produced in abundance there and/or importation of basic commodities not produced domestically.

Theoretically, the notion of the periphery originated in the context of—and holds a place of central importance in—dependency theory. This theory of economic development was formulated in the late 1950s and 1960s by Third World/poor-nation development scholars who felt that existing theories of economic development failed to account adequately for the fact that the uneven diffusion of technical progress had contributed heavily to the division of the global economy into two predominant types of countries: (1) affluent, heavily industrialized, and highly developed core nations, such as the United States and the United Kingdom, and (2) less affluent, relatively unindustrialized, and underdeveloped peripheral countries. These scholars also believed that existing concepts of economic development focused far too heavily on understanding core nations and also misguidedly laid much of the blame for the underdevelopment of poor countries on these nations and their disadvantaged peoples.

Dependency Theory

Dependency theory essentially holds that peripheral countries may suffer negative (economic, cultural, and developmental) consequences as a result of forming economic bonds with core nations heavily involved in the global economic system. Dependency proponents contend, in this regard, that the formation of economic ties with core nations may create a situation in which peripheral nations become highly dependent on the core, and self-serving core leaders may take advantage of this situation by exploiting key peripheral-nation resources.

This line of reasoning is diametrically opposed to the previously dominant modernization theory, which contends that poor-nation development is predicated first and foremost on the establishment of close economic bonds with the core as a result, for example, of (1) acceptance of foreign aid, (2) trade with foreign companies or governments, (3) foreign direct investment (i.e., allowing foreign companies to purchase or establish wholly owned production facilities in peripheral territory), and (4) taking out loans from foreign financiers.

The periphery's centrality in dependency theory is founded largely on the fact that although several forms of dependency theory exist, most are drawn from theories of imperialism—primarily late-19th and early- to mid-20th-century capitalist and economic imperialism—focused heavily on the colonistic desires of developed nations (often to the detriment of the colonized peripheral nations). As a result, regardless of their specific differences and perspectives, all variants of dependency theory have a common central theme: poor nations exist as peripheral countries whose development is dependent on (and perhaps jeopardized by) interactions with (and the actions of) global economic system leaders based in affluent core nations.

Theoretical Outcomes

It is worth noting, however, the different hypothesized outcomes of interaction with the core for peripheral countries in the two main forms of dependency theory. In the context of orthodox (or radical) dependency, increased linkage to core nations is viewed as necessarily leading to the development of underdevelopment (i.e., exploitation of resources and worsened economic conditions) in the periphery.

In the less extreme unorthodox version of dependency theory, development and underdevelopment can occur simultaneously in peripheral nations. Here, the level of meaningful development in the periphery is viewed as being a function of the manner in which the periphery interacts with the core. It is hypothesized, for example, that interactions with the core involving foreign direct investment, foreign debt, and export trade lead to a higher level of dependence and to less positive and slower peripheral development than interactions based on the acceptance of foreign aid and foreign trade.

Perquisites

The *Revised and Updated Illustrated Oxford Dictionary* defines *perquisite* as "an extra profit or allowance additional to a main income" and also as "an incidental benefit attached to employment." A perquisite is informally called a *perk;* a company car is a common perk for mid- and upper-management positions. Other examples of perquisites range from legal services to employee assistance hotlines. Although common fringe benefits such as health insurance are provided for all employees irrespective of their positions in the managerial hierarchy, perquisites are not so common and are more preferred with increased income. A perquisite such as an in-town apartment, for example, will not be available for employees throughout the company—only for top-level executives.

Perquisites are benefits quantifiable in monetary terms, provided for executives for their personal use and not available to nonexecutive employees. Perquisites are parts of tangible managerial rewards, along with bonus, salary, stock awards, and promotions. Notwithstanding this tangible quality, perquisites are valued for an intangible aspect, too: as status symbols. A coveted perquisite such as a country club membership not only allows the employee access to that facility, but also provides some attributes of raised status. Thus, employees in all businesses in practically all locations prefer some perquisite or other.

Rationale

Perquisites have achieved popularity partly because of their ability to motivate senior executives. Although most executives long for increased pay, additional pay is often not a strong-enough motivator at upper levels of the firm, where executive compensation is already rather high. These executives do not have pronounced needs for food, shelter, or other basic amenities of life. They are generally at a stage in their lives where they crave more status or self-esteem. Thus, a psychology-based explanation exists for the presence of perquisites in organizations.

Cultural Aspects

Some perquisites are common around the world; others are specific to location, need, and firm. Among globally common and established perquisites are the use of company cars, corner offices, and the services of assistants. Although access to a company car for personal use usually is available at middle-management level and higher, personal assistants usually are available only to top-level executives.

Perquisites that are not universal are often rather location specific. Some perquisites that are widely popular in the Western world are not valued much on the other side of the globe. Examples include mortgage support, in-town apartments, and country club memberships. Cultural attributes and habitual preferences influence which perquisites are valued in any given part of the world. The aforementioned examples are preferred in the West because they fit well with the Western lifestyle and value system.

Similarly, in Asian or south Asian countries, especially the Indian subcontinent, one can find perquisites that entail additional services of other human beings. It is not uncommon in Asia for a top-level executive to have a chauffeur (in addition to the company car), a personal assistant at work, a cook (for his house), and even a gardener.

Some perquisites are heavily country specific, such as bodyguards for executives in Brazil. Affluent businesspeople and executives of big companies are frequent targets for kidnapping in Brazil; this vulnerability alone necessitates bodyguards for mid- and top-level executives in that country.

Tax Aspects and Problems

Another significant aspect that affects the desirability of perquisites is tax rates. Since 1978 the U.S. Securities and Exchange Commission has required U.S. companies to reveal the monetary worth of the perquisites that their executive officers enjoy. During the same year, the Internal Revenue Service decided to impose taxes on perquisites. In fact, the Internal Revenue Code of 1954 demanded that the value of perquisites and other benefits be reported as income to the extent that the executives consumed these benefits for personal use.

Despite the code, disclosing the monetary value of perquisites was not compulsory back then. It was not until 1978 that both the disclosure law and stronger enforcement of taxation simultaneously came into effect, resulting in the lower after-tax value—and, therefore, reduced attractiveness—of perquisites. U.S. executives shifted their desires from perquisites to monetary compensation in that year.

Greed is a key reason for problems with perquisites. Perquisites are expensive and have some adverse effect on the firm's bottom line. Managers who are more concerned about their own self-interest than their firm's interest will make decisions in such a way as to justify specific perquisites for themselves. During times of austerity, for example, it is quite logical for a firm to cease operating corporate jets. Even in the face of extreme financial crisis, however, Enron executives routinely flew corporate jets—clear evidence of perquisite greed causing problems.

Persuasion

Persuasion, by definition, involves changing the opinion of another person. However, the process is significantly more complicated than mere manipulation. Effective persuasion involves a thorough understanding of the other person's interests and needs, detailed preparation and planning, and a carefully structured communication strategy. There are also several psychological triggers that can be applied throughout the process.

The art of persuasion has become extremely important in the business environment today because of two key factors. First, the globalization of industries has rendered traditional hierarchies obsolete. Second, the changing attitude of employees and the increasing reliance on electronic communication means that ideas move quickly throughout an organization. These two factors mean that employees are equally invested in the "why" of their actions and the "what." For managers to create a sense of intrinsic motivation within the company, they must be able to lead through persuasion and not simply dictation.

Persuasion is often confused with sales and negotiations, when, in reality, it is a much broader form of communication and interaction. Conventional wisdom assumes that successful persuasion consists of one person trying to convince the other that his or her viewpoint is more rational. The crux of the debate is centered solely on the validity of each participant's opinion, with little focus on relationship building.

The danger of this approach is twofold. First, it is highly ineffective. People find their own perceptions the most convincing and rational and are unlikely to spontaneously change their mind. As humans, we have a tendency to accept our view of reality as the only true reality. As such, it is virtually impossible to sway another person using one's own views. Instead, examining and understanding the other person's perceptions is at the core of successful persuasion. Second, this approach ignores the benefit of shared values. By identifying these shared benefits, a manager can build a highly cohesive consensus—not simply a winning or losing side. This is particularly important in large global corporations today, as warring internal factions can drastically affect efficiency and productivity.

Process

The initial stages of persuasion involve discovery, preparation, and dialogue. This process of learning is slow, but essential. Testing and revising ideas based on feedback from colleagues allows persuaders to incorporate multiple viewpoints into their final strategy. This also helps identify weaknesses and any alternative positions/solutions that need consideration. On a personal level, listening and learning gives the persuader a positive image. A good manager appears open-minded and genuinely concerned about others' concerns and beliefs through this dialogue. Remember, it is crucial not only to understand the views of others, but also to fully understand why they believe the way they do. By doing so, the speaker can align his or her needs with those of the audience. Another important benefit of preparation is the formation of an early coalition within the company or audience, helping lend credibility to any future discussions.

Once this initial discovery phase has taken place, the formal planning can begin. Establishing credibility along two aspects is the first challenge. To overcome the hurdle of instinctive trustworthiness, managers must build credibility in both expertise and relationships. It is not enough to have a thorough understanding of the issue—a person must also be perceived to have strong character and integrity. There are several ways to address gaps in credibility, including working with experts, launching pilot projects, and involving others who already maintain strong relationships with your target audience. The second step in planning involves the proper framing of the position. Effective persuaders must be able to describe their position in terms that identify shared benefits and highlight the advantages. This does not mean simply trying to convince the audience of the validity of the argument based on its merits alone. Instead, a manager must frame the issue in a way that aligns his or her needs with those of the audience. Effective persuaders use framing to talk about the audience's interests and create common ground.

Next, crafting a successful communication strategy requires several structural steps. First and foremost, a speaker must define the desired outcome of the conversation or debate. In other words, they must tell the audience why they should care and why it is important to them. Structuring this message in a well-organized manner, and with limited information, allows the audience to focus on the crux of the issue. It is also important to tie the information in to what the audience already knows. By working with existing beliefs and level of expertise, the speaker builds on the familiar and links the new information/opinion to the old. Last, persuasion requires more than data. By including vivid evidence—both anecdotal and emotional—the speaker can create a powerful psychological connection and feeling of mutuality. While many managers are afraid of using emotional language, the fact is that audiences absorb and retain information in proportion to its vividness.

Principles

Within this persuasion process, there are six established principles that communicators can use to effectively and efficiently shape the behavior of others. The principles include reciprocation, consistency and commitment, social proof, liking, authority, and scarcity. These principles create a form of psychological trigger that greatly increases the compliance or agreement of others. By learning how to use these innate triggers in communication, a person can subtly influence the way another person behaves—without outright manipulation or deception.

A classic academic example of these persuasion principles is found in Tupperware sales parties. All visitors receive gifts of some sort, triggering their instinct to reciprocate with a purchase of their own. Guests are encouraged to discuss Tupperware products they already own and use, which serves to remind them of their existing psychological commitment to the product, and thus leads them to purchase more in pursuit of consistency. The group environment is ideal for the social proof principle, which states that people behave in accordance with a group's perceived acceptance. The informal party atmosphere makes it easy for the salesperson to create a personal bond, because people are much more likely to say yes to the requests of someone they know and like. The salesperson's expertise on the product also factors into the sale, as it is human inclination to defer to an authority figure or expert. Most important, visitors leave these events feeling as if they have had some important individual need met, not as if they were the victims of a manipulative hard sell. While this example takes place in a social setting, these principles can be clearly applied in the business world as well.

The end goal of persuasion is to create agreement within the audience based on their own beliefs, not based on the beliefs of the speaker. By using the beliefs of the audience as leverage, persuasion becomes a win-win situation.

Peru

Peru is a liberal economy enjoying six consecutive years of growth as of 2008. The rate of growth for 2008 was 9.2 percent, which is one of the highest in the world. The country is the third-largest in South America, and almost all the world's climates are represented within its territory. It is the world's largest producer of asparagus, paprika, flour, fish oil, argent, and alpaca and vicuña cloth. The estimated gross domestic product (GDP) in 2007 was $109.069 billion.

Public debt as a percentage of GDP decreased from 28 percent in 2005 to 18.4 percent in 2007, and net international reserves were $35.603 billion in April 2008. These figures reflect a stable economy, and global financial institutions classify Peru as one of the best investment options in the region, due partly to the country's overall investment risk, which falls below the regional average. Private investment is more than $20 billion each year.

The rising disposable income of citizens and improved employment figures have boosted local demand. In turn, this demand has given rise to such dynamic sectors as manufacturing, services, and construction. The government and the private sector have recently focused on investing in construction; roads, offices, shopping centers, hotels, and new transportation terminals have been built. The spread of infrastructure has not reached many parts of the population, however.

Peruvian exports are estimated to be $27.588 billion per year. Growth stabilized at 16.3 percent in 2007 after three years of a growth rate in excess of 35 percent. Agricultural exports had an annual growth rate of 18.6 percent, with coffee, asparagus, paprika, artichokes, mangoes, grapes, and onions representing major export items. Fishing is regulated by a law that promotes aquaculture development and grants income tax reductions and other benefits. As a result, Peruvian fisheries export to 104 countries.

Mining activities put the country in first place in the region in terms of production of gold, zinc, lead, and tellurium. Important mining companies operate in Peru, including Barrick Gold Corp. (Canada), Newmont Gold (United States), Doe Run (United States), and Vale do Rio Doce (Brazil).

Foreign Investment

Peru's Proinversion is a special governmental agency that promotes foreign direct investment. No restrictions or controls exist on payments, transactions, transfers, or repatriation of profits. Foreign investment in Peru was $15.373 billion in June 2007. Spain represented 31.5 percent of this investment, followed by the United States (18.3 percent) and the United Kingdom (17.4 percent). Foreign investors have holdings in communications (31.6 percent), mining (18.8 percent), industry (15 percent), finance (12.5 percent), and energy (10.7 percent), making sectors such as mining, textiles, fibers, and infrastructure promising avenues for investment.

According to world competitiveness scoreboards for 2008, Peru is in 35th position. Moreover, 98.3 percent of Peruvian companies are small, family-owned enterprises, most of them (77 percent) in the services and commerce sectors. These companies account for 45 percent of GDP and 88 percent of employment. Nearly 3,500 of the country's small enterprises are involved in foreign trade; they are dynamic agents of the economy.

The special government agency that promotes Peru as a tourist destination is called Promperu. Peru is well known as a destination, thanks to Machu Picchu, the city of the Incas; the mysterious Nazca lines; and many other attractions. The diversity of the country's geography and gastronomy attract almost 1.8 million tourists per year, and tourism provides 5.9 percent of GDP.

Peru used to have a largely centralized economy, concentrated in Lima. Lately, economic growth has expanded to cities on the coast, along with Andean cities such as Cajamarca, Huaraz, and Huancayo (mining activities), as well as Cuco (tourism). Nevertheless, the country's rugged and varied geography presents many challenges and limits the possibility of growth for most cities in the southern Andean region. In such areas, 70 percent of the population live in poverty. As a result, two major problems need attention: (1) many Peruvians are employed in the black market by unregistered businesses with low productivity and salaries; and (2) Peru's education level ranks among the worst in international tests such as LLECE and PISA.

A notable issue is the emerging privatization process, which has encouraged the entry of foreign banks and the introduction of new technologies. Peru has a modern banking system, with 37 percent foreign capital, 61 percent private capital, and 2 percent state capital. There is less dollarization of loans and deposits, and residents and nonresidents may hold foreign exchange accounts. The structure of banking products is changing gradually from 84.5 percent of commercial credits and 14 percent of consumer and mortgage loans (1999) to 71.5 percent and 24.3 percent (2005), respectively. Moreover, deposits show a positive trend (the highest level ever recorded), whereas past-due loans diminished from 9 percent to 2.1 percent, the lowest ratio in the past 25 years.

The Peruvian securities market is small, centered on the small stock market and the pension sys-

A farmer tending to artichokes in Peru, where agricultural exports have recently grown as much as 18.6 percent a year.

tem. In 2006 the stock exchange was the developing world's best-performing equities market, increasing by 188 percent. In 2007 a new financial product, the Exchange Traded Fund (ETF), was created. This basket of shares includes the most representative securities in the Peruvian stock market.

Petrobras

Petrobras (Petroleo Brasileiro) is a state-controlled integrated energy company. Headquartered in Rio de Janeiro, Petrobras, along with its subsidiaries, engages in the exploration, production, refining, and transportation of oil from reservoir wells, shale oil, and other rocks. It owns and operates thermoelectric, petrochemical, and fertilizer plants, and is involved in the purchase, production, transportation, and distribution of liquefied natural gas and natural gas. Most recently, Petrobras formed a joint venture with Mitsui Group of Japan to produce biofuels.

Petrobras's creation and early history are intimately related to Brazilian economic nationalism and its import-substituting industrialization strategy. Public distrust of international oil companies and their geologists, who claimed that Brazil had very limited oil wealth, encouraged the nationalization of undiscovered oilfields under the aegis of the National Petroleum Council in 1939.

The combination of wartime trade disruptions in the 1940s with modest domestic exploratory efforts led to a severe shortage of petroleum, which, along with a surge in national security concerns, fueled a popular state-backed campaign for the development of the Brazilian oil industry. Under the banner "The Oil Is Ours" and with the twin objectives of supplying the nation hydrocarbons and saving on scarce foreign exchange, Petrobras was founded in 1953 under the presidency of Getulio Vargas. Despite regular and intense politicization at the top, Petrobras delivered on its mission and stood up to the formidable challenge of building an oil industry from scratch, without previous knowledge, lacking a skilled labor force, and having practically nonexistent reserves to start with.

This achievement was a two-stage process, as historian Laura Randall suggests. First, Petrobras concentrated on building refining capacity to substitute imported hydrocarbon products for those refined domestically; subsequently, it increased crude oil production. Brazil's foreign dependence on oil dropped from around 90 percent in the mid-1950s to less than 50 percent in the 1990s and keeps decreasing. Yet this is unlikely to be Petrobras's biggest accomplishment. World technological leadership in the exploration and production of oil in deep water (300–1,500 m) and ultradeep water (1,500 m and more) has proven profitable and is most promising.

Exploration and Production

Petrobras's offshore explorations in the Campos Basin first paid off in 1974 with the discovery of the Garoupa field in shallow waters (120 m). Production started in 1977. Since then, more than 40 oilfields have been found off the Brazilian coast, among which Roncador, Marlim, and more recently Tupi were so-called elephant fields—those containing proven reserves over 1 billion barrels. These deep- and ultradeep-water reservoirs now account for more than 80 percent of Brazil's oil production and proven reserves.

The challenges in economically exploiting oil at these depths are remarkable and have catapulted Petrobras to the technological frontier, via horizontal drilling, few and high-productivity wells, high-resolution stratigraphic analysis, and 3D visualization techniques. Petrobras's deep- and ultradeep-water discoveries are not only meeting Brazil's desire for self-sufficiency in oil, but also challenging the oldest myth in the industry, the peak oil theory—the idea that the rate of global oil production had reached a maximum.

As of 2007 Petrobras had 69,000 employees, ran and/or owned more than 8,000 service stations, operated 77 fixed and 32 floating production platforms, refined some 2 billion barrels per day (bpd) from 15 refineries, produced another 2 billion bpd from around 13,000 productive wells, boasted proven oil reserves of 11.7 billion barrels, and relied on a fleet of more than 150 tankers to transport its products.

Market Position

Petrobras is a player in world energy markets. Its sheer size and technological leadership have made it one of the "new seven sisters" (the industry's name for the dominant companies in the production/distribution of oil). On the financial side, Petrobras's net earnings were $102.9 billion, with net income of $12.9 billion and $27.3 billion worth of investments. Its market value exceeded $100 billion, making it the most profitable public company in South America—as well as the most valuable of all, private and public—and ranking it 50th among the world's largest firms.

The company has ventured outside Brazil and is particularly strong in Argentina, Bolivia, Colombia, Ecuador, Peru, Uruguay, and Venezuela. It also does business in countries including Angola, China, England, Iran, Mexico, Nigeria, Norway, Turkey, and the United States. Its shares are traded in the world's main stock exchanges, and its bonds are among the best rated in Brazil's capital markets.

Petronas

PETRONAS is an acronym for "Petroleum Nasional or National Petroleum" and the company is registered as Petroliam Nasional Berhad. It is located in the Petronas Twin Towers in Kuala Lumpur, Malaysia. Petronas is ranked 95th by *Fortune* for 2008. The CEO of the organization is Mohamed Hassan Marican and he leads 37,430 employees. The company Web site is www.petronas.com.my. In the fiscal year ending on March 31, 2008, Petronas had $66,218.2 million in revenue resulting in $18,118.4 million in profit.

Petronas was incorporated on August 17, 1974, under the Companies Act of 1965. The company made its first export of crude the next year. In 1981 Petronas set up the first petrol station in Taman Tun Dr Ismail, Kuala Lumpur. In 1983 its first refinery with 30,000 barrels per day capacity in Kertih, Terengganu, came online. In 1985 Petronas made its first liquefied petroleum gas (LPG) export. In 1993 Petronas first issued bonds and signed its first deep water contract with Mobil. In 1994 the marketing arm, Petronas Dagangan Bhd., became the first Petronas subsidiary listed on the Kuala Lumpur Stock Exchange (KLSE). That same year, the first of Petronas's five LNG tankers, *Puteri Intan*, was delivered. 1994 was truly a milestone year as it saw Petronas open its first overseas retail station in Cambodia and begin overseas oil production from Dai Hung field in Vietnam. In 1995 Petronas began to sponsor the Red Bull–Sauber-Petronas Formula One Racing Team. In 1996 it issued its first US$1.9 billion global bond.

The company is wholly owned by the Malaysian government and is vested with the entire ownership and control of the petroleum resources in Malaysia through the Petroleum Development Act of 1974. Petronas has operations in over 31 countries including China, Sudan, Algeria, Vietnam and Iran, and has four subsidiaries. In 1998 it launched the first oil production of the Sirri field in Iran and in 1999 it had its first oil production export from Sudan.

In 2000 the company signed agreements for two oil and gas exploration blocks in Pakistan, the East Kadanwari Block and Mehar Block, and commenced construction of the 1,070-km pipeline for the Chad-Cameroon Integrated Oil Development and Pipeline Project. In 2001 the company rolled out its high-performance prototype "GP1" motorcycle engine at the Sepang F1 Circuit. In 2002, Petronas raised US$2.675 billion equivalent from a global bond issue, the largest corporate bond issue to have ever been concluded by an Asian corporation. That same year, the company received the delivery of its first natural gas from West Natuna, Indonesia.

In 2003 Petronas opened its first service station in Sudan, officially marking its entry into the retail marketing business in the country following its acquisition of the entire retail assets of Mobil Oil Sudan Ltd. Additionally, it signed a Letter of Intent with Petroplus International NV (Petroplus) to acquire 30 percent equity in Dragon LNG, a special purpose outfit established by Petroplus to develop a proposed LNG terminal and related facilities in Milford Haven, Wales, United Kingdom. Furthermore, Petronas launched its range of premium grade automotive engine oils in Indonesia, officially entering the country's lubricants market. In 2005, Petronas commemorated 10 years of involvement in F1 racing.

In 1997 the company moved its headquarters to what were then the tallest buildings in the world: the 88-story Petronas Towers in Kuala Lumpur. Its business activities can be divided into three categories: International Operations, Downstream Activities, and Upstream Activities. Upstream activities consist of exploration, development and production of crude oil and natural gas. Downstream activities consist of refining, marketing, petrochemical business, and logistics and maritime business. Petronas has had indirect or direct business relationships with the following organizations at one time or another: BP Chemicals/BPCM Assets, Esso, Shell, and Mobil. As of January 2004, Malaysia had approximately 4.84 billion barrels of crude oil reserves and about 87.0 trillion standard cubic feet of gas reserves.

Currently, Petronas has 51 producing oil fields in Malaysia. These oil fields produce five different blends of crude: Tapis, Labuan, Miri, Bintulu, and Dulang. These blends are of high quality and generally command a premium price over benchmark Brent crudes on the world market. Petronas produces three types of automotive fuels, one type of aviation fuel, two types of gas fuels, and four types of industrial fuels. Furthermore, the company produces 11 types of gasoline engine oil, nine types of diesel engine oil, and a selection of other oils for a variety of uses.

In 2007 *Financial Times* dubbed Petronas one of the new "Seven Sisters," the oil and gas giants that now dwarf their Western rivals.

Peugeot

Peugeot is a major car manufacturer originating and headquartered in France. The company's industrial origins trace back to a steel foundry set up in a converted flour mill in the early 19th century. Since then, the company has gone through various transformations, manufacturing and selling a diversified range of groundbreaking products (cold rolling, saws, watch and clock mechanisms, coffee mills, sewing machines, bicycles, irons, washing machines, food processors, radio sets, and so on). The era of car manufacturing, which is the firm's core business activity, could be said to have begun in the late 19th century after a landmark agreement with Gottlieb Daimler and the company Panhard et Levassor.

Armand Peugeot, a dominant figure in the company's history, separated the automobile business unit from the firm's other manufacturing divisions (tools, two-wheeled vehicles, tricycles, and quadricycles with a saddle), and in 1896, he founded the company called Société des Automobiles Peugeot. After some strife between cousins who inherited the original company at the beginning of the 20th century, the company reached a point at which it accounted for almost half of French car production (just before World War I). The postwar era, however, raised the threat of financial difficulties for Peugeot, which led to the separation and independence of the automobile and cycling units again.

Peugeot has been expanding internationally to take advantage of new markets. Above, a Peugeot on display in Poland.

In the following years, Peugeot's strategy included various decisions such as concentrating mass production in one site, launching popular brands (such as the 201), and minimizing product offering (such as the single-model policy with the 203). Later, Peugeot created a holding company that could control all the group companies, and more production sites were built. A major feature of this era was the commencement of collaboration with other major car manufacturers, such as Renault (late 1960s), Volvo (early 1970s), Fiat (early 1980s for the production of utility vehicles and people carriers), Ford (late 1990s for the development of diesel engines), and Toyota and BMW (2000s for small engine models and petrol engines).

International Expansion

In addition to these decisions, some of the firm's most notable strategic decisions lay in its policy for mergers and acquisitions and its international expansion. Taking control of Citroën in 1976 and taking over Chrysler's European subsidiaries two years afterward provided growth for the firm, but this growth often was hard to handle. The company expanded to major developing countries such as China in 1985 and Brazil in 2001, and countries such as Russia are now major target markets. The firm proactively seeks to expand operations in developing markets that feature attractive segments for medium-size cars and can sustain international growth.

Currently, Peugeot sells some of the most popular brands in the global automobile market. Part of this success can be attributed to the cars' design and engineering. The firm proactively enhances its design capacity for the Peugeot and Citroën brands through a dedicated design center named Automotive Design Network (AND). Located on the outskirts of Paris, the center incorporates the firm's styling, vehicle architecture, and innovation teams, consisting of skilled individuals from more than 20 countries.

What was originally a family business is now a multinational giant with 24 production sites delivering 34 families of products and 160 models. The newly formed PSA Peugeot Citroën strives to diversify in more spheres of related business activity and develop existing strengths even further. Feasibility studies are also under way with firms such as Mitsubishi Motors to examine the possibility of extending operations in such fields as manufacturing electric power trains. In line with its Strategy and Ambition Plan for 2010–2015, the firm seeks to exploit synergies with leading car manufacturers and maintain its leadership in the manufacturing of environmentally friendly cars.

Pfizer

Pfizer, Inc., is a global pharmaceutical company based in New York City. It was ranked the biggest pharmaceutical company in terms of sales in 2007 and has been a component of the Dow Jones Industrial Average since 2004. As of February 2008, it had an approximate market capitalization of $155 billion. With $7.5 billion invested in research and development (R&D) every year, it is one of the top R&D companies in the world. Despite an enviable market position, Pfizer faces challenges including a dwindling pipeline, an unprecedented number of patent expirations, increasing generic competition, and pricing pressure.

Pfizer was founded in 1849 by Charles Pfizer and Charles Erhart in New York State. At the time, it was named Charles Pfizer & Co. The company's first pharmaceutical product was an edible form of santonin, which was used to treat intestinal worms in the mid-19th century. By combining blended santonin with almond toffee, they created a product that consumers enjoyed. It was a commercial success that helped launch the company.

Through most of the 19th century, the company focused on producing chemicals, manufacturing such products as tartaric acid (which can be used as a laxative), cream of tartar (which can be used as a cleansing agent), and citric acid (useful in caffeinated soft drinks, such as colas). It also produced many generic products, such as iodine, morphine, and chloroform. In 1950 Pfizer started to sell the first product it developed internally, a broad-spectrum antibiotic called Terramycin. With the launch of this product, Pfizer demonstrated its growing focus on pharmaceuticals and developed a strong presence in animal health products, which continues today.

Acquisitions and Divestitures

Before 2000, Pfizer completed only two major acquisitions. The first acquisition of note was of a company called J. B. Roerig in 1953, which served to prop up Pfizer's fledgling agricultural and nutritional division. Pfizer also acquired full ownership of Taito in 1983; that company contributed to Pfizer's antibiotic manufacturing and distribution activities.

After 2000, Pfizer embarked on a series of mergers and acquisitions. It merged in 2000 with Warner-Lambert and acquired Pharmacia in 2003. These mergers gave birth to the world's largest pharmaceutical company and gave Pfizer access to many blockbuster drugs. In the case of Warner-Lambert, Pfizer acquired the rights to Lipitor; the Pharmacia merger gave Pfizer access to Celebrex. Pfizer has since acquired many smaller companies, including Meridica (2004), Esperion Therapeutics (2004), Vicuron (2005), PowerMed (2006), Embrex (2007), and Encysive Pharmaceutical (2008). It is estimated that Pfizer acquires more than a half-dozen companies every year to replenish its slowing pipeline.

Pfizer has also divested major divisions in the past few years. It sold its consumer healthcare department to Johnson & Johnson in 2006 and Dorom, its Italian generic pharmaceutical marketing company, to Teva Pharmaceutical in 2004. It has also sold manufacturing plants around the globe in an effort to reduce costs.

Products

Pfizer and the companies it has acquired have developed many important drugs and innovations. In the 1940s, for example, using a proprietary fermentation process, Pfizer successfully mass-produced penicillin. Other notable innovations include Zoloft (an antidepressant), Lipitor (a cholesterol reducer), and Celebrex (a Cox-2 inhibitor for pain relief). The top pharmaceutical products produced by Pfizer include Lipitor, Zoloft, Celebrex, Diflucan (an antifungal drug), and Viagra (a drug used to treat male erectile dysfunction and arguably Pfizer's most popular product). Pfizer also provides drug-delivery products. Exubera, for example, is the first diabetes treatment for adults that can be inhaled rather than injected.

Like all big pharmaceutical companies, Pfizer is subject to scrutiny by the press and stakeholders and currently faces several controversies. It is being sued by the government of Nigeria, for example, for allegedly running a clinical test of an experimental meningitis drug without proper authorization. It was also accused in the 1990s of overpricing its AIDS treatment drug, Diflucan, in Thailand, which led to the Thai government's removing its local patent.

Philippines

The Philippines, located in the western Pacific Ocean east of mainland southeast Asia, is made up of 7,100 islands and islets, 3,144 of which are named and 1,000 of which are inhabited. Its land area is about equal to Italy and a little larger than the American state of Arizona. The 11 major islands are Luzon (which makes up more than a third of the total land area), Mindoro, Palawan, Masbate, Panay, Negros, Cebu, Bohol, Leyte, Samar, and Mindanao (which makes up another third of the land area and was given to the Muslim insurgency in the 1996 peace deal).

The tropical climate is dominated by the monsoon cycle. From June to October, the southwest monsoon carries torrential rains through most of the country; from November to February, the northeast monsoon brings warm, dry weather; and from March to May, the easterly North Pacific trade winds bring extreme heat and drought. Usually, 20 to 30 typhoons cause extensive damage to parts of the country every year.

The Philippines has a population of almost 93 million (July 2008 estimate). Its per capita gross domestic product (GDP) is $3,300. In 2007 industry made up an estimated 31.3 percent of GDP; agriculture made up 14.1 percent, and services made up 54.6 percent. Elementary education in the Philippines begins at age 7 and lasts for six years; it is compulsory.

The constitution, which was approved by a national referendum on February 2, 1987, provides for a bicameral congress. The president is head of state, chief executive of the republic, and commander-in-chief of the armed forces. The president is elected by the people for a six-year term and is not eligible for reelection. The Philippines is a member of the United Nations (UN), World Trade Organization (WTO), Asian Development Bank, Asia-Pacific Economic Cooperation (APEC), Association of Southeast Asian Nations (ASEAN; member as of 1954), and the Colombo Plan.

The first pottery was made in the Philippines from at least 3000 B.C.E., and metals were worked on by the first millennium B.C.E. Most islanders lived in barangays, which are communities of 30–100 households based largely on kinship. By the end of the 16th century, the Philippines had become a major trading center with China, the East Indies, and India. The Dutch took over the islands from around 1600.

Despite strong economic growth, the Filipino population continues to suffer from an unequal distribution of income. This situation is alleviated somewhat by remittances sent back by millions of expatriates working in other countries.

Following the Spanish-American War in 1898, the Philippines were ceded to the United States. Shortly thereafter, it received partial autonomy. In 1941 the islands were invaded by Japanese troops, who occupied them fully by 1942. Manuel Roxas became president on July 4, 1946, which is when independence was achieved. The United States had historically close ties with the Philippines after its acquisition of the islands in the late 19th century. After World War II, the United States provided aid to the islands in return for 99-year leases on several naval and air bases.

In 1996 a peace agreement between the Moro National Liberation Front (a Muslim group) and the Filipino government ended more than 20 years of insurgency that had left over 120,000 people dead. This peace was short-lived; violence broke out again in 2001. It peaked in 2005, when fighting on the island of Jolo left 90 dead and led 12,000 people to flee. In 2006 and 2007, however, the Filipino government had success in capturing or killing key wanted terrorists.

In the past two decades, market-oriented reforms have been implemented in the Philippines; as a result, foreign investment and trade barriers have been overcome, and many industries have been deregulated. Even though privatization is incomplete, most state industrial assets were privatized between 1992 and 1995, and the monopolies in the oil, civil aviation, telecommunications, power, shipping, and water industries were dismantled.

A significant challenge to the Filipino economy is high public debt. The Filipino GDP grew at its fastest pace in more than three decades in 2007—7 percent. Remittances from Filipinos abroad and a strong services portfolio have contributed to healthy economic growth. Even though its macroeconomic outlook has improved, the Philippines needs to become more competitive to catch up with the rest of the region.

Plagiarism

Plagiarism is defined as using the idea or work of someone else, claiming it as your own, and deriving an academic, material, or other benefit from having used it. In some cases, plagiarism is unintentional and involves a lack of knowledge or skill in drawing information from a source in a manner that is appropriate or legal, or that correctly attributes the creative effort of the author(s). This can take place with students or untrained employees who at times struggle with fair use of material in educational or commercial settings. In other cases, however, plagiarism is intentional and involves laziness, fear of improper interpretation, unethical behavior, a total lack of respect for the work of the author, or a complete disregard for the legal rights and protections afforded the author by U.S. and international copyright and other laws. These kinds of actions can take place when competitive pressures are high, such as in academic or business settings.

Students face regular assignments in their educational careers, and sometimes they succumb to cheating, "lifting" parts of a paper written by someone else, or even buying an entire, ready-made paper from a "paper mill" and presenting it as their own. Commercial interests often struggle to be first to reach the market with a product, and at times they can be lured by the temptation of "cutting corners" in the process and may plagiarize specific words, phrases, or entire texts to achieve their desired outcomes.

Much information lies in the public domain and is available to anyone; an example is some material printed or published many years ago, such as certain great works of literature. Some information is not in the public domain but often is made available to the public if an individual or company simply includes a specific statement or formally requests permission to use copyrighted material—documents produced by certain government entities are an example. Other information, though, is not in the public domain and is not available to anyone except authorized users. It may be extremely valuable intellectual property at the center of an organization's structure, profit, or competitive edge. An example is the original formula or logo text for a specific cola soft drink. In any case, it is important to provide acknowledgment for the source.

Techniques that can prevent a problem with plagiarism include direct quotation with citation, changed quotation with notation (e.g., square brackets) and attribution, and correct paraphrasing. These techniques require precise application; consequently, they can be misapplied or misused quite easily. Resources for avoiding plagiarism are available from the U.S. government (e.g., the U.S. Copyright Office), libraries (e.g., the American Library Association), and most educational institutions.

Today, advances in information technology have made plagiarism detection much simpler and faster than before. Basic searches of databases (e.g., ProQuest), specific computer programs (e.g., Turnitin), internet search engines (e.g., Google), and other means have made it easy to find text that has been plagiarized.

Consequences of plagiarizing vary. They can range from a student never actually learning a subject, failing a course, being expelled, or having a degree withheld or withdrawn for academic misconduct to an employee being reprimanded or dismissed from a job for lying or dishonesty to a businessperson or firm facing a lawsuit for alleged copyright or trademark violations. In the world of high-stakes business, such violations can turn into legal battles that quickly soar into the millions of dollars. The media often report some of the more extreme or sensational instances of plagiarism. This is especially true when the work in question has been published in a major newspaper, magazine, or refereed journal, or the author has been given a major award, such as a Pulitzer Prize.

Plagiarism diminishes the integrity and image of all involved in it—be it an individual, an institution, a business, or a society. Plagiarism can and should be avoided to encourage original thought, increase learning, enhance business effectiveness, and promote public integrity.

Poland

Poland traditionally has been a major center of agriculture in eastern Europe, and in the late Middle Ages, it was one of the largest political entities in the region. In the early modern period, it started to develop some industrial potential with the location of coal and iron ore in Silesia, at that time a part of Austria. However, in 1740, Frederick II "The Great" of Prussia invaded and annexed Silesia, holding it through the War of the Austrian Succession that resulted. By that time, Poland was waning as a power, and with the three partitions (in 1772, 1792, and 1793), Poland ceased to exist as an independent entity, being divided between Russia, Prussia, and Austria. During the 19th century, Poland prospered and Warsaw became a major city in the Russian Empire, although it was devastated in World War I.

In November 1918 Poland emerged again as an independent country, bringing together lands previously held by Prussia, Russia, and Austria. It started to build up its economic base, with emphasis on heavy industry, and also a shipbuilding industry—the latter partly to secure the employment of people in the northern part of the "Polish Corridor." This helped sustain Poland in the 1920s and 1930s, with the country exporting much agricultural produce and also building up a significant shipping industry and merchant navy. In addition, Poland, for strategic reasons, had also established its own munitions industry. The German invasion of Poland in September 1939 and the subsequent Soviet attack wrecked the country, and by the end of World War II, most of the country was in ruins. The boundaries of the country also changed dramatically.

From 1945, the economy of Poland was under the control of Communists who introduced a system of central planning, and also placed a great reliance on heavy industry, exploiting the coal fields and iron, with the shipyards at Gdansk helping build up Poland's industrial base. Although the economic situation was relatively bleak, Poland was able to rebuild after the devastation in war, with full employment, although foreign observers claimed there was large-scale underemployment. It remained a part of the Council for Mutual Economic Assistance (COMECON) until 1991 when there were major changes in the Polish economy.

It had been labor demonstrations at the Gdansk shipyards that resulted in problems in 1970, and Edward Girek, who came to power during this period, started embarking on a policy of borrowing from foreign banks. This was partially successful, but there were still many underlying problems. In 1980 a new wave of protests at the Gdansk shipyards led to the emergence of Lech Walesa and the Solidarity Trade Union movement. Initially, the Polish government reacted harshly against Solidarity, but it was gradually forced to make concessions.

After the end of Communism in Poland in 1989, the new government introduced free market reforms and this resulted in large-scale unemployment, and in a surprise twist, the closing of many of the shipyards where the workers had forced concessions from the Communists in the 1980s. The new Polish government has seen its future as lying in closer relations with the West, and Poland joined the North Atlantic Treaty Organization (NATO) in 1999 and the European Union on May 1, 2004.

After a process of economic liberalization in the country during the 1990s and early 2000s, Poland has experienced one of the fastest rates of growth of any of the economies in central Europe, with an extensive private sector. There have been problems in the agricultural sector with the maintenance of many inefficient small farms, which have also been hurt by a lack of investment. However, for industry, with extensive industrial retooling, and beneficial export agreements, including the Generalized System of Preferences program helping Polish exports to the United States, Poland has significantly increased its export sector.

Poland has also been important for investors as it is part of the major road network, has a significant local economy of its own, and has some 250 million consumers within 1,000 km. of the country. Machinery and transport equipment make up 30 percent of the country's exports, with the remainder largely from intermediate manufactured goods, food (especially jams), and live animals. Some 30 percent of Poland's exports go to Germany, with German goods making up 24 percent of imports, which are largely made up of manufactured toys, and also chemicals.

Polycentric

The term *polycentric* defines a decentralized organizational orientation having many centers of authority or control. This term usually refers to the assumptions and mind-sets of top managers and applies to firms with affiliates (or subsidiaries) in several different countries. Polycentric implies that the firm's conciseness has shifted from a single to a multiple country entity. In international management literature, the concept is attributed to Howard Perlmutter, whose work identifies three distinctive managerial orientations of internationalizing companies: the ethnocentric, polycentric, and geocentric. The three phases are generally considered to be progressive, whereby a firm begins from its original, ethnocentric home country orientation by which the focus and major commitment is to the domestic market and the typical structuring of any international operations is via an international division to the polycentric orientation and possibly to a geocentric world orientation whereby the firm seeks and deploys resources resulting in an integrated system around the world that rises above and beyond any national orientation to be truly global.

The polycentric is very much a host country orientation, dominated by the notion that the firm is substantially based in several different countries. According to Perlmutter, the key difference (or, perhaps, point of transition) between ethnocentric and polycentric phases is that in the latter the firm begins to identify with the foreign markets in which it now operates. It assumes that host country cultures are distinctive, making the ethnocentric, centralized, one-size-fits-all approach unfeasible. The polycentric mind-set assumes that local people know what is best for their markets and endeavors to delegate sufficient autonomy so that subsidiaries are managed as independent units and country management teams have the freedom to run their affairs largely as they see fit.

For example, local managers are more likely to understand the tastes of their customers, the realities of the local legal environment, and the availability of raw materials—so they should be responsible for customizing the marketing mix (product design, price, promotion, and distribution), negotiating their own contracts, and managing supplier relations at the local level. Also, local managers rather than home country expatriates are more likely to be given key management positions. This view alleviates the chance of cultural myopia and is often less expensive to implement than ethnocentricity, because it needs a lesser reliance on expatriate managers and less investment in centralized systems. There are, of course, several drawbacks to the polycentric approach. It can limit opportunities for local managers to gain overseas experience and thus limit career mobility for both local and foreign nationals. This can also result in headquarters managers (and staff in general) being isolated from foreign subsidiaries and reduces opportunities for sharing of ideas and resources across the multinational enterprises.

As an example of a polycentric firm, Charles Hill describes the evolution of Unilever's foreign subsidiaries into quasi-autonomous operations, or "little kingdoms," with strong national identities that resist interference from corporate headquarters. In their study of globalizing law firms, David Brock, Tal Yaffe, and Mark Dembovsky describe how European firms need to develop polycentric mind-sets in order to take advantage of potential benefits of scale and scope—like reputation, host country support, extension of product life cycles, and overseas know-how. Successful transition to polycentricism is crucial for the effective implementation of international diversification strategies in these contexts.

The choices of adopting these different world views are shaped by a number of factors such as the circumstances during which the company was formed, stage of development of international markets, the leadership style, administrative processes, and the organizational culture, myths and traditions. Perlmutter stated that these cultural orientations determine the way strategic decisions are made and how the relationship between headquarters and its subsidiaries is shaped. To continue successfully implementing the firm's internationalization strategy with a polycentric worldview, the overseas subsidiaries need to repay the corporation (and its shareholders) for the trust and autonomy. The multinational corporation looks for a return on investment in its foreign subsidiaries, as well as generally good use of the firm's brands and other intangible assets (like reputation). Pressures for a more geocentric approach will mount if the firm sees the benefit in reducing subsidiary autonomy in favor of a more global strategy involving more integration of subsidiary activities and systems.

Polycentric Human Resource Policy

The term *polycentric* is derived from the Hellenic (Greek) word *πολυκεντρικός*, a composite word that consists of the term *πολύ*, which means multi, and the term *κέντρο*, which means center. Hence, the term suggests an attitude that adopts multiple points of view. Multinational corporations that adopt a polycentric approach tend to respect and take into account the host culture in their operations abroad, including their human resource policies.

Under a polycentric human resource approach, policies and systems that are used in the home country are reconsidered to take into account the work culture and traditions of the host countries. Alternatively, popular human resource systems in use in the host countries are kept with some adaptation to the principles and philosophy of the headquarters. The idea is that particular systems and policies have been developed within particular cultures because they fit these cultures best. Hence, to achieve maximization in the added value of human resources in the host operations, local systems have to be respected and preserved. Therefore, the polycentric approach to human resource management pays maximal attention to local factors. The approach is in line with evidence suggesting that cultural factors limit the transferability of human resource systems across national boundaries.

A trademark characteristic of the polycentric human resource approach is the employment of host country nationals in key positions in operations abroad. Reasons for adopting a polycentric approach in the staffing of operations include the following:

1. Host country expectations and regulations. In many cases host country governments impose strict regulations on multinational corporations, including regulations regarding the percentage of the workforce that should be host country nationals.
2. Insufficient numbers of qualified home country nationals (expatriates) to fill professional and managerial positions in host countries. As internationalization and globalization become more potent, multinational corporations further expand their operations outside their home countries, which means that they need increasing numbers of qualified staff. However, the home country is unable to meet this demand, and, therefore, they have to consider local nationals for their staffing needs.
3. The high cost of expatriates. An expatriate may cost up to five times more than the respective incumbent in the home country, which renders the use of expatriates very expensive. Because of increasing demands of multinational corporations for qualified managers and professionals, exclusive use of expatriates for key positions in operations abroad becomes unduly expensive or not feasible. The alternative route is the employment of host country nationals, who normally cost a fraction of the cost of expatriates.
4. Host country nationals' knowledge of local culture and language as well as connections with key institutions and individuals in the host country. Knowledge of local language and culture, including how to deal with institutions, government agencies, and officials, are critical issues for the success of operations abroad. In most cases locals are able to assist in this domain.
5. Public relations exercises and the need, in certain cases, for multinational corporations to promote the image of offering opportunities to local nationals and promoting local talent.
6. The increasing levels of education in the workforces of most developing countries, where many multinational corporations choose to establish operations. This increases the pool of

qualified managers and professionals from the host country.

Although the polycentric approach has certain advantages, including greater fit of human resource policies with the local culture, increased cost efficiency, and greater potential access to local institutions and officials, it also has disadvantages. A disadvantage ensues when multinationals pay excessive attention to local cultural factors and ignore common elements between home and host cultures. This may lead to unnecessary duplication of effort (e.g., the development of different human resource systems for each host operation in cases where single centrally developed systems may be sufficient). This is illustrated by the case of American Express, which at some point was experiencing problems with the performance appraisal forms in its operations abroad. American Express initially attributed the problems to cultural differences between the home (United States) and the host countries and was set to redesign the appraisal forms it was using in its operations abroad. However, further consideration indicated that the U.S. operation also experienced similar problems with the appraisal forms. Hence, the cause of the problem did not lie in cultural factors but in the initial design of the forms.

Portugal

Civilization can be traced in Portugal back to neolithic times, through the settlements of the Phoenicians, Carthaginians, and Romans. Later, the Christian "reconquista" halted the Muslim advance and colonization of the country and gave rise to the maritime empire that provided for economic growth in the 15th and 16th centuries. This, in turn, was followed by a period of Spanish domination and occupation during the Napoleonic wars. By this stage, Portugal had lost much of its power and influence.

It was not until the end of the 19th century that poor living standards and inept government precipitated a republican backlash. The monarchy was finally overthrown on October 5, 1910, replaced by a republic. However, the political scene was far from stable. From 1910 to 1946, military intervention became the normal means of governmental change in Portugal. A Catholic monarchist, General António Óscar Carmona, emerged as president and remained in office until 1951. During this period, Portugal had many of the trappings of a fascist state, including secret police and tacit support for Franco during the Spanish Civil War.

It was also during this period that Antonio de Oliveira Salazar first served as prime minister in 1932. Salazar is often credited as being the guiding hand of Portuguese development and its progress to a modern economy. Indeed, from 1950 until Salazar's death, it is estimated that gross domestic product (GDP) per capita in Portugal rose at an average rate of 5.66 percent per year, well ahead of European counterparts. Salazar remained in power until 1968, when he suffered a stroke. He died in 1970.

The continuing economic and political problems of the right-wing government caused tensions to grow and resulted in an almost bloodless left-wing coup, led by disenchanted army officers on April 25, 1974. However, until November 1975, the situation remained precarious, with various factions vying for power. The summer of 1975 saw elections and victory for the socialist party under the leadership of Mario Soares. This signalled the beginning of a period that has seen gradual strengthening of democratic processes and further integration of Portugal into the European economy. In 1986 Portugal joined the European Community (EC), giving it access to funding and the potential for much-needed economic growth.

For administrative purposes, Portugal is divided into 18 districts and 2 autonomous regions (the Azores and Madeira), and in 2008 the population of Portugal is estimated to be approximately 10.5 million. The president is the head of state, elected by popular vote, with a five-year term. The leader of the majority party or the majority coalition is appointed prime minister and head of government by the president and leads the unicameral Assembly of the Republic. The assembly comprises 230 seats, with members elected to serve a four-year term. In the elections of February 20, 2005, the Portuguese Socialist Party was the biggest winner, with 121 seats.

The Portuguese economy has developed gradually over the last 20 years, and like many Western economies, it has diversified and become increasingly service based. The basis of this change has been policies, similar to the Thatcherite policies dominant in the United Kingdom in the 1980s, which have seen privatization of public sector organizations and liberalization of key markets.

At the turn of the millennium, the economy appeared to falter, with a widening gap in GDP per capita and a corresponding fall in living standards. The budget deficit increased from 4 percent of GDP in 2004 to 6 percent in 2005. In 2005 growth was also a major problem, running at only 0.5 percent of GDP. By 2007 GDP per capita was around two-thirds of the European Union (EU) average. One of the reasons for this could be increased competition for Portuguese business following the accession of lower-cost east European states into the EU. It is also interesting to note that in 1998 Portugal, along with 11 EU partners, joined the European Monetary Union (EMU), and the euro began circulating in January 2002.

A number of problem areas have been identified. These include poor standards of attainment at upper-secondary and tertiary education levels; regulatory restraints creating barriers to competition; an inefficient and protected public sector; a complicated tax system; and employment protection legislation that provides too much protection and causes inflexibility in labor markets. The new government of José Sócrates agreed in 2005 with the European Commission to reduce the budget deficit to below the threshold of 3 percent of GDP stipulated by the criteria for EMU by 2009. It recognized that solving these problems was central, and the government endeavored to tackle each one, although the latter one appears to be more problematic.

By 2007 statistics showed that the economy was growing at a higher and sustainable pace of 1.9 percent, driven wholly by the private sector. Export growth in traditional goods, business services, and technology was improving and also moving beyond traditional markets, and unemployment started to decrease in the second quarter of 2007. The budget deficit was reduced to under 3 percent of GDP in 2007, and public spending as a percentage of the GDP had also decreased. While there is more work to do, the government has placed Portugal in a more secure position to withstand the swings in the global economy.

Positioning

A marketing term, positioning is the act of memorably and positively anchoring a product, service, idea, individual, or experience in the minds of customers (including prospective customers). A product that is well positioned is widely perceived by the target audience as possessing distinctive, unique, and appealing features. As a result, it is not easily confused with other products, even those that occupy a similar category. Effective positioning, therefore, is critical to a product's success, because this marketing tool helps a product stand out from competitors' offerings.

While the concept of product positioning has a long history, rooted in the packaged goods industry, the perceived importance of positioning, along with a broadened understanding of the term, gained notable ground in the late 1960s and early 1970s largely because of the work of advertising executives Al Ries and Jack Trout. Ries and Trout claimed that in the modern age of heightened marketing noise and prolific advertising messages assaulting people's senses, it was more crucial than ever for a firm to pay attention to developing a solid positioning strategy for its product, one that would cut through the clutter. They also contended that anything could be positioned—not just products, for instance, but also individuals and ideas.

In 1972, in the influential trade magazine *Advertising Age*, Ries and Trout proclaimed that the "Positioning Era" had arrived, and they coauthored a series of articles exploring that topic. These articles eventually became the basis of their bestselling book, *Positioning: The Battle for Your Mind*. A critical, and controversial, tenet of their book was that positioning was not so much what a marketer does with a product, but what a marketer does to the mind of the prospect. In other words, the process of effective positioning requires marketers to get inside people's heads to understand which messages, or combination of messages, are most likely to resonate and break through the barrage of competing messages. While Ries and Trout were firm advocates of positioning and encouraged its practice, positioning, seen in this light, could be negatively perceived as a form of mind manipulation. Adroit marketers who understood how to tap into consumer psychology purportedly might be able to entice people to buy an item not necessarily because it was truly the best product but because it was packaged, promoted, and positioned in such a way as to trigger a purchase decision that was more emotional than rational. Effective positioning and ethical positioning are not, therefore, necessarily always synonymous.

In their quest to garner consumers' attention to their products, marketers often use a variety of positioning tactics and tools, such as perceptual positioning maps. The purpose of positioning maps is to illustrate how consumers perceive a certain product with regard to specific buying criteria (like price and performance) in relation to how they perceive competitors' products on those same criteria. As Philip Kotler and Gary Armstrong have explained, marketers often use positioning maps to help them design a strong positioning strategy that emphasizes the points of distinction that consumers will find most important.

Another positioning tactic is crafting a message that dovetails with people's preexisting ideas and preferences. Ries and Trout contended that this is often easier and more effective than trying to convince people to change their minds. As they also emphasized, thoughtfully naming a product is also crucial, as is disseminating an overly simplified message. With regard to the latter tactic, the theory is that short and simple messages are necessary in order to capture the attention of the masses who are being bombarded with thousands of other claims for their attention.

There may be some truth underlying this theory that simple is better. In a recent study conducted by digital video recorder maker TiVo, the television advertisements that viewers were least inclined to skip were not particularly creative or complex; they were low-budget advertisements that contained basic messages that were well tailored to their audiences. Nevertheless, marketers who propound such simple positioning messages sometimes have been accused of taking a pessimistic view of the average person's intelligence as well as the average person's willingness to expend the time and energy necessary to work through more complicated and nuanced messages.

Although much of the literature on positioning in the 1970s and 1980s focused on teaching marketers how to get the masses to pay attention to their messages, it would be a mistake to view positioning as an action always directed toward a mass audience. In fact, the rise of positioning also led a renewed focus on target markets and segmentation. As many marketers have discovered, in a crowded, noisy marketplace, it often is easier to craft a positioning statement that resonates if marketers narrow the size of their intended audience and then fine-tune their message to that specific group.

Positioning also reinforces the importance of not just target marketing, but also branding, as both positioning and branding emphasize the need for product differentiation. In addition, marketers' emphasis on positioning fosters attention on the importance of an organization developing a sustainable long-term strategy and a distinctive, inspiring mission.

With consumers today being bombarded with increasingly large numbers of marketing messages and a stunning array of products from which to choose, effective positioning remains a challenge. The louder the marketing noise in society, the more difficult it is for organizations to break through the clutter, and hence the more important it is for them to hone a well-defined, clear position for their products that will transcend that noise. Ironically, though, the difficulty of creating a memorable spot generally increases in such a competitive and loud environment.

Of course, an organization has an advantage on the positioning front if it is the first to introduce a product or service. If the whole point of positioning is to create a memorable anchor in consumers' minds, it helps to get there first. Yet, even an innovative firm with a new product may fail to position itself effectively, committing such errors as focusing its advertising on product features that consumers do not perceive as important or that consumers simply do not understand. For various reasons, many firms find it necessary to engage in repositioning. The original message may have been flawed, not resonating with consumers at the time it was introduced. Or, perhaps the entrance of new competitors into the field may necessitate a firm redefining its message and articulating more clearly its points of distinction.

Positioning therefore is an ongoing process, not just something that is done at the inception stage of marketing a product, service, or idea. Organizations and marketers today widely hail the importance of not just achieving but also retaining an effective position in a crowded, noisy, and constantly changing marketplace.

Power Distance

Geert Hofstede identifies five cultural dimensions that assign mathematical scores designating a particular country's beliefs about each of the dimensions. The five cultural dimensions are Power Distance (PDI), Individualism (IDV), Masculinity (MAS), Uncertainty Avoidance Index (UAI), and Long-Term Orientation (LTO). Hofstede defines the PDI by stating, "the extent to which the less powerful members of organizations and institutions (like the family) accept and expect that power is distributed unequally." Today, Hofstede's studies and PDI have had several implications for the U.S. business world and have been the basis for countless additional academic studies on varying cultural indicators.

Power distance is shown as a representation of inequality; however, it needs to be defined from below, not from above. Power distance "focuses on the nature of human relationship in terms of hierarchy." It is said that there are specific traits that can be linked to high and low power distance. For high power distance, these traits are that "power is a fact of life, everyone has a specific place, those in power emphasize position, respect for authority, and centralized authority." On the other hand, the traits for low power distance are "class structures, no set hierarchy, those in power minimize position, respect for individuality, and decentralized authority." As you can see, the characteristics for high and low power distance seem to be complete opposites.

When stating that power distance should be defined from below, it means that "a society's level of inequality is endorsed by the followers as much as the leaders." The concepts of power and inequality are common to any society. Any person who has some international experience should be conscious that not all societies are equal; some tend to be even more unequal than others. In Hofstede's original study with IBM, the scores for the first four dimensions were obtained for 50 countries and three regions. Scores on the fifth dimension were derived from 23 countries from student data. The "power distance scores are high for Latin, Asian and African countries and smaller for Germanic countries." When focusing on the United States, they score "a 40 on the cultural scale." This is because they have a more imbalanced allocation of wealth compared to other societies. "As the years go by it seems that the distance between the 'have' and 'have-nots' grows larger and larger."

Some research studies have suggested that you can predict power distance by factors such as climate, population size, and wealth. The degree of power distance a country has leads to various consequences for its population. When referring to cultures with high power distance, you may see that "their language is filled with power of hierarchy indicators." Specific behaviors may also be expected. For instance, people must comply with authority. It does not matter if it is to a boss, parent, or official; it is still expected. In cultures that have low power distance, there is an apparent "emphasis on challenging decisions, expecting autonomy and independence."

The PDI, like the other cultural dimensions, is calculated through a questionnaire using business employees from each individual country. Scores range from 1 to 100 where >70 is generally considered high and <40 is considered low. As of right now, over 70 countries have been included in Hofstede's study, which took place between 1967 and 1973. The United States received a score of 40 on its PDI, which is low when compared to the world average of 55. Countries possessing high PDIs include China (80), Panama (95), Guatemala (95), and India (77). Therefore, U.S. employees view themselves more on a level playing field with their bosses, placing less emphasis on the variance in power associated with different levels within a hierarchy.

Managers must be aware of power distance and the corresponding scores of the employees they work with both abroad and domestically. For example, a U.S. manager working in a factory in Guatemala should exhibit a more authoritarian style of leadership as the domestic employees expect their managers to instruct and guide them in their work processes. This again can be contributed to the Guatemalan employees ranking high on power distance. Since the introduction of Hofstede's study in the 1970s, the results have come a long way from being used only in a business and managerial context.

Other Applications

The PDI has other applications and has been the basis for several other studies. These studies have consisted of topics, such as ethical management, student/faculty communication, women in political positions, teamwork, suicide rates, health risks, and safety in relation to national cultures. One thing to keep in mind is that these studies have not only impacted the United States, but a large number of countries worldwide have also bought into Hofstede's findings.

A study came out in 2007 that took samples from 10 regions in the United States, Canada, and Mexico that examined the relation of culture and the propensity for internal reporting and whistle-blowing. Results showed that countries with a high PDI and authoritarian environments discouraged the use of an internal reporting system. In addition, it was found that countries possessing a high PDI demonstrated a "positive propensity to whistle-blow." Therefore, in this case, managers who are more familiar with PDI and the cultural links to ethics management will be better able to generate more effective ethics strategies.

Additional studies using PDI include a study that looked at 53 different regions investigating if Hofstede's cultural dimensions can indicate whether enrollment rates can affect the career and income of women in the regions studied. Studies found that PDI "has an influence on the positions held by women in the government." As a result, a higher PDI indicates that women will hold a lower percentage of government/political positions. Another study looked at the impact of power distance on culturally diverse teams. The study focused on two teams, Alpha and Beta, which each consisted of four members from different countries. Alpha contained members from countries with a low PDI, whereas Beta contained members from countries with a high PDI. Researchers found that in regard to team Alpha, "low power distance was one factor that enabled team Alpha to avoid potential conflicts due to miscommunication." Team Alpha also used a decentralized decision-making process of consensus versus a revolutionary power struggle for determining leadership. Other studies concluded that countries with a high PDI showed a positive correlation with safety in relation to national culture, more formal communications between students and faculty, and a lower probability of cardiac death over the next 20 years of employment.

Hofstede's studies and PDI have caused U.S. managers to reconsider their methods of management and have been used to support countless additional academic studies on varying cultural indicators.

Pricing

A company engages in a pricing activity when it attempts to determine the best price at which it can sell its product. This is one of the basic elements of the marketing mix. Typically, the company will aspire to find the optimal price to maximize revenues. This might imply having a high price per unit or a low price and selling many units, making profits through volume. Companies choose pricing strategy (such as premium pricing, skimming, economy, and penetration) they believe will generate the most profit, and they will choose the final price according to a price model such as cost-plus pricing, target-return pricing, value-based pricing, and psychological pricing. Some companies employ price cuts to encourage sales or to liquidate stocks.

A company that wants to determine its pricing will need to estimate market demand for the product, current cost structure of the product, and competitor pricing as well as the positioning of the product. The last item is crucial, because positioning will often determine if a product will be priced high or low. For example, if a company decides that the product will be sold as a luxury item, the pricing will be high. But if they decide to make money through volume, the price will be very low. Cost structure is also very important to ensure the company does not sell its products below production cost. Cost structures include production, promotion, and distribution. Once all the elements have been determined, and the company objective has been decided, the company can determine the pricing model.

Other concerns that can affect product pricing include perishability (perishable products have less shelf life, hence must be priced to maximize sales) and life cycle (new products can use multiple pricing strategies, whereas older products are usually limited to economy pricing).

Pricing Strategies

When determining pricing, the company must choose whether the product will be priced at a cost-plus or value-based structure. As such, four main pricing strategies exist: premium pricing, skimming, economy, and penetration.

A premium price implies that the product is of high quality and can justify an elevated price. The company will be able to demand a high price (or command premium pricing) because of the perceived uniqueness of the product. For example, companies selling products for which they have market exclusivity (because of a patent or a trademark) usually employ premium pricing. A good example is Rolex watches, which are perceived as status symbols and command a higher price than products of similar quality.

Skimming pricing is used when a new product enters a market for which a competitive advantage exists but for which the advantage is not sustainable. The advantage is not prestige, but rather technological in nature. As such, the company targets early technology adopters. For example, when the iPod was first sold in U.S. markets, Apple was able to sell its product at an elevated price; as technologically equivalent competitors entered the market, Apple was unable to justify the high price and had to drop it to compete with new competitors.

Economy pricing is used to price goods that have low cost and low differentiation. Basic commodities usually use economy pricing. Hence, the company tries to increase margins with volume sales rather than a high per-unit profit. Private labels that are developed by retail outlets are an example of economically priced goods.

Finally, penetration pricing is usually employed by a company that seeks to gain quick market share to establish a foothold in a market. For example, if a company wanted to develop a new geographic segment, they might be willing to sell their goods at a lower rate than usual to gain market recognition. Prices would be adjusted in time accordingly.

When pricing, businesses have to take into account such factors as competition, market conditions, and even perishability.

Complex Pricing Strategies

Pricing is often much more complex than the simple strategies discussed previously. As such, various complex models are used by companies. For example, some companies use captive pricing, wherein the initial purchase is low (penetration strategy) and subsequent purchases are elevated (premium pricing). Printers are a very good example of this hybrid strategy; whereas the initial purchase will be quite inexpensive (the printer), the following purchases (the ink cartridges) will usually be quite expensive. Other hybrid strategies include product bundling pricing (selling a premium item with economy items to move slow-moving items) or optional pricing (selling an economy product with premium options, which is often found in products such as cars). As such, the pricing strategy is limited only by the company's creativity.

Pricing Models

Once a pricing strategy is chosen, a pricing model must be determined. The four main pricing models are cost-plus pricing, target-return pricing, value-based pricing, and psychological pricing. Cost-plus pricing occurs when a company decides that the price of the item it wants to sell should be set at a fixed amount higher than the cost to produce. So, for example, a company for which a product costs $10 to produce could decide to apply a cost-plus pricing of 50 percent; hence it would sell its products for $15. Although cost pricing is simpler to implement, it does not take into account market demands and competition.

A company that chooses target-return pricing determines the sales objective it wants to reach. For example, a company that wants to achieve $1 million in net sales for its product may estimate it can sell 100,000 units this year, and the product costs $10 to produce. Hence, the final pricing of the product will be $10 (cost) and $10 (return per product unit) for a total cost of $20 per unit. Nonetheless, there is circular reasoning in target pricing; because the number of sales affects pricing, which, in turn, affects the number of sold units, it is mostly used in "stable" competitive environments.

Value-based pricing is commonly used when the company is in a very competitive market and needs to price its product relative to competitors. Hence, the product is priced according to competing products. For example, if competitors are selling a similar product at around $12, the product will have to be priced around the same price range (depending on market elasticity).

Finally, some companies use psychological pricing models when selling their products. Hence the price of their product will be a mix of popularity, perceived quality, and what the customer is willing to accept. Luxury items are the most often priced this way. For example, some running shoes are often priced upward of $150 per pair, even though costs to manufacture are relatively negligible and competing products of similar quality can be found much cheaper. In this case, customer willingness to pay $150 justifies the pricing model. This pricing model requires the most market knowledge, because it is quite easy for a company to overestimate consumer willingness to pay a premium and to price itself out of the market.

Although companies usually set a fixed price, there are a number of situations where they will engage in pricing discount. These techniques include quantity discounts (where prices are lowered when items are purchased in bulk), seasonal discounts (where prices are lowered depending on the season goods are purchased), cash discounts (where a rebate is offered to companies who pay their bills early), and promotional discounts (short-term discounts given to stimulate sales, often to clear out inventory or to regain market shares).

PRINCE Analysis

The PRINCE model was designed in 1969 by William D. Coplin and Michael K. O'Leary as an analytical system for forecasting decision outcomes. Initially built as a Programmed International Computer Environment (PRINCE), it was first used in an American foreign policy simulation run on mainframe computers. In their book *Everyman's PRINCE*, Coplin and O'Leary demonstrated applications in family decisions, neighborhood policy development, city politics, national economics, and international business. In *Power Per-*

suasion, they describe how to use the system to achieve personal and business goals in corporate settings. Beginning in 1979, the PRINCE forecasting method has been used as a basis for projecting 18-month and 5-year political risk as a part of the Political Risk Services (PRS) risk model. PRINCE is used to project the probabilities of primary, secondary, and tertiary "regimes" (governments) for which risk is forecast for 12 political variables in the PRS system.

Beginning with a theoretical projection by the chief analyst of the likely outcome of the decision, PRINCE analysis involves the systematic use of expert data to build a projection matrix. Experts providing the basic data input are generally expected to have language capability, roughly 20 years experience in the country or region, 5 years of residence in the country, and to be giving continuous attention to the country. Academic analysts, former foreign service and intelligence officers, corporate executives, reporters, and others with this experience are generally the experts being used. They are asked to provide data for five variables that make up the PRINCE matrix (see example below).

1. Actors or players involved in the decision in some way. These actors may be individuals, groups, or ministries within the government, or opponents of the government, as well as individuals or groups within the society as a whole, such as businesses, unions, or ethnic organizations. Actors may also include foreign individuals or institutions, such as the International Monetary Fund or foreign governments. The number of actors may vary from country to country and may vary between 18-month and 5-year forecasts. The actors are simply listed down the left column of the matrix. Determining who the actors are is a research project in and of itself and involves a thorough understanding of the society and how it works.
2. Orientation or position on the issue. This indicates whether, in the expert's view, each actor supports or opposes the outcome being forecast. Support for the outcome is indicated by a + (plus) sign, opposition by a – (minus) sign. This is a simple dichotomous declaration. If an actor is neutral, there is no point in including the actor in the matrix configuration.
3. Certainty of the position. For group players, certainty is a function of the extent to which there is consensus of support or opposition among the membership. Certainty is measured on a scale ranging from 1 (little certainty) to 5 (extremely high certainty). Individuals likewise can be uncertain in varying degrees on a decision, but this is more difficult for the expert to determine. Where a group vote or poll can determine group uncertainty, for individuals, competing or even contradictory statements might be the indicator. The expert will have had to read the actor's views carefully.
4. Power. This indicates the degree to which each player can exert influence, directly or indirectly, to support or oppose a particular outcome relative to all other players. A player's power can have a variety of bases, and the exercising of power takes many forms. Power may be based on such factors as group size, monetary contributions, physical resources, institutional or personal authority, prestige, political skill, or dedication to the cause ("little old ladies in tennis shoes" as in the 1960 Kennedy election). Power is measured on the same scale as Certainty, ranging from 1 (little power) to 5 (extremely high power).
5. Priority or salience on the issue. This indicates the importance attached to supporting or opposing a particular position, relative to all other concerns facing that player. For example, while a group may want to have President Evans reelected, it may be more important to them to gain a majority in the country's parliament, and they may choose to use their resources there instead of in the presidential race. Salience is measured on a scale ranging from 1 (little importance) to 5 (extremely high importance).

The variable scores are multiplied and totaled in positive and negative columns, and the positive scores are weighed against the absolute total on decision strength to determine the probability of the outcome initially theorized. PRS rounds the probabilities to the nearest 5 percent (so, the figure of 61 percent in the example would be rounded to 60 percent).

The PRINCE model for the 18-month projection is a relatively simple multiplicative model, which weighs certainty, power, and salience equally. The five-year forecast involves building on the 18-month forecast, adding national and global forces as actors. One of the strengths of the model is that it can be easily modified by changing the scales or adding variables according to an alternative theory. However, over the last 40 years, the PRINCE model as it stands has proven to be consistent and useful in the PRS political risk forecasting process.

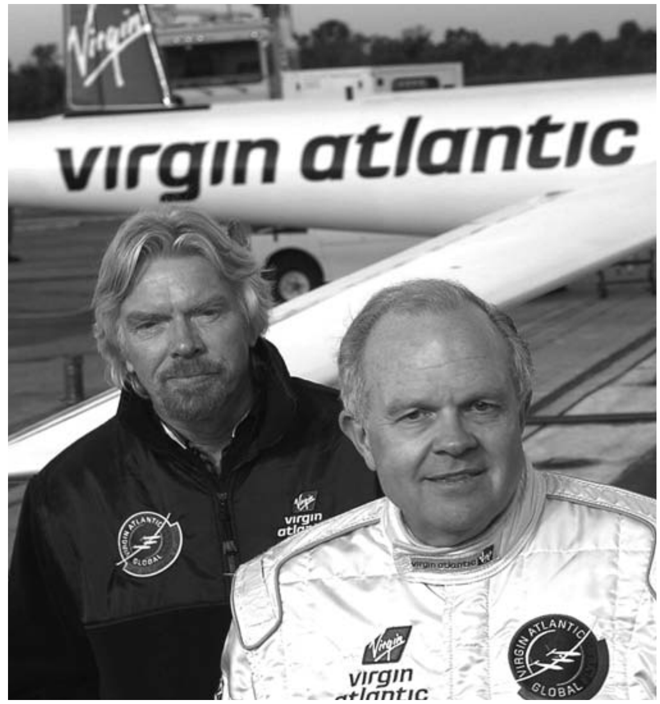
Private Spaceflight Industry

Although nothing about spaceflight inherently demands government involvement, in the first generations of successful spaceflight only national governments had the resources necessary to pursue it; even the first commercial satellites were launched with government-owned rockets. Even now, more than 50 years after the launch of Sputnik, the only profitable commercial use of space is in satellites (and manufacturing and other contracting on behalf of government clients). But the long-term success and safety of reusable spacecraft like NASA's space shuttle, combined with the reduced cost of computing power and other advanced technology, has led to a still-developing private spaceflight industry.



Sir Richard Branson (left) of Virgin Galactic and pilot Steve Fossett with a test aircraft at Kennedy Space Center in 2006.

Europe led the way in spaceflight deregulation, creating Arianespace in 1980 as a commercial space transport agency. American deregulation began in 1984 with the Commercial Space Launch Act, which legalized the private operation of expendable launch systems. But throughout the 20th century, private spaceflight remained unmanned—expendable rockets used to launch satellites into space, but no reusable or passenger flights. That has lately begun to change.

Toward the end of the century, the Russian space program began taking private citizens—paying tourists—into space as a way to offset their operating expenses; the trips were arranged by various private corporations, beginning with MirCorp. Currently the Virginia-based company Space Adventures arranges trips on Russian spacecraft to the International Space Station for fees in the millions of dollars.

The first privately funded spacecraft was launched in 2004: SpaceShipOne was a spaceplane (a concept often proposed within the aerospace industry but never explored in the public sector due to the popularity of the shuttle), launched to suborbital altitudes. It was developed by Mojave Aerospace, a joint venture between Microsoft cofounder Paul Allen and the aviation company Scaled Composites. Months later, Virgin signed a deal with Mojave to develop the spacecraft for Virgin Galactic, the first passenger space travel company. While ventures like MirCorp charged fees in the neighborhood of $20 million, Virgin's tickets sell for only one percent of that—with prices expected to drop after the company recoups expenses. The SpaceShipTwo is being designed for this purpose, with seats for two pilots and six passengers, for flights that will include six minutes of weightlessness.

Though Virgin will likely be the first major venture to begin flights, it is not alone in the field. There are now dozens of companies developing suborbital or orbital commercial flights, while Space Adventures now offers space walks on its International Space Station trips.

Privatization

Privatization is a transfer of management, ownership, and/or control of any aspect of an enterprise from the public (governmental) sector to the private (nongovernmental) sector. The term (spelled *privatisation* in the United Kingdom and most Commonwealth countries) is very broad, encompassing a wide range of activities and/or assets and methods of transferring those activities from public to private entities.

Privatization runs a gamut from large scale to small scale and from full public transfer to the private sector to more limited partial transfer. The purest example of privatization is the outright sale of a governmental asset or operation to a private corporate entity. Infrastructure assets such as roads and power-generating facilities are often in this category, having in many cases been built, owned, and operated by the government, which then decides, perhaps many years later, to sell the asset to a private operator. The asset may be directly sold, in which case the method of transfer is referred to as an asset sale; alternatively, the shares of an incorporated entity that holds the asset for the government may be floated on public share markets, or those shares may be sold to selected private entities, in which case the method of transfer is referred to as a trade sale.

An alternative method of public-to-private transfer is the concession or lease arrangement. For example, suppose a government decides to transfer a public commuter rail to a private entity. As noted above, the government could sell the rail line directly (an asset sale) or sell the shares of a governmental corporate entity that owns the rail line (a trade sale). A third alternative is for the government to retain ownership of the rail line but lease the line to a private entity for some period of time, after which the line reverts back to public ownership. This arrangement would constitute a lease or concession agreement. If the lease term is long enough (20 years or more; 75- or 99-year leases are quite common in the infrastructure field), the government has de facto (i.e., in fact), though not de jure (i.e., by law) transferred ownership because of the long-term control exercised over the asset by the private entity through the lease. Leases and concession agreements can have many different legal provisions, and through these provisions, the degree of privatization can be modified. For example, shorter or more-limited lease terms can allow the governmental owner to retain more management control over the privately managed asset.

Leasing is an example of a widely used method of privatization known as *contracting out*. In contracting out, a service or activity (as opposed to an asset) is paid for by the government but is provided, by means of a service agreement, through a private entity. Almost any conceivable example of public service has been provided in this way, though some, such as garbage collection and information technology services, are more widely contracted out by governments than others, such as police protection. *Outsourcing* is another label often used to designate contracting out, though the former term is broader in that it is used for both public-to-private transfers of responsibility as well as private-to-private transfers. If the service is outsourced to a provider in another country, then it is sometimes referred to as *offshoring*.

This continuum of privatization has led to development of the term *public-private partnership* (PPP), which is often used synonymously. A broad definition of PPP refers to working arrangements based on a mutual commitment between a public sector organization with any organization outside the public sector. The common theme between privatization and a PPP is some sort of blending of private and public institutions and missions. However, privatization refers to some definite transfer of activity or authority from the public to the private sector, whereas a PPP can also include joint public-private efforts that do not involve such a transfer.

Privatization can be completed in one step or completed through a series of intermediate steps. Corporatization, in which a public operation is first transferred to a new corporate entity that is governmental but is typically run outside governmental budget and policy frameworks, is often a framework used for ultimate privatization. For example, when the Australian central government decided to privatize a number of airports that it owned and operated, it first transferred ownership of and responsibility for those airports to the Federal Airports Corporation (FAC). The FAC operated these airports for a few years before putting them up for sale, mostly using trade sales. Even if corporatization is a final outcome, the final effect may be much the same as privatizing if that corporation operates much like a private company, even though technically a governmental entity retains ownership and control.

Privatization has become widespread throughout the world with, however, a wide variation across industry sectors and countries. One study of transfers of state-owned enterprises (SOEs) to private corporations from 1977 to 1999 counted 2,459 deals in 121 countries, worth approximately US$1.11 trillion. (An SOE is a governmental corporation that is nominally operated as a company but that is typically majority-owned and usually controlled by a central government.) Surveys of government managers in the United States have found large numbers of respondents, indicating outsourcing of a wide range of programs in areas as diverse as wastewater to health services.

Rationales

Governments choose to privatize for numerous reasons, the major stated rationales being that the private sector operates more efficiently and cost-effectively than the public sector in many instances, that government can achieve better overall outcomes by focusing on its core missions and core competencies while giving peripheral activities and programs outside its skill set to capable private operators, that privatization allows access to private capital that would otherwise be unavailable, that the method shifts risk to market-based entities better able to handle them, and that greater flexibility in operations is achieved.

Maintenance of the public interest is a prime concern with any privatization, and this constitutes one of the main counterarguments against its use. It is not a given that the public interest will be maintained when private parties with perhaps countervailing interests take over. A related issue is that of equity. Private operators are generally return driven and may be inclined to charge market rates and/or cut costs to maximize returns. This may be inequitable if service cuts or charges fall on groups deemed to be disadvantaged.

In general, economists note that there is a difference between an actual gain in resources and a mere transfer of resources from one party to another in which case government budgets may see a gain but other parties, such as labor unions or consumers, might see a loss. This is especially a problem where a natural or other monopoly exists (e.g., an electrical or telecommunications utility) and in which price and quality is not subject to much competition. Privatization can be said to enhance efficiency only if the gains are above and beyond any shifts of resources across different groups.

There is no a priori case for or against privatization that prevails, so the matter rests on evidence and this is mixed. There are examples of very successful privatizations that have delivered superior incomes for both public and private sectors (e.g., Japan Rail, mostly completed by the 1960s), those that did poorly on both counts (e.g., the initial privatization of British Rail), and many much more ambiguous cases. Probably the most overall successful set of privatizations has been the transfer of SOEs to private enterprises. Many privatized SOEs were running large losses, and being corporate in organization, there seemed to be little economic reason to keep them in public hands. Even here, however, there have been failures, even transfers back to the public sector in a few cases.

In general, it is clear that privatizations, being negotiated arrangements between governmental and nongovernmental entities, will be successful only if the agreements are sound and well implemented and, in some cases, regulated afterward. Some transfers, such as an SOE, will be relatively straightforward to sell to the private sector, while others, such as complex public services, will be more difficult to arrange successfully. Privatizations certainly have wide applicability and do offer one of many alternatives for governments to use in providing services, but to work they need to be designed properly and may not always be the best available method of reform.

Procter & Gamble

Procter & Gamble (P&G) is an American consumer packaged goods corporation headquartered in Cincinnati, Ohio. It manufactures a wide range of consumer goods such as Ivory soap, Crisco oil, Tide detergent, Crest toothpaste, and Gillette razors. In 2007 it was the 25th largest U.S. company in terms of revenues, with $76.5 billion in sales and close to $10.3 billion in total revenues. P&G was created in 1837; its products are present in more than 180 countries. These products are sold primarily through mass merchandisers, grocery stores, membership club stores, drug stores, and, soon, e-retailing. P&G is credited with many business innovations, including brand management, sponsoring television shows, and profit-sharing with its employees, and it is constantly ranked as one of the world's most admired companies.

Procter & Gamble was founded in Cincinnati in 1837 by William Procter (a candle maker) and James Gamble (a soap maker). The company produced both candles and soap for the better part of the 19th century, but it moved away from producing and selling candles with the advent of electricity in the 1920s. Soap continued to be an important revenue stream for P&G. At one point, the company sold over 30 different brands of soap; Ivory, one of P&G's most recognized brands, made its appearance during the late 19th century.

P&G continued expanding its operations into other consumer products such as cooking oil (Crisco), health products, cleaning products (Tide), and toothpaste (Crest). Simultaneously, P&G expanded international operations, opening manufacturing offices in Canada (1915), Mexico (1948), France (1954), and Saudi Arabia (1961).

The company has had a long tradition of organic growth for its product line, but it shifted its strategy to complete a series of acquisitions in the second half of the 20th century to broaden its product line. These acquisitions included Folgers Coffee, Old Spice, Richardson-Vicks, and Iams Company. The latest acquisition was the Gillette Company, which made P&G the biggest consumer goods company in the world. It also added many household name products to P&G's product line such as Gillette razor, Duracell batteries, and Oral-B toothbrushes. In 2007, 23 of P&G's brands had more than a billion dollars in net annual sales, and another 18 products had sales that ranged between $500 million and $1 billion.

Since 2007 the company has been structured into three global business units (GBUs). Each of these GBUs is responsible for its own business segments. The first is the Beauty GBU, which includes both the Beauty and the Grooming Segment. The Household GBU comprises both the Baby & Family Care Segment and the Fabric Care and Home Care Segment. The third Unit, Health & Well-Being, includes the Health Care and the Snacks, Coffee, and Pet Care Segments.

Contributions to Management Practices

Procter and Gamble is often described as a key innovator in the way companies interact with their consumers. Hence, they are believed to be among the first companies to engage in brand management as well as media sponsorship. P&G created its marketing department in 1931. The department focused on creating specific brand messages for each of the company's products. It also invested heavily in marketing research so P&G could understand how to make its products much more appealing to the consumer. Both of these approaches, quite common today, were revolutionary when they were developed by Procter & Gamble.

Following these developments, market research found that there was an opportunity in sponsoring radio shows. These shows became known as soap operas (a tribute to Procter & Gamble's soap product lines). In the 1930s, P&G heavily sponsored radio shows, and progressively moved to sponsoring television shows in the 1950s. Two of the first series P&G sponsored (*As the World Turns* and *Guiding Light*) are still on the air today and are produced by a division of P&G called Procter & Gamble Productions. This approach to sponsorship and production extended into many other types of shows, including prime-time shows (such as *Our Private World*), comedy series (such as *Down to Earth*), as well as supporting many Spanish-language *novelas*. Even today, P&G continues to invest heavily in soap operas as a major marketing channel.

On the employee relationship side, P&G developed some remuneration programs that were uncommon at the time. In 1887 it established a profit-sharing program for its workforce, hoping that giving a stake in the company to workers would reduce chances of them going on strike. It continued to incorporate the interest of workers into its constituting charter, and continues today to be viewed as a prime location to work.

Procurement

Procurement can be simply defined as the acquisition of goods and services for the firm at the "best" price. Procurement includes sourcing (identifying and working with appropriate suppliers) and purchasing (the specific functions associated with the actual buying) and covers all the activities necessary to obtain goods and services consistent with user requirements from the placement of an order through to its delivery.

Companies procure direct goods that go straight into the production of a product, such as coffee beans or rubber; indirect goods that do not directly go into a product, such as office supplies and furniture; and services that support the production process or the supply chain, such as warehousing, distribution, or information systems. Purchased parts and materials may account for over 60 percent of the cost of finished goods. Procurement is therefore one of the primary activities related to the supply chain.

A major element when developing a procurement strategy is the establishment of links between the company and its suppliers. To sustain these links communication and proximity are the keys. Today many suppliers work alongside their clients in product-design development from the very beginning of the production process, and to minimize inventory levels and support Just-in-Time (JIT) systems, have moved closer to their customers, sometimes on the same industrial park. Many companies have instituted certification and award programs to recognize their best suppliers.

The development in IT systems is having a major impact on procurement activities. The most common technology used is electronic data interchange (EDI) that involves the electronic transmission of data (e.g., purchase orders, order status, tracking, and tracing information) between a firm and its suppliers. Another e-procurement application is the development of electronic catalogues, allowing buyers rapid access to product specifications and prices. Buying exchanges or e-marketplaces are another development. They represent cooperative efforts among companies, frequently competitors, to deal with their common base of suppliers. A process used by e-marketplaces is the reverse auction, where suppliers bid on order contracts. When the auction is closed, the company can compare bids on the bases of purchase price, delivery time, and supplier reputation for quality.

According to John Coyle, Edward Bardi, and John Langley, there are 11 steps in the procurement process: identify new or existing needs of the users; define and evaluate user requirements; decide whether to make or buy; identify the type of purchase (routine purchase, modified rebuy, new buy); conduct a market analysis to determine the number of suppliers in the market and which method of buying (e.g., negotiation, competitive bidding) might be most effective; identify all possible suppliers that might be able to satisfy the user's needs; prescreen all possible sources to reduce the number of possible suppliers to those that can satisfy the user's demands; evaluate the remaining supplier base; choose a supplier; receive delivery of the product or service; and make a post-purchase performance evaluation.

Some products or services purchased by a company are more important than others and require greater procurement attention. Products may be placed in a two-by-two matrix on the basis of value and risk. Four different categories can be found: Generics are low-risk, low-value goods that typically do not enter the final product (e.g., office supplies). The procurement process should be simplified to reduce the purchasing cost. Commodities are low-risk, high-value goods that are fundamental to the finished product (e.g., bolts or packaging) but with many sources of supply. Procurement strategies include volume purchasing to reduce price and JIT to lower inventory costs. Critical items are high-risk, low-value goods that pose a threat to continued operation (e.g., parts with a long lead time). Strategies include ensuring availability and developing a standardization program moving these items to generic. Finally, strategic items are high-risk, high-value items that give the final product a competitive advantage in the marketplace. Close and long-term supplier relationships should be looked for.

Products and services may be sourced from around the world. The main advantages of local/national sourcing are close cooperation, lead times not affected by transport delays, short lead times may eliminate inventory, fulfilment of social responsibilities to the local community, easier resolution of disputes. Global sourcing may allow for lower costs but risks are often higher and companies have to be aware of cultural differences, variable lead times resulting from shipping schedules or storms at sea, lower quality, use of child labor, higher costs of doing business, laws and regulations, and nontransparent costs (such as procurement costs, management time, plant visits).

A final issue relates to the number of suppliers. A single supplier may allow for better prices or an easier establishment of EDI and JIT links but may also be regarded as a risk. The trend in sourcing today is to have fewer suppliers and to build better relationships with them.

Product Component Model

Product component models are part of bill of materials (BOM) management. The BOM describes the materials, assemblies, parts, and components required to manufacture a particular final product, like the list of ingredients and equipment at the header of a recipe in a cooking magazine. BOMs are prepared toward various ends—during the design phase of a project, as the product is built, or when it is ordered, for instance, depending on the product and the industry. They're especially handy for products produced on an assembly line. Database software can often automate the process of generating a BOM.

Modeling techniques are used to manage BOMs. A complicated product—a circuit board, for instance, or an automobile—has many components, both independent and interdependent, and factors such as the final size, shape, weight, or cost of the product may impact changes to many components when one component is changed. A scarcity of a component could necessitate this, or new regulations or standards, or the availability of an improvement that replaces an old component. The product can be complicated in ways other than its physical construction, as well, as in the ingredients used in a commercial flavoring blend, which may shift in proportion to one another according to the prices on the global market or the capsaicin content of the season's crop of chile peppers.

During the modeling process, the components of the product are defined in three ways. The BOM identifies a raw list of parts, with quantities of each. Subassemblies are then defined: Subassemblies are the configuration of specific parts together, in operations that need to be performed before those subassemblies are then integrated into the final product. Subassemblies are familiar to anyone who has assembled his or her own furniture or bicycle at home. In the recipe analogy, subassemblies are the butter and sugar creamed together before adding the flour and baking soda that were combined in advance. The configuration of the product—the recipe for putting it together from those subassemblies—is then outlined.

In this terminology, a batch of cookies is an assembly or product, and the instructions for how to create them is its configuration, headed by the BOM; the butter and sugar, a subassembly; the other ingredients, if no manipulation is done to them before adding them to the bowl, are components. A commercial cookie company might model different ingredients on the computer—not for taste, which can be tested in the test kitchen, but in order to calculate the cost, complexity, and dietary information of different possible recipes.

The BOM is complemented by the bill of quantities (BOQ) and bill of resources (BOR). The BOQ delineates the cost of the labor and materials necessary to build or repair a structure. The BOR itemizes the resources required to complete a product, especially toward the end of advance arrangement of resources that are in short supply or have limited availability.

Product Development

Product development refers to the process of creating new goods and services or modifying existing goods and services. Why do companies develop products? Companies have financial, sales, and market share goals; products can be developed to reach these goals. In addition, companies can initiate product development to respond to rivals' actions, to commercialize an invention, to get benefit of a new technology, to get involved in global markets, or to modify the product with respect to its life-cycle phases. Being a source of revenue, and thus profit, goods and services are the heart of any business. Nowadays, technologies have been changing very quickly, and this rapid change brings new technologies that ultimately result in changes in products by shortening their life span. Therefore, product development is crucially important for both domestic and international companies, because successful new products increase company revenues.

To be successful in developing new products and modifying existing products, companies need to be able to answer various questions: Does a new or modified product satisfy customers' perceived needs? Is it likely to survive in the competition? How will the competitors fight back? What is the size and growth of the (target) market? Is the company a market leader or follower? What are the monetary and engineering requirements to develop the product, and how capable is the company in meeting these requirements?

Marketing plays an important role in answering some of these questions, and in product development. Technology will be used to create products that consumers need and want; in addition, products should be positioned and competitively priced in a way to meet market needs and expectations. When a marketing element in product development is missing, products may not be effectively engineered and priced. Therefore, marketing helps effectively design and develop products.

Product development can be classified into two categories, the development of new goods and services that were not available earlier and the development of the existing products through modifications. For instance, cell phones and laptops with new features that were not available earlier can be examples of the second category of product development. Both types of product development are important. The first type introduces a new product and service, and if these are successful, the company is expected to lead the industry. However, this leadership is contingent on how successfully the company develops, upgrades, and modifies the new product through time against the attacks of rivals.

In today's business environment, competition becomes more and more intensified every day. Companies struggle to decrease production costs, increase productivity, develop new products, modify existing products, acquire or partner with other companies, construct close relationships with their suppliers, expand across national borders, and follow and adopt the latest technology. The major goals of these practices are no doubt to survive in a competitive business environment and to create and sustain competitive advantage over rivals.

Although all these practices are important, perhaps product development is more important than others, because products are the sources of revenues and are crucial to successful and increased company growth and profit. Companies can get the latest technology, hire good employees, expand overseas markets, and engage in partnerships with other companies. In these instances, money is important. However, developing products requires much more than money.

There are essential questions to be answered. How to come up with some potential ideas to be converted into physical goods and services? What products to develop? How to develop products? What features to include? Is there really demand for it? Is it profitable? Is it strategic? How long does it last? These and many other related questions are not easy to answer. That is why product development is very difficult, costly, and risky. Nevertheless, the success in product development is very rewarding.

A company successful in developing a product can easily be a market leader, set standards, and be a unique brand in the market. A good example in this regard would be Microsoft with its operating system that has been leading the industry and has become a unique brand among operating systems. Therefore, product development is very important in surviving and leading in today's competitive business environment.

Product Development Process

Product development is a process consisting of opportunity identification, design, testing and improving, and introduction. Product development approaches can be classified in two ways: reactive and proactive product development. When companies develop products just to respond to rivals' actions, this is a reactive way of approaching product development; however, when companies develop products under a strategic plan and according to their perceptions of the market's current and future needs, then this is a proactive way of approaching product development. There is no single answer as to which one is the best way of initiating product development; conditions may determine the appropriate type.

The first step in the product development process is opportunity identification. Market definition is important in this step, because it shows the boundaries and scope of the competition. Markets can be defined using different criteria such as products competing with each other, customer needs, demographics, attitudes, preferences for product benefits, price, decision rules, usage, product form, and so forth. Ultimately, the market definition will be useful in identifying the related customer groups or segments, in finding the customers and determining their basic needs and habits, as well as in understanding competing products within the segments. Idea generation involves formulating creative ideas that will be converted into products having value for customers in the markets defined earlier. Creative ideas can come from many different sources, such as employees, managers, customers, suppliers, environments, and company departments, such as research and development departments. These product ideas are then subjected to strict analyses to see whether they are feasible, useful, and appropriate for the company objectives.

The second step in the product development process is the design stage, which involves the identification of key values the product will offer, the positioning of these values versus those of competitive products, and the development of physical products, marketing strategy, and service policy to accomplish these values. Customers buy products based on their judgment of the product's ability to satisfy needs. The aim in the design stage is to identify the needs and priorities of consumers and develop an appropriate design to deliver and communicate values to satisfy consumers' needs. Some keys features of the design stage are that a new product becomes a tangible entity and is psychologically positioned. In addition to its features, how customers think of it (positioning) is important. The design is iterative and integrative; product design requires many attempts in which the design is evaluated, refined, and modified. Therefore, different organizational departments such as production, marketing, research and development, and engineering should work in a cooperative manner.

The next step in the product development process is the testing phase, which involves advertising and product testing, pretest and prelaunch market forecasting, and test marketing. The quality of advertising content is important in creating awareness and communicating the product. Through advertising testing, a good ad can be selected among many available alternatives; in addition, advertising testing can provide managers with insights into whether a particular ad is sufficient for a new product introduction. Product testing involves an analysis of whether the product performs or delivers its intended benefits; this test can be useful in identifying product deficiencies and thus improving the product. Laboratory tests, expert evaluation, and customer tests are some ways of conducting product testing.

After the test of the product design with respect to its physical and communication features, the integrated new product also needs to be tested. This test can give managers a more precise conjecture so that potential failure risks can be minimized or prevented. However, a pretest market analysis can be beneficial if the company is able to obtain enough accurate predictions, if the analysis can be done without using a large number of resources, if new knowledge to improve the product can be obtained, and if the cost of such an analysis is within the budget of the testing. At the end of this analysis, the company expects to obtain a forecast of sales and diagnostics. Some ways of implementing pretest market analysis are judgment and past product experience, trial/repeat measurement, laboratory measurements, and attitude change analysis. The last test in the testing phase is test marketing that is targeted at acquiring market information to reduce risk and improve the product. Test marketing is actually introducing the product to a limited number of customers in a number of cities representative of the country and/or at controlled stores.

In the last step, if all tests have been successful, then the product is approved and ready to be introduced to the market. At this point the company has a physical product, advertising, personal selling tactics, promotion plans, price, distribution channels, and service procedures in place. There are two alternatives with respect to the introduction phase if a test market was not implemented: introduction under a quick adaptive control system and market by market introduction to control the failure risk. Learning from the customer feedback and production experience is the key in such introductions. In addition, an effective coordination of production and marketing activities is necessary to ensure all the components of the introduction work properly and are timely.

The product development process becomes the product life cycle management process with the product introduction. Like people, products have different periods in their life: introduction, growth, maturity, decline, and death. The life cycle begins with the introduction; as the product becomes successful, there will be more demand and the product will grow until the demand reaches its highest level, called the maturity phase, or market saturation. After a while, the demand will decline as the product is not demanded anymore, and the company will sooner or later stop producing the product. There are many strategies to manage the product throughout its life cycle. However, these are beyond the scope of this entry.

In sum, product development is a strategic process, and product development and design activities are important corporate tools that are essential to wealth creation. However, product development involves risks and uncertainties; it can be very costly and can last years in some industries, for example, in the aviation and pharmaceutical industries. In addition, product development is complicated; the management of products themselves, their sales and sustainability, and their environmental impacts are not easy to manage. However, a very carefully planned management of the product development process can increase the likelihood of success. Companies that are able to compress or shorten their product development cycles are also in a more advantageous position.

Productivity

Productivity is a measure of how efficiently a company, industry, or society uses inputs, or factors of production (e.g., labor, energy, capital) to generate products and services. A number of methods can be used to measure productivity. In a factory, productivity might be measured based on the number of man-hours to produce a good, and in the service sector, a common measure of productivity would be revenue per employee, that is, the total amount of revenue

Technology in the workplace is having a significant impact on productivity, especially in the United States. In 2008 over 75 percent of economic growth came from technological change; by 2030 it may account for 80–90 percent of a country's economic growth.

generated by an employee divided by that employee's salary. It should be noted that, because output is more difficult to measure in the services sector, productivity measurements in that sector tend to be less reliable than is the case in manufacturing.

Productivity is a central issue in global business. Productivity is driven by a number of forces, including technological and organizational innovation, interest rates and availability of capital for investment, the level of entrepreneurialism within a society, and, more recently, scale and effectiveness of outsourcing activity undertaken by a society's corporate community in order to realize economies of specialization. Because it is a crucial component in the degree of competitiveness of one country relative to another, productivity is an important indicator of how attractive a country is as a host for foreign direct investments as well as how able one country will be in gaining foreign markets.

The Industrial Revolution from the mid-19th to the early 20th century saw an unprecedented rise in productivity, first in England and then within the United States. Labor-saving technology, innovation in organizing work and process flow, and the coming of the mass production revolution continually raised the upper limit of efficiency with which factors of production were used to create final products and services. Productivity grew, not simply because of the introduction of new types of production technology onto the factory floor, but also in the ability of enterprises to effectively link this technology to all phases of business operations, including supply, distribution, and marketing.

By the 1970s, certain industries that regularly expanded their productivity, such as power generation, reached the technological limit to these increases. Similar barriers to productivity growth are anticipated in computers and information technology by 2020. At that point, semiconductor chips reach the point of diminishing returns to specialization and Moore's Law begins to break down. Another technological revolution will then be required, involving a new generation of advanced materials and hardware to break through these barriers and set semiconductors on a new path of expanding productivity.

Within the United States, the trend rate of labor productivity in the post–World War II period went through three phases: rapid growth—annual average rate (AAR) of 3.2 percent—from the late 1940s to 1973; slower growth (AAR 1.5 percent) from 1973 to 1994; and an acceleration in growth (AAR 2.5 percent) from 1995 to 2005. The two decades following the war saw rapid and effective development of productivity-enhancing innovation, part of which originated prior to and during World War II. The decline in productivity during the 1970s and 1980s came in the wake of a technological slowdown by the large corporations in such traditionally productivity-enhancing areas as petrochemicals, advanced materials, and mechanical systems, in part the result of increasing costs of R&D; it was also because of the continued inability of companies to effectively integrate the output of an emerging information and communications sector (ICT) across the functional areas of business activity.

The acceleration of productivity in the 1990s, especially within the United States, resulted from a resurgence of technological innovation, not from the large corporations as in the past, but from small start-up firms—supported by an increasingly specialized venture capital community—and licensing the fruits of research conducted by universities and government laboratories. These innovations, such as a new generation of advanced materials that started coming on line in the late 1980s, fed into the ICT sector, also composed of a growing proportion of innovative small and medium-sized firms. This technology transfer between sectors, in turn, pushed the memory capacity of, and thus the number of functions accomplished at faster speeds by, a new generation of ICT hardware to ever higher levels. At the same time, it opened the way for a significant reduction in the costs in the production of semiconductors, resulting in sharply falling prices in ICT equipment and systems.

By the 1990s, the business community invested in ICT equipment and software as never before. It integrated the technology throughout companies, thus linking together different functional areas all along the supply chain, from cash registers linked to bar code systems and connected to inventory control units in warehouses to computers and peripherals connecting different floors within buildings and different facilities across the United States and globally. The implementation of ICT systems across business operations accelerated productivity in such areas as data processing, inventory control, and Just-in-Time (JIT) delivery.

Productivity, Economic Growth, and the Competitive Advantage of Nations

The ability of a country to achieve economic growth, and so compete globally, closely shadows productivity trends. In the first place, slack productivity growth prevents resources from being generated and used in the most effective manner. Thus, critical resources are wasted that could be applied to augmenting opportunities for improving the material qualities of life and this dampens prospects for robust economic growth. Conversely, robust productivity increases private purchasing power and, through an expanding tax base, the prospects of heightened government services for technology creation, infrastructure, education, healthcare, and other important factors driving economic growth. Higher productivity also reduces inflationary pressures since the economy could (theoretically) grow at a faster rate without fear of widespread price increases. In general, long-term productivity growth is commonly viewed as the speed limit for sustainable economic growth.

Comparing productivity trends in the United States vs. the European Union (EU), we find that the United States has surged ahead of Europe, especially during the 1990s. In terms of gross domestic product (GDP) per worker and GDP per hour, the United States, by 2000, exceeded European productivity by 20 percent. Starting in 1990, growth of real GDP in the United States was greater than that of both the EU (and Japan as well) by 25 percent to 30 percent. Because of its achievements in productivity growth from the 1990s, stemming for the most part from its technological leadership, the American economy has been growing faster than the economies of many European countries, and of the EU as a whole. From 1980 to 2005, the economic growth rate for the EU averaged 2.1 percent—with a number of major economies such as Germany doing considerably worse on average—in comparison with an average annual rate of 3 percent for the United States. Indeed, despite the elimination of trade barriers and the close economic integration resulting from the single market, the EU continued to lag behind, and significantly so, the United States as an economic performer, with several EU members—including Germany, France, and Italy—close to economic stagnation during this period

A number of reasons can be brought forward to account for this global discrepancy in productivity, economic growth, and competitiveness. These include the EU's constraint by inflexible labor markets, rising energy prices, and increased competition from Asia. Cultural differences regarding leisure time as an influence on productivity differences also come into play; the significantly greater number of hours dedicated to work in the United States appears to be one component in America's production gains. However, even when these factors are taken into account, the divergence in productivity between the United States and the EU remains, indicating the primary importance of U.S. technology creation and implementation across business functions to productivity growth.

Over the next two decades, technology is expected to play an even greater role in driving productivity gains and, in turn, economic growth within and between nations. In the 1970s, less than 50 percent of economic growth came from technological change. In 2008 this figure has increased to over 75 percent; by 2030 it is estimated that new technology will account for between 80 percent and 90 percent of a country's economic growth. Assuming that the technical barriers imposed by the limits of Moore's Law can be scaled, information and communication technology (ICT) systems and their implementation across business operations will continue to dominate the industrialized and emerging economies. However, energy and biotechnology innovation will generate an increasing proportion of productivity (and economic) growth, especially within the developed part of the world.

Product Life Cycle Hypothesis

Attempting to explain patterns of international trade, Raymond Vernon observed a circular phenomenon in the composition of trade between countries in the world market. Advanced countries, which have the ability and competence to innovate as well as high-income levels and mass consumption, become initial exporters of goods. However, they lose their exports initially to developing countries and subsequently to less-developed countries and eventually become importers of these goods. Vernon's hypothesis was an attempt to advance the trade theory beyond the static framework of the comparative advantage of David Ricardo and other classical economists to explore hitherto ignored or unexplained areas of international trade theory such as timing of innovation, effects of scale economies, and the role of uncertainty and ignorance in trade patterns. His intent was not to propose a biological analogy such as is understood by the theory of product life cycle as commonly understood by marketing theorists.

Vernon's product cycle is a macro-level attempt to generalize patterns of trade between nations based on empirical data. It offers innovation and economies of scale as predominant explanatory variables. Vernon hypothesized a circular pattern of trade composition that occurs between trading partners in different stages of economic growth. Vernon's hypothesis identifies four stages that the trade patterns go through.

1. Introduction: New products are introduced to meet local or national needs, and new products are first exported to similar countries, that is, countries with similar needs, preferences, and incomes. If we also presume similar evolutionary patterns for all countries, then products are introduced in the most advanced nations. This is the traditional idea of the home country as the producer of first-of-a-kind products and the exporter of products to countries with similar needs, preferences, and incomes.
2. Growth: A copy product is produced elsewhere and introduced in the home country (and elsewhere) to capture growth in the home market. This moves production to other countries, usually on the basis of cost of production. At this stage foreign production starts.
3. Maturity: The industry contracts and concentrates—the lowest cost producer wins here. At this stage, foreign production is competitive in export markets.
4. Decline: Poor countries constitute the only markets for the product. Therefore, almost all declining products are produced in lesser-developed countries at this stage, import competition begins.

Vernon stresses degree of standardization as evidence of product maturation: a mature product typically may become standardized across international markets.

Vernon's product cycle model is fundamentally production oriented and based on industrial goods in manufacturing sectors, virtually ignoring trade in intangibles such as services or brand names. While it provides a broad, long-term macro frame of reference, it is not particularly valuable in making micro-level and short-term managerial decisions in firms. His approach is more likely to provide insights for national policy formulation at macro levels.

Cornelia Navari acknowledges the theory's important implications for thinking about processes of industrial growth in a one-world-system in which industrialization was, at least in part, an autonomous, dynamic process, not a product of special talents, and in which the less developed depended on the more developed to develop and simplify technology, allowing them to evade the costs of innovation, while the more developed were pushed by the less developed into new product innovation, allowing them to stay in the advance of industrial growth.

Vernon's hypothesis also had its critics. Edward K. Y. Chen and Peter Drysdale argue that product life cycle theory has been called into question by four main forces: the narrowing of the income gap between countries to the extent that there is no longer a hierarchical sequence with respect to investment location, the shortening of the product life cycle because of the growing emphasis on technology as the basis for competition, the compression of time to market for competitive advantage, and the rising cost of investment to create new technologies and product innovations. Those firms that are the technological leaders and that are first to get their products onto the market set the rules of the game, establish the critical standards, and thus define the overall terms of competition. Certainly, rising investment costs have forced firms to develop and produce first-of-a-kind products outside the home market and often to sell first of the kind conterminously in many markets to achieve first mover advantage and delay competitive response.

Other critics have found difficulty with Vernon's hypothesis as an explanation of growth after World War II on grounds such as the theory's inability to explain nonexport-substituting investments, the appearance of nonstandardized products being produced abroad, and the case of carefully differentiated products to suit the local market. Christos Pitelis and Roger Sugman point out another criticism of the theory: the decline in the rate of growth of demand in the maturity phase can be avoided through unrelated diversification to products at a different phase of their cycle.

Profit-Sharing

Profit-sharing is an incentive pay system where the employees are entitled to a predetermined part of the company's profits. It can be applied in various ways and for various reasons. In the theoretical literature, profit-sharing is often seen as an arrangement with the purpose of aligning the interests of employees and capital owners. Profit-sharing was known already in the 19th century and has become particularly common in countries where legislative measures have prescribed or encouraged its application. A defining feature of profit-sharing is that the employees' share of the company's performance is determined beforehand and not in a discretionary fashion. Usually, profit-sharing is thought of as remuneration in addition to the base wage covering all or most employees.

Three basic types of schemes are commonly distinguished. In cash-based schemes, profit shares are paid immediately in ready money. In share-based schemes, employees are encouraged to become part owners of the company. In deferred profit-sharing, employees cannot take part of the profit shares until a certain time has passed. Gains-sharing can be regarded as a bonus incentive system related to, but distinguished from, profit-sharing. In gains-sharing schemes, employees are entitled to a predetermined part of efficiency gains. Generally, gains-sharing runs on a monthly basis, whereas profit-sharing usually runs on an annual or quarterly basis.

In theory, there are several reasons why some employers apply profit-sharing. An important motive is to link the employees' interests to the company owners'. By connecting a part of the remuneration to the company's performance, employees get incentives to perform at their best and encourage their colleagues to do the same. However, some economists argue that the positive incentive effect is hampered by a free-riding problem. If the profits are shared between a large number of individuals and the contribution of each individual to the company's results is small, profit-sharing has weak prospects of boosting employee effort.

Another property of profit-sharing that may be attractive for employers is that it has the potential of reducing personnel turnover and making investments in firm-specific training more worthwhile. As labor costs automatically adjust to the business cycle, firms can avoid layoffs in bad times and employees will be less inclined to quit voluntarily in good times. In empirical research it has proven hard to establish an effect of profit-sharing on productivity. This is partly because of problems with establishing the direction of causality; it is difficult to know whether companies become more productive by imposing profit-sharing or if more productive companies are more inclined to impose profit-sharing.

Historically, profit-sharing has its origins in the 19th century or even farther back in time. A pioneer company was Redouly & Co., whose owner, Edme Jean Leclaire, introduced a profit-sharing scheme in 1842, along with participation in management, for a selected group of employees. Some decades later, profit-sharing had spread to such countries as France, Great Britain, and the United States. The idea had several famous advocates among scholars and intellectuals, and it was discussed in 1889 at a congress in Paris. This congress, among others, established the definition of profit-sharing that basically is still in use today.

During the 19th and early 20th centuries, profit-sharing was seen as a way of reconciling the interests of workers and capital owners. The incentive system was often used by employers alongside corporate welfare systems, such as pension schemes, company housing, and healthcare. Politically, profit-sharing had advocates among both conservatives and progressive-liberals, but generally, the idea was regarded with suspicion by socialists.

By the late 20th century, profit-sharing was a well-known business practice, though more common in some countries than in others. This is partly related to institutional differences. Two countries have made profit-sharing compulsory for certain categories of firms and other countries have introduced legislation that encourages the remuneration form.

Mexico is the country with the longest tradition of statutory profit-sharing. According to the constitution, a national commission establishes the percentage of company profits that is to be shared with employees. The profits share received by each employee is governed by number of days worked during the year and wages received during the year. Directors, general managers, and administrative staff are not included in the statutory profit-sharing in Mexico. The other country with statutory profit-sharing is France, where legislation prescribing schemes with deferred payment for companies with 100 employees or more was introduced in 1967. The threshold was later lowered to 50 employees.

Legislation that encourages profit-sharing, for example, by means of tax concessions, is more common. In the United Kingdom, for example, legislation for cash-based schemes was passed in 1987. This legislation includes prescriptions for how schemes should be designed in order to qualify for concessions. Among others, schemes have to be approved by the workforce, include at least 80 percent of the employees, and payments have to be allocated according to a uniform procedure.

Tax concessions for profit-sharing are also given in the United States and Canada, but here the legislation encourages schemes with deferred payment. In the United States, the legislation allows schemes where companies, at their own discretion, decide how much of the profits to distribute among the employees. In Canada it has been observed that cash-based schemes have proliferated, although not encouraged by tax concessions.

Japan is thought of as a country with a comparatively high incidence of profit-sharing. However, empirical inquiries have shown that while various forms of bonus payment are encouraged by legislation, and commonly applied by large Japanese firms, only a small part of these bonus systems can be defined as profit-sharing. A recent study indicates that about 25 percent of traded firms in Japan apply profit-sharing.

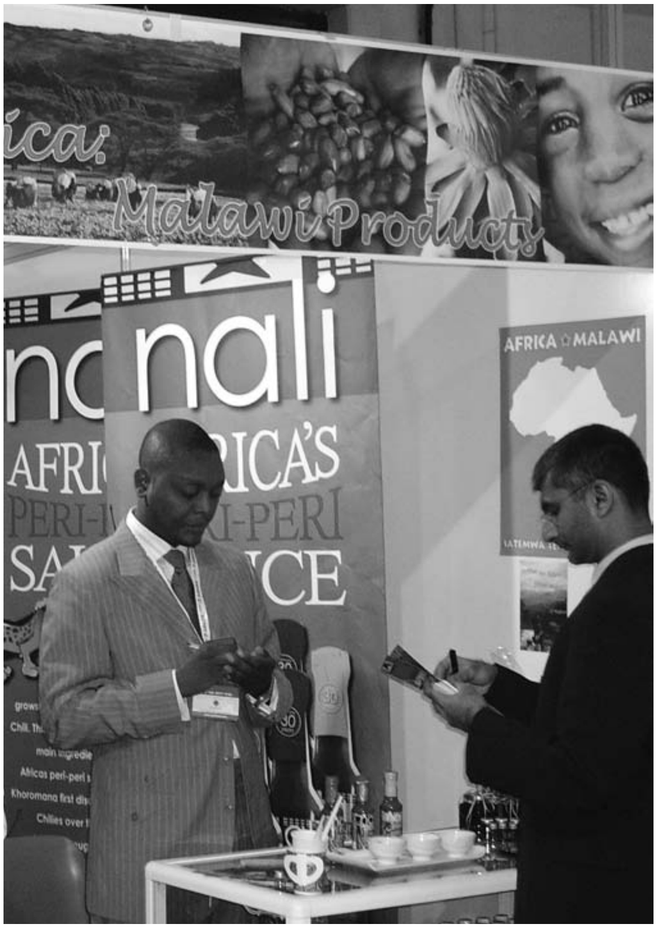
Promotions

Promotion is one of the four activities traditionally included in the marketing mix (the other three being product, price, and place). Promotion aims to increase the customer's familiarity with the product by using a vast array of techniques and tools. Activities included in the promotion mix consist of personal selling, sales promotion, public relations, direct mail, trade fairs, advertising, and sponsorships. Each of these methods has an impact on the customer's awareness of the product, comprehension, and conviction to purchase the item and the probability that all these actions will translate into a purchasing action by the client. During the course of the promotion activity, the company manages both the promotion budget size and how that



Wholesale food companies from Malawi using personal selling and product displays at a 2008 trade fair in Dubai.

budget is allocated. Maximizing this budget through low-cost methods is one of the keys of a successful promotional campaign (through word-of-mouth or viral marketing, for example).

Promotion is separated into two categories: above-the-line promotion describes activities that directly target customer sensibility (such as advertising and personal selling), while below-the-line promotion is usually much more subtle (such as product placement and public relations).

Above-the-Line and Below-the-Line Promotion

Above-the-line promotion refers to activities the firm performs to promote its product by directly targeting the potential customer. Advertising is one of the main methods companies use to engage in above-the-line promotion. The main advantage of advertising is that the firm is able to reach multiple buyers simultaneously, resulting in a low total cost per user, but there is the likelihood of reaching many consumers who will not convert into buyers. For example, some companies purchase ads in generalist newspapers; although the ad is read by thousands of people (generating a low cost per consumer), only a small percentage could actually be considered to be potential customers. Hence, companies increasingly target consumers through specialized media (like specialized magazines) to increase the chance of being read by a potential customer.

The other major technique used for above-the-line promotion is personal selling; this occurs when the firms employs dedicated staff to sell its product. Targeted selling, while highly efficient, is often offset by the high cost per contact, as the firms need to retain and train an adequate sales force.

Below-the-line promotion encompasses all activities the firm engages in to promote its product in a much more subtle manner. Examples of such activities include product placement (wherein the firm pays for its product to be featured prominently in a media setting), public relations (wherein the firm deploys various public-related efforts to garner public attention), or sponsorship (wherein the firm sponsors an event in exchange for visibility).

In all cases, companies that use below-the-line promotions must be careful to keep the balance between having too much or too little visibility. A careful balance is necessary to assure that below-the-line promotions do not become too prominent, which will generate criticism. For example, some recent movies and television series have been criticized for having movie story lines influenced by product placement to the point of affecting the content of the show and annoying consumers.

Objectives and Evaluation

Promotion is mainly used to stimulate sales for the company by convincing customers to purchase the product, but a company might engage in promotional activities with other objectives in mind. For example, some promotional campaigns are used to increase customer awareness of the company's offerings; this is especially true when the company is a new entry in a market. Other campaigns intend to provide information to the customer; rather than stimulating sales directly, this type of campaign will target customers who are at the decision-making stage and are comparing the different products. Finally, some promotional campaigns are used to reinforce the brand to increase the opportunity for repeat purchases by customers, increasing the relationship with the company.

Companies find it very important to measure the return on investment (ROI) that each dollar invested in promotion will generate for the company. Hence, if a company can demonstrate a promotion's influence on sales, it will be able to justify further budget increases. It is important to be able to justify the returns and not blindly invest money in nonmeasurable activities.

The most common way of measuring the effect of promotions is analyzing sales or market share data over a set period. Hence, if over a set period, sales have not changed following a promotional activity, the company might conclude there is no effect in continuing this activity. It is also possible to measure success by doing a consumer survey to measure the level of satisfaction or experimenting on markets by targeting two geographies differently (for example, running an ad campaign in some cities and then comparing sales in both geographies). These two methods are more costly and are often used by larger corporations.

Prospectus

A prospectus is a document that provides detailed information about an investment. The prospectus first arrived in the investment arena with the Securities Act of 1933, which was created to improve investor confidence, prohibit fraud and misrepresentation in securities, and facilitate the creation of the Securities and Exchange Commission (SEC). The Securities Act emerged after litigation showed that investors did not have access to reliable information on which to make an informed decision regarding the investment. Thus, a prospectus has two purposes. First, it acts to protect investors from unreliable, fraudulent, or missing information. Second, a prospectus also acts to protect investment firms from dishonest investors claiming that they were not informed about the investment.

In the United States, a prospectus is considered a legal and binding agreement between a firm and its investors. This document must contain information on the public offering, the firm, its industry, financial statements, management, legal agreements, risks, and concerns. If any of this information is missing or incorrect, the prospectus becomes null and void. The SEC also requires that the prospectus be written in clear and concise language. Highly legal or technical language is discouraged. The SEC requires that all publicly traded firms and investments (such as mutual funds, bond funds, and real estate investment trusts) have a prospectus on file and sent to investors. Firms that are not publicly traded are not required to file a prospectus. It must be updated annually or with any significant change in the investment's strategy or structure.

When an investment is initially placed for sale to the public (such as initial public offering or IPO), the firm representing the investment is required to write a prospectus. A preliminary prospectus (also known as a red herring because of the color of some of the print on the cover) is written before the stock sale goes into effect. It provides all of the information required in a final prospectus except the offer date and price, because those may not be known at the time. When the sale of the investment is made effective and the offer date, price, and final number of shares offered is known, a final prospectus is written and filed. The final prospectus supersedes the preliminary prospectus.

Similar to investments into public firms, the SEC also requires that a prospectus be filed by the managers of mutual funds and provided to their investors. Mutual fund investors also must be provided a prospectus upon investing. The regulations regarding mutual funds differ slightly from those for public firms. For example, investment companies of closed-end funds (which are created with a fixed number of shares and investors are allowed to purchase shares either during the fund's first round or on a secondary market) are required to provide the fund's prospectus only to the investors in the first round. Investors purchasing shares of a closed-end fund on the secondary market may not receive a prospectus since the purchase is through another investor and not the fund.

Mutual fund and closed-end fund prospectuses must contain information about three main areas: the logistical information of investing, the fund's strategy and performance, and its management. The logistical information of investing includes details about the date of issue, fees, expenses, pricing, and share purchase and redemption. The strategy and performance information includes details about past performance, the investment's objectives, investment strategies, risks of investing in the fund, and past performance. It will also contain a bar chart showing the total returns for the fund at the end of each of the last 10 years, or the life of the fund if it was issued within the last 10 years. The bar chart will be followed by a table summarizing the before and after tax returns for the past one, five, and 10-year periods. Management information includes the identities of fund managers and advisers and will often include biographical information as well. Last, the fund's SEC file number will be provided on the back page.

The laws surrounding prospectuses vary by country and each stock exchange has differing regulations regarding the content and review of prospectuses. For example, firms in the European Union must abide by the EU Prospectus Directive. Those seeking admission to the Hong Kong Stock Exchange abide by the Hong Kong Companies Ordinance, the Securities and Futures (Stock Market Listing) Rules of Hong Kong, and the Hong Kong Listing Rules. The Australian Stock Exchange is governed by the Corps Act, which requires a security's prospectus to be reviewed by the Australian Securities and Investments Commission. The Singapore Stock Exchange requires that the Monetary Authority of Singapore review each prospectus under the Listing Manual & Securities & Futures Act.

Prudential

Prudential plc is a holding company headquartered in London, England, created in October 1999. The company was founded in 1848 as the Prudential Mutual Assurance Investment and Loan Association and provided loans secured by life insurance to professional people. Prudential became a limited company in 1881 and became a public company listed on the London Stock Exchange in 1924. In June 2000, it also listed its shares on the New York Stock Exchange.

As of December 31, 2007, Prudential listed approximately 75,948 shareholders. It is an international retail financial services company currently managing over £267 billion in funds derived from its customers, policyholders, and clients in Asia, the United States, and the United Kingdom. Prudential plc employs over 28,000 people around the world. The Prudential company is structured around four core business units: Prudential Corporation Asia, Jackson National Life Insurance Company, Prudential UK, and M&G. Group. Strategy, reputation management, cash and capital management, leadership development and succession, and other core functions are handled centrally.

Business Units

Prudential Corporation Asia was formed in 1994 in Hong Kong as a regional head office. Prudential Corporation Asia currently has life insurance and asset management operations in 13 markets across Asia: China, Hong Kong, India, Indonesia, Japan, Korea, Malaysia, the Philippines, Singapore, Taiwan, Thailand, Vietnam, and the United Arab Emirates. Prudential Corporation Asia serves over 10 million customers in these markets, with some 410,000 agents providing savings, investment, and protection products tailored to each local market. Its top life insurance markets in Asia (as a percentage of total new life business) for 2007 were Korea (19), Taiwan (18), India (13), Hong Kong (13), and Singapore (10). Prudential Corporation Asia manages 17.4 billion pounds worth of branded mutual funds (equities, fixed income, private equity, and structured products) for retail investors, and manages £19.6 billion of institutional and internal assets. Its top retail mutual funds markets in Asia (as a percentage of total new business) for 2007 were Japan (250), India (21), Korea (20), Taiwan (12), and Singapore (7). Prudential Corporation Asia has strategic partnerships with CITIC Group in China, ICICI Bank in India, and the Bank of China International in Hong Kong.

The Jackson National Life Insurance Company was named after Andrew Jackson, the seventh president of the United States, and was founded in Jackson, Michigan. In 1961 Jackson was acquired by the Prudential Group in 1986 and is now headquartered in Lansing, Michigan. Jackson National Life Insurance Company provides products and services in all 50 states as well as the District of Columbia. Jackson provides variable annuities, fixed annuities, fixed index annuities, term insurance, and life insurance targeted to clients in the mass and mass-affluent markets in the United States through independent broker-dealers, regional broker-dealers, independent financial agents, and financial institutions. In 2005 Jackson acquired the Life Insurance Company of Georgia (now JNL Southeast Agency) with more than 100 career agents who also sell its products directly to customers residing in the southeastern United States. Jackson also sells institutional products such as guaranteed investment contracts (GICs), funding agreements, and medium-term notes (MTNs). Jackson's Curial Capital subsidiary provides financial professionals with fee-based separately managed accounts (SMAs). Jackson's affiliated network of independent broker-dealers, National Planning Holdings (NPH), is the investment holding company for four firms: INVEST Financial Corporation, Investment Centers of America, SII Investments, Inc., and National Planning Corporation.

M&G originated in 1901 as the Municipal and General Securities Company and was acquired by Prudential in 1999. M&G is Prudential's European fund management business, with assets of some €167 billion (of which some €116 billion are internal corporate funds). M&G now runs operations in Germany, Austria, Luxembourg, Italy, France, Switzerland, and South Africa. M&G is composed of the M&G Asset Management business and Prudential Capital (renamed in 2007 Prudential Financial). M&G manages about €22.3 billion of retail assets invested in equities, fixed income instruments, and property. Its retail business offers open-ended investment companies (OEICs), investment trusts (ITs), individual savings accounts (ISAs), personal equity plans (PEPs), and mutual funds to investors in the UK, Europe, Asia, and South Africa.

Prudential Portfolio Managers (PPM) is the management entity for Prudential's institutional funds. M&G manages some €28.9 billion of institutional assets for pension funds, insurance companies, and other financial institutions. It offers both segregated funds and pooled funds, as well as structured and private finance products. PPM Ventures provides private equity finance through offices in London, Paris, Munich, and Sydney. Prudential Property Investment Managers (PruPIM) is the property investment part of M&G with global property investments, including its Singapore joint venture Asian property fund entity, PRUPIM.

Prudential UK provides retirement savings and income solutions for its seven-plus million retail customers in the United Kingdom. These products and services include individual annuities, individual and corporate pensions, lifetime mortgages, and health insurance. The company also operates selectively in the wholesale market for insurance through bulk and back-book buyouts that appear actuarially favorable. Prudential UK uses a number of channels to reach customers: direct (telephone, mail, and internet), financial advisers and partnerships, and business-to-business advisers and consultants.

As suggested by its name, Prudential seeks to secure profitable growth through long-term value while acting responsibly with integrity. For its fiscal year 2007, Prudential delivered a European Embedded Value (EEV) calculated operating profit from its long-term business of 15.4 percent, about £2,542 million, and its International Financial Reporting Standards (IFRS) calculated an operating profit about £1,213 million. The operating profits by business unit for 2007 were as follows: Prudential Corporation Asia accounted for 41 percent of the EEV operating profits and 17 percent of the IFRS profits; Jackson National Life Insurance Company accounted for 25 percent of the EEV operating profits and 30 percent of the IFRS profits; Prudential UK accounted for 34 percent of the EEV operating profits and 36 percent of the IFRS profits; and M&G accounted for 17 percent of the IFRS profits.

Prudential Financial

Prudential Financial (Prudential Financial, Inc.), as a holding company, is one of the biggest insurance companies in the United States. The company offers a variety of financial products and services, including life insurance, mutual funds, annuities, pension and retirement-related services, asset management, banking and trust services. Prudential Financial operates largely in the United States, but also in over 30 other countries. Prudential Financial incorporated in 1999 and now employs around 40,000 people (as of January 1, 2008). Its headquarters is located in Newark, New Jersey. Prudential Financial is quoted in the New York Stock Exchange with the ticker symbol of PRU. It has approximately 2.5 million shareholders (as of January 1, 2008).

Prudential Financial generates its revenues from four business divisions: insurance (28 percent of its revenues in 2006), investment (22 percent of its revenues in 2006), international insurance and investments (26 percent of its revenues in 2006), and closed block business (24 percent of its revenues in 2006).

The insurance division includes Individual Life, Individual Annuities, and Group Insurance segments. The Individual Life segment provides individual variable life, term life, universal life, and nonparticipating whole life insurance products. The Individual Annuities segment offers individual variable and fixed annuity products through independent financial planners, banks, and agents. The Group Insurance segment provides group life, long-term and short-term group disability, long-term care, and corporate and trust-owned life insurance products to institutional clients.

The investment division includes Asset Management, Financial Advisory, and Retirement segments. The Asset Management segment provides investment management and advisory services, mutual funds, and other structured products. The Financial Advisory segment provides trading, investment services, equity sales, and research operations. The Retirement segment provides recordkeeping, actuarial advisory services, planning, communication services, and institutional and retail investment funds to public, private, and not-for-profit organizations.

The company's international insurance and investments division offers private banking, proprietary and nonproprietary asset management, and investment advice and services to high-net-worth retail clients and to institutional clients in certain international markets. The international insurance and investments division includes international insurance and international investments segments. The international insurance segment provides individual life insurance products to foreign countries.

The company's closed block business is managed separately from its financial services business. The segment includes the closed block assets and certain related assets and liabilities, including its "IHC debt."

Prudential Financial has numerous subsidiary companies. These include, but are not limited to, Prudential Equity Group, Pruco Securities, Prudential Investment Management Services, Pruco Life Insurance Company, Pruco Life Insurance Company of New Jersey, and the Prudential Insurance Company of America.

Prudential Financial was founded in 1875 to operate as a provider of industrial insurance to workers and people of limited means. During the 1950s, Prudential Financial established regional home offices across the United States to reinforce its operations. Its common stock began trading on the New York Stock Exchange in 2001. The company reorganized its operations into four divisions in 2002. Prudential Financial preferred to grow by acquiring other insurance companies. As a result, it acquired Jennison Associates Capital Corporation in 1985; acquired Kyoei Life Insurance, a Japanese stock life insurance company in 2001; and acquired Aoba Life Insurance Company of Japan in 2004.

There are many reasons why Prudential Financial is successful. First of all, the company has a diversified product portfolio, including a range of financial products and services to various client segments. A wide collection of services enhances the company's cross-selling opportunities. The second reason is Prudential Financial is one of the largest financial services companies in the United States. The company's leading market position gives it a competitive advantage against its rivals. The company also owns a multinetwork distribution channel, including advisers, fee-based consultants, specialized consultants, independent financial planners, insurance agents, banks, and direct channels. This strong distribution network provides Prudential Financial with many profitable opportunities.

Public Finance Reform

Public finance is concerned with the financing and administration of government activities—and thus includes taxation, expenditure, fiscal policies, monetary reform, and so forth. Public finance reform seeks to streamline and improve these activities.

Tax Reform

Not all advocates of tax reform want the same thing. In the United States, tax reform efforts in recent years, and ongoing, have focused separately on the abolition of income tax; the adoption of a flat tax instead of the progressive income tax rate in use; the "FairTax" that would replace federal income tax with a federal progressive sales tax; shifts of the tax burden to or away from one class of society or another; and state-specific concerns, such as the ongoing debate over sources of tax revenue in New Hampshire, the only state with neither sales nor income tax. In the United States, perhaps more than in some other countries or perhaps simply with uniquely American rhetoric, there is a special emphasis on the importance of fairness in taxation, harkening back to the "taxation without representation" thorn in the Patriots' side.

The means by which fairness is achieved can vary from party to party, persuasion to persuasion; for some it may mean taxing principally those who can afford to be taxed, for others it means a flat tax, and for still others it means taxing only those who participate in the systems and services funded by the tax. For some, a cigarette tax is a valid way to attach a tax to an opt-in item, the use of which no one enters into involuntarily; for others, it is an unfair tax that creates a special class of citizen.

Monetary Reform

Monetary reform calls for changes in the creation of money and maintenance of its supply. In the past, monetary reformers typically wanted a change to the government's stance on gold and silver—either the return to a gold standard or the adoption of bimetallism. There are still some who want to readopt a gold or other precious metals standard, but 21st-century monetary reformers are more likely to focus on the abolition of central banks and fractional reserve private banking, in favor of full reserve private banking.

Economists like Ludwig von Mises and the Austrian school criticize fractional reserve banking—in which banks are legally obligated to keep only a fraction of their cash in reserve, expanding the money supply by loaning money to one client that still belongs to another client—as a form of fraud, and blame it for the highs and lows of the business cycles. Money is created every time a new loan is approved, but this money is not represented by anything tangible; money represents obligation where it once represented a receipt for gold or other tangible assets. Full reserve banking was in use until the 19th century, and some reformers seek a return to it as an inoculation against the economic upheavals of the last two centuries. Critics of full reserve banking point out that a return to it would not be a reform of monetary policy so much as an abandonment of it, as banks would be all but unable to issue loans at all, and there would be no means through which the government could manipulate the money supply. (Interestingly, Islamic banking comes close to full reserve banking, because Muslim religious law proscribes the charging of interest. In practice, the banks find ways around this; a mortgage transaction may be conducted by the bank buying the home and selling it to the buyer in installments, rather than explicitly lending the funds to the buyer.)

Public finance reform is also a concern during times of transition. China has faced issues of reform as it adopts some free market initiatives; Hungary went through the same debates in the 1990s, when it shifted from a socialist economy to a free market one.

Public Relations

Public relations (PR) is the business function charged with planning and managing an organization's relationships with key stakeholders through the effective use of a range of communication channels and methods. The purpose of public relations is to gain and maximize the support of stakeholders for the organization and to ameliorate the risk posed by any who might be opposed to it.

The jurisdictional boundaries and precise function of public relations are open to some debate, and the role ascribed to it depends on where it is located within the organizational structure and the span of activity allocated to it. In some organizations, it is represented at board level and is regarded as essential for strategic decision making; in others, it is deployed as a tactical promotional tool and a part of the marketing function. This lack of consensus on the purpose and activity-set of public relations is reflected in the literally hundreds of definitions that seek to delineate and describe it. One that has broad acceptance is that proposed by the International Public Relations Association in 1978, which, as written by Sam Black, states that

> public relations is the art and social science of analysing trends, predicting their consequences, counselling organisational leaders, and implementing planned programmes of action which will serve both the organisation's and the public's interest.

This statement encapsulates a number of key features that help to explain public relations' inherent complexity and tensions.

Public Relations Definitions

First, the phrase *public relations*—this identifies that the function is responsible for those organizational relationships that are not private; they are available to scrutiny by others. The word *public* also introduces other concepts particular to the field. The "general public" often is identified as a "target" for public relations activity, because one of the many purposes of the discipline is to influence public opinion, often through the mass media. Also implicit is the notion of the "public sphere," where debate and discussion about issues affecting the general public and the nature of society itself occur. These debates, in turn, affect "public opinion."

A term specific to the field is *publics*. Publics are groups (usually called stakeholders in the business and management literature) who have characteristics in common. Thus, typical publics for organizations are employees; customers; the local community; financial investors and analysts; local and national government entities; suppliers and distributors; opinion formers; professional, trade and regulatory bodies; and increasingly, ill-defined online communities with multiple relationships with organizations. These groups, in turn, have specific labels within the practice. Hence, work with employees is called internal or employee relations; with customers, consumer or marketing PR; with local and national governments, public affairs or lobbying; and with financial investors and analysts, city or financial PR.

Stakeholding as a concept emerged in the 1980s. Stakeholders are those groups or individuals who both affect or are affected by an organization. A differentiating concept between the notions of stakeholders and publics is that the latter are active or potentially active and that they collect around interests, issues, or opportunities that usually have been created by the organization, for example, polluting the local environment, introducing new services, moving to a new location, or acquiring another company.

Second, the phrase *art and social science* illustrates the duality of the practice in that it has a creative side that finds expression in the problem-solving capabilities required of practitioners and in the tactics used in public relations programs such as imaginative events, creative writing, the use of powerful imagery, and the effective exploitation of channels such as newspapers or mobile technologies. The other side of the practice emphasizes that public relations is a measurable, scientific discipline that systematically employs communication tools to persuade target publics to think, feel, or, ultimately, behave in particular ways. To do this requires a knowledge of the social sciences, including psychology, sociology, politics, anthropology, philosophy, and management theory.

Third, the analytical and predictive aspects of public relations work point to one of its key tasks: to see the organization in context. Organizations are constantly affected by changes in the external environment. The social, political, technological, economic, and regulatory environment is in constant flux, and stakeholder reactions to these changes need to be monitored and predicted, because this could well alter stakeholder perceptions of and attitudes toward the organization. For example, if an organization does not adapt quickly to changes in attitude to a particular political regime, it may find itself out of step with the views of its stakeholders, who may then withdraw their support for its products or shares. Analyzing these broader trends and predicting their consequences is at the heart of issues management, a mainstay of strategic public relations.

Public relations seeks to create a "buffer" against undesired consequences by identifying those issues that are potentially dangerous to the organization and recommending mitigating courses of action. These recommendations may include that the organization must align itself to public opinion or, if this is not possible, recommend courses of action that will minimize the damage caused by being misaligned, for example, explaining why a plant has to be closed in an area of high unemployment. The key is that public relations is concerned with maintaining the organization's "license to operate" with the publics with which it is engaged and on which it depends. It also seeks to build a "bridge" to key stakeholders through communication so that those stakeholders are engaged with the organization in a positive way. Hence, when the organization is acting in ways that carry stakeholders' approval, they will become its supporters and ideally its advocates. Stakeholders with whom there is ongoing dialogue also act as a sounding board so that when organizations are about to act in ways that may alienate stakeholders, early warning signals can be detected.

Counselling Organizational Leaders

The role of public relations practitioners as counsellors of organizational leaders implies that it is a senior management activity. In some organizations public relations is relegated to a tactical role, often known as the "journalist in residence" role. In this position the public relations practitioner is treated as the "post boy," tasked with getting out the message in as favorable light as possible after all the important decisions have been made. In its strategic manifestation, public relations is seen as integral to decision making at the most senior level. It sets the context for decisions by providing the trend analysis and predictions indicated earlier, and it informs senior management of the likely consequences of decisions by predicting what stakeholder reaction will be. By facilitating good decision making and articulating the process and the resultant content, indeed often negotiating these factors with stakeholders, public relations again seeks to reinforce the legitimizing of the organization, and hence diminish risk.

Planning

Public relations programs are planned. They are not haphazard, but are purposeful and deliberate. Good practice mirrors typical business planning models and embraces four stages. Stage 1 is situation analysis, where research will reveal the context of the issue under consideration, the nature of the communication task, and the benchmark position. Stage 2 is program strategy in which objectives for the program are set, target publics identified, appropriate content designed, the overall approach and individual tactics decided, and the appropriate resources and timescales allocated. Stage 3 is implementation, where the strategy is executed and monitored. Stage 4 is evaluation, where the effect of the program is measured against the benchmarks and objectives set. It is estimated that in good organizations, up to 70 percent of the public relations work is planned, with the remaining 30 percent being taken up with capitalizing on ad hoc opportunities such as exploiting emerging topics in the media or dealing with crises.

Also implicit in the word *planned* is that the relationships that result from these communication programs will be long term and sustained. Indeed, if the "bridge" to stakeholders is to be a solid one, communication must be two-way, ongoing, and built on principles of openness, honesty, commitment, and mutuality in order to generate trust.

Ethics

The professional bodies for public relations practitioners, for example, the Public Relations Society of America and the Chartered Institute of Public Relations in the United Kingdom, have a code of ethics that states that public relations practitioners must not only serve their organization and clients with integrity and competence, but that they should also serve the public interest.

It is in this arena that much of the controversy surrounding public relations resides. There are numerous books that describe the excesses of public relations in furthering organization interests above the public interest, notably those by Sheldon Rampton and John Stauber. In the realm of political public relations, too, the concept of "spin doctoring," where spokespeople will, for example, put the best possible gloss on an unfeasible position, or even appear to lie or mislead by omission to justify a political decision, has done much to undermine public trust. The term *public relations exercise* is synonymous with slick activity that disguises deceitful intent. There is no escaping the fact that public relations is purposive and persuasive in intent and that in a democracy there are serious questions about the legitimate limits of persuasion, access to the public agenda by those who have the power and/or resources to buy professional help, and the nature of the relationship between the press and organizational and political spokespersons.

Activities

Public relations practitioners work in all industry sectors and for the public sector, nongovernmental organizations, and charities. They also work for a nation's political parties and for individuals seeking to represent themselves, whether they be football players or royalty. They work on short-term projects such as product launches, or on long-term behavioral change programs such as antismoking or climate change mitigation. At the heart of public relations work is change. Organizations and their publics engage with each other in a relationship where, ideally, both are seeking benefits either for themselves or for others and where both are prepared to give benefit in return. However, it has to be recognized that sometimes relationships are fostered for purely instrumental reasons, and even where relationships are mutually beneficial, the balance of give and return may vary over time. Implicit in the communication and relationship-building paradigm is proactivity, response, and adaptation to change.

The activities that practitioners undertake to effect that change are broad-ranging and include intelligence gathering and interpretation in order to advise senior management, issues and crisis management, and planning and implementing relationship-building programs with the key publics (or stakeholders) of the organization. In practical terms this may include activities such as organizing face-to-face or small group meetings, organizing events and exhibitions, managing and producing content for bespoke or bulk publications (including Web-based materials), media relations, corporate social responsibility activities, sponsorship, and corporate advertising.

Public relations is a fast-developing discipline. The emergence of new technologies along with the challenges of globalization have given it added prominence as organizations seek to establish and preserve their legitimacy with a growing number of diverse and demanding stakeholder groups. Organizations are defined by what they say about themselves and also by what others say about them. The ability of public relations to build and maintain relationships over the long term is being increasingly recognized as a vital element in the strategic capability of organizations and is essential if organizations are to maintain their license to operate.

Purchasing Power Parity

The theory of purchasing power parity (PPP) explains movements in exchange rates by changes in countries' price levels. It is derived from the "law of one price," which says that identical goods should sell for the same price in all countries if there are no impediments to international trade. If prices for an identical good differ, a profit can be made by a process of "arbitrage"—buying the good from a low-priced country and selling it in the high-priced country. This process will alter supply and demand and force the prices to converge to a common equilibrium level in each country, when expressed in the same currency.

The theory of PPP is simply the application of the law of one price to all goods in an economy and thus to the general level of prices rather than to the price of a specific good. The exchange rate between two countries should thus equal the ratio of the prices of the baskets of goods used in the construction of the price indices that measure inflation. This is known as "absolute PPP," because it refers to the exchange rate that should exist at a given point in time. In contrast, "relative PPP" is concerned with how exchange rates alter over time to maintain equal purchasing power. When a country's price level is increasing at a faster rate than the price level in another country, its exchange rate must depreciate to counteract the higher inflation in order to return to PPP. This occurs because foreign demand for goods in the high-inflation country will decrease because of the higher prices, while home demand for foreign goods will increase because they are cheaper. If changes in actual exchange rates, known as "nominal" exchange rates, are fully offset by changes in inflation, then the "real" exchange rate will remain constant.

The ideas underlying PPP can be traced back to scholars at the University of Salamanca in the 16th century, although the term was first used by the Swedish economist Gustav Cassel (1918) when suggesting a means of adjusting the exchange rates of those countries intending to return to the gold standard after World War I to account for inflation. Cassel's idea was picked up by John Maynard Keynes, who used it to argue against Winston Churchill's decision to return the British pound to its prewar parity against gold in 1925, because it overvalued the currency relative to its PPP level; the criticism proved to be justified, because British exports duly declined and unemployment rose sharply.

A simple way of assessing whether PPP is valid is to compare the prices of similar, or identical, goods across countries. A well-known example of such an exercise is provided by *The Economist* magazine's "Big Mac Index," which divides the local price of McDonald's Big Mac hamburgers around the world by the U.S. dollar price. By comparing this "PPP exchange rate" with actual exchange rates, the extent to which a currency is undervalued or overvalued can be measured. Although burgers cannot be traded across borders, and are thus not subject to arbitrage, the "Big Mac Index" nevertheless has an impressive record in predicting exchange rates, with currencies identified as overvalued tending to depreciate in later years.

The evidence from extensive testing of PPP is that the theory holds up well in the long run but poorly for shorter time periods and that it holds better for countries with relatively high inflation rates and underdeveloped capital markets. Deviations from PPP are caused by transport costs and barriers to trade, such as tariffs and quotas, which prevent arbitrage opportunities from being exploited. Deviations may also be because not all goods included in a price index are tradable. In addition, a component of household income is spent on services, such as healthcare, that cannot effectively be traded between countries and for which arbitrage, which drives PPP, is not therefore possible.

Because of deviations from PPP, international comparisons of gross domestic product per head using market exchange rates tend to give a misleading picture of international differences in productive potential and living standards. To correct for these differences, the United Nations International Comparison Project (ICP) collects data on the prices of goods and services for most countries in the world by calculating PPP exchange rates.

Qatar

With a population of about a million people and an area smaller than Connecticut, the 11,500 sq. km of Qatar are home to Al Jazeera, the Arab world's most popular television network; the U.S. military's Central Command; the Doha Round of World Trade Organization (WTO) negotiations; and the world's finest museum of Islamic arts. This small peninsula, jutting out into the Persian Gulf from the land mass of Saudi Arabia, has a free press and women's political rights, and dabbles in partial democracy.

With a long early history as a trading and fishing outpost, by the third century C.E., the peninsula witnessed active exchange of copper, spices, sandalwood, and teak from the east for purple dye, clothing, pearls, dates, gold, and silver from the Gulf region and elsewhere. By 628, Islam arrived via the Bahrain ruler who controlled the region, and fine textile crafts flourished. During the late 18th century, the Al Khalifa branch of the Utub tribe in Kuwait emigrated to Qatar. Accomplished sailors and skilled traders, Al Khalifa became the mainstay of commercial development in this region.

The Ottoman and British Empires had contesting imperial interests in the region. The British found the peninsula ideal for shipping routes to their colonies in India. Following World War II and India's independence in 1947, pressure for British withdrawal increased. Britain announced a political withdrawal from the Gulf region in 1968, resulting in Qatar's joining seven other Trucial States in a federation. Regional disputes ensued, and Qatar ultimately became an independent sovereign nation on September 3, 1971. In a bloodless 1995 coup, Emir Hamad bin Khalifa Al-Thani deposed his father to become the ruler of Qatar and ushered in a period of liberalization.

Only 40 percent of the residents of Qatar are of Arab descent, and international expatriates are crucial to the economy. Pakistanis and Indians contribute 18 percent each to Qatar's population. Qatar has the world's ninth-highest per capita income. It has the highest per capita gross domestic product in the Arab world, at $75,900. Its citizens pay no income tax, and Qatar is the second-least-taxed sovereign state in the world, after Bahrain. The economy has experienced a robust 7.8 percent growth per year. The country's primary export is liquefied natural gas, with enough reserves to supply global demand for more than a century. Oil is the second-largest export, with 1.9 percent of the world's reserves in Qatar.

To diversify away from fossil fuels, the Qatari government is investing heavily in tourism development. To create a cultural magnet for foreigners, the Pearl—

a $2.5 billion, 4 million-sq.-meter artificial island—is under construction. With five-star hotels, 2 million sq. meters of high-end shopping, and more than 15,000 residences, the Pearl is expected to attract 1 million visitors per year upon completion in 2010. The real estate industry has benefited from these immense projects. The Lusail City project, just north of Doha, will eventually house more than 200,000 people. Large-scale construction projects such as the Dubai Towers and the Aspire Tower in Doha's Sports City are expected to attract tourists and sports fans.

In 1995 the Qatar Foundation, headed by First Lady Sheikha Al-Missend, was established to fund education, science, and community development. Qatar is building an Education City in the capital, Doha. Six American and two Canadian universities already operate there, and the race is on to catch up to Dubai's huge Academic City.

Quality

Quality as defined by the American National Standard Institute (ANSI) and the American Society for Quality (ASQ) is the totality of features and characteristics of a product or service that bears on its ability to satisfy stated or implied needs. Quality is a subjective term for which each person has his or her own definition. Quality can be also understood as a product or service free of deficiencies. Quality matters to any customer, future employee, or manager and it affects the entire organization from supplier to customer.

All processes in an organization are affected by quality, from locating a facility, designing products and services, planning production and service processes, designing jobs and work activities, and managing the supply chain, to planning and scheduling the flow of products or flow of customers through the system. Quality is a competitive strategic issue, because it leads to increased productivity, lower rework and scrap costs, lower warranty costs, lower production costs, increased profits, improved company reputation, higher customer satisfaction, and expanded markets. Poor quality can be very costly to businesses and investors in the form of product recalls and lost customers. Numerous recalls of cars by General Motors in 2005 (more than 300,000 car recalls) and Chinese toy recalls in 2007 provide examples of serious quality issues. Poor-quality products and services result not only in higher costs but also lead to injuries, deaths, lawsuits, and more government regulations.

20th-Century Developments

During the last century, many leaders contributed to the field of quality and quality management. Walter Shewhart, who in 1931 introduced statistical process control (SPC) charts, noted that price has no meaning without quality. Dr. W. Edwards Deming (1900–93), a famous quality guru, insisted that managers accept responsibility for building good systems. He recognized the importance of viewing management process statistically and as a system. During World War II, he taught quality courses to the U.S. military, and after the war, he was invited to Japan to help the country take a census. Deming's teaching was instrumental in improving Japanese industry. He received Japan's highest honor, the Royal Order of the Sacred Treasure, from the emperor, and the Union of Japanese

Scientists and Engineers (JUSE) established the Deming Application Prize to recognize companies that had a high level of achievement in quality practices.

Deming synthesized his approach to quality in 14 Management Points, known as "A System of Profound Knowledge," which consists of four interrelated parts: appreciation for a system, understanding variation, theory of knowledge, and psychology. Deming identified two primary sources of process improvement: eliminating special causes of quality problems, such as specific equipment or an operator, and reducing common causes, such as poor product design or insufficient employee training. According to Deming, workers are responsible for 10 to 20 percent of the quality problems, and the remaining 80 to 90 percent are under management's control. He was against the use of final-product inspection as a waste of time and resources. He advocated continuous improvement, and he is known for developing a Plan-Do-Check-Act (PDCA) cycle, originally formulated by Walter Shewhart.

PDCA cycle is a four-step process for continuous improvement. Continuous improvement refers to both incremental changes and large and rapid improvements. These improvements may take many forms, such as enhancing value to the customer through new and improved products and services, reducing errors and defects, increasing productivity and effectiveness, and reducing customers' complaints. In the United States, Deming's teaching was ignored for many years, until in 1980 NBC aired the program, "If Japan Can, Why Can't We?" This was the beginning of Deming's recognition in the United States.

Another leader in quality was Joseph M. Juran (1904–2008), who believed strongly in top management commitment, support, and involvement in quality efforts. His definition of quality was fitness for use, not necessarily the written specifications. Juran created a "quality spiral" that shows that each element of the business process and each function— not just the final product or service—is important for the customer. Juran included quality in the strategic planning process. He proposed a "quality trilogy process" composed of quality planning (developing the products and processes required to meet customer needs), quality control (meeting product and process goals), and quality improvement (exceeding customer satisfaction levels of performance).

Philip B. Crosby (1926–2001) created the term *zero defects* and stated that there is absolutely no reason for having errors or defects in any product or service. According to him, "quality is conformance to requirements or specifications." In his book *Quality Is Free*, he emphasized that the cost of poor quality is understated and leads to a large loss in profits. He said that concentrating on making quality certain would increase profit by any amount from 5 to 10 percent of sales. Crosby introduced a quality management grid, which is divided into five stages of maturity and six measurement categories of evaluating process. This grid serves as the evaluation tool for operations that have potential for improvement.

In the 1980s Armand V. Feigenbaum introduced the *total quality control* term to reflect total commitment of management and employees throughout an organization to improve quality. In Japan this concept is called *company wide management*. The Toyota production system (TPS) and Japanese scientists contributed significantly to the current quality improvements. Dr. Kaoru Ishikawa (1915–89) promoted quality circles and quality improvement teams. They were very successful in Japan, where more than 20 million Japanese workers and supervisors have participated in quality circles and several million projects have been undertaken since 1960. Quality circles in the United States did not achieve the same popularity as in Japan. However, many leading American firms, such as General Electric, Ford, Coors, and Westinghouse were able to establish successful quality circles and process improvement teams. Many firms have an "employee suggestion box," for individual suggestions for quality improvement. Ishikawa created a cause-and-effect (or fish-bone) diagram that is instrumental in finding causes of poor quality.

Another Japanese engineer, Genichi Taguchi, contributed significantly to current quality topics. He explained the economic value of reducing variation, and he is known for "Taguchi loss function." His loss function is a quadratic function that is used to determine the loss to society when quality moves away from the target. The quality loss function is expressed in monetary units.

New Approaches

A new approach to quality is to build quality into the product and into the service. Interdisciplinary teams are created to improve quality in the design stage of a product or service. Managing processes to achieve maximum customer satisfaction at the lowest overall cost to the organization, while still maintaining process improvement, is called *quality management*. Planned and systematic activities implemented within the quality system that can be demonstrated to provide high confidence that a product or service will fulfill requirements for quality are called *quality assurance*. A systematic and independent examination or review whether quality activities comply with planned procedures and if they are effectively implemented to achieve objectives is called a *quality audit*. Quality audits can be performed by internal or external teams.

The global implications of quality are so important that the International Organization for Standardization (ISO) developed ISO 9000 standards, which were revised in 2000 into more of a quality management system. For companies doing business in Europe and globally, it is critical to be ISO 9000 certified. Also, many countries established national quality awards. The United States established the Malcolm Baldrige National Quality Award in 1987 to stimulate U.S. companies to improve quality and set as examples those companies that were successful in improving quality.

Among international quality awards there are the European Quality Award, the Canadian Quality Award, the Australian Business Excellence Award, and the Deming Prize in Japan. The American Society for Quality sponsors a number of individual awards, including the Armand V. Feigenbaum Medal, the Deming Medal, the E. Jack Lancaster Medal, the Edwards Medal, the Shewhart Medal, and the Ishikawa Medal. The George M. Low trophy is NASA's Quality and Excellence Award to contractors, subcontractors, and suppliers for excellence in quality and productivity. Many states have created various quality awards and excellence awards to recognize high-quality achievements in organizations.

Quality Control

The systematic approach to quality control was developed in industrial manufacturing in the interwar years. With the impact of mass production required during World War II, it became necessary to introduce a more rigorous form of quality control. Some of the initial work is credited to Walter Shewhart of Bell Labs, starting with his famous one-page memorandum of 1924.

Control charts are often employed to detect changes in a process mean over time. In the traditional approach, a sample is drawn, and the sample mean ($\bar{x}$) is calculated and plotted on a Shewhart $\bar{X}$ chart having control limits, which depict the extremes of pure chance fluctuations. A point outside the limits suggests that the process is off target. While a Shewhart $\bar{X}$ chart is relatively easy to use and interpret, according to W. H. Woodall, a cumulative sum (CUSUM) chart is more capable of detecting small changes in the process mean, as well as pinpointing the exact time when the process goes "out of control." Faster detection of significant changes means tighter control, which is necessary if corrective action is to be taken promptly.

Like Shewhart and CUSUM control schemes, an exponentially weighted moving average (EWMA), as discussed by J. M. Lucas and M. S. Saccucci, control scheme is easy to implement and interpret. The ability of the EWMA chart to detect small shifts in the process mean is on a par with the CUSUM chart and superior to the Shewhart $\overline{X}$ chart. Lucas and Saccucci argued that the EWMA chart is simpler to explain to the lay user than the CUSUM chart, by noting its similarity to the classical Shewhart $\overline{X}$ chart. Both the CUSUM and EWMA charts are more suitable for single sampling schemes.

A control chart procedure has been proposed for which the Shewhart $\overline{X}$ chart, the cumulative sum chart, and the exponentially weighted moving average chart are special cases. The procedure for constructing these charts has been described by C. W. Champ and colleagues.

A typical statistical test examines the validity of a null hypothesis, H_0 (the process is on target), against an alternative, H_A (the process has changed). A Type I error is said to occur if H_0 is rejected when it is true and occurs with a probability α. That is, the process is on target, but, by chance, lies outside the control limits. A Type II error is said to occur if H_0 is accepted when H_A is true and occurs with a probability β. That is, the process has deviated, but lies within the control limits. The power of a test is defined to be the probability of correctly rejecting a false null hypothesis, and is equal to $1-\beta$. For a given α, one test is more powerful than another if $1-\beta$ for the former is greater than for the latter for all possible changes in the process mean.

Referring to the process under consideration, assume a batch has a true mean μ. Let τ be an acceptable target value for μ; therefore a batch is acceptable if $\mu=\tau$. In this case H_0 is $\mu=\tau$ and H_A is $\mu\neq\tau$. If a batch is rejected when, in fact, the mean is $\mu=\tau$, this is unfair to the producer. This is called the producer's risk or Type I error, and occurs with a probability α. Conversely, if a batch is accepted when, in fact, the mean is $\mu\neq\tau$, this is unfair to the consumer. This is called the consumer's risk or Type II error, and occurs with a probability β.

The consumer's risk (β) depends on the absolute difference between μ and τ. This is the drift Δ, where $\Delta=\tau-\mu$. The sample size and control limits may be selected to obtain acceptable values of α and β for a specified Δ.

The Average Run Length (ARL) for a given Δ gives the average number of batches sampled till one is rejected. The ARL is dependent on both α and β and is an important factor in selecting a control chart. The plan (the sample size and control limits) is usually chosen so that the ARL is large (500 to 1,000) when the process is on target, and small (1.1 to 10) when the process changes by Δ. The criteria are acceptable risks of incorrect actions, expected average quality levels reaching the customer and expected average inspection loads.

All the charts described so far examine the sample mean. In a process the mean might appear acceptable, but there could be a change in the inherent process variation. To monitor this variability, a range chart should also be used.

Quota

A quota is a threshold quantity, used as either a minimum required (such as in a sales quota) or a maximum permitted (such as an import quota), depending on the context. The purpose of a quota is to control the degree of variation in a factor. A sales quota properly met ensures a certain amount of profit over the period of the quota; an import quota that is sufficiently less than the domestic demand for an item ensures a certain amount of domestic sales in that industry. A quota is not the same thing as a goal; a country imposing an import quota would probably be much happier with even fewer imports of that item, and a business requiring a sales quota certainly would like to see sales exceed them. Quotas are baselines.

Import quotas are devices used by protectionist governments—national governments that restrict trade with other nations, especially import trade, in order to "protect" domestic businesses, workers, and profits. Protectionism has been condemned for as long as capitalism has held sway; it was one of the foundations of the mercantilism criticized by Adam Smith, and nearly every economic school of thought in the two centuries since has said that the problems of protectionist policies outweigh their benefits. Nevertheless, in a struggling economy, they can appear necessary, or offer short-term gains (or stops to short-term losses) that are politically attractive.

Import quotas and administrative barriers are the most common protectionist actions after tariffs. They limit the amount of a particular good that can be imported into the country, by each foreign country, in order to reduce the impact that foreign goods have on the equilibrium point where the domestic supply curve and the demand curve intersect. Foreign goods may be significantly cheaper, more plentiful, or more desirable, their presence thus hurting domestic competitors. Import quotas clearly benefit domestic producers, not consumers, but the underlying theory when they are put in place is that the economy itself is being protected, which benefits consumers in a less direct way.

Such quotas are kept in place by requiring importers to seek licenses, permits, or other official permission for the goods they send to the country, which represents another problem: rarely is the government agency in charge of such paperwork capable of, or necessarily interested in, making sure that the quota is distributed principally to the best or most efficient producers. There is a "deadweight loss" to the global economy inflicted by such trade circumstances, as the presence of import quotas and the potential of rewarding any but the best producer interferes with the natural mechanics of the economy under free trade, artificially shifting circumstances away from those of the equilibrium that unrestricted market forces would naturally seek out.

On the other hand, import quotas are not used only to protect inefficient domestic producers from competing with better and more efficient foreign producers. Such quotas are often defended, in industry- and country-specific contexts, in order to prevent foreign producers from flooding the market with underpriced shoddily made goods, or from "dumping"—an act in international trade in which goods are sold for less than fair value. Many international trade agreements that otherwise strongly support free trade, such as the General Agreement on Tariffs and Trade and the World Trade Organization, allow restrictive actions such as quotas to be taken in order to prevent dumping.

A special type of import quota is the voluntary export restraint, which is voluntary only in the sense that it is adopted by the exporting country at the strong urging of the importing country. VERs were permitted under GATT and bilateral VER agreements were common, in which two countries would agree to restrict their trade of two types of goods—one import and one export—in an arrangement that theoretically benefited the economies of both countries.

Real Hedge

The meaning of a real hedge varies with the context in which it is used. A real hedge involves taking of positions by investors to alter their exposure to risk. The term *real hedge* is most widely used in the risk management literature to mean a hedge based on real options. A hedge is any device used by an investor to reduce the risk of a given investment. This can take the form of the purchase of any asset or array of assets to issue against fluctuations in wealth from alternative sources.

The distinguishing feature then of a real hedge is the kind of assets used in such a hedge portfolio or collection of hedge portfolios. If the hedge portfolio consists of only financial assets, then this is a financial hedge whereby the holder acquires the right to buy or sell a traded asset such as a stock. For example, a forward foreign exchange contract can be used by a company based in Europe that exports its products to the United States and is exposed to the risk of changes in exchange rates between the euro and the U.S. dollar. In a case such as this, if the firm exports goods worth US$10 million annually and there transpires a 10 percent depreciation of the U.S. dollar against the euro, it stands to lose €10 million per annum. The firm can sell U.S. dollars forward, thereby using a financial hedge to offset its exposure to foreign exchange risk in the short run. Considering long-run horizons, however, if the underlying transactions do not materialize because of unanticipated changes in business conditions, the intended financial hedge can be transformed into a form of financial speculation. A real hedge, based on real options, is more suitable in the long run.

A real option is the right to take a specific business decision such as making or not making a capital investment. An important distinction between real and financial options is that the underlying assets on which real options are based are not traded in competitive markets. This distinction thus also applies with respect to real hedges and financial hedges. Real options give an investor the flexibility to choose the most attractive alternatives subsequent to the availability of new information and thereby add value to investment opportunities. Real options are almost always investment specific. In the example above, the European-based firm has, at least in theory, the real option of starting up production in the United States. This specificity makes it difficult to describe a general theory of real options on which real hedging is based. There are, nonetheless, three main types of options that are commonly encountered in the literature. These are the option to delay an investment opportunity, the option to grow, and the option to abandon an investment opportunity. The option to delay an investment opportunity gives the firm a chance to choose an optimal time to commit to an investment and thus add value to it. The growth option entails a firm having a real option to invest in the future, especially when market conditions are better than expected. The growth options can involve expanding the capacity of an existing product line, going into new geographic markets, or adding new products.

The abandonment option is the option to walk away from a project. In the example above, the European-based manager does not have to be restricted to a financial hedge. The company can use a real option of shutting down production in Europe and starting production in the United States. This is subject to absence of barriers to entry in the U.S. market, if the firm does not have any facilities in the United States initially.

From this perspective of real hedging, the decision as to whether a financial hedge or real hedge should be adopted depends on whether the described level of risk is for the short run or part of a long-term problem. Empirical studies show a preference for financial hedges in the short run, while real hedges are more commonly used for the longer-term risk strategies. The decision also hinges on the costs and benefits of hedging, it being the case that the real cost of hedging is what the firm incurs by not hedging.

Recruitment

Recruitment is the process of generating a pool of qualified candidates for a particular job. The firm must announce the job's availability to the market (inside and outside the organization) and attract qualified candidates to apply.

To date most of the research conducted has addressed recruitment sources, recruiters, and realistic job previews. Once an employer has decided that external recruitment is necessary, a cost-effective and appropriate method of recruitment must be selected. There are a number of distinct recruitment sources to choose from, each of which is more or less appropriate in different circumstances. As a result, most employers use a wide variety of different recruitment sources at different times; the most prominent are the following (in many situations there is also a good case for using different sources in combination when looking to fill the same vacancy):

1. Current employees. Internal job postings give current employees the opportunity to move into the organization's more desirable jobs. Internal advertising has the advantage of providing maximum information to all employees, who might then act as recruiters. It also provides the opportunity for all internal employees to apply, and is speedy and cost-effective. Conversely, it is limited to a certain number of applicants, the internal candidates are not matched against those from outside, and it could be unlawful if it inserts indirect discrimination.
2. Referrals from current employees. Studies have shown that employees who were hired through referrals from current employees tended to stay with the organization longer and displayed greater loyalty and job satisfaction than employees who were recruited by other means. Employee referrals can be an effective recruitment tool, because employees have a good sense of what it takes to be a successful worker and member of the organization.
3. Former employees. An organization may decide to recruit employees who previously worked for the organization. Forming an online alumni network could be a simple and cost-effective way to maintain a hiring pool of competitive candi-

dates. Moreover, a network of former employees can be a source of employee referrals, because they are familiar with the company, its culture, and its values.

4. Print and radio advertisements. Advertisements can be used both for local recruitment efforts and for targeted searches. Advertising in the national press has the advantage of reaching large numbers and constitutes the accepted medium for search by those seeking particular posts. Conversely, the cost might be high and much of the cost could be wasted in reaching inappropriate people. Advertising in the technical and targeted press has the advantage of reaching a specific population with minimum waste, but it is inappropriate when a nonspecialist is needed or where the specialism has a choice of professional publications.
5. Internet advertising and career sites. Employers are increasingly turning to the Web as a recruitment tool, because online ads are relatively cheap, are more dynamic, and can often produce faster results than newspaper ads. For employers the principal attraction is the way that the internet allows jobs to be advertised inexpensively to a very large audience. The cost of setting up a good Web site is quite low. The other big advantage is speed. People can respond within seconds of reading about a job opportunity by e-mailing their CV. Shortlisting can also be undertaken quickly with the use of CV-matching software or online application forms.

   In practice, however, there are major problems. A key drawback is the way that employers advertising jobs tend to get bombarded with hundreds of applications. To prevent this, online shortlisting software that is able to screen out unsuitable applications must be used. Such technologies, however, are not wholly satisfactory. Those that work by looking for key words in CVs inevitably have a "hit and miss" character and can be criticized for being inherently unfair. The alternative is to require candidates to apply online by completing an application form or psychometric test. Other problems concern fears about security and confidentiality, which serve to deter people from submitting personal details over the Web. Criticisms have also been made about poor standards of ethicality on the part of cyber agencies.
6. Employment agencies. Many organizations use external contractors to recruit and screen applicants for a position. Agencies can be particularly effective when the firm is looking for an employee with a specialized skill.
7. University or college recruiting. Many organizations recognize that there is value in interacting with university or college students, developing relationships, and generating interest in the pool of candidates through activities such as company visits to college campuses, job fairs, and internships.
8. Customers. An innovative recruitment source is the organization's customers, who are already familiar with the organization and what it offers. Customers may bring more enthusiasm to the workplace than other applicants and, as the recipients of the firm's product or service, may have valuable insights into how the organization could be improved.

With regard to recruitment sources, it is expected that different sources might be associated with different recruitment outcomes. Two main explanations have been offered that try to understand this association. The realistic information hypothesis proposes that persons recruited via certain sources are likely to have more accurate information about what a job entails. Possessing such information is thought to enable an applicant to make a more informed decision about whether to pursue a job. Lacking such information, the individuals are thought to be less likely to be able to self-select out of consideration for jobs that may not be a good fit in terms of their skills and interests. If hired, these less-informed individuals are more likely to be unhappy with their job choice and may be more likely to resign. The second explanation is known as the individual difference hypothesis. This explanation is based on the premise that sources differ in the types of individuals they reach and that these differences result in different outcomes.

The human resource manager needs to monitor the effectiveness of the recruitment sources, first to ensure value for money, and second, to ensure that the pool of applicants produced by the various sources is suitable. Researchers have suggested four numbers to collect to monitor the effectiveness of the recruiting: (1) number of initial inquiries received that resulted in completed application forms; (2) number of candidates at various stages in the recruitment and selection process, especially those shortlisted; (3) number of candidates recruited; and (4) number of candidates retained in the organization after six months. There is also a good case for monitoring the numbers of men and women who are successful at each stage of the process and the numbers of people from different ethnic minorities. Where an imbalance becomes apparent, the organization can then take remedial action.

Recruiters and Job Previews

In addition, recruiters play a central role in the recruitment process, because applicants' perceptions of recruiters' behaviors (e.g., their willingness to provide information) and attitudes (e.g., their interest in the candidate) are associated with applicants' expectations of receiving a job offer and their reported probability of accepting the offer. In terms of recruiter demographic characteristics, there is a weak relationship between demographic characteristics and applicant reactions. However, it could be argued that similarity on certain dimensions with the recruiters might be important to job applicants, especially for variables such as job attractiveness. Finally, the evidence regarding the effect of recruiter experience, training, and functional area on applicants' reactions remains quite inconclusive.

Recruiters might have an effect on job candidates because they serve a key role in directly communicating information about a position and an organization to applicants. To carry out this communication role effectively, a recruiter needs to have both the ability to communicate effectively and personal credibility. Moreover, recruiters could be seen by applicants as signals of unknown aspects of the organization, especially when the applicants lack detailed knowledge of the hiring organization and when the recruiter is from their functional area.

Finally, realistic job previews play a crucial role in the recruitment process. A realistic job preview refers to the presentation by an organization of both favorable and unfavorable job-related information to job candidates. Most realistic job preview models hypothesize that providing realistic job information to applicants results in their having their job expectations met. It is further assumed that providing realistic job previews influences job clarity and individuals' perceptions that the organization is honest with them. Given that candidates perceive alternatives to accepting an undesirable job, providing a realistic job preview results in applicant self-selection, which, in turn, results in a higher level of job satisfaction, a lower level of voluntary turnover, and a higher level of performance.

In addition to the above-mentioned traditional sources of recruitment, many companies recruit from nontraditional labor pools and use innovative methods to attract new employees. Nontraditional labor pools can include prisoners, welfare recipients, senior citizens, and workers from foreign countries.

Other Considerations

An integral part of many organizations' recruitment efforts, both externally and internally, is attracting women, minorities, people with disabilities, and other employees in the protected groups. Many private sector employers believe that policies such as affirmative action make good business sense for them. A good rule of thumb is to target potential recruits through media or recruitment methods that focus on minorities. However, when a company puts too much emphasis on hiring of minorities in ads, candidates may feel resentful or believe they are being hired simply to fill a quota. Thus, recruitment experts say that minority candidates should be addressed the same way all candidates are.

It is also important to provide certain types of documentation to recruits as a means of focusing their minds on whether the job will suit them or not. Documents that are commonly provided for applicants are the following: a copy of the relevant job description and personnel specification, a copy of the advertisement for reference purposes, a copy of any general recruitment brochure produced by the organization, the staff handbook or details of a collective agreement, details of any occupational pension agreements, and general information about the organization. It is also essential to have some method of tracking recruitment, so that an immediate and helpful response can be given to applicants inquiring about the stage their application has reached. It is also necessary to ensure that all applicants are informed about the outcome of their application. This will reduce the number of inquiries that have to be handled, but it is also an important aspect of public relations, as the organization dealing with job applicants may also be dealing with prospective customers.

Finally, it is useful and far more satisfactory to have in place a fair and objective system for shortlisting candidates that produces the best group of alternative candidates to move forward to the interview stage. This can be achieved by using a panel of managers to undertake shortlisting, reducing the likelihood that individual prejudices will influence the process. Another way is by employing a scoring system with which to score each CV or application form received against the key shortlisting criteria identified at the start of the process.

Redundancy

In business terminology, redundancy is the condition of having more employees—specifically, more man-hours of labor—than there is work that needs to be done. Though desirable in some sense, as it can be the consequence of improved efficiency particularly if demand does not increase enough to take up the slack, from the employee's point of view it is a workplace bogeyman, leading to the dreaded layoffs.

Changes to a company can also lead to redundancy—even if the company is expanding, it may find itself with employees it no longer has work for, such as if a merger results in combining departments or middle management positions. Restructuring often follows a leveraged buyout of a company, especially with the aim to improve efficiency and profitability—nearly always leading to lost jobs. Because the collective bargaining agreements of labor unions may include clauses restricting layoffs, companies may try to attract volunteers for "voluntary redundancy."

Like the passenger bumped off an overbooked flight in exchange for free tickets another time, voluntarily redundant employees are given financial incentives in exchange for terminating their employment. The financial incentive will usually be a reasonable severance package, and in some cases there may be pension benefits awaiting; voluntary redundancy is often offered to the older employees, for much the same reason that early retirement is encouraged. As the average age of the company decreases, so—as a broad rule of thumb—does its average wage. Voluntary redundancy severance packages may include a continuation of pay over a certain period, a bonus payment, and assistance in job searching. Benefits specific to the company's industry may also be included—when Delta Airlines offered a voluntary redundancy package to some of its employees, one benefit was free airfare on Delta flights for a limited period of time. Positive letters of recommendation are, of course, to be expected as well, and there is no particular stigma attached to having left a job because of voluntary redundancy.

Restructuring often leads to renegotiating labor contracts while retaining—even rewarding—upper management, which can make involuntary layoffs an option even at companies where the collective bargaining agreement previously limited them. This is the sort of redundancy that is typically referred to by one euphemism or another: *downsizing, smartsizing, rightsizing, simplification, workforce optimization.* Thanks to euphemism drift—the process by which one term after another is introduced to replace the one that has become sullied by its associations with a negative thing, like *recession* replacing *depression*, which replaced *panic*—these terms have become as reviled as *layoff* and *redundancy*. The term *attrition*, on the other hand, specifically indicates that the positions being vacated will be eliminated.

Workers who are laid off involuntarily may or may not be offered a severance package, though it is typical and traditional to do so. The severance package typically includes an extension of benefits coverage (health and life insurance) for several months to a year after termination of employment; a balloon payment based on length of employment; and compensation for unused vacation or sick days. Additional payments may be made to employees in some cases in order to compensate for a lack of notice before termination; this becomes common when companies worry about morale and performance of employees aware that they are being forced out of the company. Layoff severance packages may be predetermined by company policy or labor union agreements. Employees who are involuntarily laid off are eligible for state unemployment benefits; voluntary layoffs usually are not.

Reentry

Reentry of expatriates (or repatriation) refers to the process and the outcomes of the return to the home country of employees who have been sent on assignments abroad. The reentry of expatriates has been given minimal attention until recently, as most practitioners and scholars focused on problems faced by expatriates during their stay in the host country (which is termed *expatriation*). However, in recent years it has become evident that repatriates also face substantial problems, which incur negative consequences for both themselves and their employers.

It is not unusual for repatriates to experience an intense cultural shock (which signifies the inability to accept and adapt to differences between the culture one is familiar with and the culture one is required to live and work in) when they return to their mother country after completing their assignments. It can be similar to the cultural shock experienced by expatriates when they are sent abroad. This is because these individuals have stayed for substantial amounts of time (normally for a minimum of three years, but in some cases for considerably longer) in countries with different cultures and have adapted and functioned within these cultural environments. Cultural values, assumptions, habits, and behavioral patterns are entirely learned. Hence, during the assignment to the host country, individuals tend to learn and acquire the cultural characteristics of the host country, while at the same time they unlearn (or set in latent mode) the cultural features of their home country. In this sense, repatriation may require similar levels of cultural adaptation as expatriation.

There are, however, additional problems that go beyond cultural readaptation. These can be categorized in terms of problems in personal readjustment and problems in reabsorption to the home country workplace. Problems in personal readjustment include the loss of fringe and other benefits that are typically enjoyed by expatriates; loss of certain privileges; and in some cases, "demotion" in the cultural lifestyle. For example, expatriates normally enjoy attractive financial packages that are lost upon return to the home country; a fact that forces them and their families to adjust to lower standards of living. At this point it must be kept in mind that in most cases personal readjustment includes the family, which tends to play a pivotal role in the lives of the majority of individuals.

Problems in reabsorption to the home country workplace include dealing with organizational changes while abroad. It is likely, for example, that during the time the individual has been abroad, the home country unit the individual was based in restructures and the individual's position either becomes redundant or less pivotal. It is also likely that while abroad key peers, mentors, and allies of the individual in his/her home country workplace are transferred or leave the organization.

Other problems may stem from technological advances in the home country operation while abroad. Such advances are likely to make the knowledge and skills of the individual (for which he/she was sent abroad in the first place) obsolete in the home country; meaning that the value the repatriate adds to his/her company upon return has to be reconsidered and adjusted at lower levels. The home country unit in which the individual was based may also learn to operate without him/her, and may "forget" the contributions and value of the individual.

It appears that the majority of repatriates experience work readjustment and reabsorption problems in various degrees. These are likely to result in negative evaluations of the organization, which may be manifested in terms of repatriates' perceptions that they have been "demoted" upon return to the home country, that their acquired foreign experience is neither appreciated nor used, and that the organization misled them in its promises. These, in turn, are translated in low motivation and high turnover intentions. Indeed, evidence suggests that repatriates are significantly more likely than other employees to leave their employer.

Because of the problems experienced by expatriates, and consequently by their employing organizations, a number of methods have been developed to manage the transition back home smoothly:

- Establishing repatriation agreements. This should take place before the individual leaves for the expatriate assignment. Repatriation agreements reduce the likelihood that false expectations develop and, hence, reduce the likelihood that repatriates feel that they have been misled or betrayed by their employer.
- Mentoring or sponsorship during the expatriate assignment by senior colleagues or peers in the home country. This increases the likelihood that individuals are kept informed on changes and developments in the home country while abroad and, hence, reduces the likelihood that individuals face totally unexpected situations upon return.
- Maintenance of regular contact between the home operation and the individual during the expatriate assignment. This can be achieved in terms of regular memos as well as briefings during the visits of the expatriate to the home operation. The advances in information and communication technology greatly facilitate the implementation and running of such policies.
- A dedicated human resources unit to deal with repatriate and expatriate issues. Some large corporations have resorted to the establishment of such units. The specialist unit can function as a link between the individual and the home country and can assess the personal and professional needs of the individual before his/her return to the home country in order to identify (a) areas in which the repatriate can contribute to the home operation and (b) knowledge, skills, and competencies of the repatriate that need improvement.

Repatriates are at risk for a number of problems and may be much more likely to leave their employer than other staff.

Regiocentric Human Resource Policy

A multinational organization is able to pursue one of a number of different approaches in relation to its international staffing. One of these approaches is the regiocentric staffing approach. A regiocentric approach is applicable to situations where regional groups of subsidiaries reflecting the organization's strategy and structure work as a unit. Where multinational corporations structure their organizations based on regions, they are more likely to view their staffing on a regional basis rather than on a host-country basis. A regiocentric staffing approach is one where the human resource policies reflect the strategies used by the multinational organization in that particular geographic region. This approach is similar to a geocentric approach in the sense that a wider pool of managers is used. Unlike the geocentric approach, however, the movement of managers is restricted. Under this strategy, regional staff have the capacity to move outside their countries, but they are limited to their geographical regions. While regional managers are also not able to be promoted to positions at headquarters outside their region, they do experience autonomy in terms of decision making within their regional boundaries.

A regiocentric staffing approach develops regional staff for key positions anywhere in the region that is defined by the multinational organization. For example, a United Kingdom–based company could differentiate into a number of different regions, including western Europe, eastern Europe, North America, Latin America, the Caribbean, southeast Asia, the Pacific Rim, the Middle East, and west Africa. Their staff could easily be transferred between countries in the western European region (e.g., from the United Kingdom to France; from Ireland to Italy), however, transfers between the regions (e.g., United Kingdom to Japan) would be rare. Regiocentric policies allow multinational organizations a means of gradually progressing from a strictly ethnocentric or polycentric approach to a more geocentric approach by breaking down the steps of transition.

Regiocentric staffing policies can involve the use of a mixture of host country and parent country nationals. Given the regional focus, all transfers within the region are considered to be host country nationals. Where parent country nationals are used, they are more likely to be allocated to a region rather than a particular country.

Because local subsidiaries are staffed almost entirely by host country nationals, the staffing policy is one that reflects sensitivity to local operations with less corporate integration, similar to the polycentric approach. Language and culture barriers are reduced alongside the costs associated with hiring. Additionally, this approach allows interactions and the sharing of information between those managers who have been transferred to regional headquarters from subsidiaries within the region and the parent country nationals who have been posted to regional headquarters.

The disadvantages associated with a regiocentric approach mirror those that accompany the use of largely host country nationals. Because of the high levels of control given to regional managers, the levels of control held by global headquarters may be inhibited. Furthermore, although a regiocentric approach does improve career prospects at national levels, opportunities are largely limited beyond the given subsidiary or region of operation. Thus, while opportunities may exist at the level of regional headquarters, these seldom extend to those at parent headquarters. Because a regiocentric approach constitutes a large concentration of host country nationals, there is also a risk that it can produce federalism among the regional units, rather than on a national basis. This, in turn, may hinder the organization from establishing a global stance.

Research has shown that better-performing multinationals are more likely to make use of regional transfers. Multinational organizations in certain regions may, however, experience difficulties finding adequately qualified managers to staff their operations. Those located in emerging markets such as China, eastern Europe, southeast Asia, the Middle East, and Africa, in particular, may encounter difficulties locating managers with the right mix of skills necessary to manage regional operations. In these situations, it is far more likely that parent country nationals will be posted.

Regional Development Banks

Regional development banks (RDBs) are public regional financial organizations established by governments of countries in a region with an aim to spur economic development in a region (or continent). They are, to a large extent, the result of mimicking the International Bank for Reconstruction and Development (IBRD), better known as the World Bank. However, the focus of the regional development banks is somewhat narrower, and they usually do not have as large a portfolio of services. Regional development banks are the product of the 20th-century trend of promotion of multilateral diplomacy.

The era of multilateral diplomacy basically started with the end of World War I and the attempts to create a long-lasting peace in Europe. Although the United States actively participated in World War I (from 1917) the U.S. Senate did not look favorably at further U.S. involvement in European affairs and full U.S. participation in the League of Nations. So, although the Bank for International Settlements (BIS) was created to support financial stability in Europe, acting as the "bank of the central banks," it has, to a large extent, failed to play the role that it was supposed to play.

The end of World War II brought another attempt to create a more efficient and stable world order, where the basic ideals of democracy and universal freedom would be upheld. With the establishment of the Organization of United Nations (OUN), a large part of the political infrastructure has been set up, while the Bretton Woods institutions (IBRD and the International Monetary Fund, or IMF) were created to cover the economic sphere. The IBRD had more or less universal coverage, operating in the majority of the countries. However, already in the late 1950s, there was dissatisfaction with the World Bank, and a series of regional financial organizations were set up. Although they are regionally based, some founding members are not countries from the region, but are the leading countries in the world (most Organisation for Economic Co-operation and Development [OECD] countries are founding members of regional development banks).

Regional development banks share the same broad objective with the IBRD, which is to promote the social and economic development of the population of their beneficiary member countries through the provision of financial assistance. However, over time, most of the regional development banks are providing, increasingly, technical assistance in the implementation of the project, as well. Although regional development banks are regarded as regional (public) financial institutions, they are still banks. They may not be profit-driven organizations, but they have to ensure that their operations have some surpluses that can be reinvested in the bank. These banks are characterized by a broad membership, including both borrowing developing countries and developed donor countries, and are not limited to member countries from the region.

All regional development banks are multilateral organizations that are established by both countries that are beneficiaries (clients) and those countries that have interests in promoting economic development, and are usually providers of finance, rather than users of the banks' funds. All the banks have a separate legal structure, although a closer look at their internal organization and modus operandi suggests that IBRD was the blueprint for designing their internal infrastructure.

Banks operate through loan support to the beneficiary member governments for a specific project and/or program. They are lending institutions, not the donor agencies. Their loans focus on one of three areas: works, supplies, or services. In the first area, the focus is on infrastructure projects, especially those that can promote sustainable development and spur economic growth. Financing for acquiring supplies usually focuses on particular goods (for instance, medical supplies), while services focus on technical knowledge—consultancy and/or other various technical assistance projects.

Banks will grant short- to medium-term credit at market rates, and one of the advantages is that usually what the regional development banks may finance, some purely commercial banks/entities would not consider economically viable and would not extend credit at regular market rates. Long-term credits are often granted to less developed countries (LDCs) to support development in a particular area. Often these credits may be given with a generous grace period, or very easy terms for servicing, compared to the usual market rates and conditions.

Some regional development banks have a private (finance) arm, which supports economically viable projects that come from private persons/entrepreneurs. Increasingly, both international and regional development banks are looking for new ventures in the near future and to improve the visibility of these projects.

Examples

At present the most well-known regional development banks are the Asian Development Bank (ADB), the African Development Bank (AfDB), the Inter-American Development Bank (IADB), and the European Bank for Reconstruction and Development (EBRD). There also are the Caribbean Development Bank, Central Asian Development Bank (CADB), Black Sea Trade and Development Bank (BSTDB), Islamic Development Bank (IDB), Central American Bank for Economic Integration (CABEI), East African Development Bank (EADB), West African Development Bank (BOAD), and others. There are also other organizations that are genuinely multilateral and promote development in third world countries. Those are the International Fund for Agricultural Development (IFAD), Nordic Development Fund (NDF), and OPEC Fund for International Development. There are also two banks that are regional but that have more than a classical development function, because they operate primarily in highly developed Western countries: the European Investment Bank (EIB) and the Nordic Development Bank (NDB).

ADB, AfDB, IADB, and EBRD are "real" multilateral development banks that focus on a particular region but that have in their membership both regional and nonregional members, and the membership is rather wide. In other cases, the membership is usually regional, and the countries that own the bank are, at the same time, the beneficiaries. Often the creation of these regional banks has been connected with the discovery of oil and significant inflow of oil money and the desire to support sustainable development from mineral extracting revenues. Regional development banks that are less multilateral and do not have any or significant numbers of regional members are often referred to in the World Bank parlance as "subregional development banks."

Regional development banks have primarily been organized to serve developing countries and only in

Financing from the African Development Bank reached this Egyptian firm via a 2005 deal with the National Bank of Egypt.

the case of the EIB is there a quasi-development bank operating in the advanced industrialized economies (and new member states that have graduated in the process of economic, political, and social transition). The target countries are often subjected to serious economic and financial crises, and there is relatively little that can be done about their stability from the global level. The provision of financial and economic stability may be a task for the national governments, but a longer view is also needed to see to what extent the regional policies may assist in development of financial stability.

Regional development banks have been serving and will probably continue to serve not only as a source of financial resources for worthwhile projects that the governments of member states cannot fund or are not within their immediate priorities, but they will also continue providing technical assistance and sound development advice. Even the EIB is an active investor that offers assistance in management of the projects and provides necessary advice. RDBs are expected to continue supporting, along with the World Bank, the implementation of so-called second generation reforms to create an institutional setting adequate for a modern market economy, encompassing the rule of law, promoting property rights and adequate enforcing mechanisms, giving transparency to economic and political activities, improving financial regulations and supervision, strengthening the financial institutions (banks, microfinancial institutions, financial markets, and so on), and furthering similar structural reforms.

Overall, the role of RDBs is important, because they primarily operate through financing projects in the real sectors of economy and therefore could provide stabilization behavior ex ante. They are also active in the long-term end of finance provision, and therefore they can offer long-term solutions in securing stability and holding off occasional systemic shocks. And, finally, they are, as a rule, in a "coterminosity" position with the Bretton Woods institutions (World Bank and IMF) when it comes to promotion and enforcement of far-reaching structural reforms. These reforms are much needed in countries in the process of building a modern, vibrant, functioning market economy and addressing adverse remnants of past (state-dominated) economic behavior.

Regional Divisions

A regional division is a multinational firm's organizational structure by which the primary division of the firm is by a small number of geographic regions. For example, an insurance firm may be primarily divided into four regional divisions (Americas, Africa/Middle East, Asia/Pacific, Europe), and each of these divisions may then contain various product, market, and country structures.

A school of thought exists, largely led by Alan Rugman and associates, that sees regionalism as an a priori level of analysis. However, most writers seem to understand the regional mind-set with respect to global and multinational mind-sets. Whereas the global mind-set sees the similarities across markets and tends to compete as if national borders did not exist and the multidomestic philosophy recognizes the uniqueness of national markets and organizing the firm to compete at that level, the regional philosophy seeks to emphasize that there are significant similarities within the world's geographic regions.

The traditional way to think of regional divisions was as some variation on the "multidomestic structure." Thus, having recognized the uniqueness in the Argentinean versus the Brazilian versus the Colombian national markets, and granted some level of autonomy to subsidiary businesses units in each country, the firm with a regional worldview would likely set up a South American regional office. The basic purpose of this regional division would be to coordinate and aggregate managerial efforts for this part of the world. However, the region itself may have a strategic imperative—for example, to growth, profit, or innovation—searching for synergies within the region and may give different countries within the region different strategic roles.

Thus, for example, the Nestlé Group has three global geographic zones (Europe, Americas, and Asia/Oceania/Africa), each headed by a zone director who reports to Nestlé's CEO and also sits on the corporate board. Additionally, as an indication of the local responsiveness (or multidomestic) aspect of the overall structure, it is telling to note that each of the geographic zones is divided into individual countries or country groups. For example, the Americas zone contains the Latin American and Caribbean groups and the United States and Canada.

The other way to think of regional divisions is as a variant of a global strategy and structure. Thus, the baseline mentality would be one that considers the world as one market and tends to ignore national boundaries. However, the firm may see some strategic advantage to setting up a few regional divisional offices for some combination of administrative/control and strategic purposes. Microsoft, for example, which has a highly integrated global strategy and standardized products, has hundreds of local sales offices clustered into six regions, namely Asia, Europe, Middle East and Africa, North and Central America, South America, and South Pacific. These offices are mainly for marketing, sales, product support, and customer service.

George Yip reminds us that a region does not necessarily imply geographic proximity. He provides the example of Gillette, which uses a socioeconomic/usage criteria resulting in countries like Canada, the United States, Britain, Australia, and New Zealand being included in the same region. Another example comes from the Nissan Corporation. In addition to its corporate headquarters in Japan, Nissan has three regional offices with various roles. The North American office in Tennessee serves as headquarters for North American operations, for the manufacturing and sale of vehicles and auto parts. Nissan International SA, based in Switzerland, covers the management of European sales and manufacturing operations. And Nissan Europe S.A.S, based in France, is a holding company for European subsidiaries and pan-European operational support.

The regional concept is more relative than taxonomical. Structures of contemporary multinational firms are complex, commonly featuring global, regional, multidomestic, matrix organizations.

Regional Integration

Regional integration is an arrangement between nation states to cooperate in some comprehensive way for their mutual benefit. The term usually applies to neighboring states, and it usually entails a series of agreements to benefit the well-being of the region—for example, by promoting free trade, enabling easier flow of financial transactions, implementing uniform environmental and other legal standards, and allowing easier travel within the region. The scope of integration can grow to issues like security, culture, environmental protection, and social issues, and may extend also into the political realm. The aim of the integration is explicitly to benefit the members of the region (or bloc), but it comes at the cost of national sovereignty.

According to Luk Van Langenhove and colleagues, regional integration initiatives have the potential to fulfill important functions that are beyond the sphere of trade integration, such as the creation of an appropriate enabling environment for private sector development; the development of infrastructure programs in support of economic growth and regional integration; the development of strong public sector institutions and good governance; the reduction of social exclusion and the development of an inclusive civil society; contribution to peace and security in the region; the building of environment programs at the regional level; and the strengthening of the region's interaction with other regions of the world.

There are several forms of regional integration, each with varying levels of commitment and influence. Oded Shenkar and Yadong Luo discuss four forms of economic integration (or trading blocs) as follows: First, a free trade area is the least restrictive and loosest form of trading bloc among countries and aims to abolish all barriers to trade among member countries. The North American Free Trade Agreement (NAFTA) is an example of this form of integration. The next level is the customs union, whereby member nations dismantle barriers to trade in goods and services among themselves; it establishes a common trade policy with respect to nonmembers—for example, the Central American Common Market. A common market includes the features of the customs union with additional mobility of factors of production such as capital, labor, and technology as well as a common external trade policy by which members should cooperate closely in monetary, fiscal, and employment policies. Finally, the economic union is the ultimate form of regional economic integration that simply aims to eliminate all barriers that may impede trade and other economic interactions among member nations. As with the example of the European Union (which evolved from the European Common Market), members aim to harmonize monetary policies, taxation, and government spending, and a common currency would be used by all members. Beyond this level is the concept of "political union" that results in a single political entity like the United States.

Examples of prominent regional economic agreements are the Andean Community of Nations (CAN for Comunidad Andina de Naciones), Association of Southeast Asian Nations (ASEAN), Asia-Pacific Economic Cooperation (APEC), European Union (EU), Mercosur/Mercosul, and North American Free Trade Agreement (NAFTA). These agreements are never etched in stone and often change. However, the general historic trend is toward growth, strengthening, and affiliation to these blocs. For example, beginning from the Treaty of Rome in 1957, six European nations (France, Germany, Italy, Netherlands, Belgium, and Luxembourg) formed a customs union that grew in stages to become a common market and, in 1995, to the EU with 15 members. In 2007 EU membership was extended to Romania and Bulgaria so that total membership is now 27 members, and ongoing negotiations for future membership are also under way with a number of other states including Turkey.

More recently, in 2008, the Union of South American Nations (UNASUR or UNASUL) was formed largely by merging two existing South American customs unions (Mercosur and CAN) as part of a continuing process of South American economic and political integration. UNASUR is modeled on the European Union. However, it is unique in that it includes every sovereign nation on the continent (with the exception of French Guiana), and is currently working for the introduction of a regional identity card that will eliminate the need for passports for travel by citizens of members within South America.

The overall effect of these trends is not only a strengthening of regionalization but also adds to general globalization trends. Opinions differ as to whether this is a good or bad effect. Authors like Luk Van Langenhove, Isabella Torta, and Ana-Cristina Costea, who believe that institutions need to counter the trends toward globalization, argue that regional integration can itself be a significant factor in tackling deleterious global trends and forces. They argue that regional governance structures can be important in backing and complementing nation states and other international organizations. For example, they believe that, because regionalism entails building relationships among member nations, interactions and cultural ties will also improve, and these will facilitate the reaching of interstate agreements. These agreements have some chance of standing up for the rights and values of citizens of the region. For example, they may value environmental standards, labor conditions, protection of intellectual property, support for basic food prices, or other issues of local rather than global significance.

Regional Trade Agreements

A number of multilateral trade agreements have accelerated the pace of global integration. NAFTA has expanded trade between the United States, Canada, and Mexico. The General Agreement on Tariffs and Trade (GATT), which was ratified by more than 120 nations in 1994, has created the World Trade Organization to promote and protect free trade. In Europe, the expanding membership of the European Union is lowering barriers to trade within the region. In Asia, the expanding membership of ASEAN (Association of Southeast Asian Nations) is promoting closer economic cooperation and trade within the member southeast Asian nations.

The WTO and NAFTA

The World Trade Organization (WTO), previously known as GATT, is a 123-country organization whose objective is to promote trade among its members. These countries account for over 90 percent of world trade. There are about 20 countries from the industrialized nations of the West, including Japan, and over 100 members or associates from the less developed countries. To achieve its aim, the WTO has over the years provided a forum where countries have met to negotiate on tariffs and trade. As a result of these forums or conferences, the tariff rates for tens of thousands of items have been reduced, and a high proportion of world trade has seen an easing of restrictions.

In 1988 the United States signed the North American Free Trade Agreement (NAFTA) with Canada, the scope of which was enlarged in 1993 to include Mexico. The United States, Canada, and Mexico promote economic growth via expanded trade and investment. All three governments acknowledge that free trade will help all countries to meet the economic challenges of the future. The gradual elimination of barriers to the flow of goods, services, and investment, coupled with strong intellectual property protection, will benefit all. Canada and Mexico rank first and third as the United States's most important trading partners (Japan ranks second).

The European Union

The European Union is composed of 27 independent sovereign countries, which are known as member states: Austria, Belgium, Bulgaria, Cyprus, the Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, the Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, and the United Kingdom. The European Community (EC) was established by the Treaty of Rome, which came into force on January 1, 1958. A step-by-step reduction of internal customs duties on industrial goods resulted in their complete removal by July 1, 1968. Simultaneously, the duties applied to imports from third countries were gradually aligned, and the common external tariff within the EC also came into force on July 1, 1968, and there was a target of removing all internal barriers to the movement of goods and services by 1992.

A common agricultural policy has been adopted and the removal of internal agricultural duties has been completed. The external customs duties for the majority of agricultural products, which are subject to EC regulations, were suspended and replaced by variable import levies designed to bring the price of products imported from third countries in line with those prevailing from inside the community. The community has made progress in abolishing restrictions on the movement of capital, in the alignment of taxes, and in developing a community policy on competition, and restrictive practices such as price fixing, and company mergers. In addition, EC companies have received freedom for workers from member countries to obtain employment anywhere in the community and freedom for firms to establish and operate anywhere in the community.

The Treaty of Rome also provided for links between the European Community and the colonies and other dependencies in Africa and elsewhere of France, Belgium, the Netherlands, and Italy. The first association agreement signed in 1963, known as the Yaounde Convention, which was renewed in July 1969, specified duty-free entry for industrial goods to the common market and also specified that agricultural products subject to EC market regulations and some tropical products would enjoy a slightly improved preferential treatment in the EC. The associated African states may reimpose duties or other restrictions on imports for the EC if it is necessary for their economic development.

In 1975 the EC entered into a new trade and economic cooperation agreement with 46 African, Caribbean, and Pacific countries (ACP). The agreement, known as the Lome Convention, allowed the EC duty-free access to all the industrial goods and 96 percent of the agricultural products of the ACP. This agreement was extended to 70 ACP countries. Included in this agreement was an Export Revenue Stabilization Plan through which the EC provided development assistance to the ACP countries.

The economic influence of the EC expanded to the other developed countries in western Europe as well. In 1972, when the European Free Trade Association (EFTA) members Britain, Denmark, and Ireland joined the EC, it agreed to establish a free trade area with the remaining EFTA members (Iceland, Norway, Sweden, Finland, Austria, and Switzerland). Since then the European Union has continued to expand; it has developed its own currency, the euro, and has expanded the union to include the 27 countries that form the European Union today with other countries, e.g., Croatia, the Republic of Macedonia, and Turkey recognized as potential candidate countries interested in joining the European Union.

Association of Southeast Asian Nations

Finally, the Association of Southeast Asian Nations (ASEAN) was established in 1967 in Bangkok to accelerate economic progress and to increase the stability of the southeast Asian region. The member countries are Brunei, Malaysia, Singapore, the Philippines, Thailand, Indonesia, Myanmar (Burma), Laos, Vietnam, and Cambodia. Vietnam became the first communist country in the group when it was admitted in 1995. Cambodia and Laos were admitted to ASEAN in 1997. Myanmar was admitted in 1998. The countries have agreed to eliminate most tariffs by 2010.

The ASEAN industrial complementation program, begun in 1981, encourages member countries to produce complementary products in specific industrial sectors for preferential exchange among themselves (for example, components to be used in the automobile industry). Member countries have negotiated tariff reductions within the association and a customs code of conduct has been adopted.

Although the 10 countries of ASEAN are geographically close, they have been divided in many other respects. In mid-1987 President Corazón Aquino of the Philippines urged the association to become a real political and economic force, and it is well on its way to achieving that, with ASEAN becoming a platform upon which new expanded regional economic organizations such as Asia-Pacific Economic Cooperation (APEC) developed in the 1990s.

Regulation

As embodied in administrative rules, public regulation is any attempt by the executive branch of government to implement statutory law controlling the behavior of citizens, business and nonprofit enterprises, and subunits of national or state/regional/ provincial governments. In effect, public regulation is the government's attempt to limit the choices available to the regulated entity. The focus here, however, will be on the government's regulation of business enterprises and achievement of policy goals. In industrialized nations with democratic forms of government, the legislative branch enacts statutes that codify public policy. These statutes, or laws, are then executed by the executive branch or, in some cases by independent agencies, which implement the law through the development and codification process of administrative rule making. These administrative rules are used to guide agency oversight activities and to assess penalties against the regulated party for noncompliance. The judicial branch is responsible for ruling on the constitutionality of administrative rules or legislative intent in the law. It does not have to be an "all-or-nothing" judicial decision, as sections of a regulation may be judicially upheld or struck down.

There are two approaches to analyzing business regulation: positive and normative analysis. Positive analysis examines when and what type of business regulation will occur, while normative analysis asks when government agencies should intervene in private markets. It is normative analysis that presumes government intervention is required in cases where competitive markets do not exist to an optimal level, resulting in "market failure" allocating resources inefficiently. In the public interest, political leaders will subsequently intervene to correct this market failure by enacting laws and codifying and implementing public regulations.

Market failure conditions exist when (1) negative externalities occur, a condition when business transactions create uncompensated costs for third parties, including abuses of "public goods" such as common natural resources, or negative internalities, where the regulation of product quality or workplace safety, for example, are not reflected in market exchanges; (2) there are natural monopolies, such as public utilities, when economies of scale are of such a magnitude (also referred to as an "entry barrier") that a market can be serviced at the lowest cost only if production is limited to a single product; and (3) when market participants have inadequate information for markets to allocate resources efficiently. There is also a moral rationale for instituting business regulation. Elected representatives may put forth utilitarian fairness and justice ethical rationales to establish health and safety standards of behavior to protect employees, consumers, and other stakeholders.

"Public choice" economics provides another perspective on the normative analysis of public regulation. According to the public choice perspective, government officials, elected officials, and those in the executive branch and interest groups (including the business community) pursue their private interests in the regulatory arena with the same enthusiasm they individually display in the private market arena. Therefore, the pursuit of public regulation should be recognized as nothing more than an effort by government officials and interest groups to use public authority to redistribute income from one interest group to another, maximizing private gain at the expense of others. According to the public interest perspective, any benefits accruing to private groups from lobbying efforts to obtain these *regulatory rents* should not be considered as a subversion of the democratic process, but only as a reflection of the nature of the regulatory process.

From a positive analysis perspective, public regulation comes in essentially two forms: economic or social. Economic, or competitive, regulation is the oldest form of regulation and is most often industry specific (although industry wide as pertaining to, for example, labor issues) with public agencies concerned about the overall economic performance of the industry, while seeking to compensate for market failure by mimicking market conditions through administrative rule-making procedures. This form of regulation uses economic controls on prices, interest rates, and wages (using price ceilings or floors); places restrictions on the quantity of goods; establishes service territories; limits the number of participating firms; and allocates public resources. While some scholars view antitrust as a form of economic regulation, a stronger case can be made for the promulgation of antitrust, or competition, laws as an effective tool for avoiding public regulation, thus leaving resource allocation to competitive market forces rather than public regulators. The absence of competition in the marketplace is more likely to result in direct public regulation of price and profits or direct public regulation of a good or service. When antitrust policy fails to prevent the creation or maintenance of private monopoly power through the use of unfair business practices, direct public regulation is the usual response by government officials in a democratic market society.

The normative public interest justification for most economic regulation is to control prices established by so-called natural monopolies. While economic regulation has as its intention to protect consumers by adjusting prices so that they are equal to the competitive market price, there is no guarantee this will occur when decided by a public regulatory authority. There are five major reasons for this regulatory outcome not to occur: (1) regulatorily established prices that are below competitive market levels can create shortages, deterioration in the quality of service, or other problems diminishing consumer welfare; (2) regulation can hold prices above costs, thus increasing prices and reducing consumption; (3) regulation and monopoly inflate costs, thus firms fail to operate at minimum cost; (4) regulation stifles innovation and entrepreneurial incentives to lower costs, improve quality, and develop new products and services; and (5) expenditures by business firms or groups to retain monopoly profits, or to protect themselves from below-competitive prices that expropriate assets, is considered wasteful and may even exceed the size of the wealth transfer ("regulatory rent").

Social Regulation

Social, or protective, regulation is a more recent form of public regulation—emerging in the 1960s and 1970s—and tends to be industry wide in coverage (although industry-specific as it pertains to, for example, the consumer safety of a specific pharmaceutical). The purpose of social regulation is to improve the quality of life or social conditions by protecting individual members of society from mainly noneconomic public policy issues concerning the adverse effects of discrimination or serious risks to public health, safety, or the natural environment. As commerce has become increasingly global in nature, the public health and safety of imported products has become a serious regulatory concern, especially from developing countries importing their products into developed countries' economies. Social regulation may directly affect the conditions and physical characteristics under which products are manufactured (see command-and-control approach below). The normative public interest justification for most social regulation, particularly those addressing health, safety, and environmental concerns, is due to "externalities" or "information asymmetry."

Social regulations can be designed by agencies using a number of compliance approaches. A command-and-control approach to regulation specifies in the administrative rule the technologies which a business enterprise must adopt in its operations to be in compliance. An output approach to public regulation specifies a performance level, but not the production methods, which a company must meet to be in compliance with the administrative rule. An incentive approach to regulation offers economic benefits to companies—which exceed a technical performance standard—by allowing these companies to sell their unused credits to other companies not meeting the technical performance standard in the administrative rule. Lastly, a disclosure approach to regulation allows consumers to make informed purchasing decisions on products or services by providing accurate information on their attributes to the potential buyers. In a descending order of magnitude following command-and-control public regulation, these respective regulatory approaches each represent a declining level of direct government intervention in business operations and consequently, an increasing emphasis on market-based solutions.

Because social regulation so often concerns people's health and safety, risk assessment analysis is often applied to this form of administrative rule. Risk management analysis employs the science of risk assessment (which attempts to find out how much risk is presented by a certain factor "X"), as well as other pertinent information, and to find out how much risk is too much for society to accept. To acquire these answers, public regulators must balance the risk with the costs and benefits of reducing it. The evaluative methodologies applied to risk assessment include (1) risk-risk analysis, which compares the risks associated with regulating with the risks associated with not regulating; (2) cost-effectiveness analysis, which compares the cost of different approaches to meet the legislative charge underpinning the administrative rule against a quantitative metric—such as life-years saved or tons of pollutants removed from the atmosphere; and (3) cost-benefit analysis, which attempts to quantify and assign dollar values to the benefits and costs of different policy approaches. Economic regulation can also be evaluated using the above-cited methodologies of cost-effectiveness and cost-benefit analyses.

Self-Regulation

While public regulation receives the most attention, there is also a growing interest in private regulation, also referred to as self-regulation. Self-regulation, in its broadest sense, involves planning and policy making regarding issues and activities not covered by public regulation. Self-regulation exists when a firm, an industry (or profession), or the business community establishes its own standards of behavior, through a code of conduct or ethics, either self-established or adopted, or technical specifications where no such statutory or regulatory requirements exist, or when such standards assist in complying with or exceeding existing statutory or regulatory requirements. In general, self-regulation is a voluntary activity that involves behavior or activities (such as abiding by social, political, environmental, or economic principles) of a discretionary nature.
