INSIDER TRADING

Insider trading is the act of buying or selling company stocks and securities based on information not known to the public. An insider is considered any officer, manager,

or executive of the firm in question; in some cases, it can also be a person who was given the proprietary information by a company figurehead. Generally, insider trading is illegal, but there are laws and regulations that some are willing to skirt in order to practice trading that they consider "legal" insider trading.

Insider trading is considered by many people to be no different than outright stealing. U.S. laws concerning insider trading have become increasingly more strict throughout the years and include swift punishment for those who garnered the insider information to make the trades as well as those who do the trading, regardless of their involvement or relationship (or lack thereof) to the firm. Several laws now protect companies and employees from insider trading and its negative impact on stocks and the open market in general. Even firms with highly globalized presences with identities on all the world markets now have the legal protection to combat insider trading.

U.S. LAWS AND REGULATIONS AGAINST INSIDER TRADING

Insider trading laws have evolved with the open market since its onset, but many were born after the devastating crash of the stock market in 1929. The 1934 Securities Exchange Act is the backbone for almost any law or regulation against insider trading as well as other types of securities fraud. Considered an appendage of (or sister to) the 1933 Securities Act, the Securities Exchange Act reaches further to protect stocks, while the Securities Act covers issues more germane to securities. Essentially, sections 16(b) and 10(b) of the Securities Exchange Act outline unlawful trading practices and these sections explain— through various rules of the U.S. Securities and Exchange Commission (SEC)—exactly what fraudulent trades are and who can perpetrate them. The 1934 act also denotes when a trade is considered unlawful.

Insider trading can cause major shifts in what the public chooses to do in terms of buying or selling of a firm's stocks or securities. This is the main reason why stocks and companies, as well as their shareholders, must be protected against trades that are based on information that is unknown to the public. In a 1966 federal court case (*SEC vs. Texas Gulf Sulphur Company*), it was decided that any person who is party to information not yet publicly known about a firm's stocks or securities has a duty to stockholders and to the firm in question. The privy person can either choose not to trade and sit on the information, or share what he or she knows in a public manner so that everyone can benefit. In this way, the shareholders and the company's holdings are not devalued by trades based on the information at hand.

Many of the parameters that determine the difference between legal and illegal insider trading are determined by the SEC. According to the SEC, the two most recent rules (10b5-1 and 10b5-2) further protect both investors and companies by outlining exactly when information is considered public or nonpublic and by determining when exceptions are to be made (for example, when a trade is made but the person trading can prove that it was made on the basis of something other than nonpublic information). Additionally, 10b5-2 explains when a person would be required to pay a penalty for use of insider information and what, exactly, constitutes misappropriated information in regards to information used by parties with no direct ties to the firm in question.

EFFECTS AND FUTURE OF INSIDER TRADING

The rules and regulations established by the acts of 1933 and 1934—as well as various court cases that further tailored the laws against insider trading—were further built upon, reexamined, and revised following the boom of corporate mergers in the 1980s. It was not until this time that it became illegal to sell insider information. The case *United States vs. Newman* made it illegal for the first time for a nonrelated party, not just a company insider, to engage in trades based on nonpublic information.

The laws and regulations against insider trading have become progressively more severe because the potential negative effects that insider trading can have are devastating. With mergers on the rise as they were in the 1980s, and with more money invested in the stock market by more people than ever before, insider trading is again a deadly threat. Businesses moving to a global stage will want to protect assets to the best of their abilities, and a strong policy against insider trading is a crucial aspect of that protection.

The United States has the reputation for the least acceptance and lowest tolerance for insider trading. Other major world players—including China, India, and members of the European Union—have started to adopt many of the same perspectives and laws concerning insider trading of stocks and securities as corporations from every locale move in the multinational direction.

INSTANT MESSAGING

Instant messaging (IM) is a general term encompassing a variety of software applications that enable users to have real-time text conversations, play turn-based games, and share pictures, music, and data files over the Internet. IM is quickly replacing e-mail as the preferred method for rapid communication both within and without the corporate community. IM software allows users to maintain a list of contacts—sometimes referred to as a buddy list—which they can use to exchange messages whenever both parties are online. These messages appear in a dialogue box on the computer or mobile device screen that both the sender and the recipient can see. The most popular IM utilities—America Online Instant Messenger (AIM), Microsoft MSN Messenger, Yahoo! Messenger, and Google Chat—offer a number of other features, including chat rooms, voice communication, and streaming content capabilities.

While each different IM utility is proprietary, they all work on a client-server model. Client software resides on the user's computer and connects with a central server. Users open an IM session by logging into their account on the server. The server makes a record of the Internet address of the user's computer, then calls up the user's buddy list and checks to see who else is online. Once this information is provided to all connected clients, the buddies can exchange messages directly in real time.

IM has exploded in popularity since ICQ, the first free, public instant-messaging utility, was introduced in 1996. Many fans of IM took the technology to work with them, downloading IM client software onto corporate computer networks and using it as a tool to facilitate business communications. IM offers both advantages and disadvantages in the workplace. Proponents claim that it boosts employee productivity by allowing them to get immediate answers from co-workers and suppliers. Sales personnel and help desk technicians, in particular, find that it enables them to serve customers more effectively. Businesses can also use IM to conduct virtual meetings and facilitate collaboration on group projects. "Backers say IM, once dismissed as a plaything for the under-twenty set, dramatically speeds up the flow of information in and out of a company," Esther Shein wrote in *CFO*. Google Chat, made available in the Google apps bundle in 2006, offers possibly the most user-friendly model for the workplace.

Most public IM utilities were created for personal use, which can create problems in a business setting. But most importantly, IT managers emphasize that public IM is not a secure form of communication. "When a user carries on a discussion with the person in the cube right next to him, if it's not a corporate IM utility, the message doesn't go from one computer right next door to the other one," network security consultant Dan Wooley explained on InstantMessagingPlanet.com. "It goes out of the corporate network and across different networks and then back to the other person's desk." As a result, anyone with access to the networks in between can intercept message traffic, potentially exposing confidential business information. IT managers also point out that the major public IM clients do not provide monitoring, virus protection, encryption, or other features usually associated with corporate IT applications. Finally, some business managers question whether IM truly increases productivity or instead creates a source of distraction for employees. How productively IM is used varies from one place of work to the next.

Despite such potential problems, however, many businesses are reluctant to block IM for fear of alienating employees who rely upon it. Instead, businesses have increasingly sought to manage its use through enterprise instant messaging (EIM) solutions. One approach involves implementing a software application called an IM gateway, which can intercept, log, and approve communication that takes place through the corporate network using public IM systems. Other companies choose to develop their own in-house IM systems, which can be designed to include such features as user authentication, network security, virus and spam protection, message encryption, and message archiving. Logging and archiving of messages is particularly important in light of Securities and Exchange Commission rules that require companies to retain electronic correspondence that divulges key corporate information.

Some IM applications available on the Internet are moving away from the notion that they have to be engineered with all work and no play in mind. Applications on sites such as Twitter.com and other IM services (like the MySpace.com messenger) are geared more toward simply checking in from time to time. And while some more progressive companies may use a network like Twitter.com to establish regular check-ins, the predominance of messages on these types of networks are purely for entertainment and social value.

With proper management, IM technology is likely to play an important role in future business communications. "Instant messaging is just one of a whole Swiss Army knife set of tools that will be used to conduct business," Nate Root of Forrester Research stated in *CFO*. As one application under an umbrella of collaborative methods that can be used by several people at once (such as company-wide Web accessible calendars, domain management software, and security tools), IM is the method by which all other telecommuting tools are managed by groups and their administrators. The newfound ability to tele-collaborate, or communally manage projects and day-to-day business via multiple locations, is a trend brought on by IM that will shape the new face of business tomorrow.

INTELLECTUAL PROPERTY RIGHTS

Intellectual property is a term used to cover goods and services protected under the laws governing patents, trademarks, copyrights, and trade secrets. Although the legal rights concerning different kinds of intellectual property are similar in a general sense, they differ specifically in what they protect and in how the particular rights are established. Patents protect an inventor's right to exclude others from making, manufacturing, using, or selling an inventor's invention. Trademarks protect words, phrases, symbols, and designs. Copyrights protect original artistic, musical, and literary works, including software. Intellectual property rights can also encompass state trade secrets laws, which protect a company's proprietary and confidential information, such as methods of manufacturing, customer lists, supplier information, and the materials used during the manufacturing process.

PATENT RIGHTS

A patent is a grant of a property right by the United States government, through the Patent and Trademark Office (PTO), to the inventor of an invention. In 1995 U.S. patent law was changed so that it would conform to the World Trade Organization's Agreement on Trade-Related Aspects of International Property Rights as decided in the Uruguay Round. Applications filed on or before June 8, 1995 have a term of twenty years from the earliest filing date. Applications pending on June 8, 1995 and patents that were in force on this date have the longer term of either seventeen years from the issue date or twenty years from the earliest filing date. Design patents, as opposed to

utility patents, have fourteen-year terms. Some patents require the payment of patent fees. A patent is not a grant of the right to make, manufacture, use, or sell the invention, but rather the right to exclude others from making, manufacturing, using, or selling the invention.

The power to grant rights in patents arises from Article I, section 8 of the U.S. Constitution. The first patent law was passed in 1790, and the current law governing patents took effect in 1953. Since the first statute, over 6.5 million patents have been granted. The current statute set forth the subject matters for which patents may be granted and the conditions under which a patent will be issued. It also established the Patent and Trademark Office (PTO).

Under the law, anyone who "invents or discovers any new and useful process, machine, manufacture or composition of matter, or any new and useful improvements thereof, may obtain a patent." Courts have interpreted this language to include nearly anything that could be fabricated. One cannot, however, patent literary works, compilations of data, compositions of music, legal documents, or forms of energy. An invention must meet the test of being "new" under the standards in the law before a patent will be granted. The subject matter of an invention must be sufficiently different from what has been described before in a printed publication of some sort anywhere in the world, or on sale in the United States before the date of the application for the patent. In addition, the invention must not be obvious to a person who has ordinary skill in the relevant technical or scientific area at the time the inventor applies for the patent. Finally, an invention must be determined "useful" before obtaining a patent, although this requirement is interpreted very broadly.

The legal status of business method patents varies from country to country. It is difficult to obtain a patent for methods of doing business in China, India, Mexico, Israel and most of Europe. Under U.S. patent law, business methods are judged according to the same requirements as any other application. Before the 1980s and 1990s, the PTO stated that business methods were not patentable, but it became difficult to differentiate between technological inventions and business methods when judging applications for computer-implemented methods of doing business. Therefore, the PTO decided that business methods were patentable if they used the "technological arts," but this position was overturned in 2005. Currently, the PTO requires that a process produce a useful and concrete result to be eligible for a patent.

Only the inventor may apply for a patent, unless he has died or has been declared insane. An inventor applies for a patent by sending to the Commissioner of Patents and Trademarks a written specification, which is a description of the invention and of the process by which the

invention is made and how it is used. The specification must contain one or more claims about the subject matter that the applicant believes pertains to the invention, and include necessary drawings. The specification must be accompanied by a sworn oath or declaration by the inventor that he or she is the original and first inventor of the subject matter of the application, and the necessary filing fees.

TRADEMARK RIGHTS

A trademark is a word, name, phrase, symbol, or design, or a combination of these elements, which identifies and distinguishes the source of goods or services. The term *trademark* also encompasses service marks, which identify and distinguish the source of a service rather than a product. Trademark rights are used to prevent others from making, promoting, or selling goods or services which have a name, symbol, or design that is confusingly similar to that of an established trademark. It does not, however, prevent others from making or selling the same goods or services, as long as it is under a different, non-confusing mark.

There are two distinct types of rights in a trademark or service mark: the right to use the mark and the right to register the mark. These rights arise from either using the mark in actual commerce, or filing an application for registration of the mark with the PTO.

The Trademark Act of 1946, 15 U.S.C. Section 1051 et seq.; the Trademark Rules, 37 C.F.R. Part 2; and the Trademark Manual of Examining Procedure (2nd ed. 1993) control the registration of marks. The first party who either uses a mark in the course of commerce or business or files an application for registration with the PTO usually has the right to register that mark. A party can use a mark, or establish rights in it, without filing an application for registration. The registration, however, creates a presumption that the party who has registered the mark is the owner of the mark for the goods and services set forth in the registration application, and therefore has the right to use the mark anywhere in the country. This presumption can become important when two parties unintentionally begin using similar marks and become involved in a lawsuit over who has the right solely to use the mark. This is not determined by the PTO, but by a federal court, which has the power to issue an injunction to stop a party from using a mark, and to award damages for a party's improper use of another's mark.

Similarly, the owner of a mark may use the trademark (^{TM}) or service mark (^{SM}) designation with the mark to make it clear that the owner is claiming rights in the product or service so designated. The trademark or service mark designation may be used without the owner having registered the mark with the Patent and Trademark Office. If it is registered, however, the owner may use the registration symbol (®) with the mark.

Rights in a trademark, unlike rights in a copyright or a patent, can last for an indefinite period if the owner of the mark continuously uses the mark for its products or services. Federal registrations last for ten years, but between the fifth and sixth year after the date of the initial registration, the person who registered the mark must file an affidavit with information about the mark and ownership. If the registrant does not file this affidavit, the registration is cancelled. After the initial registration period, the mark can be renewed for successive ten-year terms. Registration of a mark with the PTO provides protection from others using the mark in the United States and its territories, but does not extend to its use in other countries.

COPYRIGHTS

A copyright gives an owner of "original works of authorship" the exclusive right to reproduce the work; prepare derivative works based on the copyrighted work; and distribute, perform, or display the work. Copyrights are registered with the Library of Congress Copyright Office. The first Copyright Act was passed in 1790, and it has been revised many times, most recently in 1976. This act sets forth eight categories of works that can be copyrighted. These are as follows:

1. Literary works
2. Musical works, including lyrics
3. Dramatic works, including music
4. Pantomimes and choreographic works
5. Pictorial, graphic, and sculptural works
6. Motion pictures and other audiovisual works
7. Sound recordings
8. Architectural works

These categories are interpreted broadly, so that, for example, software is considered copyrightable as a literary work. However, the act does not protect an "idea, procedure, process, system, method of operation, concept, principal or discovery regardless of the form in which it is described, explained, illustrated or embodied in such work."

The term of a copyright is for the period of the life of the owner, plus fifty years. An entity or person can become the owner of a copyright in two ways, either by creating the work personally, or through owning a work for hire. Works for hire cover situations where an employee creates a work at the request of an employer (and the employer thereby owns the copyright), or where someone commissions the creation of a work, and the party commissioning the work and the creator have agreed in writing that the commissioning party shall be the owner and that the work shall be a work for hire.

In 1988, the United States became a signatory to the Berne Convention, by enacting the Berne Convention Implementation Act. The Berne Convention provides copyright protection for a copyright owner simultaneously in most countries in the world. To become a signatory country, the United States had to amend the Copyright Act to create a copyright in a work automatically upon completion of the creation. Now, as soon as a composer finishes a work or an author writes the last words of an article, there exists a copyright. However, if an owner wishes to sue for copyright infringement, the owner must register the copyright with the United States Copyright Office by completing an application, and sending it with two copies of the "best edition" of the work and the filing fee.

INTELLECTUAL PROPERTY IN THE INTERNET AGE

Efforts to protect intellectual property became vastly more complicated with the growth of Internet technology in the late 1990s and early 2000s. The global computer network gave people greater access to all kinds of creative works, and in many cases enabled them to copy such works without regard to legal protection. "Virtually all creative content can be digitized, even if it was not initially created on a computer, and the Internet has become the primary distribution channel for every kind of digital material," Jonathan Cohen explained in his article "Copyright and Intellectual Property in the Age of the Internet."

Since the Internet has an international reach, the digital age has also brought to light discrepancies in intellectual property laws between nations. Several attempts have been made to bring the protection granted by developed and developing nations in line. In 2002, for example, the World Intellectual Property Organization Copyright Treaty (WCT) was ratified by the United States, Japan, and the European Union. The WCT updated the Berne Convention to apply to the Internet age, setting international standards for the protection of literary and artistic works in digital form.

Simultaneously, major content providers have taken steps to protect their own intellectual property from unauthorized reproduction through digital rights management (DRM) technology. DRM systems involve antipiracy measures that are built into software, video, and music files sold over the Internet to ensure that the owners of intellectual property are compensated for its use. DRM has proved cumbersome to consumers, however, because different content providers have established their own, usually incompatible, DRM systems—making it difficult for users to access content packaged and distributed with one DRM technology using a device that supports a different technology.

Some legal experts have also expressed concern that content providers will use DRM technology to erode the rights previously granted to the public under the "fair use" doctrine of copyright law. Whether a specific use of copyrighted material is determined to be fair depends on four factors: the purpose and character of the use; the nature of the work; the portion of the work used; and the effect of the use on the market for the work. Fair use protects such activities as videotaping a television program for later viewing, posting a newspaper cartoon on an office bulletin board, and quoting from a book in a report. In view of the rapidly evolving nature of intellectual property protection in the Internet age, business managers should seek legal advice in order to protect their own creative works as well as to avoid infringing on the rights of others.

INTERNAL AUDITING

The Institute of Internal Auditors (with more than 120,000 members as of 2008) defines internal auditing as ". . .an independent, objective assurance and consulting activity designed to add value and improve an organization's operations. It helps an organization accomplish its objectives by bringing a systematic, disciplined approach to evaluate and improve the effectiveness of risk management, control, and governance processes."

One way to distinguish between internal auditors and their more familiar counterparts (external auditors) is the intended audience of their reports. External auditors are hired by a company to audit that firm's financial statements and issue an opinion on the reliability of those financial statements. While external auditors are in a contractual relationship to the firm whose financial statements are being audited, external auditors owe their primary fiduciary responsibility to groups outside of the firm, such as investors and creditors. The external auditor's report or opinion is provided to groups outside of the firm that hired him to

audit by including it in that firm's annual report. In contrast, internal auditors are employed by the organization that they are auditing. Similar to external auditors, the internal auditor might provide a written opinion based on his evaluation. However, in contrast to external auditors, the audience for that opinion will always be corporate management instead of investors and creditors.

Typically, the role of internal auditors is broader than that of external auditors. While a company's external auditors will focus on evaluating the firm's financial statements, internal auditors can provide financial, compliance, and operational auditing.

FINANCIAL AUDITS

The significance of the contribution of internal auditors to financial audits was dramatically increased with the passage of the Sarbanes-Oxley Act of 2002. That act made widespread changes in the responsibility of the parties involved in the financial reporting process.

One change that has enhanced the role of the internal auditor is the requirement in Section 302 of Sarbanes-Oxley that a firm's certifying officers (typically the chief executive officer and chief financial officer) must state that they are responsible for establishing and maintaining internal controls over financial reporting. As part of this certification, they must also indicate that the internal controls were designed to provide reasonable assurance regarding the reliability of financial reporting and the preparation of financial statements in accordance with generally accepted accounting principles in the United States. These Section 302 certifications are required to be included with the firm's annual financial statements. Most firms will rely extensively on the work of their internal auditors to provide the justification for the Section 302 certifications.

Section 404 of the Sarbanes-Oxley act also increased the responsibilities of internal auditors. This section requires that management include a report on internal controls in the firm's annual financial statements. The report must indicate that management is responsible for establishing and maintaining internal controls over financial reporting, and management's conclusions regarding the effectiveness of those internal controls. In most companies, the internal auditors will provide the documentation and testing of internal controls that will be necessary for management to make that report.

COMPLIANCE OR OPERATIONAL AUDITS

A compliance audit assures that the company's activities comply with relevant laws and regulations. An operational audit explores the effectiveness and efficiency of the firm's activities, seeking to reduce the risks faced by the specific firm. In performing an operational audit, performance standards may include a variety of criteria other than monetary measures, such as the percentage of late deliveries or idle labor time. It is the responsibility of the internal auditor to determine appropriate measures on the basis of experience and insight into the integrated functions of the company's activities. Typically, performance is measured against prior periods, industry standards, other operational units, or budgeted activity.

ENTERPRISE RISK MANAGEMENT

Internal auditors can provide an enterprise-wide approach to risk management. Enterprise Risk Management, or ERM, is a broader approach to risk management than that taken by a single department within an organization. ERM can identify risks and opportunities affecting the creation or preservation of value within the enterprise. Internal auditing can ensure that ERM processes are effective in managing key risks as well as provide important information to the company's board and senior management.

Internal auditing provides a broad-based, independent, value-adding function that is essential for the effective management of a firm. The value of internal audit has been greatly enhanced by the passage of the Sarbanes-Oxley Act of 2002.

INTERNATIONAL BUSINESS

International business is defined as business transactions that take place across national borders. This broad definition includes the very small firm that exports (or imports) a small quantity to only one country, as well as the very large global firm with integrated operations and strategic alliances around the world. Within this broad array, distinctions are often made among different types of international firms, and these distinctions are helpful in understanding a firm's strategy, organization, and functional decisions (for example, its financial, administrative, marketing, human resource, or operations decisions). One distinction that can be helpful is the distinction between multidomestic operations, with independent subsidiaries that act essentially as domestic firms, and global operations, with integrated subsidiaries that are closely related and interconnected. These may be thought of as the two ends of a continuum, with many possibilities in between. Firms are unlikely to be at one end of the continuum, though, as they often combine aspects of multi-domestic operations with aspects of global operations.

International business grew over the last half of the twentieth century and the early twenty-first century partly because of liberalization of both trade and investment, and partly because doing business internationally had become easier. In terms of liberalization, the General Agreement on Tariffs and Trade (GATT) negotiation rounds resulted in trade liberalization, and this was continued with the formation of the World Trade Organization (WTO) in 1995, which is responsible for the regulation of trade on the global level. Other regional trade agreements include the North Atlantic Free Trade Agreement (NAFTA) between The United States, Canada and Mexico and the MERCO-SUR between South American Countries. At the same time, most governments liberalized worldwide capital movements, particularly with the advent of electronic funds transfers. In addition, the introduction of a new European monetary unit, the euro, into circulation in January 2002 has impacted international business economically. The euro is the currency of the European Union, and it has replaced the national currency of many European countries. As of early 2005, the United States dollar continues to struggle against the euro and the impacts are being felt across industries worldwide.

In terms of ease of doing business internationally, two major forces are important: technological developments that make global communication and transportation relatively quick and convenient, and the disappearance of a substantial part of the communist world, opening many of the world's economies to private business.

DOMESTIC VS. INTERNATIONAL BUSINESS

Domestic and international enterprises, in both the public and private sectors, share the business objectives of functioning successfully to continue operations. Private enterprises seek to function profitably as well. Why, then, is international business different from domestic? The answer lies in the differences across borders. Nation-states generally have unique government systems, laws and regulations, currencies, taxes and duties, and so on, as well as different cultures and practices. An individual traveling from his home country to a foreign country needs to have the proper documents, to carry foreign currency, to be able to communicate in the foreign country, to be dressed appropriately, and so on. Doing business in a foreign country involves similar issues and is thus more complex than doing business at home. The following sections will explore some of these issues. Specifically, comparative advantage is introduced, the international business environment is explored, and forms of international entry are outlined.

THEORIES OF INTERNATIONAL TRADE AND INVESTMENT

In order to understand international business, it is necessary to have a broad conceptual understanding of why trade and investment across national borders take place. Trade and investment can be examined in terms of the comparative advantage of nations.

Comparative advantage suggests that each nation is relatively good at producing certain products or services. This comparative advantage is based on the nation's abundant factors of production—land, labor, and capital—and a country will export those products/services that use its abundant factors of production intensively. Simply, consider only two factors of production, labor and capital, and two countries, X and Y. If country X has a relative abundance of labor and country Y a relative abundance of capital, country X should export products/services that use labor intensively, and country Y should export products/services that use capital intensively.

This is a very simplistic explanation, of course. There are many more factors of production, of varying qualities, and there are many additional influences on trade such as government regulations. Nevertheless, it is a starting point for understanding what nations are likely to export or import. The concept of comparative advantage can also

help explain investment flows. Generally, capital is the most mobile of the factors of production and can move relatively easily from one country to another. Other factors of production, such as land and labor, either do not move or are less mobile. The result is that where capital is available in one country it may be used to invest in other countries to take advantage of their abundant land or labor. Firms may develop expertise and firm-specific advantages based initially on abundant resources at home, but as resource needs change, the stage of the product life cycle matures, and home markets become saturated, these firms find it advantageous to invest internationally.

THE INTERNATIONAL BUSINESS ENVIRONMENT

International business is different from domestic business because the environment changes when a firm crosses international borders. Typically, a firm understands its domestic environment quite well, but is less familiar with the environment in other countries and must invest more time and resources into understanding the new environment. The following considers some of the important aspects of the environment that change internationally.

The economic environment can be very different from one nation to another. Countries are often divided into three main categories: the developed countries, the least developed countries, and developing or emerging economies. Within each category there are major variations, but overall the more developed countries are the rich countries, the less developed the poor ones, and the newly industrializing those moving from poorer to richer. These distinctions are usually made on the basis of gross domestic product per capita (GDP/capita). Better education, infrastructure, technology, health care, and so on are also often associated with higher levels of economic development.

When discussing emerging economies, the "BRIC" nations hold a prominent place. The BRIC countries refer to the emerging economies in Brazil, Russia, India and China. The term was used first by Goldman Sachs investment bank in 2003 in a paper that argued that these rapidly developing nations would surpass the richest countries in the world by 2050. Jim O'Neill, head of global economic research at Goldman Sachs, claims that the BRIC countries are moving toward the creation of an economic bloc similar to the European Union. The BRIC Summit that took place in 2008 indicates that these countries are beginning to formalize their association.

In addition to level of economic development, countries can be classified as free-market, centrally planned, or mixed. Free-market economies are those where government intervenes minimally in business activities, and market forces of supply and demand are allowed to determine production and prices. Centrally planned economies are those where the government determines production and prices based on forecasts of demand and desired levels of supply. Mixed economies are those where some activities are left to market forces and some, for national and individual welfare reasons, are government controlled. In the late twentieth century and early twenty-first century there has been a substantial move to free-market economies but most countries maintain some government control of business activities. The People's Republic of China (PRC) has implemented market-based economic reforms since the death of Chairman Mao in 1976, after which the Communist Party's control over citizens was diminished. Now the PRC has a mixed economy that incorporates many aspects of a free-market environment while retaining government control over industries that are considered to be of vital strategic importance to the state.

Clearly the level of economic activity combined with education, infrastructure, and so on, as well as the degree of government control of the economy, affect virtually all facets of doing business, and a firm needs to understand this environment if it is to operate successfully internationally.

The political environment refers to the type of government, the government relationship with business, and the political risk in a country. Doing business internationally thus implies dealing with different types of governments, relationships, and levels of risk.

There are many different types of political systems, for example, multi-party democracies, one-party states, constitutional monarchies, and dictatorships (military and non-military). Also, governments change in different ways, for example, by regular elections, occasional elections, death, coups, and war. Government-business relationships also differ from country to country. Business may be viewed positively as the engine of growth, it may be viewed negatively as the exploiter of the workers, or somewhere in between as providing both benefits and drawbacks. Specific government-business relationships can also vary from positive to negative depending on the type of business operations involved and the relationship between the people of the host country and the people of the home country. To be effective in a foreign location an international firm relies on the goodwill of the foreign government and needs to have a good understanding of all of these aspects of the political environment.

A particular concern of international firms is the degree of political risk in a foreign location. Political risk refers to the likelihood of government activity that has unwanted consequences for the firm. These consequences can be dramatic as in forced divestment, where a government requires the firm to give up its assets, or more moderate, as in unwelcome regulations or interference in operations. In any case the risk occurs because of uncertainty about the likelihood of government activity

occurring. Generally, risk is associated with instability, and a country is thus seen as more risky if the government is likely to change unexpectedly, if there is social unrest, if there are riots, revolutions, war, terrorism, and so on. Firms naturally prefer countries that are stable and that present little political risk, but the returns need to be weighed against the risks, and firms often do business in countries where the risk is relatively high. In these situations, firms seek to manage the perceived risk through insurance, ownership and management choices, supply and market control, financing arrangements, and so on. In addition, the degree of political risk is not solely a function of the country, but depends on the company and its activities as well—a risky country for one company may be relatively safe for another. Additionally, countries that can be said to have little political risk may have a strict regulatory environment. In the United States, regulations make for a stable business environment, but the compliance burden—particularly since the Sarbanes-Oxley code was introduced in 2002—can be so expensive as to deter foreign companies from doing business in the United States.

The cultural environment is one of the critical components of the international business environment and one of the most difficult to understand. This is because the cultural environment is essentially unseen; According to Kluckhohn and Strodtbeck, it can be described as a shared, commonly held body of general beliefs and values that determine what is right for one group. National culture is described as the body of general beliefs and values that are shared by a nation. Beliefs and values are generally seen as formed by factors such as history, language, religion, geographic location, government, and education; thus firms begin a cultural analysis by seeking to understand these factors.

Firms want to understand what beliefs and values they may find in countries where they do business, and a number of models of cultural values have been proposed by scholars. The most well known is that developed by Hofstede in 1980. This model proposes four dimensions of cultural values including individualism, uncertainty avoidance, power distance, and masculinity. Individualism is the degree to which a nation values and encourages individual action and decision making. Uncertainty avoidance is the degree to which a nation is willing to accept and deal with uncertainty. Power distance is the degree to which a nation accepts and sanctions differences in power. And masculinity is the degree to which a nation accepts traditional male values or traditional female values. This model of cultural values has been used extensively because it provides data for a wide array of countries. Many academics and managers found this model helpful in exploring management approaches that would be appropriate in different cultures. For example, in a nation that is high on individualism one expects individual goals, individual tasks, and individual

reward systems to be effective, whereas the reverse would be the case in a nation that is low on individualism. While this model is popular, there have been many attempts to develop more complex and inclusive models of culture.

The competitive environment can also change from country to country. This is partly because of the economic, political, and cultural environments; these environmental factors help determine the type and degree of competition that exists in a given country. Competition can come from a variety of sources. It can be public or private sector, come from large or small organizations, be domestic or global, and stem from traditional or new competitors. For the domestic firm the most likely sources of competition may be well understood. The same is not the case when one moves to compete in a new environment. For example, in the United States most business is privately owned and competition is among private sector companies, while in the People's Republic of China some businesses remain under the direction of the state. Thus, a U.S. company in the PRC could find itself competing with organizations owned by state entities. This could change the nature of competition dramatically.

The nature of competition can also change from place to place as the following illustrate: competition may be encouraged and accepted or discouraged in favor of cooperation; relations between buyers and sellers may be friendly or hostile; barriers to entry and exit may be low or high; regulations may permit or prohibit certain activities. To be effective internationally, firms need to understand these competitive issues and assess their impact. In addition to trade liberalization, there has been an effort to negotiate trade facilitation, which focuses on the cost of trade and customs procedures.

An important aspect of the competitive environment is the level, and acceptance, of technological innovation in different countries. The last decades of the twentieth century saw major advances in technology, and this is continuing in the twenty-first century. Technology often is seen as giving firms a competitive advantage; hence, firms compete for access to the newest in technology, and international firms transfer technology to be globally competitive. It is easier than ever for even small businesses to have a global presence thanks to the Internet, which greatly expands their exposure, their market, and their potential customer base. For economic, political, and cultural reasons, some countries are more accepting of technological innovations, others less accepting.

INTERNATIONAL ENTRY CHOICES

International firms may choose to do business in a variety of ways. Some of the most common include exports, licenses, contracts and turnkey operations, franchises, joint ventures, wholly owned subsidiaries, and strategic alliances.

Exporting is often the first international choice for firms, and many firms rely substantially on exports throughout their history. Exports are seen as relatively simple because the firm is relying on domestic production, can use a variety of intermediaries to assist in the process, and expects its foreign customers to deal with the marketing and sales issues. Many firms begin by exporting reactively; then become proactive when they realize the potential benefits of addressing a market that is much larger than the domestic one. Effective exporting requires attention to detail if the process is to be successful; for example, the exporter needs to decide if and when to use different intermediaries, select an appropriate transportation method, prepare export documentation, prepare the product, arrange acceptable payment terms, and so on. Most importantly, the exporter usually leaves marketing and sales to the foreign customers, and these may not receive the same attention as if the firm itself undertook these activities. Larger exporters often undertake their own marketing and establish sales subsidiaries in important foreign markets.

Licenses are granted from a licensor to a licensee for the rights to some intangible property (e.g. patents, processes, copyrights, trademarks) for agreed on compensation (a royalty payment). Many companies feel that production in a foreign country is desirable but they do not want to undertake this production themselves. In this situation the firm can grant a license to a foreign firm to undertake the production. The licensing agreement gives access to foreign markets through foreign production without the necessity of investing in the foreign location. This is particularly attractive for a company that does not have the financial or managerial capacity to invest and undertake foreign production. The major disadvantage to a licensing agreement is the dependence on the foreign producer for quality, efficiency, and promotion of the product—if the licensee is not effective, this reflects on the licensor. In addition, the licensor risks losing some of its technology and creating a potential competitor. This means the licensor should choose a licensee carefully to be sure the licensee will perform at an acceptable level and is trustworthy. The agreement is important to both parties and should ensure that both parties benefit equitably.

Outsourcing is where a business subcontracts one aspect of its business operations, such as payroll or advertising. Offshoring refers to when a company outsources a business process to a company in another country. Often companies outsource in order to take advantage of lower labor costs. Other motivations for outsourcing include the transfer of risk to a third party.

Contracts are used frequently by firms that provide specialized services, such as management, technical knowledge, engineering, information technology, education, and so on, in a foreign location for a specified time period and fee. Contracts are attractive for firms that have talents not being fully utilized at home and in demand in foreign locations. They are relatively short-term, allowing for flexibility, and the fee is usually fixed so that revenues are known in advance. The major drawback is their short-term nature, which means that the contracting firm needs to develop new business constantly and negotiate new contracts. This negotiation is time consuming, costly, and requires skill at cross-cultural negotiations. Revenues are likely to be uneven and the firm must be able to weather periods when no new contracts materialize.

Turnkey contracts are a specific kind of contract where a firm constructs a facility, starts operations, trains local personnel, then transfers the facility (turns over the keys) to the foreign owner. These contracts are usually for very large infrastructure projects, such as dams, railways, and airports, and involve substantial financing; thus international financial institutions such as the World Bank often finance them. Companies that specialize in these projects can be very profitable, but they require specialized expertise. Further, the investment in obtaining these projects is very high, so only a relatively small number of large firms are involved in these projects, and often they involve a syndicate or collaboration of firms.

Similar to licensing agreements, franchises involve the sale of the right to operate a complete business operation. Well-known examples include independently owned fast-food restaurants like McDonald's and Pizza Hut. A successful franchise requires control over something that others are willing to pay for, such as a name, set of products, or a way of doing things, and the availability of willing and able franchisees. Finding franchisees and maintaining control over franchisable assets in foreign countries can be difficult; to be successful at international franchising, firms need to ensure they can accomplish both of these.

Joint ventures involve shared ownership in a subsidiary company. A joint venture allows a firm to take an investment position in a foreign location without taking on the complete responsibility for the foreign investment. Joint ventures can take many forms. For example, there can be two partners or more, partners can share equally or have varying stakes, partners can come from the private sector or the public, partners can be silent or active, partners can be local or international. The decisions on what to share, how much to share, with whom to share, and how long to share are all important to the success of a joint venture. Joint ventures have been likened to marriages, with the suggestion that the choice of partner is critically important. Many joint ventures fail because partners have not agreed on their objectives and find it difficult to work out conflicts. Joint ventures provide an

effective international entry when partners are complementary, but firms need to be thorough in their preparation for a joint venture.

Wholly owned subsidiaries involve the establishment of businesses in foreign locations which are owned entirely by the investing firm. This entry choice puts the investor parent in full control of operations but also requires the ability to provide the needed capital and management, and to take on all of the risk. Where control is important and the firm is capable of the investment, it is often the preferred choice. Other firms feel the need for local input from local partners, or specialized input from international partners, and opt for joint ventures or strategic alliances, even where they are financially capable of 100 percent ownership.

Strategic alliances are arrangements among companies to cooperate for strategic purposes. Licenses and joint ventures are forms of strategic alliances, but are often differentiated from them. Strategic alliances can involve no joint ownership or specific license agreement, but rather two companies working together to develop a synergy. Firms form strategic alliances for a variety of reasons. Ideally, each partner can bring complementary assets to the table, resulting in a competitive advantage for the participants collectively. Businesses in a strategic alliance can benefit from many aspects of a cooperative relationship: access to unfamiliar or untapped markets, risk sharing, economies of scale, shared technology, and decreased costs. Joint advertising programs are a form of strategic alliance, as are joint research and development programs. Strategic alliances seem to make some firms vulnerable to loss of competitive advantage, especially where small firms ally with larger firms. In spite of this, many smaller firms find that strategic alliances allow them to enter the international arena when they could not do so alone.

International business grew substantially in the second half of the twentieth century, and this growth is likely to continue. The international environment is complex and it is very important for firms to understand this environment and make effective choices in this complex environment. The previous discussion introduced the concept of comparative advantage, explored some of the important aspects of the international business environment, and outlined the major international entry choices available to firms. The topic of international business is itself complex, and this short discussion serves only to introduce a few ideas on international business issues.

INTERNATIONAL MANAGEMENT

During the 1990s and early 2000s, many companies took advantage of a world market that was increasingly open to international expansion and trade. Obstacles to free trade were eased through the General Agreement on Tariffs and Trade (GATT), the North American Free Trade Agreement (NAFTA), and the Association of South East Asian Nations (ASEAN).

Economies opened, and due to technological developments in communication, transportation, and finance, there were fewer difficulties with the practical issues of conducting business across national borders. Communications technology showed exponential growth, including innovations that facilitated doing business anywhere at anytime, such as remote access and net conferencing.

As shown in Table 1, the number of Internet users in the world grew from 30 million to over 562 million over six years. By 2002 almost 10 percent of the world population used the Internet. As of 2008, more than 21 percent of the world population is online.

Table 1

Internet Users 1996-2002

Year	Internet Users (millions)	Internet Users as a Percentage of World Population
Jan 1996	30	.73
Jan 1997	57	1.41
Jan 1998	102	2.49
Jan 1999	153.5	3.75
Jan 2000	254.29	4.27
Jan 2001	455.55	7.5
Jan 2002	562.47	9.43

Accompanying all of these changes was an increase in need for international management for people who understand business and cultural issues well enough to manage and grow an international business effectively. Among those issues are:

- Business structure
- Competition
- Political and economic environments
- Finance and business issues such as contracts, taxation, intellectual property, and risk
- Employment and leadership
- Cultural norms and values
- Technology

BUSINESS STRUCTURE

An international manager has the task of reopening business in a radically different environment. He or she must determine the overall structure of the business and its workflow. In a functional-based business (i.e., the new location needs to be able to perform standardized tasks that comply with overall corporate practices), skilled labor and ability to perform these tasks is key.

Technological infrastructure could be a crucial factor. For an area-based business, location is key, and detailed knowledge of the country and its culture is critical. Products may have to be adapted to the host market.

A global-based structure may have a varied set of product lines, each of which can be made and marketed across locations. These approaches can be mixed, but choosing the structure of the business should support the firm's primary goals.

Many businesses start by first establishing the new office or facility as an "export division" that falls under the umbrella of Operations or Marketing—which may

eventually become an "International Division." How this new entity best fits within the parent organization's overall structure depends on the purpose for the new location and how much the parent company plans to grow the business.

Other options include opening a wholly owned subsidiary or an overseas joint venture, contracting from an international company (IC) to manufacture products to specification, or purchasing supplies and/or materials from an IC manufacturer.

Other considerations include the additional costs of globalization, such as international freight, insurance, packing (up to 12 percent of manufacturing prices), sales terms, import duties, broker's fees, inventory costs, and international travel.

COMPETITION

Competition in the global marketplace continues to grow, particularly between the United States, the European Union, and Asian nations. For this reason, companies need to evaluate the competitive landscape of the host country. First, it is helpful to understand that the nature of competition varies by region and industry. Some nations support an atmosphere of pure competition; for example, there may be any number of sellers, each with relatively small market share, with competition based solely on price. Others may be more monopolistic. Understanding the type of environment in which a firm will participate in its host country ensures the use of appropriate business practices.

More specific threats to companies comes from existing competitors, new competitors who may also enter the market, and the bargaining power of suppliers and buyers in the host country or region. Also, some countries' business environments make entering the marketplace harder than others. For example, foreign businesses find it hard to compete with industry in Japan, where groups of firms are connected financially and rarely do business outside of that group (called "keiretsu").

When investigating the competitive climate, it is also helpful to understand the power wielded by many of the world's transnational corporations (TNCs). Many of the world's top TNCs earn more in revenues each year than most nations. While this does not mean other companies cannot compete with the products and services offered by these companies, it helps to know that these TNCs are involved in establishing direction, lobbying industry, and other activities that have direct impact on the laws and regulations that affect entire industries and how smaller companies can conduct international business.

Finally, an understanding of international anti-trust laws and when they are enforced is critical to assessing the risks to an international business. The United States is the toughest nation in regard to anti-trust, even trying to

enforce laws outside the country. The European Union is relatively lax on enforcing anti-trust laws, but does use them as a means to levy fines on cartels. In Japan, enforcement of anti-trust legislation, which was enacted only under great pressure from outside the country, is weak at best, and usually nonexistent. Learning how "fair competition" is viewed in foreign business environments better prepares a manager to protect his or her own business.

ENVIRONMENTAL FACTORS

Both the economic and political environments of countries and regions have great impact on the managing of international operations. A few of the economic factors that impact international business are:

- Host nation's economy: free-market vs. centrally planned, or mixed.

- Gross Domestic Product (GDP), Gross National Product (GNP), and per capita income—all are gauges to consumer buying power.

- Spending patterns of the host population.

- Variation in the degree of development or industrialization.

- Infrastructure and technology available to business.

- Differences in available education and health care.

Some economies are less hospitable to job creation than others. For example, in Western Europe high minimum wages, healthy unemployment benefits, and employment protection laws are significant barriers to companies hoping to produce job growth in this part of the world. This and other issues also have an impact on finding employees to help staff and manage international operations.

The political environment plays a large role in determining how international companies will be able to manage business operations. Examples of political forces affecting international corporations include:

- Governments, political parties, and ideological beliefs (communism, capitalism, socialism, liberal, conservative, etc.).

- Nature of government-business relationships.

- Laws and attitude toward business.

- Tariffs and quotas.

- Currency controls (limits on the amount of money entering or leaving a country).

All businesses must abide by the laws, regulations, and bureaucracy in the host nation, including the United States and other capitalist countries. Examples of the obstacles an international corporation may encounter include complying with government restrictions on regulated professions and industries such as law, medicine, banking, insurance, transportation, and utilities. State and local governments may also require specific licenses for business and restrict foreign use of buildings. For all of these, proper compliance takes knowledge, time to learn, and expense.

While all of the above factors have significant impact on multi-national corporations, perhaps the most important factor for an international manager is awareness of the degree of risk associated with various political forces in the host region. In addition to weighing the stability of the established government in the region in which it conducts business, governments can seize property owned by foreigners within its borders. This is known as expropriation in cases where the government follows up with quick, adequate compensation for former owners of the property. However, some governments may confiscate property, meaning former owners do not receive proper compensation.

CONTRACTS

When parties representing different nations enter into a contract, dispute resolution becomes especially complicated. The United Nations (UN) Convention on Contracts for the International Sale of Goods (CISG) established legal rules for international sales contracts, including rights and obligations for both buyer and seller. Unless the parties to the contract expressly exclude the CISG, it applies to all contracts signed by companies from the countries that ratified the Convention. In the European Union (EU), the Rome Convention (1991) also applies to contracts formed between EU residents. Outside of these two agreements, companies must rely on private solutions and arbitration (which is used with increasing frequency).

INTELLECTUAL PROPERTY

Intellectual property is well protected in the United States, with patents, trademarks, and copyrights. But when companies engage in business with other countries, they take risks. For example, product counterfeiting, common in Asia, costs U.S. business between $200 and $250 billion annually, according to the U.S. Federal Bureau of Investigation.

Other risks to business included trade secrets and industrial espionage. Most often, competitive information is obtained from inside the company, from published business materials, customers, competitor employees, and sometimes through direct observation.

Each nation has its own laws to protect intellectual property, but which products those laws protect differs as well. The UN's World Intellectual Property Organization (WIPO) was created to administer international property treaties, as was TRIPS, a World Trade Organization (WTO) agency.

The United States adopted its Foreign Corruption Practices Act (FCPA), which unfortunately acts as a barrier to United States companies. The FCPA was not adopted in Europe, or elsewhere, and compliance with the FCPA means American exporters lose business. Most importantly, international managers need to be aware piracy of and counterfeiting, particularly in certain markets, and take steps to protect proprietary corporate information.

LIABILITY

Product liability is a much bigger issue in the United States than in other countries. For example, the United States is the only country that conducts jury trials or pays punitive damages in cases of product liability. There was a principle of strict liability adopted in Europe, but company defense is strong and some countries cap damages.

The United States places many burdens upon its own companies, which impacts how well American companies can conduct business internationally and what it costs them to do so. Like the FCPA, boycott legislation often applies only to the United States. These become significant obstacles to international competition when other countries do not follow suit.

FINANCE

Financial management of international corporations is particularly challenging, as countries change in value in terms of each other based on currency exchange rates. Companies must comply with financial laws and regulations in the host country. International managers need to:

- Understand how fluctuations in currency value change international business transactions.

- Learn about financial tools such as derivatives, hedges, payment timing, exposure netting, price adjustments, balance-sheet neutralizing, and swaps, and how they affect business performance.

- Meet, network, and cooperate with counterparts in other organizations to protect and/or benefit the organization.

- Learn when and how to pay exporters in forms other than money; buyers frequently prefer payment rendered in the form of goods or services (countertrade).

- Differentiate between two types of currency: hard, convertible currency is accepted around the world at uniform rates; soft, nonconvertible currency is rarely of value outside the host country.

- Use international finance centers as a resource—these accumulate expertise and information to conduct financial transaction for international company units most profitably and at the lowest cost.

For an example of how legislation can affect a nation's financial markets, Americans need to look no further than 2002. The Sarbanes-Oxley Act became United States federal law that year; in part, the legislation was a response to corporate scandals including Enron and WorldCom. The Public Company Accounting Reform and Investor Protection Act (or Sarbox) ramped up the requirements for financial reporting at public companies. The Securities and Exchange Commission is responsible for enforcing these laws, and the newly created Public Company Accounting Oversight Board is responsible for overseeing the accounting firms that audit public companies. Opponents of this legislation argue that Sarbox has resulted in the loss of business from New York to London, where the U.K.'s Financial Services Authority is less strict.

EMPLOYMENT AND LABOR FORCES

Investigation of the available labor force should be performed before a company chooses to expand its business to a given region. Managers should determine whether there are enough people of the right skill level for a company to run the business effectively, and whether or not they will want to work for a foreign employer.

When staffing international operations, managers must be able to fill positions from a pool of labor with the right education and skill to maintain and grow the business. Hiring options include choosing from the parent company, choosing people from the host country, or hiring from a local subsidiary. Refugees are often pulled into operations. However, they may lack the skills, health, or education to work. Guest workers may also provide labor, and are particularly helpful in times of rapid growth—when native workers are not willing or able to fill all positions and they do not feel displaced. However, even in times of growth, bringing in large numbers of guest workers (foreigners) often causes friction with citizens of the host country.

Proper planning also helps a company to recognize other forces that cannot be controlled (but must be managed) and plan accordingly. Managers of international operations need to understand the effects of price and wage controls, labor laws, and currency exchange in the host country. In Europe, the government plays a very active role in legislating wages and working conditions, particularly in Germany and France. In Japan, unions align more with specific companies than with industry, so union members have a stake in how well the company does and how much money it makes. They often work with company management.

Understanding cultural issues is critical to international management in general, but culture plays a particularly important role in building a labor force outside the United States. Though U.S. businesses have come to see

women as part of the employment pool, women are less accepted as part of the workforce in many other countries.

Another consideration is race, which is still a source of conflict and discrimination in many areas, as is social status. Religious, tribal, racial, and other cultural factors have an impact, not just on employment, but on how an international company will be viewed by the host culture (and how many people will buy products made by the company). However, if managers are well informed and handle cultural issues properly, people from different cultures, speaking different languages, and possessing various abilities and levels of experience can strengthen the overall management of an international company.

Many corporations have particular difficulty finding qualified executives to effectively manage international companies. Successful leaders of international companies need to understand motivation, leadership, communication, conflict, and other behavioral issues that arise in cross-national and cross-cultural context. The ability to address these issues depends on an understanding of the host culture's values. Other skills cited as keys to successful international management include the following:

- Technical competence

- Ability to speak, or willingness to learn, the host language

- Tolerance for ambiguity and ability to manage uncertainty

- Nonjudgmental attitude

- Ability to emotionally connect with people from diverse cultures and backgrounds, and to understand differing viewpoints

- Personal integrity

- Strong commitment to personal and company standards.

- Inquisitive mindset/continuous learning

Managers of international operations need to be adaptable and have a high tolerance for change and ambiguity. They are most successful when given autonomy and discretion in the workplace. Overall business savvy on the part of executives helps to ensure an international company will run well.

Thorough understanding of both the company and industry is important, along with an ability to leverage that understanding when planning, organizing, and implementing ideas. On a more practical level, international managers need to be able to manage accounting and auditing, business plans, policies and procedures, information systems, and corporate culture—all of which vary based on the infrastructure and culture of the host country.

CULTURAL ISSUES

Defined as the body of beliefs, norms, and values shared by a group of people, culture presents the biggest challenge to businesses working internationally. It is a key factor in how all other areas of business work together. Culture influences negotiation tactics, decision making, and rewards and recognition programs. For example, when conducting business, members of some cultures sit right down to business after shaking hands. In other countries, it is considered rude to mention business at all until after both parties have spent a significant amount of time establishing a relationship.

As stated by Geert Hofstede, "Culture is more often a source of conflict than of synergy. Cultural differences are a nuisance at best and often a disaster." A summary of Hofstede's major factors impacting international business relationships that also influence the practice of international management are shown in Table 2.

Hofstede's framework is one of the most prominent in international management. He identified four major dimensions of cultural values (individualism-collectivism, power distance, uncertainty avoidance, and masculinity-femininity) along with a fifth dimension subsequently identified as Confucian Dynamism, or long-term orientation. Finally, Trompenaars and Hampden-Turner extended Hofstede's classification with seven dimensions that include universalism versus particularism, collectivism versus individualism, affective versus neutral relationships, specificity versus diffuseness, achievement versus ascription, orientation toward time, and internal versus external control. The different classifications provide different and overlapping approaches to organize the many complex dimensions that make up culture. A major premise underlying the need for organizing different cultural dimensions is a means to avoid costly mistakes in conducting international business.

Managers of international operations should be aware of the importance of context in various countries. Context indicates the level in which communication occurs outside of verbal discussion. High-context communication depends heavily on gestures, body language, and other nonverbal cues. Much of what is communicated is implicit, or unspoken, and assumed to be understood through other cues. Low-context communication is explicit and precise, relying little on nonverbal embellishment for meaning. Many of these, and other cultural practices, are learned through socialization.

Increasing one's ability to work effectively across cultures also provides positive support to address a range of adjustment issues for expatriates who often face culture shock in the acculturation process. Overall, the most important key of cultural intelligence and intercultural competence is the integration of multiple spheres of cross-cultural learning to effectively engage in international

Table 2
Hofstede's 5 Cultural Dimensions

Value Dimension	Value Description	High Score	Low Score
Power Distance Index (PDI)	The degree of equality, or inequality, between people in the country's society.	Indicates that inequalities of power and wealth have been allowed to grow within the society. These societies are more likely to follow a caste system that does not allow significant upward mobility of its citizens.	Indicates the society de-emphasizes the differences between citizen's power and wealth. In these societies equality and opportunity for everyone is stressed.
Individualism (IDV)	Degree to which a society reinforces individual or collective achievement and interpersonal relationships.	Indicates that individuality and individual rights are paramount within the society. Individuals may tend to form a larger number of looser relationships.	Typifies societies of a more collectivist nature with close ties between individuals. Reinforce extended families and collectives where everyone takes responsibility for fellow members of their group.
Masculinity (MAS)	Degree to which a society reinforces, or does not reinforce, the traditional masculine work role model of male achievement, control, and power.	Indicates the country experiences a high degree of gender differentiation. Males dominate a significant portion of the society and power structure, with females being controlled by male domination.	Indicates the country has a low level of differentiation and discrimination between genders. Females are treated equally to males in all aspects of the society.
Uncertainty Avoidance Index (UAI)	Level of tolerance for uncertainty and ambiguity within the society - i.e. unstructured situations.	Indicates the country has a low tolerance for uncertainty and ambiguity. Creates a rule-oriented society that institutes laws, rules, regulations, and controls in order to reduce the amount of uncertainty.	Indicates the country has less concern about ambiguity and uncertainty and has more tolerance for a variety of opinions. Reflected in a society that is less rule-oriented, more readily accepts change, and takes more and greater risks.
Long-Term Orientation (LTO)	Degree to which a society embraces, or does not embrace, long-term devotion to traditional, forward thinking values.	Indicates the country prescribes to the values of long-term commitments and respect for tradition. This is thought to support a strong work ethic where long-term rewards are expected as a result of today's hard work. However, business may take longer to develop in this society, particularly for an "outsider".	Indicates the country does not reinforce the concept of long-term, traditional orientation. In this culture, change can occur more rapidly as long-term traditions and commitments do not become impediments to change.

business situations. Effectiveness in reconciling cross-cultural differences often leads to creativity, innovation, and synergy for productive workplace performances.

TECHNOLOGY

Technology is an important factor that can vary significantly, depending on the purpose of foreign investment and how important it is for technology to be standardized across business divisions. While some business leaders may choose to expand internationally to take advantage of cheaper labor or manufacturing costs, particularly in developing nations, they may also need to plan for "intermediate and appropriate technology."

The production processes used may vary from advanced to primitive, depending on the economic, cultural, and political variables of the host nation. Some governments urge investors to consider intermediate technology rather than the highly-automated equipment and processes of industrialized countries, in part because less advanced countries lack the infrastructure to support such technology. Companies may respond by searching for an appropriate technology that matches a country's resources, or it may choose to invest elsewhere.

Technology has also contributed significantly to the spread of globalization and international expansion. Advances in technology enable international businesses to conduct international financial transactions, purchase products, analyze data rapidly, make capital improvements, and streamline communications, transportation, and distribution channels.

The summaries above are brief introductions to broad issues to which entire semesters are devoted in business programs. International management requires a broad knowledge base in many areas, as well as an ability to adapt to working conditions in which the only constants are change and a devotion to continuous learning.

Most critical to international management is the desire and ability to work well with people of various cultures, interests, degrees of education, and intelligence—from employees to colleagues to government officials, with home country and host country, and across national and industrial borders.

INTERNATIONAL MANAGEMENT SOCIETIES AND ASSOCIATIONS

One of the most noteworthy developments in business in the second half of the twentieth century was the rise of the professional business manager. Whereas previously individuals with a wide range of training, usually including experience in a given business, rose to management positions within corporations, in the present managers are often graduates of general business administration and related programs. Accompanying the rise of business management as a profession has been the development of management societies and associations.

International organizations exist to represent business managers engaged in a multitude of economic enterprises. These organizations serve many purposes, including the coordination of members' activities, facilitating exchange of information and the spread of new findings of interest to business managers, disseminating business information

to members and other interested parties, monitoring trends in specific industries and areas of business management, and gathering and compiling statistics. Thus, business management associations and societies generally seek to encourage the professional advancement of their members, the economic advancement of specific industries or areas of business, and the development of more effective business management practices. In many cases their activities are closely linked to those of management institutes. The following list of some of the leading international management organizations shows both their diversity of scope and the similarity of their activities.

LEADING INTERNATIONAL MANAGEMENT ASSOCIATIONS

Association of Management/International Association of Management (AOM/IAOM). The Association of Management (AoM) and the International Association of Management (IAoM) were founded in 1975 as professional organizations representing business academicians and business management practitioners. The organization was first known as the Association of Human Resources Management and Organizational Behavior (HRMOB), and the name was changed to AoM/IAoM in 1993. According to their mission, both organizations seek to bridge the gap between theory and practice in management, education, technology, and leadership across multiple disciplines. A primary goal is the continuing professional development of individual business managers. In this regard they are closely related to national business management associations worldwide. Together, the associations created a forum called MELT (Management, Education, Leadership, and Technology) to facilitate interdisciplinary discussion about a paradigm shift that is said to be affecting each of the four fields. Both organizations also sponsor regularly scheduled meetings and issue publications to facilitate exchange of information among their members and between members and the wider business community and the public. These publications include: *The International Association of Management Journal, The Journal of Management Systems, The Journal of Information Technology Management, Global Education Management Systems, Computer Science and Information Management,* and *The Journal of Management in Practice.*

American Management Association (AMA). In 1923 the National Personnel Association changed its name to the American Management Association. The AMA's mission is to be "a global, not-for-profit, membership-based association that provides a full range of management development and educational services to individuals, companies, and government agencies worldwide." The organization serves as a forum for information and ideas on management practices and business trends disseminated worldwide

through multiple distribution channels, including seminars, webcasts, podcasts, conferences, business books, and research papers. The AMA seminars are led by executives, managers, authors, and consultants, who cover topics such as communication, finance, human resources, information technology, leadership, management marketing, project management, and sales and strategic planning. The association's flagship publication is *MWorld*.

All India Management Association (AIMA). The All India Management Association (AIMA) claims to be the one Indian body helping to equip Indian managers to make the most of opportunities arising from transition. Begun in 1957 with support from the Indian government and industry, AIMA now has over 30,000 Professional Individual Members and over 3,000 Corporate/Institutional Members. Activities include management education and development, publications, and testing services. Additionally, the association publishes an annual survey on the "Best Business Schools" in India in order to promote management education. AIMA is represented on a number of committees involved with policy making in the Indian government, and is associated with the Asian Association of Management Organizations and the World Management Council, among other groups. AIMA publishes *Indian Management*, which is one of the most widely read management periodicals in India.

European Federation of Management Consulting Associations (FEACO). Founded in 1960, FEACO is an umbrella organization for twenty national associations representing management consultants. In addition to formulating standards of ethics and practice for the field, FEACO conducts industry surveys and compiles statistics on the performance of management consultancy companies in Europe. FEACO also comprises working group and discussion forums concerned with topics such as relations within the European community on procurement-related issues, as well as relations between European institutions and management consultancy companies on free movement of services.

International Project Management Association (IPMA). Initiated in 1965 as an informal discussion group involving managers of international projects, the IPMA held its first official congress in 1967. In 2008 the IPMA represented forty-five national project management associations. The IPMA is the prime international promoter of project management. The IPMA confers professional certification upon qualified individuals, serves as a forum for information exchange within the project management field, conducts research and disseminates information on project management, and sponsors continuing professional education programs for project managers. The

four-level certification program provides a standard for project management performance. The Association publishes *The International Journal of Project Management* as well as posting *PM Practice* and *Project Management Perspectives* on its Web site.

Central and East European Management Development Association (CEEMAN). Originally, CEEMAN was primarily concerned with advancing business and management education in Eastern Europe, and providing for information exchange among members but now, CEEMAN has grown into a global network, which includes 170 institutional and individual members from 42 countries in Europe, North America, Latin America, and Asia. The association is devoted to the development of education, research, consulting, and networking. The organization publishes a quarterly newsletter called the *CEEMAN News*.

Association of International Management Sales Executives (AIMSE). This group represents management sales personnel, pension fund managers, and marketers at money market management firms worldwide. AIMSE seeks to advance the management sales profession and encourages the professional development of its members by conducting educational programs, gathering and disseminating management sales information, and facilitating exchange of information among members at its annual meeting. AIMSE has members in the United States, Canada, the United Kingdom, the Netherlands, Sweden, Denmark, France, Germany, South Africa, Italy, Switzerland, Spain, Greece, and Australia.

Australian Institute of Management (AIM). This is Australia's largest professional body for managers and is well known for providing management training and consulting. AIM maintains a network of bookshop and library facilities dedicated to applied management information. AIM membership is around 25,000 personal members and 6,000 key corporate members; the organization has a staff of 250 people worldwide.

European Association of Personnel Management (EAPM). Founded in 1962 the EAPM represents a specific constituency within business management, namely, personnel managers. The association functions as the European representative of national personnel management organizations, and formulates standards of conduct and practice for personnel managers.

European Women's Management Development Network (EWMD). Founded in 1984 the EWMD represents women in business management in thirty countries regardless of their specific field of endeavor. The network works for the professional advancement of its members,

serves as a forum for the exchange of information regarding women in management, and seeks to ensure gender equity in the business management professions. The EWMD includes 800 members, individual and corporate.

Institute of Management Specialists (IMS). Founded in 1971 the IMS comprises business managers and commercial business and technical professionals. IMS is part of a group that promotes performance excellence, along with the Institute of Manufacturing, the Professional Business and Technical Management, the Academy of Multi-Skills, and the Academy of Executives and Administrators. The institute formulates standards of practice for management specialists, and conducts examinations and bestows professional certification upon qualified individuals.

Institute for Supply Management (ISM). The Institute for Supply Management is the largest supply management organization in the world. Founded in 1915 the institute is a not-for-profit association that provides research, promotional activities, and education to 40,000 supply managers.

International Association for Business and Society (IABS). The IABS is a society concerned with research and teaching about the relationships between business, government, and society. Founded in 1990 the organization has over 300 members from over 100 universities in more than 20 countries, in addition to the membership of corporations and various nonprofit entities. The Association conducts research with regard to corporate social responsibility, business ethics, business and government relations, and business ethics, among others. Additionally, the IABS sponsors the journal, *Business & Society*.

UNIVERSITY MANAGEMENT INSTITUTES

A somewhat related category of organizations concerns university management institutes. These organizations are similar to management societies and associations, but they generally pursue somewhat different goals. Management institutes exist world wide, and although they are primarily engaged in educational activities, they also occasionally work with management associations and industrial groups to gather data on specific industries or areas of economic activity. This information can be useful for companies that wish to benchmark their business operations against other companies in the same industry. The research and knowledge carried out by the International Institute for Management Development (IMD) provides an example of this sort of cooperation between academia, industry, and business management associations.

Among the research centers at the IMD is the World Competitiveness Center, which releases an annual report

on the competitiveness of nations. This report ranks countries according to the degree to which the business environment fosters competitive enterprises. The research centers consolidate information from the IMD faculty, Corporate Learning Network companies, researchers, and outside specialists to provide information about best practice, sustainability, and leadership strategies.

The IMD Manufacturing 2000 Project (M2000), a ten-year project begun in 1990, brought together an operating team comprising researchers, professors, business managers, and corporate board members representing sixteen large manufacturing firms. Each firm participating in the project submitted their plans for managing change and developing best practices for consideration and revision by the entire M2000 operating team. Corporate, managerial, and academic participants in M2000 found that the project facilitated information exchange and had a positive influence on all concerned. Keeping in touch with the realities of everyday business management helped academicians develop more useful research projects, while remaining familiar with academic developments proved useful for managers wishing to make changes in corporate procedure or structure. Thus, although it is essentially an academic program, the International Institute of Management Development fulfills a function similar to that of leading business management associations.

Similarly, the Decision Analysis Society (DAS), operated by the Fuqua School of Business at Duke University, is an organization comprising business academicians and researchers, managers, and other corporate representatives. DAS seeks to promote and develop the use of logical methods for the improvement of the decision-making process in both public and private enterprises. The society develops model procedures, risk analysis and assessment techniques, and expert systems for decision support.

Another example of a university management institute, the Federation for Enterprise Knowledge Development (FEND), is a collaborative effort involving representatives of leading corporations and business academics. FEND serves as a think tank, analyzing business management tools and methods, and researching new management strategies. The federation also develops business management software applications, conducts educational programs for business managers, and provides assistance to businesses wishing to improve their management practices.

Other international university management institutes include the European Foundation for Management Development, through which academicians, corporations, managers, and educational institutions in forty-five countries work to address current issues in management development; the Institute for Administrative Management, an organization of professional managers and business management students united to identify and disseminate new trends

and techniques in administrative management; and the Strategic Planning Society, through which educational institutions, government officials, business executives, and corporations of all sizes work to improve public policies regulating the practice of business management.

In a somewhat separate category is the International Academy of Management (IAM), an organization comprising fellows elected for their contributions to the field of management. The IAM is in large measure an educational organization whose main goal is to identify and objectively evaluate new hypotheses in the study and practice of business management.

THE ROLE OF MANAGEMENT ASSOCIATIONS AND SOCIETIES

As the above examples suggest, management associations, as distinct from university management institutes, exist primarily to advance their members' interests, or to advance a particular class or type of business manager. They can be active in the formulation of professional standards of ethics and practice, the development of national and international public policies pertaining to business and trade, business and management education, and the gathering and dissemination of information on the entire spectrum of business and management topics. They may also serve as certification bodies and sources of ethical and practice standards within a particular business management field. International management associations and societies all share one common function: facilitating the exchange of information among professionals from different countries. As such, they play a vital role in stimulating global trade and promoting the advancement of business management as a profession.

INTERNATIONAL MONETARY FUND

Headquartered in Washington, D.C., the International Monetary Fund (widely known as the IMF) is an international cooperative institution whose main mission is to promote and assist in international monetary stability. With its initial organization coming at the end of World War II, for many years the main goal of the IMF was to oversee a system of stable, fixed exchange rates among the currencies of member nations. Since 1971, the exchange rates of the world's currencies have been allowed to float, with supply and demand market forces determining their value. In 2008, the IMF consisted of 185 member countries, which pay an initial quota subscription to become members. The organization works to achieve and enhance a stable world economy through the promotion of open financial disclosure among member nations, the provision of loans during periods of economic crises, and technical assistance provided through educational and promotional means.

The IMF has come under criticism from some sources for its role in high-profile assistance offered to the Mexican, South Korean, and Russian economies, among others. The member nations, however, continue to support the organization in its efforts to sustain international economic stability and promote international trade.

HISTORY

The events that ultimately led to the creation of the IMF had their origins in the conclusion of World War I. The economic terms of surrender were negotiated at the 1919 peace conference in Paris. As part of the peace treaty, known as the Treaty of Versailles, England and France demanded large amounts of war reparation payments from Austria and Germany to help rebuild their war-torn economies. However, the Austrian and German economies were depleted, too. This forced them to rely on foreign imports for goods and services unable to be produced locally. When a country imports more than it exports, it runs a balance of payments deficit. Together with other factors, the result may be a devaluation of the currency, since foreign sellers often demand to be repaid in their own currencies. The addition of war reparations on top of a large balance of payments deficit exacerbated the economic crisis, resulting in hyperinflation and political instability in Germany.

The great British economist John Maynard Keynes had participated in the peace conference following World War I and foresaw the scenario described above. Indeed, his book *The Economic Consequences of the Peace* predicted a second world war as an inevitable consequence of the severe penalties and lack of political and economic cooperation following the conclusion of World War I.

THE CREATION OF THE IMF

Keynes was determined to avoid repeating the mistakes made in the Treaty of Versailles. As World War II came to a close in 1944, an international conference was held at the resort community of Bretton Woods, New Hampshire. Forty-four nations were represented at the conference, with the chief negotiators being Keynes from Great Britain and Harry Dexter White from the United States. The result of their deliberations was the creation of the International Monetary Fund. The original goals of the fund were to aid members needing foreign exchange to conduct international trade and to promote a system of fixed exchange rates.

The original plan called for the U.S. dollar to be pegged to gold at a rate of $35 per ounce. Other currencies were set at fixed exchange rates to the dollar, and thus indirectly tied to gold. Countries participating agreed to set a "par" value for their currency based on this fixed exchange rate, allowing for a 1 percent fluctuation band. Should a country experience problems maintaining its par value, the IMF stood ready to lend foreign exchange to aid the cause. Member nations made an initial deposit into the fund known as a quota subscription. These deposits formed a pool from which the IMF could extend loans to members. As a special provision, if a member nation experienced chronic problems maintaining its par value, it would be allowed a one-time devaluation of its currency of up to 10 percent.

SPECIAL DRAWING RIGHTS

In 1969 the IMF created a new hybrid asset to serve as a reserve currency. The new financial asset was named a special drawing right, or SDR. The value of an SDR is a function of the current value of five different currencies from which it is comprised. They include the U.S. dollar, the Japanese yen, the United Kingdom pound sterling, and the respective euro values of Germany and France. The respective weights of the currencies, which constitute SDRs value, are revised every five years.

Member nations may use SDRs in a variety of ways. These include exchanging SDRs for other monetary assets or for maintaining operations, and exchanging SDRs directly with other members in exchange for foreign currencies to address a balance of payments problem. Since part of the mission of the IMF is to promote and enhance international trade, the board of governors has the option to decide on periodic special allocations of SDRs to augment members' existing reserve accounts.

THE IMF AND THE WORLD BANK

In addition to the IMF, the Bretton Woods Agreement resulted in the formation of the World Bank. Formally known as the International Bank for Reconstruction and Development, the World Bank's primary goal is to promote economic growth among the world's developing nations. It does so by effectively serving an investment-banking role, issuing bonds and notes to raise new investment capital, which it in turn lends to poor nations to finance specific projects. Typical projects include those associated with enhanced transportation routes, electric power development, and increased agricultural production.

As they share the ancestry of the Bretton Woods conference plus related economic roles, confusion between the IMF and the World Bank is common among the general public. They remain, however, two distinct organizations with their own individual goals and agendas aimed at promoting economic health and development among the world's nations.

THE END OF BRETTON WOODS

The system of fixed exchange rates created by the Bretton Woods Agreement and overseen by the IMF lasted from 1946 until 1971. For much of that period, the system worked very well. The U.S. dollar was pegged to gold and most other currencies were pegged to the dollar. During much of this period the United States ran a trade surplus, exporting more goods and services than it imported. Thus, the amount of U.S. dollars held domestically on net increased, causing little strain on the international monetary system.

This scenario changed during the 1960s. As the United States expanded its level of imports and increased industrial output during the Vietnam War, the amount of dollars held overseas expanded greatly. These dollars were deposited in foreign banks, allowing the banks to extend U.S. dollar denominated loans. The supply of U.S. dollars outstanding expanded significantly. At the same time, as more dollars were presented for redemption, the U.S. gold supply was being depleted. By the end of the decade, there were more dollars outstanding than there was gold to back them. In August 1971 the Nixon administration acknowledged the situation by closing the gold window, refusing to allow foreign central banks to exchange U.S. dollars for gold.

The Smithsonian Agreement of that year began the process of ending the Bretton Woods system of fixed foreign exchange rates. The initial agreement called for expanded fluctuation of exchange rates from 1 percent to 2.25 percent; subsequent economic activity made these bands unfeasible. Governments then decided to let their

respective currencies float relative to each other, and the world moved to a floating exchange rate system.

THE ROLE OF THE IMF EVOLVES

In 1978, the IMF formally amended its constitution to alter its role in the world economy. It now plays a number of roles in its overall mission of promoting international stability and growth. These roles fall generally under three areas: surveillance, technical assistance, and financial assistance.

In its surveillance function, the IMF serves as a watchdog over member nations' economic policies. In 2007, the IMF dramatically revised its policies on surveillance with its Decision on Bilateral Surveillance of Members' Policies. Some important points from the Decision include:

- Focus on external stability. Country surveillance is focused on exchange rate and monetary, fiscal, and financial strategies, along with assessment of risk and vulnerabilities

- Definite guidelines are set out for countries about how they run their exchange rate policies

- Surveillance is deemed a collaborative process that "has a multilateral, medium-term perspective."

IMF surveillance is an open process, and currently nearly all member nations publish a Public Information Notice, which creates a transparent oversight environment.

Technical assistance to member nations takes up a large amount of daily operations at the fund. The IMF provides expertise and consultation on matters involving the implementation of both fiscal and monetary policy, trade laws and tariff measures, and programs aimed at strengthening and stabilizing local currency values. The organization has also implemented a regional model for technical assistance, and has six regional technical assistance centers. In addition, it offers training for member countries' officials through a network of seven different regional training institutes. Other forms of technical assistance include placement of experts and resident advisors, online support, and diagnostic studies.

Perhaps the one area that has brought the IMF the most attention and raised its image among the general public has been its role of providing financial assistance to nations experiencing economic crises. This involves providing credits or arranging loans for nations experiencing such problems as severe balance of payments deficits or a sudden devaluation of their currency.

The 1990s saw the IMF make global headlines with several widely publicized financial assistance programs. The first occurred in 1995 with the crisis in Mexico. Faced with a severe devaluation of its currency due to a rapid loss of confidence in its policies, the Mexican government turned to the IMF for what was then a record $17.8 billion financial assistance package. While attempting to move towards a market-oriented economy, Russia required financial assistance several times during the 1990s. Included were large loans in both 1996 and 1998. And, in 1997, an extended crisis throughout much of east Asia resulted in the IMF arranging financial assistance for South Korea, Indonesia, and Thailand.

These financial assistance programs, which have grown successively larger in amount, have met with severe criticism from some sources. The IMF has been labeled a "bailout" source for poorly run economies, serving as a safety net for policymakers unable or unwilling to make difficult decisions which market discipline demanded. In addition, critics claim that IMF policies encourage poor nations to carry huge amounts of international debt, forcing them to use a large proportion of their annual revenues to make interest payments. The IMF has responded to its critics by actively working with both the public and private sectors to promote better information flow and legislation designed to prevent additional financial crises from taking place. The organization continues to develop systems and procedures designed to limit such crises from spreading to other countries and enveloping entire geographical regions.

The modern International Monetary Fund remains a major player on the global economic stage. The fund continues to grow and expand in its new roles within a world of floating exchange rates and rapid capital flows. The modern IMF wears a number of hats, including overseer and communicator of national policies and legislation, consultant and educator on numerous fiscal and monetary issues, and intermediary and lender for nations whose currencies come under pressure.

Critics continue to denounce the IMF for forcing nations in need to adopt its policy recommendations as a condition of assistance. In addition, the fund raises concerns among those who claim it acts as a safety net to alleviate poor or ineffective domestic monetary and trade policies. The IMF is also frequently charged with favoring bankers and elite classes, obstructing debt reduction for the world's poorest countries, and ignoring human rights violations. "Street protesters have it exactly right, for example, when they argue that the economic policies imposed on developing nations by the International Monetary Fund and World Bank have hammered the poor," Eric Pooley wrote in *Time*. "Using loans and the threat of default as levers, the IMF has pushed more than 90 countries to accept its brand of free-market shock therapy: lowering trade barriers, raising interest rates, devaluating currencies, privatizing state-owned industries, eliminating subsidies and cutting health, education, and welfare spending." In a 2007 article in *Global Politician*, Carol Welch,

coordinator of the U.S. efforts for the United Nations' Millennium Campaign, criticized the dominant role the United States plays in the global economy to "impose SAPs [structural adjustment policies] on developing countries," and opening "their markets to competition from U.S. economies." In the article, Welch stated that she believes SAPs are "based on a narrow economic model that perpetuates poverty, inequality, and environmental degradation."

Such criticisms are not likely to dissipate soon. Nevertheless, the 185 member nations continue to support the IMF in the belief that open communication and coordinated policies will lead to greater stability and promote a climate which fosters growth in international trade and development.

INTERNATIONAL ORGANIZATION FOR STANDARDIZATION

The International Organization for Standardization (ISO) is a non-governmental organization based in Geneva, Switzerland, that works to develop technical standards for products and services sold around the world. The steady rise in international trade began in the mid-nineteenth century and has persisted until the present day providing impetus for the global standardization of goods and services. Companies with overseas operations must know that products or services they contract for outside their home country will conform to their needs, and the only way to ensure this is for both parties in the transaction to meet a single set of standards. Thus, as economic interdependence increased among nations on all continents, the need for an authoritative international standards body became increasingly apparent. To address this need, the International Organization for Standardization (ISO) was founded in 1947.

The ISO comprises national standards bodies representing 15,748 countries and serves a variety of functions. It facilitates communication and cooperation among its members, eases the distribution of scientific and technical information on standards and standardization, and maintains online databases covering international standards and other organizational activities. The ISO also seeks to ensure that standards are not used as a non-tariff barrier to international trade by formulating international standards applicable to the full scope of commercial activity in any locale worldwide.

The ISO has a relationship with the World Trade Organization (WTO) because the organizations have the mutual goal of reducing technical barriers to trade. Additionally, the ISO collaborates with various UN agencies and commissions including CODEX Alimentarius, (on food safety), the UN Economic Commission for Europe, (on the safety of vehicles and the transportation of goods), the World Health Organization, (regarding health technology), and the World Tourism Organization (concerning the quality of tourism-related services). The ISO is also involved in international development organizations, including the United Nations Conference on Trade and Development, the United Nations Industrial Development Organization, and the International Trade Center.

Although the majority of standards promulgated by the ISO are the result of the internal activities of its technical committees and working groups, ISO standards are not necessarily handed down to companies from the central organization. Companies often send their own internal standards to the ISO for consideration as international standards. Similarly, national standards organizations work with the ISO to make accepted national standards internationally applicable.

Adherence to standards formulated by ISO is completely voluntary, but many standards set by the organization are incorporated into treaties and national laws. Companies that do conform to them have a distinct advantage over those that do not, particularly when trading overseas. ISO standards cover the entire spectrum of scientific, industrial, and commercial activities, including computer operating systems, manufacturing processes, product quality, safety, management technique, and environmental protection.

The ISO is not the only organization seeking to set global standards. The ISO and the International Electrotechnical Commission (IEC) formed a joint committee to set standards related to information technology. The ISO and the IEC are also partnered with the International Telecommunication Union (ITU). Together, the three committees form the World Standards Cooperation.

In addition to its specific quality standards, the ISO has issued two sets of general standards, the ISO 9000 and ISO 14000 families, to govern manufacturing and organizational processes and environmental protection, respectively.

THE ISO 9000 QUALITY STANDARDS SERIES

Released in 1987 and updated in 2000, the ISO 9000:2000 standards series governs general international quality assurance for products and services. A new edition of ISO 9001 will be submitted for approval by the ISO membership in the fall of 2008, but no new requirements will be added to the 2000 version. ISO 9000 is divided into five specific areas. ISO 9000 is an overview, which includes guidelines for the selection, and use of quality management and quality assurance standards, provides definitions of quality concepts, and serves as a guide for the selection of ISO quality models applicable to specific industries. ISO 9001 provides a model for quality assurance in design and development, production, installation, and services. ISO 9002 provides a model for quality assurance in production and installation. ISO 9003 provides a model for quality assurance in final inspection and testing of products. Finally, ISO 9004 sets forth guidelines for developing and implementing internal corporate quality management programs and quality systems.

Each facet of the ISO 9000 standards series is general and can be applied to any industrial activity. In fact, the series' lack of specificity has led critics to note that two companies complying with ISO 9000 could conceivably produce goods that were radically different in terms of quality. The U.S. Department of Defense holds this view, stating that the ISO 9000 standards "are not adequate for use without significant supplementation." Despite these limitations, many corporations worldwide choose to adhere to the ISO 9000 standards. ISO 9000 is the most widely implemented quality management system standard. Under the General Agreement on Tariffs and Trade (GATT), companies may demand that their suppliers or other trading partners achieve ISO 9000 certification, and this demand will not be considered an illegal restraint of trade under GATT. Regardless of corporate opinions regarding ISO 9000, many countries are mandating that the foreign companies with which they trade achieve certification. For example, overseas producers of computer switches and pacemakers must be certified under ISO 9000 to trade with the European Union, as must computer software producers wishing to sell their goods in Japan.

Companies wishing to attain ISO 9000 certification must first register with the ISO. Prior to registration, a third-party registrar must be found to audit and evaluate the company's operations and recommend changes that must be made to ensure conformation. Prior to this audit, companies must prepare a quality assurance program; define, document, and implement new procedures; and compile a corporate quality manual and pre-assess the manual with the selected auditor.

Many adherents to the ISO 9000 standards have found that several components are necessary to ensure certification. First, companies must carefully evaluate their trading relationships to determine whether adherence to the ISO 9000 standards will result in increased profitability. If this is judged to be the case, management must be completely committed to achieving certification and a competent registrar must be secured. Staff must be carefully educated regarding the changes in processes and products required for conformation, and a core cadre of employees must be trained to constantly audit procedures following certification and conduct the periodic audits required to ensure that standards are being maintained. Additionally, some organizations have a third party independently verify that they have fully complied with the ISO 9000 standards in order to substantiate their assurance of quality.

In its early years, the ISO 9000 series of standards was not adopted as readily as had been anticipated, but by the early 1990s the standards were beginning to receive more widespread use. The U.S. Commerce Department finally endorsed global acceptance of ISO 9000 in 1994, and the formation of the International Accreditation Forum during the same year also provided an impetus to ISO 9000 certification. By 2005 more than half a million organizations in over sixty countries had either implemented or were in the process of implementing the quality management framework outlined in ISO 9000.

Although the ISO 9000 series eventually caught on and began to fulfill its role in regulating international industrial, commercial, and management activity, even its staunchest adherents found that the series did not account for environmental protection. This oversight allowed too much latitude for differences in process between companies in different countries, particularly those in the chemical industries. The Global Environmental Initiative held in Rio de Janeiro, Brazil, in 1992 further established the need for an internationally recognized set of standards governing industrial and commercial environmental protection policies and processes. In response to this need, ISO began work on a new series of standards designed to govern environmental protection.

THE ISO 14000 SERIES OF STANDARDS

Released in 1996 and updated in 2004, the ISO 14000 series of standards is designed to supplement the ISO 9000 series. The ISO 14000 standards provide generic requirements for maintaining a sustainable environment management system at any organization. The standards do not define specific levels of environmental performance, but they do require that organizations conform to all environmental legislation applicable to their activities and commit

to striving for "continual improvement." Adherence to ISO 14000 assures customers, regulators, and the general public that a company has sound environmental protection policies and processes. ISO 14000 is divided into ten separate areas of standardization:

1. ISO 14001 provides a model framework for the establishment of an environmental management system.

2. ISO 14004 offers a checklist for companies wishing to implement ISO 14001, and is not mandatory for ISO 14000 certification.

3. ISO 14010 is also voluntary and establishes guidelines for corporate environmental auditing procedures, including definition of quality audit evidence.

4. ISO 14011 provides guidance for the voluntary formation of corporate environmental auditing procedures, including a general outline of an effective environmental audit.

5. ISO 14012 delineates qualification criteria for environmental auditors.

6. ISO 14020 establishes standards for scientific evidence presented in corporate environmental management audits

7. ISO 14021 allows companies to self-declare environmental claims under certain circumstances.

8. ISO 14024 provides guidelines for verifying corporate environmental management claims and delineates the criteria which must be met for companies to use ISO-recognized labels advertising their compliance with ISO 14000 environmental standards.

9. ISO 14031 establishes standards for corporate review of existing environmental management systems.

10. ISO 14040 provides guidelines and criteria for long-range environmental assessments, which are required to determine whether or not certain commercial activities can be considered environmentally sustainable.

Although the ISO 9000 standards are currently viewed favorably in the corporate world, ISO 14000 has proven more controversial. ISO 14000 does not stipulate standards of corporate environmental performance, but rather governs only the means a company must employ to make its production activities environmentally sustainable. National standards for compliance with ISO 14000 also differ widely, as the third-party audits required to attain certification are conducted differently in different countries and with differing criteria for compliance. Finally, while the GATT agreements allow companies to stop doing business with trading partners that fail to achieve ISO 9000 certification, refusing to do business with a company that failed to achieve ISO 14000 certif-

ication could be considered an illegal restraint of trade under the GATT provisions. Companies based in the United States have been particularly unwilling to secure ISO 14000 certification, given the amount of time, money, and effort they already expend in meeting the standards of environmental performance and practice set by the federal Environmental Protection Agency (EPA). Not only do U.S. firms feel that the addition of ISO 14000 makes the regulatory burden too great, many corporations object to public disclosure of environmental information, which may damage their reputation as well as expose them to the possibility of litigation.

Although widespread corporate compliance with ISO 14000 did not occur in the series initial years, increased awareness of environmental concerns among both government agencies and the public worldwide will provide an impetus for ISO 14000 certification in the future. For instance, the rigorous European Union Eco-Management and Audit Scheme (EMAS) has proven difficult for many companies to implement, yet compliance with EMAS may become essential for firms wishing to trade in Europe. Companies have been participating in EMAS since 1995 and the scheme has been open to all economic sectors since 2001. In 2008 the European Commission proposed to decrease the burden and cost of implementing EMAS in order to encourage participation. Compliance with ISO 14000 standards will automatically make a company also eligible for EMAS certification. Similarly, compliance with ISO 14000 will provide a powerful marketing tool for companies wishing to sell products to environmentally conscious consumers. Compliance with ISO 14000 also provides legal evidence of due diligence, which would mitigate in favor of any ISO 14000-certified company which is sued for creating environmental damage or hazards. Finally, ISO 14000 certification removes barriers to international trade in the same manner as does ISO 9000 compliance.

THE FUTURE

Since its founding in 1947, the ISO has published more than 17,000 international standards, covering everything from dimensions of freight containers to symbols that provide danger warnings. ISO has addressed the standardization of protocols to allow different types of computers to communicate with one another, as well as the standardization of interfaces and connections to ensure the interoperability of various technologies. Although the majority of ISO standards are specific to individual products, materials, or processes, the ISO 9000 and 14000 series provide generic management system standards that can be applied to any product or service, by any type of organization.

ISO standards are not without their critics in the business world. Critics claim that the standards can be costly and time-consuming to implement, for example. But proponents

point out that ISO certification enables businesses to increase knowledge of their capabilities, improve their processes and performance, ensure consumer and stockholder confidence, and gain a source of competitive advantage. As a result, the ISO seems likely to play an increasingly important role in international trade in the future. The general lowering of tariff barriers worldwide in recent years has led to a contradictory rise in the use of standards to exclude products of certain countries or regions, a practice that global adoption of ISO standards would eradicate. Furthermore, in the case of the ISO 14000 series, increased public environmental consciousness will provide a powerful incentive for corporate compliance and in the long run will also result in the passage of public policies mandating environmental sustainability such as the EMAS.

THE INTERNET

The Internet is the world's largest computer network. It is a global information infrastructure comprising millions of computers organized into hundreds of thousands of smaller, local networks. The term "information superhighway" is sometimes used to describe the function that the Internet provides: an international, high-speed telecommunications network that offers open access to the general public.

The Internet provides a variety of services, including electronic mail (e-mail), the World Wide Web (WWW), Intranets, File Transfer Protocol (FTP), Telnet (for remote login to host computers), and various file-location services.

HISTORY OF THE INTERNET

The idea for the Internet began in the early 1960s as a military network developed by the U.S. Department of Defense's Advanced Research Project Agency (DARPA). At first, it was a small network called ARPANET, which promoted the sharing of super-computers amongst military researchers in the United States. A few years later, DARPA began to sponsor research into a cooperative network of academic time-sharing computers. By 1969, the first ARPANET hosts were constructed at Stanford Research Institute, University of California, Los Angeles (UCLA), University of California Santa Barbara, and the University of Utah.

A second factor in growth was the National Science Foundation's NSFNET, built in 1986 for the purpose of connecting university computer science departments. NSFNET combined with ARPANET to form a huge backbone of network hosts. This backbone became what we now think of as the Internet (although the term "Internet" was used as early as 1982).

The explosive growth of the Internet came with major problems, particularly related to privacy and security in the digital world. Computer crime and malicious destruction became a paramount concern. One dramatic incident occurred in 1988 when a program called the "Morris worm" temporarily disabled approximately 10 percent of all Internet hosts across the country. The Computer Emergency Response Team (CERT) was formed in 1988 to address such security concerns.

In 1990, as the number of hosts approached 300,000, the ARPANET was decommissioned, leaving only the Internet with NSFNET as its sole backbone. The 1990s saw the commercialization of the Internet, made possible when the NSF lifted its restriction on commercial use and cleared the way for the age of electronic commerce.

Electronic commerce was further enhanced by new applications being introduced to the Internet. For example, programmers at the University of Minnesota developed the first point-and-click method of navigating Internet files in 1991. This program, which was freely distributed on the Internet, was called Gopher, and gave rise to similar applications such as Archie and Veronica.

An even more influential development, also started in the early 1990s, was Tim Berners-Lee's work on the World Wide Web, in which hypertext-formatted pages of words, pictures, and sounds promised to become an advertiser's dream come true. At the same time, Marc Andreessen and colleagues at the National Center for Supercomputing Applications (NCSA), located on the campus of University of Illinois at Urbana-Champaign, were developing a graphical browser for the World Wide Web called Mosaic (released in 1993), which would eventually evolve into Netscape.

By 1995, the Internet had become so commercialized that most access to the Internet was handled through Internet service providers (ISPs), such as America Online and Netcom. At that time, NSF relinquished control of the Internet, which was now dominated by Web traffic.

Partly motivated by the increased commercial interest in the Internet, Sun Microsystems released an Internet programming language called Java, which promised to radically alter the way applications and information can be retrieved, displayed, and used over the Internet.

By 1996, the Internet's twenty-fifth anniversary, there were 40 million Internet users; by 2002, that number had increased to 531 million, and by 2006 the number of Web users was roughly 750 million. Internet-based electronic commerce has reached major proportions as well, totalling roughly $140 million in revenue in the United States alone in 2007. This number continues to rise steadily throughout the 2000s.

BANDWIDTH

Bandwidth is the capacity of a particular pathway to transmit information for online purposes. It is bandwidth that controls how fast Web sites download. In analog settings (such as dial-up), bandwidth is measured by frequency, the difference between the highest and lowest frequencies, expressed in Hertz. Digital lines measure bandwidth in bits/bytes per second (the amount of information transferred every second). Companies often determine and set the amount of bandwidth allowed for certain activities, an activity called bandwidth allocation.

INTERNET CONNECTIONS

There are many types of Internet connections, which have changed in sophistication and speed throughout the Internet's history. The first kind is the analog connection, or dial-up, one of the cheapest and slowest ways to connect. The computer dials a phone number to access the network and the modem can convert the data to either format, as required. This analog format is the slowest connection, and the one most subject to quality issues. ISDN, or integrated services digital network, is the international format for normal phone-related Internet connections. B-ISDN is a more recent format for other phone connections, such as fiber optics.

DSL is a constant connection that will take up the phone line the way an analog connection does. There are two main types of DSL—ADSL, which is used most commonly in America, and SDSL, which can transmit a larger amount of information and is more often found in Europe.

Others receive Internet through cable, a broadband connection that operates through TV lines. Certain TV channels are used to take and receive Internet information, and since these coaxial cable connections can handle a much higher rate of data than phone lines, cable Internet service tends to be faster.

Wireless Internet is also becoming popular—connecting computers to the Internet through radio-wave transmissions. This requires a wireless hub or router that transmits information into radio waves, but the connection can be accessed from anywhere in the radius of the broadcast.

E-MAIL

Electronic mail, or e-mail, is the most widely used function used on the Internet today. Millions of messages are passed via Internet lines every day throughout the world. Compared to postal service, overnight delivery companies, and telephone conversations, e-mail via the Internet is extremely cost-effective and fast. E-mail facilities include sending and receiving messages, the ability to broadcast messages to several recipients at once, storing and organizing messages, forwarding messages to other interested parties, maintaining address books of e-mail partners, and even transmitting files (called "attachments") along with messages.

Internet e-mail messages are sent to an e-mail address. The structure of an e-mail address is as follows: PersonalID@DomainName

The personal identifier could be a person's name or some other way to uniquely identify an individual. The domain is an indicator of the location of that individual, and appears to the right of the "at" (@) sign. A domain name is the unique name of a collection of computers that are connected to the Internet, usually owned by or operated on behalf of a single organization (company, school, or agency) that owns the domain name. The domain name consists of two or more sections, each separated by a period.

From right-to-left, the portions of the domain name are more general to more specific in terms of location. In the United States, the rightmost portion of a domain is typically one of the following:

- com—indicating a commercial enterprise
- edu—indicating an educational institution
- gov—indicating a governmental body
- mil—indicating a military installation
- net—indicating a network resource
- org—indicating a nonprofit organization

In non-U.S. countries, the rightmost portion of a domain name is an indicator of the geographic origin of the domain. For example, Canadian e-mail addresses end with the abbreviation "ca."

WORLD WIDE WEB

The World Wide Web (WWW) is a system and a set of standards for providing a graphic user interface (GUI) to Internet communications. The Web is the single most important factor in the popularity of the Internet, because it makes the technology easy to use and gives attractive and entertaining presentation to users.

Graphics, text, audio, animation, and video can be combined on Web pages to create dynamic and highly interactive access to information. In addition, Web pages can be connected to each other via hyperlinks. These hyperlinks are visible to the user as highlighted text, underlined text, or images that the user can click to access another Web page.

Browsers. Web pages are available to users via Web browsers, such as Mozilla/Firefox, Apple's Safari, Opera, or Microsoft's Internet Explorer. Browsers are programs that run on the user's computer and provide the interface that displays the graphics, text, and hyperlinks to the user. Browsers recognize and interpret the programming language called Hypertext Markup Language (HTML). HTML includes the ability to format and display text; size and position graphics images for display; invoke and present animation or video clips; and run small programs, called applets, for more complex interactive operations. Browsers also implement the hyperlinks and allow users to connect to any Web page they want.

Search Engines. Sometimes a user knows what information she needs, but does not know the precise Web page that she wants to view. A subject-oriented search can be accomplished with the aid of search engines, which are tools that can locate Web pages based on a search criterion established by the user. By far, Google is the most commonly used search engine.

Blogs. The ease with which users can publish their own information using the World Wide Web has created an opportunity for everyone to be a publisher. An outcome from this is that every topic, hobby, niche, and fetish now has a thriving community of like-minded people. The ease of publishing information on the Web became easier with the advent of Web logs or "blogs," online diaries that opened the floodgates to an even greater level of individual participation in information sharing and community.

UNIFORM RESOURCE LOCATORS (URL)

A Uniform Resource Locator (URL) is a networked extension of the standard filename concept. It allows the user to point to a file in a directory on any machine on the Internet. In addition to files, URLs can point to queries, documents stored deep within databases, and many other entities. Primarily, however, URLs are used to identify and locate Web pages.

A URL is composed of three parts:

Protocol. This is the first part of the address. In a Web address, the letters "http" stand for Hypertext Transfer Protocol, signifying how this request should be dealt with. The protocol information is followed by a colon. URL protocols usually take one of the following types:

- http—for accessing a Web page
- ftp—for transferring a file via FTP
- file—for locating a file on the client's own machine
- gopher—for locating a Gopher server
- mail—for submitting e-mail across the Internet
- news—for locating a Usenet newsgroup

Resource Name. This is the name of the server/machine at which the query should be directed. For an "http" request, the colon is followed by two forward slashes, and this indicates that the request should be sent to a machine.

Path and File Name. The rest of a URL specifies the particular computer name, any directory tree information, and a file name, with the latter two pieces of information being optional for Web pages. The computer name is the domain name or a variation on it (on the Web, the domain is most commonly preceded by a machine prefix "www" to identify the computer that is functioning as the organization's Web server, as opposed to its e-mail server, etc.).

If a particular file isn't located at the top level of the directory structure (as organized and defined by whoever sets up the Web site), there may be one or more strings of text separated by slashes, representing the directory hierarchy.

Finally, the last string of text to the right of the right-most slash is the individual file name; on the Web, this often ends with the extension "htm" or "html" to signify it's an HTML document. When no directory path or file name is specified (e.g., the URL http://www.domain.com), the browser is typically pointed automatically to an unnamed (at least from the user's perspective) default or index page, which often constitutes an organization's home or start page.

Thus, a full URL with a directory path and file name may look something like this:

http://www.mycompany.com/files/myfile.html

Lastly, a Web URL might also contain, somewhere to the right of the domain name, a long string of characters that does not correspond to a traditional directory path or file name, but rather is a set of commands or instructions to a server program or database application. The syntax of these URLs depends on the underlying software program being used. Sometimes these can function as reusable URLs (e.g., they can be bookmarked and retrieved repeatedly), but other times they must be generated by the site's server at the time of use, and thus can't be retrieved directly from a bookmark or by typing them in manually.

Spam. Commercial abuse of e-mail continues to be problematic as companies attempt to e-mail millions of online users in bulk. This technique is called "spam," (so named after a skit by the comedy troupe Monty Python that involved the continuous repetition of the word). Online users are deluged with a massive amount of unwanted e-mail selling a wide array of products and services. Spam has become a network-wide problem as it impacts information transfer time and overall network load. Several organizations and governments are attempting to solve the spam problem through legislation or regulation.

Viruses. Computer viruses spread by e-mail have also grown as the Internet has grown. The widespread use of e-mail and the growing numbers of new, uninformed computer users has made it very easy to spread malicious viruses across the network. Security issues for both personal computers and for network servers will continue to be a crucial aspect of the ongoing development of the Internet and World Wide Web.

INTRANET

Intranets are private systems, contained within servers owned by companies. They are based on the same principles that govern the Internet but are not widely available; instead, they are used only for communicating and transferring company information between employees. Companies utilize intranets to protect valuable information from outside access, creating them with layers of protection in place. Because intranet systems are private, they do not suffer from some of the problems the Internet faces, such as speed-related performance issues from too many users trying to access the same sites. Companies can place multimedia presentations on their systems more easily, showing presentations and running training programs for employees.

Company uses for intranet systems are varied, including procedural manuals, employee benefit resources, orientation programs, software and hardware instructions, and even company social networks or e-zine postings. Intranets can also be constructed for a company's specific needs, tailored in functions and appearance. They can include simple files of information, such as spreadsheets or word documents. They can also incorporate search engines that employees can use to find particular components or analyze sets of data. Many also provide links to the Internet and relevant Web sites.

VOIP

VoIP, or Voice over Internet Protocol, is a developing technology allowing users to access audio communication through their Internet settings. The Internet line sends voice transmissions in the form of data packets, like all other types of information stored in servers, which are then changed in audio on a receiving phone system. Users of VoIP benefit by not having to pay for separate phone and Internet services. Beyond the software and hardware required to set up VoIP, companies usually do not need to pay for more than their normal Internet service.

The most important factors in VoIP service are audio quality and accessibility. VoIP can be provided by many different companies, including CoolTalk, Vonage, and Phone Power, but companies should always be sure to conduct tests of the audio quality to ensure it is as good as normal phone service. Also, some companies may prefer to have a back-up system installed in case of emergencies, such as Internet shut-downs or power outages.

SOCIAL NETWORKING

Social networks have become increasingly popular in the past few years with the rise of such Web sites as MySpace and Facebook, where Internet users can create their own profiles and structure personal Web sites in online communities. Thanks to the ease of Internet communication, participants can form friendships and spread information at a high speed across a vast area. Businesses can make use of these social networks in several ways.

Many social networks employ widgets, or embedded advertisements, often in the form of rich media. These interactive advertisements can be posted along the edges of the Web sites and can serve as both marketing and analyzing tools. By making an animated advertisement that can be clicked on or interacted with, a business can judge how attractive the advertisement is through programs designed to collect widget data. Because social networks spread information so quickly, businesses can also use them as platforms to propagate their messages and brand. Some companies have their own MySpace sites to use for marketing purposes, trying a more personal form of promotion that many social network users find honest. Other organizations are beginning to view social networks as an effective way to recruit new employees.

SMARTPHONES AND PDAS

Mobile, handheld computer devices are very common in today's business world. PDAs, which offer online interaction and note-taking abilities, are being increasingly replaced by smartphones, which are phones configured to offer the same services, including connection to the Internet, e-mail, and document programs. While many companies are eager to offer these mobile devices to their employees as a communication tool, only some are currently taking advantage of handhelds as a marketing tool. Websites can be configured to the mini-browsers smartphones rely on, giving those using handheld devices easier access to online information and advertisements. The primary problem cited with smartphones and PDAs is security, since they are not affected by companies' intranet or Internet protections.

E-COMMERCE

E-commerce can take many different forms. Some companies use a "click and mortar" system where they operate stores or factories in physical locations while also offering their products in an online store where orders can be made. Other companies have a central, physical hub and warehouses from which they conduct a large amount of business over the Internet without other bases, such as Amazon.com. Some companies exist by offering purely online services with only a central office, such as eBay.

A company's online store can be constructed to help customers personally, by keeping track of what they view, what they order, and offering similar products that they may be interested in. This is called *personalization*, and the ability to offer each customer their own experience every time they access the company Web site is a powerful marketing tool. It is also important for companies to consistently update their online stores to reflect their changing services or merchandise, including deals and discounts. The interface companies use is also important—how the Web site looks and reacts to customers, especially in response to searches and guided navigation.

WEB CAMS

The current quality of web cams allows companies to transfer video images in real time, letting them use the Internet to video-conference. Some companies are beginning to use video-messaging, a service that often accompanies instant messaging. This technology works for one-on-one meetings and conferences involving multiple attendees.

INTRAPRENEURSHIP

Intrapreneurship describes the process of developing new products, services, and lines of business within an existing company. It is perhaps best understood as a form of internal entrepreneurship that takes place with the encouragement and support of management. An employee who takes responsibility for developing an innovative idea into a marketable product is known as an intrapreneur. Management consultants Gifford and Elizabeth Pinchot coined the term in 1976 and helped popularize the concept of intracorporate entrepreneurship in their pioneering book *Intrapreneuring: Why You Don't Have to Leave the Corporation to Become an Entrepreneur.*

The Pinchots and other experts recognized that entrepreneurial ventures often lost their innovative edge as they grew into established companies. In order to help organizations remain creative and competitive as they grew, the consultants came up with guidelines and models to foster this entrepreneurial spirit among employees. "There are many advantages in working with intrapreneurs in any organization. Given the business environment in this day, any organization needs people who can bring in new ideas and see them through," Emily Hwengere wrote in the Financial Gazette in 2002. "Without intrapreneurs who can identify and exploit new opportunities, organizations will naturally die."

One of the most commonly cited intrapreneurship success stories is 3M Corporation, which has a policy that allows employees to spend 15 percent of their working hours developing their own business or product ideas. This policy led to the creation of Post-It-Notes by an

employee that was looking for something to mark pages in his prayer book.

Intrapreneurship is particularly valued in the information technology industry because product innovation is highly competitive. Employees at large tech companies invented many of the well-established products used today. Steve Jobs and twenty other employees at Apple Computers engineered the Macintosh computer to compete with the Apple II. A former employee of Oracle designed Business Objects, a world leader in business intelligence software.

Experts recommend that business organizations create a culture that provides employees with both freedom and encouragement to develop new ideas. They emphasize that support for intrapreneurship must start with top executives and work its way down in the form of policies, programs, and reward systems. "The real challenge for any company trying to unleash new businesses is that people have to believe that this is not an unnatural act," Gary Hamel told *Inc.* in 2000. "This is what's going to have to happen in companies-bringing ideas, capital, and talent together from all across the corporate entities. Companies have to learn how to leverage the competencies and the assets that they already have within." Some companies foster intrapreneurship by encouraging employees to form competing teams that function like small businesses or internal vendors. Other companies create formal innovation programs to ensure that every new idea receives a fair hearing. In some companies, upper management behaves like a venture capital firm, evaluating and providing financial support for promising new ideas.

Employees who succeed as intrapreneurs tend to possess many of the same talents and traits as traditional entrepreneurs as well as a commitment to the organization and its goals. Working within an existing company—rather than launching an independent start-up business—offers a number of advantages to such individuals. Access to the company's resources increases their chances of success, for example, while maintaining a salaried position provides them with added security in case of failure. Intrapreneurs also gain experience that they can apply to future entrepreneurial ventures, as well as a stimulating work environment. In this way, supporting intrapreneurship can help companies retain valuable employees. "One of the most wonderful things organizations have going for them is that people already have an intrinsic desire to go beyond—to learn, to grow, and to aspire to possibilities within themselves," according to Jacqueline Byrd and Paul Lockwood Brown, authors of the 2002 book *The Innovation Equation*.

Melih Oztalay, author of 2007's *Business Growth: Taking A Look At Innovating For Cash*, cautions companies against being taken in by the innovation myth. Oztalay cites studies that found between 50 percent and 90 percent of new products are financial failures. She points out that the top twelve of Proctor & Gamble's 250 brands make half of the company's sales and more than half of its net profits. Oztalay argues that the "innovation spree" of the 1990s, where companies encouraged intrapreneurs and venture capitalists and invested in countless start-ups, did not generate returns. She concludes that "there's an important difference between being innovative and being an innovative enterprise: The former generates lots of ideas; the later generates lots of cash."

Numerous books, articles, Web sites, and workshops exist to provide advice for companies and employees hoping to take advantage of the opportunities presented by intrapreneurship. In general, such sources recommend that intrapreneurs be willing to take risks, find an internal champion from senior management, negotiate measures of success for their project, ensure that the project is given adequate time to succeed, and select fellow employees who can contribute needed skills. Some of the major factors that inhibit intrapreneurship include resistance to change in organizations, a corporate bureaucracy that slows down project approval, a refusal to allocate resources to new ideas, a lack of training and support for employees, low rewards for success coupled with high costs of failure, and performance evaluation based solely on job descriptions. "When you set up a new unit, be careful that you steer a line between two paths," Hamel explained. "Totally isolating it, which is fine if it isn't at all related to what you're doing, and giving it a bear hug, where you hold on to it so tight that it can never escape the gravitational pull of old beliefs."

INVENTORY MANAGEMENT

Inventory management, or inventory control, is an attempt to balance inventory needs and requirements with the need to minimize costs resulting from obtaining and holding inventory. There are several schools of thought that view inventory and its function differently. These will be addressed later, but first we present a foundation to facilitate the reader's understanding of inventory and its function.

WHAT IS INVENTORY?

Inventory is a quantity or store of goods that is held for some purpose or use (the term may also be used as a verb, meaning to take inventory or to count all goods held in inventory). Inventory may be kept "in-house," meaning on the premises or nearby for immediate use; or it may be held in a distant warehouse or distribution center for future use. With the exception of firms utilizing just-in-time methods, the term "inventory" typically implies a stored quantity of goods that exceeds what is needed for the firm to function at the current time (e.g., within the next few hours).

WHY KEEP INVENTORY?

Why would a firm hold more inventory than is currently necessary to ensure the firm's operation? The following is a list of reasons for maintaining what would appear to be "excess" inventory.

Meet Demand. In order for a retailer to stay in business, it must have the products that the customer wants on hand when the customer wants them. If not, the retailer will have to back-order the product. If the customer can get the good from some other source, he or she may choose to do so rather than electing to allow the original retailer to meet demand later (through back-order). Hence, in many instances, if a good is not in inventory, a sale is lost forever.

Keep Operations Running. A manufacturer must have certain purchased items (raw materials, components, or subassemblies) in order to manufacture its product. Running out of only one item can prevent a manufacturer from completing the production of its finished goods.

Inventory between successive dependent operations also serves to decouple the dependency of the operations. A machine or workcenter is often dependent upon the previous operation to provide it with parts to work on. If work ceases at a workcenter, then all subsequent centers will shut down for lack of work. If a supply of work-in-process inventory is kept between each workcenter, then each machine can maintain its operations for a limited time, hopefully until operations resume at the original center.

Lead Time. Lead time is the time that elapses between the placing of an order (either a purchase order or a production order issued to the shop or the factory floor) and actually receiving the goods ordered.

If a supplier (an external firm or an internal department or plant) cannot supply the required goods on demand, then the client firm must keep an inventory of the needed goods. The longer the lead time, the larger the quantity of goods the firm must carry in inventory.

A just-in-time (JIT) manufacturing firm, such as Nissan in Smyrna, Tennessee, can maintain extremely low levels of inventory. Nissan takes delivery on truck seats as many as 18 times per day. However, steel mills may have a lead time of up to three months. That means that a firm that uses steel produced at the mill must place orders at least three months in advance of their need. In order to keep their operations running in the meantime, an on-hand inventory of three months' steel requirements would be necessary.

Hedge. Inventory can also be used as a hedge against price increases and inflation. Salesmen routinely call purchasing agents shortly before a price increase goes into effect. This gives the buyer a chance to purchase material, in excess of current need, at a price that is lower than it would be if the buyer waited until after the price increase occurs.

Quantity Discount. Often firms are given a price discount when purchasing large quantities of a good. This also frequently results in inventory in excess of what is currently needed to meet demand. However, if the discount is sufficient to offset the extra holding cost incurred as a result of the excess inventory, the decision to buy the large quantity is justified.

Smoothing Requirements. Sometimes inventory is used to smooth demand requirements in a market where demand is somewhat erratic. Consider the demand forecast and production schedule outlined in Table 1.

Notice how the use of inventory has allowed the firm to maintain a steady rate of output (thus avoiding the cost of hiring and training new personnel), while building up inventory in anticipation of an increase in demand. In fact, this is often called anticipation inventory. In essence, the use of inventory has allowed the firm to move demand requirements to earlier periods, thus smoothing the demand.

CONTROLLING INVENTORY

Firms that carry hundreds or even thousands of different part numbers can be faced with the impossible task of monitoring the inventory levels of each part number. In order to facilitate this, many firms use an ABC approach. ABC analysis is based on Pareto Analysis, also known as the "80/20" rule. The 80/20 comes from Pareto's finding

Table 1

	January	February	March	April	May	June
Demand	50	50	0	100	200	200
Produce	100	100	100	100	100	100
Month-end inventory	50	100	200	200	100	0

that 20 percent of the populace possessed 80 percent of the wealth. From an inventory perspective it can be restated thusly: approximately 20 percent of all inventory items represent 80 percent of inventory costs. Therefore, a firm can control 80 percent of its inventory costs by monitoring and controlling 20 percent of its inventory. But, it has to be the correct 20 percent.

The top 20 percent of the firm's most costly items are termed "A" items (this should approximately represent 80 percent of total inventory costs). Items that are extremely inexpensive or have low demand are termed "C" items, with "B" items falling in between A and C items. The percentages may vary with each firm, but B items usually represent about 30 percent of the total inventory items and 15 percent of the costs. C items generally constitute 50 percent of all inventory items but only around 5 percent of the costs.

By classifying each inventory item as an A, B, or C, the firm can determine the resources (time, effort, and money) to dedicate to each item. Usually this means that the firm monitors A items very closely but can check on B and C items on a periodic basis (for example, monthly for B items and quarterly for C items).

Another control method related to the ABC concept is cycle counting. Cycle counting is used instead of the traditional "once-a-year" inventory count where firms shut down for a short period of time and physically count all inventory assets in an attempt to reconcile any possible discrepancies in their inventory records. When cycle counting is used the firm is continually taking a physical count but not of total inventory.

A firm may physically count a certain section of the plant or warehouse, moving on to other sections upon completion, until the entire facility is counted. Then the process starts all over again.

The firm may also choose to count all the A items, then the B items, and finally the C items. Certainly, the counting frequency will vary with the classification of each item. In other words, A items may be counted monthly, B items quarterly, and C items yearly. In addition, the required accuracy of inventory records may vary according to classification, with A items requiring the most accurate record keeping.

BALANCING INVENTORY AND COSTS

As stated earlier, inventory management is an attempt to maintain an adequate supply of goods while minimizing inventory costs. We saw a variety of reasons companies hold inventory and these reasons dictate what is deemed to be an adequate supply of inventory. Now, how do we balance this supply with its costs? First let's look at what kind of costs we are talking about.

There are three types of costs that together constitute total inventory costs: holding costs, set-up costs, and purchasing costs.

Holding costs. Holding costs, also called carrying costs, are the costs that result from maintaining the inventory. Inventory in excess of current demand frequently means that its holder must provide a place for its storage when not in use. This could range from a small storage area near the production line to a huge warehouse or distribution center. A storage facility requires personnel to move the inventory when needed and to keep track of what is stored and where it is stored. If the inventory is heavy or bulky, forklifts may be necessary to move it around.

Storage facilities also require heating, cooling, lighting, and water. The firm must pay taxes on the inventory, and opportunity costs occur from the lost use of the funds that were spent on the inventory. Also, obsolescence, pilferage (theft), and shrinkage are problems. All of these things add cost to holding or carrying inventory.

If the firm can determine the cost of holding one unit of inventory for one year (H) it can determine its annual holding cost by multiplying the cost of holding one unit by the average inventory held for a one-year period. Average inventory can be computed by dividing the amount of goods that are ordered every time an order is placed (Q) by two. Thus, average inventory is expressed as $Q/2$. Annual holding cost, then, can be expressed as $H(Q/2)$.

Set-up costs. Set-up costs are the costs incurred from getting a machine ready to produce the desired good. In a manufacturing setting this would require the use of a skilled technician (a cost) who disassembles the tooling that is currently in use on the machine. The disassembled tooling is then taken to a tool room or tool shop for

maintenance or possible repair (another cost). The technician then takes the currently needed tooling from the tool room (where it has been maintained; another cost) and brings it to the machine in question.

There the technician has to assemble the tooling on the machine in the manner required for the good to be produced. (This is known as a "set-up.") Then the technician has to calibrate the machine and probably will run a number of parts, that will have to be scrapped (a cost), in order to get the machine correctly calibrated and running. All the while the machine has been idle and not producing any parts (opportunity cost). As one can see, there is considerable cost involved in set-up.

If the firm purchases the part or raw material, then an order cost, rather than a set-up cost, is incurred. Ordering costs include the purchasing agent's salary and travel/entertainment budget, administrative and secretarial support, office space, copiers and office supplies, forms and documents, long-distance telephone bills, and computer systems and support. Also, some firms include the cost of shipping the purchased goods in the order cost.

If the firm can determine the cost of one set-up (S) or one order, it can determine its annual setup/order cost by multiplying the cost of one set-up by the number of set-ups made or orders placed annually. Suppose a firm has an annual demand (D) of 1,000 units. If the firm orders 100 units (Q) every time it places an order, the firm will obviously place 10 orders per year (D/Q). Hence, annual set-up/order cost can be expressed as $S(D/Q)$.

Purchasing cost. Purchasing cost is simply the cost of the purchased item itself. If the firm purchases a part that goes into its finished product, the firm can determine its annual purchasing cost by multiplying the cost of one purchased unit (P) by the number of finished products demanded in a year (D). Hence, purchasing cost is expressed as PD.

Now total inventory cost can be expressed as:

Total = Holding cost + Set-up/Order cost + Purchasing cost
or
Total = $H(Q/2) + S(D/Q) + PD$

If holding costs and set-up costs were plotted as lines on a graph, the point at which they intersect (that is, the point at which they are equal) would indicate the lowest total inventory cost. Therefore, if we want to minimize total inventory cost, every time we place an order, we should order the quantity (Q) that corresponds to the point where the two values are equal. If we set the two costs equal and solve for Q we get:

$$H(Q/2) = S(D/Q)$$
$$Q = 2\,DS/H$$

The quantity Q is known as the economic order quantity (EOQ). In order to minimize total inventory cost, the firm will order Q every time it places an order. For example, a firm with an annual demand of 12,000 units (at a purchase price of $25 each), annual holding cost of $10 per unit and an order cost of $150 per order (with orders placed once a month) could save $800 annually by utilizing the EOQ. First, we determine the total costs without using the EOQ method:

$$Q = \$10(1000/2) + \$150(12,000/1,000) + \$25(12,000) = \$306,800$$

Then we calculate EOQ:

$$EOQ = 2(12,000)(\$150)/\$10 = 600$$

And we calculate total costs at the EOQ of 600:

$$Q = \$10(600/2) + \$150(12,000/600) + \$25(12,000) = \$306,000$$

Finally, we subtract the total cost of Q from Q to determine the savings:

$$\$306,800 - 306,000 = \$800$$

Notice that if you remove purchasing cost from the equation, the savings is still $800. We might assume this means that purchasing cost is not relevant to our order decision and can be eliminated from the equation. It must be noted that this is true only as long as no quantity discount exists. If a quantity discount is available, the firm must determine whether the savings of the quantity discount are sufficient to offset the loss of the savings resulting from the use of the EOQ.

There are a number of assumptions that must be made with the use of the EOQ. These include:

- Only one product is involved.
- Demand is deterministic (known with certainty).
- Demand is constant (stable throughout the year).
- There are no quantity discounts.
- Costs are constant (no price increases or inflation).

While these assumptions would seem to make EOQ irrelevant for use in a realistic situation, it is relevant for

items that have independent demand. This means that the demand for the item is not derived from the demand for something else (usually a parent item for which the unit in question is a component). For example, the demand for steering wheels would be derived from the demand for automobiles (dependent demand) but the demand for purses is not derived from anything else; purses have independent demand.

OTHER LOT-SIZING TECHNIQUES

There are a number of other lot-sizing techniques available in addition to EOQ. These include the fixed-order quantity, fixed-order-interval model, the single-period model, and part-period balancing.

Fixed-Order-Quantity Model. EOQ is an example of the fixed-order-quantity model since the same quantity is ordered every time an order is placed. A firm might also use a fixed-order quantity when it is captive to packaging situations. If you were to walk into an office supply store and ask to buy twenty-two paper clips, chances are you would walk out with one hundred paper clips. You were captive to the packaging requirements of paper clips, i.e., they come one hundred to a box and you cannot purchase a partial box. It works the same way for other purchasing situations. A supplier may package their goods in certain quantities so that their customers must buy that quantity or a multiple of that quantity.

Fixed-Order-Interval Model. The fixed-order-interval model is used when orders have to be placed at fixed time intervals such as weekly, biweekly, or monthly. The lot size is dependent upon how much inventory is needed from the time of order until the next order must be placed (order cycle). This system requires periodic checks of inventory levels and is used by many retail firms such as drug stores and small grocery stores.

Single-Period Model. The single-period model is used in ordering perishables, such as food and flowers, and items with a limited life, such as newspapers. Unsold or unused goods are not typically carried over from one period to another and there may even be some disposal costs involved. This model tries to balance the cost of lost customer goodwill and opportunity cost that is incurred from not having enough inventory, with the cost of having excess inventory left at the end of a period.

Part-Period Balancing. Part-period balancing attempts to select the number of periods covered by the inventory order that will make total carrying costs as close as possible to the set-up/order cost.

When a proper lot size has been determined, utilizing one of the above techniques, the reorder point, or point at which an order should be placed, can be determined by the rate of demand and the lead time. If safety stock is necessary it would be added to the reorder point quantity.

Reorder point =
  Expected demand during lead time +
  Safety stock

Thus, an inventory item with a demand of 100 per month, a two-month lead time and a desired safety stock of two weeks would have a reorder point of 250. In other words, an order would be placed whenever the inventory level for that good reached 250 units.

Reorder point =
  100/month × 2 months + 2 weeks'
  safety stock = 250

OTHER SCHOOLS OF THOUGHT IN INVENTORY MANAGEMENT

There are a number of techniques and philosophies that view inventory management from different perspectives.

MRP and MRP II. MRP and MRP II are computer-based resource management systems designed for items that have dependent demand. MRP and MRP II look at order quantities period by period and, as such, allow discrete ordering (ordering only what is currently needed). In this way inventory levels can be kept at a very low level; a necessity for a complex item with dependent demand.

Just-In-Time (JIT). Just-in-time (JIT) is a philosophy that advocates the lowest possible levels of inventory. JIT espouses that firms need only keep inventory in the right quantity at the right time with the right quality. The ideal lot size for JIT is one, even though one hears the term "zero inventory" used.

Theory of Constraints (TOC). Theory of constraints (TOC) is a philosophy which emphasizes that all management actions should center around the firm's constraints. While it agrees with JIT that inventory should be at the lowest level possible in most instances, it advocates that there be some buffer inventory around any capacity constraint (e.g., the slowest machine) and before finished goods.

THE FUTURE OF INVENTORY MANAGEMENT

The advent, through altruism or legislation, of environmental management has added a new dimension to inventory management-reverse supply chain logistics. Environmental

management has expanded the number of inventory types that firms have to coordinate. In addition to raw materials, work-in-process, finished goods, and MRO goods, firms now have to deal with post-consumer items such as scrap, returned goods, reusable or recyclable containers, and any number of items that require repair, reuse, recycling, or secondary use in another product. Retailers have the same type of problems dealing with inventory that has been returned due to defective material or manufacture, poor fit, finish, or color, or outright "I changed my mind" responses from customers.

Finally, supply chain management has had a considerable impact on inventory management. Instead of managing one's inventory to maximize profit and minimize cost for the individual firm, today's firm has to make inventory decisions that benefit the entire supply chain. Through the use of real-time and end-to-end supplier chain reporting technologies, buyers can know exactly where their products are in the supply chain, how much they have in stock, and even how much their supplier can provide.

Management consultants from McKinsey & Company said in late 2007 that emerging technologies have increased and will continue to increase automation for managing capital and assets. Carrefour, Metro, Wal-Mart Stores, and other large retailers have adopted (and asked suppliers to adopt) digital-tagging technologies, such as radio frequency identification (RFID). These stores are further automating their supply chain and inventory management by integrated digital tag technologies with other supply chain systems. As the price of these digital tags falls, they will reduce the costs of managing distribution and increase revenues by helping companies to manage supply more effectively.

INVENTORY TYPES

Inventory is defined as a stock or store of goods. These goods are maintained on hand at or near a business's location so that the firm may meet demand and fulfill its reason for existence. If the firm is a retail establishment, a customer may look elsewhere to have his or her needs satisfied if the firm does not have the required item in stock when the customer arrives. If the firm is a manufacturer, it must maintain some inventory of raw materials and work-in-process in order to keep the factory running. In addition, it must maintain some supply of finished goods in order to meet demand.

Sometimes, a firm may keep larger inventory than is necessary to meet demand and keep the factory running under current conditions of demand. If the firm exists in a volatile environment where demand is dynamic (i.e., rises and falls quickly), an on-hand inventory could be maintained as a buffer against unexpected changes in demand. This buffer inventory also can serve to protect the firm if a supplier fails to deliver at the required time, or if the supplier's quality is found to be substandard upon inspection, either of which would otherwise leave the firm without the necessary raw materials. Other reasons for maintaining an unnecessarily large inventory include buying to take advantage of quantity discounts (i.e., the firm saves by buying in bulk), or ordering more in advance of an impending price increase.

In theory, the higher the level of finished goods inventory on hand, the higher the achievable customer service level, as long as the inventory includes the right goods in the right location. Also, with increased levels of finished goods inventory, companies are able to promise customers shorter order-to-delivery lead times. They also enable companies to accept longer inbound lead times from both internal and external suppliers.

Generally, inventory types can be grouped into four classifications: raw material, work-in-process, finished goods, and MRO goods.

RAW MATERIALS

Raw materials are inventory items that are used in the manufacturer's conversion process to produce components, subassemblies, or finished products. These inventory items may be commodities or extracted materials that the firm or its subsidiary has produced or extracted. They also may be objects or elements that the firm has purchased from outside the organization. Even if the item is partially assembled or is considered a finished good to the supplier, the purchaser may classify it as a raw material if his or her firm had no input into its production. Typically, raw materials are commodities such as ore, grain, minerals, petroleum, chemicals, paper, wood, paint, steel, and food items. However, items such as nuts and bolts, ball bearings, key stock, casters, seats,

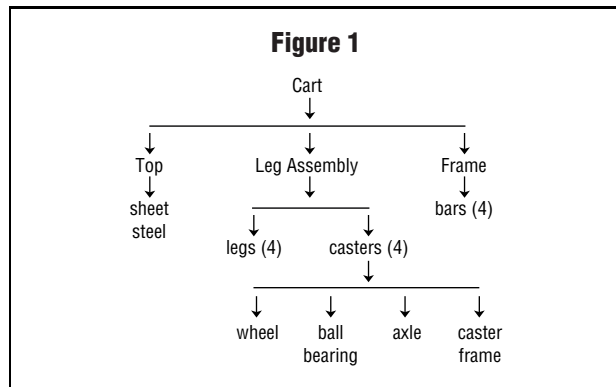
Figure 1

Cart

Top — Leg Assembly — Frame

sheet steel — bars (4)

legs (4) — casters (4)

wheel — ball bearing — axle — caster frame


wheels, and even engines may be regarded as raw materials if they are purchased from outside the firm.

The bill-of-materials file in a material requirements planning system (MRP) or a manufacturing resource planning (MRP II) system utilizes a tool known as a product structure tree to clarify the relationship among its inventory items and provide a basis for filling out, or "exploding," the master production schedule. Consider an example of a rolling cart. This cart consists of a top that is pressed from a sheet of steel, a frame formed from four steel bars, and a leg assembly consisting of four legs, rolled from sheet steel, each with a caster attached. An example of this cart's product structure tree is presented in Figure 1.

Generally, raw materials are used in the manufacture of components. These components are then incorporated into the final product or become part of a subassembly. Subassemblies are then used to manufacture or assemble the final product. A part that goes into making another part is known as a component, while the part it goes into is known as its parent. Any item that does not have a component is regarded as a raw material or purchased item. From the product structure tree it is apparent that the rolling cart's raw materials are steel, bars, wheels, ball bearings, axles, and caster frames.

Order-to-delivery lead times for getting finished goods to end customers are affected by the raw material inventory because of their affect on production capacity requirements. For example, a U.S. paint manufacturer discovered that its plant was stalled waiting for raw materials to arrive from suppliers or simply to be found in its own warehouse. This manufacturer was able to compensate because the manufacturing and labor capacity of the plant made up for the poor inbound supply chain; the company could still ensure on-time delivery to customers. However, additional costs were incurred due to these plant inefficiencies.

WORK-IN-PROCESS

Work-in-process (WIP) is made up of all the materials, parts (components), assemblies, and subassemblies that are being processed or are waiting to be processed within the system. This generally includes all material—from raw material that has been released for initial processing up to material that has been completely processed and is awaiting final inspection and acceptance before inclusion in finished goods.

Any item that has a parent but is not a raw material is considered to be work-in-process. A glance at the rolling cart product structure tree example reveals that work-in-process in this situation consists of tops, leg assemblies, frames, legs, and casters. Actually, the leg assembly and casters are labeled as subassemblies because the leg assembly consists of legs and casters, and the casters are assembled from wheels, ball bearings, axles, and caster frames.

FINISHED GOODS

A finished good is a completed part that is ready for a customer order. Therefore, finished goods inventory is the stock of completed products. These goods have been inspected and have passed final inspection requirements so that they can be transferred out of work-in-process and into finished goods inventory. From this point, finished goods can be sold directly to their final user, sold to retailers, sold to wholesalers, sent to distribution centers, or held in anticipation of a customer order.

Any item that does not have a parent can be classified as a finished good. By looking at the rolling cart product structure tree example one can determine that the finished good in this case is a cart.

Inventories can be further classified according to the purpose they serve. These types include transit inventory, buffer inventory, anticipation inventory, decoupling inventory, cycle inventory, and MRO goods inventory. Some of these also are known by other names, such as speculative inventory, safety inventory, and seasonal inventory. We already have briefly discussed some of the implications of a few of these inventory types, but will now discuss each in more detail.

TRANSIT INVENTORY

Transit inventories result from the need to transport items or material from one location to another, and from the fact that there is some transportation time involved in getting from one location to another. Sometimes this is referred to as pipeline inventory. Merchandise shipped by truck or rail can sometimes take days or even weeks to go from a regional warehouse to a retail facility. Some large firms, such as automobile manufacturers, employ freight consolidators to pool their transit inventories coming from various locations into one shipping source in order to take advantage of economies of scale. Of course, this can greatly increase the transit time for these inventories, hence an increase in the size of the inventory in transit.

BUFFER INVENTORY

As previously stated, inventory is sometimes used to protect against the uncertainties of supply and demand, as well as unpredictable events such as poor delivery reliability or poor quality of a supplier's products. These inventory cushions are often referred to as safety stock. Safety stock or buffer inventory is any amount held on hand that is over and above that currently needed to meet demand. Generally, the higher the level of buffer inventory, the better the firm's customer service. This occurs because the firm suffers fewer "stock-outs" (when a customer's order cannot be immediately filled from existing inventory) and has less need to backorder the item, make the customer wait until the next order cycle, or even worse, cause the customer to leave empty-handed to find another supplier. Obviously, the better the customer service the greater the likelihood of customer satisfaction.

ANTICIPATION INVENTORY

Oftentimes, firms will purchase and hold inventory that is in excess of their current need in anticipation of a possible future event. Such events may include a price increase, a seasonal increase in demand, or even an impending labor strike. This tactic is commonly used by retailers, who routinely build up inventory months before the demand for their products will be unusually high (i.e., at Halloween, Christmas, or the back-to-school season). For manufacturers, anticipation inventory allows them to build up inventory when demand is low (also keeping workers busy during slack times) so that when demand picks up the increased inventory will be slowly depleted and the firm does not have to react by increasing production time (along with the subsequent increase in hiring, training, and other associated labor costs). Therefore, the firm has avoided both excessive overtime due to increased demand and hiring costs due to increased demand. It also has avoided layoff costs associated with production cut-backs, or worse, the idling or shutting down of facilities. This process is sometimes called "smoothing" because it smoothes the peaks and valleys in demand, allowing the firm to maintain a constant level of output and a stable workforce.

DECOUPLING INVENTORY

Very rarely, if ever, will one see a production facility where every machine in the process produces at exactly the same rate. In fact, one machine may process parts several times faster than the machines in front of or behind it. Yet, if one walks through the plant it may seem that all machines are running smoothly at the same time. It also could be possible that while passing through the plant, one notices several machines are under repair or are undergoing some form of preventive maintenance. Even

so, this does not seem to interrupt the flow of work-in-process through the system. The reason for this is the existence of an inventory of parts between machines, a decoupling inventory that serves as a shock absorber, cushioning the system against production irregularities. As such it "decouples" or disengages the plant's dependence upon the sequential requirements of the system (i.e., one machine feeds parts to the next machine).

The more inventory a firm carries as a decoupling inventory between the various stages in its manufacturing system (or even distribution system), the less coordination is needed to keep the system running smoothly. Naturally, logic would dictate that an infinite amount of decoupling inventory would not keep the system running in peak form. A balance can be reached that will allow the plant to run relatively smoothly without maintaining an absurd level of inventory. The cost of efficiency must be weighed against the cost of carrying excess inventory so that there is an optimum balance between inventory level and coordination within the system.

CYCLE INVENTORY

Those who are familiar with the concept of economic order quantity (EOQ) know that the EOQ is an attempt to balance inventory holding or carrying costs with the costs incurred from ordering or setting up machinery. When large quantities are ordered or produced, inventory holding costs are increased, but ordering/setup costs decrease. Conversely, when lot sizes decrease, inventory holding/carrying costs decrease, but the cost of ordering/setup increases since more orders/setups are required to meet demand. When the two costs are equal (holding/carrying costs and ordering/setup costs) the total cost (the sum of the two costs) is minimized. Cycle inventories, sometimes called lot-size inventories, result from this process. Usually, excess material is ordered and, consequently, held in inventory in an effort to reach this minimization point. Hence, cycle inventory results from ordering in batches or lot sizes rather than ordering material strictly as needed.

MRO GOODS INVENTORY

Maintenance, repair, and operating supplies, or MRO goods, are items that are used to support and maintain the production process and its infrastructure. These goods are usually consumed as a result of the production process but are not directly a part of the finished product. Examples of MRO goods include oils, lubricants, coolants, janitorial supplies, uniforms, gloves, packing material, tools, nuts, bolts, screws, shim stock, and key stock. Even office supplies such as staples, pens and pencils, copier paper, and toner are considered part of MRO goods inventory.

THEORETICAL INVENTORY

In their book, *Managing Business Process Flows: Principles of Operations Management*, Anupindi, Chopra, Deshmukh, Van Mieghem, and Zemel discuss a final type of inventory known as theoretical inventory. They describe theoretical inventory as the average inventory for a given throughput assuming that no WIP item had to wait in a buffer. This would obviously be an ideal situation where inflow, processing, and outflow rates were all equal at any point in time. Unless one has a single process system, there always will be some inventory within the system. Theoretical inventory is a measure of this inventory (i.e., it represents the minimum inventory needed for goods to flow through the system without waiting). The authors formally define it as the minimum amount of inventory necessary to maintain a process throughput of R, expressed as:

$$\text{Theoretical Inventory} = \text{Throughput} \times \text{Theoretical Flow Time}$$
$$I_{th} = R \times T_{th}$$

In this equation, theoretical flow time equals the sum of all activity times (not wait time) required to process one unit. Therefore, WIP will equal theoretical inventory whenever actual process flow time equals theoretical flow time.

In a 2006 survey conducted by the Aberdeen Group, supply chain professionals identified four supply chain technologies that will enhance inventory practices. These include:

- Multi-tier management solutions that optimize inventory by determining how much and where to hold inventory across multiple supply chain tiers.

- Supply chain visibility, which enables users to quickly respond to changes (or anticipated changes) by taking actions such as reshaping demand and/or redirecting supply.

- Precision demand management technology, which supports specific product, customer, and channel forecasts.

- Supplier/contract manufacturer collaboration technology, which are platforms that enable customers to collaborate with overseas suppliers and contract manufacturers on forecasts, inventory planning, replenishment, and shipping activity.

Again in 2007, the Aberdeen Group found inventory optimization to be the number one focus for companies, demonstrating a corporate trend toward being more responsive to customers and reducing cost.

Inventory exists in various categories as a result of its position in the production process (raw material, work-in-process, and finished goods) and according to the function it serves within the system (transit inventory, buffer inventory, anticipation inventory, decoupling inventory, cycle inventory, and MRO goods inventory). As such, the purpose of each seems to be that of maintaining a high level of customer service or part of an attempt to minimize overall costs.

JAPANESE MANAGEMENT

The Japanese have had a phenomenal impact on world markets. Many industries, such as electronics, cameras, watches, motorcycles, machine tools, automotive products, shipbuilding, and even some aspects of aerospace are either dominated by Japanese firms or are heavily impacted by them.

Many people mistakenly attribute this phenomenon strictly to cultural differences. The vision of dedicated Japanese workers giving their life to the company for substandard wages surely accounts for the difference, they reason. Of course, this view doesn't always square with reality. First, Japanese factories have some of the highest wage structures seen outside the United States. Second, this "Japanese miracle" is also happening outside Japan. Most Japanese automobile manufacturers have successful plants located within the United States—all of them manufacturing quality automobiles utilizing American workers. When Matsushita bought a U.S. television plant in Chicago, they managed to maintain the one thousand hourly employees while trimming the indirect labor by half. Utilizing the same workers employed by the U.S. firm, Matsushita doubled daily production while improving quality forty-fold. Outside warranty costs fell from $16 million per year to $2 million per year while selling twice as many sets.

Word of these success stories soon aroused considerable interest from U.S. firms. Interest in Japanese management was first generated in the U.S. with the appearance of a book by William Ouchi entitled *Theory Z*, and later a book by Richard J. Schonberger entitled *Japanese Manufacturing Techniques: Nine Hidden Lessons in Simplicity*, and the broadcast of an NBC television white paper titled *If Japan Can...Why Can't We?*

William Ouchi's book *Theory Z* detailed much of the success being realized by the Japanese manufacturing firms. The Japanese style of management (as opposed to McGregor's Theory X and Theory Y) mystified many U.S. businesspersons with its talk of cultural differences and notions such as lifetime employment.

In his book *Japanese Manufacturing Techniques: Nine Hidden Lessons in Simplicity*, Richard Schonberger presented nine "lessons" the world could learn from the Japanese. These lessons included:

1. Management technology is a highly transportable technology.

2. Just-in-time production exposes problems otherwise hidden by excess inventories and staff.

3. Quality begins with production and requires a company-wide "habit of improvement."

4. Culture is no obstacle; techniques can change behavior.

5. Simplify, and goods will flow like water.

6. Flexibility opens doors.

7. Travel light and make numerous trips, like the water beetle.

8. More self-improvement, fewer programs, less specialist intervention.

9. Simplicity is the natural state.

For many American business executives, this was their first encounter with the concepts (and even just the terms) of just-in-time, *kanban*, Total Quality Management, and quality circles.

The NBC documentary *If Japan Can...Why Can't We?* introduced Americans to the progress made in Japanese manufacturing and served as a "wake-up call" for American businesses that manufacturing had entered a new generation. For many viewers, this was their first introduction to W. Edwards Deming, statistical process control (SPC), and quality circles.

By the early 1980s it was evident that Japan was well on its way to a position as a worldwide dominant force in manufacturing. Japan's rise to economic dominance sent ripples throughout the industrialized world. Since the early 1960s, Japan has systematically increased its share of world trade in industrial and consumer goods, although persistent economic problems during the 1990s have arrested its rapid growth.

A number of reasons have been tendered to explain the success of the Japanese. When Japanese automobile manufacturers' market position began to strengthen in the 1970s, it was easy to suppose that the 1973 Arab oil embargo and subsequent escalation in gas prices was the antecedent. Customers went searching for small, fuel-efficient vehicles. Since the Japanese were already entrenched in the small car market, they had a considerable natural competitive advantage. However, it was expected that this advantage would wane as the Big Three automakers had time to react by incorporating small cars into their product line and as oil prices began to decrease.

However, as the Big Three were able to produce smaller cars and gas prices fell, the Japanese market share of the automobile industry continued to increase. This reasoning did not account for the simultaneous surge in Japanese market share in areas such as steel, consumer electronics, copiers, and heavy equipment. After all, if the oil embargo was responsible for the increase in Japanese market share, why didn't other traditional small car manufacturers (such as Renault and Volkswagen) have comparable success? Manufacturers began to realize that the Japanese success story was more than simply a matter of timing.

HISTORY

When Japanese industry was in its infancy stage, the Japanese market was too small to absorb the increasing domestic production. Japan needed a global market in order to further develop. By creating an export market, Japan was able to structurally transform its economy, thereby granting it access to the technology it needed to develop.

The Japanese goal became one of full employment through industrialization. This called for dominating the market in very select product areas. They carefully chose areas in which they had the confidence to dominate and concentrated on them rather than diluting their efforts over many areas.

A number of tactics were utilized to support this strategy. First of all, the Japanese imported their technology, thus avoiding the risks involved with major R&D expenditures. Instead, they negotiated license agreements to make workable new products. Then the best engineering talent was directed to the plant floor rather than to the product design department, thereby concentrating their ingenuity on high productivity and low cost rather than innovative design. Finally, they strove continuously to improve quality and reliability to the highest possible levels and then beyond, to levels competitors could not or would not supply. Implementation of these tactics was guided by a solid respect for people and the belief that waste must be eliminated (these two areas are discussed in depth below).

The Japanese example of success shows that neither massive research and development investment nor abundant natural resources is necessary for sustainable industrial development. For years Japan was well known as an imitator, not an innovator; they copied, borrowed, and licensed technology from other countries. By building competence in adapting existing product designs and speeding up the processes, the Japanese were able to manufacture superior quality at competitive prices, giving them a distinct advantage in world markets.

Japan showed the world that efficient production and quality control methods could overcome transportation cost disadvantages and tariff costs. They proved that cultural differences could be overcome and that the critical cultural points necessary for successful production could be transferred across national boundaries.

Japan's success as an economic superpower strongly implied that the West might lose its world dominance as the leader in technology. Emboldened by the success of the Japanese, other Pacific Rim countries began to follow their example, thus accelerating the diffusion of innovative technology throughout the industrial world. Eventually, new centers of industrial superiority were created as a result.

Japan's success is also an indicator of the importance of quality as a strategic variable. When it looked like Japan could only hope to carve out a niche as a producer of outdated Western goods for the Asian market, Japanese leadership came to the conclusion that it could play a leading role in global industry by changing its quality image; a change made by producing quality goods for a sustained period of time. The Japanese learned from the

price they paid for their reputation for inferior-quality products. They learned that quality reputations are built by producing quality products with a painstaking attention to detail and craftsmanship. They were also willing to make the necessary investment in human resources and technology needed to improve their quality image.

In the early 1960s North American, British, and German motorcycle manufacturers lead the market. Today, Harley-Davidson is the only serious competitor for Japanese-made motorcycles. In fact, Harley-Davidson teetered on the brink of nonexistence until wholeheartedly adopting Japanese manufacturing techniques, most notably just-in-time and Total Quality Management. Another example, Xerox, suffered embarrassing market share losses to Japanese manufacturers Canon, Sharp, and Minolta.

The emphasis placed on quality by Japanese manufacturers has been continuous since the inspiration derived from the first visit of Dr. W. Edwards Deming. Today, Japan is certainly seen as the worldwide symbol of quality. While Western firms measure quality in parts per thousand (the acceptable quality level or AQL), the leading Japanese manufacturers are achieving defects that are barely measurable, perhaps 3.4 defective parts per million. The Japanese turnaround in quality can clearly be attributed to such variables as worker training, employee involvement, and firm-wide delegation of authority and responsibility for quality. A change in attitude and vision on the part of Japanese top management brought quality to the forefront as a strategic mission, one that allowed them to liberate the creative talent and resources necessary for long-term improvement and the eventual mastery of the quality concept.

In the last two decades, however, managers have been less successful in convincing young Japanese citizens to continue in the manufacturing field. This problem threatening the future of Japan's manufacturing business is the *rikei banare* or "flight from science." According to Japanese educators and executives, Japanese students are choosing better-paying or more creative fields rather than following ancestors into manufacturing, which could lower the number of knowledgeable managers for that industry. One ministry of internal affairs estimate shows that Japan's digital technology industry was already short almost half a million engineers in 2008. The shortage is causing anxiety about Japan's competitiveness, particularly with China, a country that produces about 400,000 engineers every year and is hoping to replace Japan as Asia's greatest economic power.

RESPECT FOR PEOPLE

There are a number of facets to the Japanese respect for and treatment of workers. One of the most prominent is lifetime employment, which gained notoriety from William Ouchi's book *Theory Z*. When many Japanese workers are hired for permanent positions in major industrial firms, they can generally consider it a job for life. However, this kind of benefit applies only to permanent workers, about one-third of the Japanese workforce. It is felt that if workers can stay with one firm for life, they more easily identify with the firm's goals and objectives.

Unlike the case for American labor unions, workers who are members of Japanese labor unions identify more with the company than the type of work they are doing. Also, Japanese unions tend to share the management's view. The better the company performs, the more the worker benefits. As a result, Japanese management believes in giving the workers more opportunity to expand their job boundaries rather than waiting until the worker proves himself. The Japanese also spend more on education and training, for all levels, than any other industrial nation. Also, because the Japanese believe that robots free people for more important tasks, they have invested heavily in robotics and automated equipment, making theirs perhaps the most automated manufacturing sector in the world.

Another area in which Japanese management has successfully tapped into worker potential is in the use of small group improvement activities (SGIA). One example is quality circles, a small group of volunteer employees who meet once a week, on a scheduled basis, to discuss their functions and the problems they are encountering. They then propose solutions and make a sincere attempt to implement real change.

Finally, the Japanese believe in what they call "bottom round" management. This concept, sometimes called consensus management or committee management, is an innate part of Japanese culture. It involves a slow decision-making process that attempts to reach a true consensus rather than a compromise. While the decision-making process is slow, the implementation process is quite fast.

Throughout the examples used in literature to describe Japanese management practices, researchers often attribute three essential features: people orientation, long-term view, and process culture. Process culture refers to how the work gets done, rather than the end result. As a result of this focus, Japanese managers expect and reward effort even though it may not immediately result in short-term gain.

ELIMINATION OF WASTE

When the Japanese say "elimination of waste" they mean anything other than the absolutely essential minimum amount of workers, equipment, and materials necessary to meet demand. This means no safety stock, no inventory stored for use in smoothing production requirements, and so forth. If it can't be used right now, it is considered waste.

A number of concepts are central to this idea of waste elimination. Instead of building a large manufacturing plant that does everything, the Japanese tend to build small plants that are highly specialized and form them into focused factory networks. It is difficult to manage a large facility; the bigger it is, the more bureaucratic it tends to be. Bureaucracy is not conducive to the Japanese style of management. Also, a specialized plant can be more economically constructed and operated.

Along with the idea of smaller plants, the Japanese make considerable use of group technology. Japanese engineers examine each operation required to make a part and attempt to group dissimilar machines into clusters designed to be work centers for a given part or family of parts, thus eliminating or at least greatly shortening the time necessary for set-up and changeover.

Just-in-time (JIT) production is an important part of waste elimination. In fact, JIT has often been defined as the elimination of waste. JIT is the production of precisely the necessary unit in the correct quantity at the correct time in order to maintain perfect performance to schedule. Over-producing is considered just as bad as under-producing since unnecessary inventory would be wasteful.

For JIT to work effectively, production must flow smoothly. Any changes can cause disturbances in the flow, which can be amplified throughout the supply chain, causing disruptions and delays. In order to ensure a more uniform flow, the Japanese adopt a uniform plant load. This means that they simply plan to build the same mix of products each day. If you run some of everything you need each day, it only takes one day before you have more (as opposed to large lot sizes which tie up capacity for lengthy periods, causing delays in shipping).

Uniform plant loading requires that everything be produced in small lot sizes, implying that the number of set-ups required will increase. The principle of economic order quantity (EOQ) states that as lot sizes increase set-up costs decrease but as lot sizes decrease set-up costs increase. Therefore, this emphasis on small lots requires that set-up times be minimized. Instead of taking established set-up times as a given, the Japanese have managed to reduce set-up times tremendously, often to the point of single digits (i.e., less than ten minutes).

The Japanese also use a self-regulating system for production control known as *kanban*. It uses dedicated containers and recycles traveling requisitions/cards (often known as *kanbans* themselves) to regulate the system. It is also referred to as a "pull" system since the authority to produce or supply comes from downstream operations.

Finally, the Japanese utilize a number of quality control techniques to ensure maximized quality and minimized waste. Among these are *jidoka*, *bakayoke*, and poka-yoke.

Jidoka is a quality concept that means "stop everything" whenever an error occurs. It is controlling quality at the source. Instead of using inspectors to find problems someone else created, the Japanese worker is his own inspector, responsible for his/her own quality. When an error or defect is discovered, the worker has the authority and the responsibility to halt the production process. Usually, this is controlled by some mechanism such as push buttons. When the line stops, lights flash, bell ring, and flags wave as all attention is directed at the problem.

The Japanese also believe that, whenever possible, inspection should be performed by a machine, for the sake of speed and accuracy. A technique known as *bakayoke* is used for this purpose. *Bakayokes* are devices that are attached to machines to automatically check for abnormalities in the process, such as malfunction or tool wear, as well as measuring dimensions and warning when tolerances are close to being exceeded. For manual assembly, the Japanese utilize *poka-yoke* or "mistake proofing."

Today, all these Japanese techniques have been repackaged and are now know as "lean" management techniques. With the introduction of the lean label has also come a broader application of these principles to where they are now being used in the service sector and in the front office, with the same high degree of success.

JAPANESE *KEIRETSU*

A *keiretsu* is an organizational structure unique to Japanese major corporations. While not all major Japanese businesses are keiretsu, most of Japan's major corporate entities are. Moreover, the influence of the keiretsu on the Japanese business world is important even to non-keiretsu organizations. There are two types of keiretsu: the classical keiretsu and the vertically integrated keiretsu.

The so-called Big Six Japanese business groups are all examples of classical keiretsu. These are the Fuyo/Fuji Group, Sumitomo, Sanwa, Mitsui, Mitsubishi, and Daiichi-Kangyo Ginko. Classical keiretsu are bank-centered with no specific central industry.

While not considered classic keiretsu, many major single-industry companies in Japan are increasingly becoming viewed as vertical keiretsu. These include Hitachi, Toyota, Nissan, Toshiba, and Matsushita. These keiretsu are more pyramid-shaped, with a single industry or company at the pinnacle of the pyramid and the member companies collected beneath.

KEIRETSU DEFINED

Japan's keiretsu are not single entities. Each keiretsu is formed of an interdependent collection of individual firms woven into a common enterprise. In this, the keiretsu are similar to the Korean *chaebol*, but there the similarities stop.

The keiretsu form a type of family of member companies, each connected to the others through cross-shareholdership. In other words, each company within the keiretsu holds significant shares of stock in each of the other keiretsu members. The companies remain independent of each other, and are not subsidiaries of holding companies, as holding companies were outlawed after World War II.

Additionally, the size of the keiretsu corporate families can be deceptive. Most keiretsu have well over one hundred members, while many far exceed that amount. While shareholder control is coordinated, technically the stock of each member firm in the keiretsu can be traded independently.

CLASSICAL KEIRETSU

In the classical keiretsu, member firms share in the compositions of their boards of directors or council of presidents. While legally independent of each other, the boards of directors for each member firm are largely made up of the same members. Although a coordinating role may be given to the head of the central bank around which the keiretsu is formed, there is no central president in a classical keiretsu. In any case, it is the coordination of shareholderships and directorships that allows the members of the classical keiretsu to act in concert financially, since members use the keiretsu's select bank and insurance companies. The banks, in turn, give favored treatment to keiretsu members, enabling comparatively easy access to financing of keiretsu projects.

Classical keiretsu often have no single industry on which they focus their output. Yet is their goal to create what is called a "one-set" principle. In the "one-set" principle, keiretsu members attempt to create a situation in which they would never have to rely on non-keiretsu firms to produce an end-product.

VERTICALLY INTEGRATED KEIRETSU

More common than the classical keiretsu is the vertically integrated corporate giant that focuses on a single industry. Technically these giant companies may not be viewed as keiretsu, since they have no central bank and do tend to have a specific company with a single leader as their chairperson. Yet these corporate giants are increasingly beginning to resemble keiretsu in most other respects. As a result, it is unclear as to what is and is not an actual keiretsu.

Giant Japanese companies such as Toyota have begun to control enough subsidiary companies to attain a "one-set" principle. These large companies have become a sort of vertically organized keiretsu that have grown out of a central manufacturing company. Thus companies like Toyota can be viewed as a single-industry keiretsu.

For example, beneath the central Toyota Motor Corporation are several direct group companies each tied only to a specialized function in the production of Toyota automobiles. These include Toyota Central R&D Laboratories, Kanto Auto Works (car assembly), Toyota Auto Body, Aichi Steel, Toyoda Gosei (resin and rubber products), Toyoda Boshoku (air filters), Toyota Tsusho Corporation (the keiretsu's wholesaler), Towa Real Estate, Aisin Seiki (auto parts), and the giant Denso (electronics).

Many of these direct group companies, in turn, control several of their own subsidiaries. Thus, Denso (also called Nippondenso) controls Nippon Wiperblade, Asmo, Tsuda Industries, and Anjo Denki, and so on. Similarly, Aisin Seiki controls Aichi Giken, Aisin Takaoka, and Aisin-AW.

In this way, Toyota's orientation is vertical and spreads downward in a pyramid of related companies. Like the classical keiretsu, Toyota also has many closely affiliated companies it does not control directly. Thus several companies are part of the greater Toyota Group without formally being part of its actual structure. These are controlled not by bank loans, as in the classical keiretsu, but by supplier dependence.

RELATIVE INDEPENDENCE OF MEMBER FIRMS

Most keiretsu member firms act with considerably greater independence than subsidiary firms of large U.S., Canadian, or European companies. The Japanese firm that is a keiretsu member is highly specialized, and thus less self-sufficient than its non-Japanese counterparts. Yet while this dependence in effect coordinates their actions with the keiretsu as a whole, the leaders of the keiretsu member firms make agreements and arrangements separate from their central bank or parent company.

Indeed, several vertically organized keiretsu members, far from acting in the subservient role of the Western corporation's subsidiary, have grown to be the dominant members of their keiretsu. Toyota Motor Corporation, for instance, grew from a dependent member of the Toyoda Automatic Loom keiretsu in 1937 to become the dominant member of today's Toyota keiretsu, under whose umbrella its former parent company now stands.

ORIGINS OF THE KEIRETSU

Whatever the direction of the classical and vertically integrated keiretsu, it is in the past that the keiretsu as an organizational structure has its source. The keiretsu have a long history in Japanese society. The keiretsu evolved directly from Japan's pre-World War II industrial groups called *zaibatsu*. These zaibatsu were family-dominated,

and resembled the chaebol structures that dominate South Korea industry today. Most of the leading zaibatsu families came to power during Japan's rapid industrialization following the Meiji Restoration in 1868; however, the companies' corporate organization and even some of the key families had their roots in Japan's feudal period. By 1945, four zaibatsu (Mitsui, Mitsubishi, Sumitomo, and Yasuda) controlled fully one-fourth of all Japanese business.

After World War II, U.S. occupation forces dismantled the four main zaibatsu as well as six smaller ones, blaming them for Japan's militarism. The zaibatsu members, in turn, simply came together again to form new entities centered on common business needs and relationships. The keiretsu that took their place were essentially identically to the pre-war zaibatsu with one main difference: the keiretsu centered on a bank and common financial resources in place of the earlier kinship ties of key individuals. Ironically, when reformed as keiretsu, the former zaibatsu members were given an excuse to drop the less profitable member firms, thus making the punitive measures imposed by the American occupation forces a sort of blessing in disguise. Three of the four leading pre-war zaibatsu reformed under the same name. The last of the four great pre-war zaibatsu, Yasuda, joined with many firms from the smaller dismantled zaibatsu (such as the Asano and Nezu zaibatsu) to form the Fuyo Group centered around Fuji Bank.

NEGATIVES OF JAPANESE MANAGEMENT

Despite the success of Japanese management techniques, some do not see them the panacea others credit them as being. Even though research has shown that management techniques developed in Japan can be successfully applied in other countries with remarkable results, critics claim that their success comes not from catering to intrinsic values but to an array of stifling constraints unlikely to be tolerated in the West. Rather than a carefully nurtured atmosphere of trust and common enterprise, they see a restrictive system of internal controls. Much of this criticism has come from labor unions. It has been noted that workers in JIT systems have more stress than their counterparts in more traditional systems. Stress is seen to originate not only from additional authority and responsibility, but also from the fast-paced system where there is little slack and a continual push to improve. Apparently, some see the authority and responsibility delegated to the worker as a way for management to further burden the worker without a comparable increase in take-home pay. Constant improvement through use of *kaizen*, just-in-time, and Total Quality Management is felt to be within the purview of management, not the worker.

There is really no mystery to the success attributed to Japanese management. The Japanese were convinced that a shift, caused by natural competitive forces, was taking place worldwide. They then rode this change, which was international in scope, to financial success by becoming the premier producer of products known for quality. They were prepared to sacrifice short-term financial results in order to invest for the long-term in superior quality, a variable consumers would soon demand.

Consumers are still showing their confidence in Japanese goods by purchasing what they see as commensurate quality at a fair price. Japanese-produced television sets, for example, have an average life span that is twice that of similar sets produced in North America. Any country that can manage to achieve this kind of quality and parlay it into a strategic weapon should continue to have a competitive position within the markets in which it competes.

JOB ANALYSIS

A job analysis is a step-by-step specification of an employment position's requirements, functions, and procedures. Just as a seed cannot blossom into a flower unless the ground is properly prepared, many human resource management (HRM) practices cannot blossom into competitive advantage unless grounded on an adequate job analysis.

Successful HRM practices can lead to outcomes that create competitive advantage. Job analyses, properly performed, enhance the success of these HRM practices by laying the foundation. Job analysis information can be applied to a variety of HRM practices. We now take a brief look at some of them.

ESTABLISHING FAIR AND EFFECTIVE HIRING PRACTICES

An employer's recruitment and selection practices seek to identify and hire the most suitable applicants. Job analysis information helps employers achieve this aim by identifying selection criteria, such as the knowledge, skills, and abilities (KSAs) needed to perform a job successfully. A firm's managers and human resource (HR) professionals can then use this information to choose or develop the appropriate selection devices (e.g., interview questions, tests). This approach to selection is legally required.

An employer facing discrimination charges must demonstrate to the courts that its selection criteria are job-related. To support this type of claim-relatedness, a firm must demonstrate that the challenged selection practice was developed on the basis of job analysis information. As one judge noted during a discrimination hearing, without a job analysis on which to base selection practices, an employer "is aiming in the dark and can only hope to achieve job-relatedness by blind luck."

In the 1990s, the need for firms to base selection criteria on job analysis information became even more important due to the passage of the Americans with Disabilities Act. This law states that employment decisions concerning disabled candidates must be based on their ability to perform the essential functions of the job. For instance, if report reading were an essential job function, then applicants whose disabilities prevented them from reading could be lawfully denied employment (assuming there was no way to accommodate them). If, however, report reading were not an essential function, the inability to read could not lawfully serve as a basis for denial. The determination of which job functions are essential is made during a job analysis.

DEVELOPING TRAINING AND APPRAISAL PROGRAMS

Firms can also use job analysis information to assess training needs and to develop and evaluate training programs.

Job analyses can identify tasks a worker must perform. Then, through the performance appraisal process, supervisors can identify which tasks are being performed properly or improperly. The supervisor can next determine whether improperly performed work can be corrected through training.

HR professionals also use job analysis information to develop relevant training programs. The job analysis specifies how each job is performed, step by step, allowing HR professionals to develop training materials to teach trainees how to perform each task. To evaluate the effectiveness of a training program, the organization must first specify training objectives or the level of performance expected of trainees when they finish the program. The success of a training program is judged on the basis of the extent to which those performance levels have been reached. Expected performance levels are often specified during a job analysis.

Information obtained from a job analysis can be used to develop performance appraisal forms. An example of a job analysis-based form would be one that lists the job's tasks or behaviors and specifies the expected performance level for each. The role of job analysis is crucial here. Without job analysis information, organizations typically use a single, generalized form in which all workers are appraised on the basis of a common set of characteristics or traits that are presumed to be needed for all jobs (e.g., cooperation, dependability, leadership).

Job analysis-based appraisal forms are superior to the generalized forms because they do a better job of communicating performance expectations and because they provide a better basis for giving feedback and for making HRM decisions.

Most companies base pay rates, in part, on the relative worth or importance of each job to the organization. Job worth is typically determined by evaluating or rating jobs based on important factors such as skill level, effort, responsibility, and working conditions. The information provided by a job analysis serves as the basis for job worth evaluations.

Job analysis also plays an important role in the development of productivity improvement programs. Various pay-for-performance programs provide rewards to employees who perform their jobs at or above some desired level. Job analysis is used to identify that level of performance.

REMEDIAL USES

Managers must sometimes discipline employees for their failure to properly carry out their job responsibilities. For instance, workers may be disciplined for refusing to perform tasks that they believe are not part of their jobs. If the responsibilities and limits of authority of a job are

delineated in a job analysis, this information may be used to help resolve such problems.

Job analysis information can also be useful from a safety and health point of view. While conducting a job analysis, an employer may uncover potential dangers or hazards of a job. The job analysis may also identify unsafe practices, such as tasks that are performed in a way that could cause injury.

DETERMINING THE TYPE OF INFORMATION TO BE COLLECTED

A wealth of information may be gathered during a job analysis. Job analysis information may be divided into three categories: job content, job context, and worker requirements. Job content refers to workers' job activities or what workers actually do on the job. Job context refers to the conditions under which the work is performed and the demands such jobs impose on the worker. Worker requirements refer to the worker qualifications needed to perform the job successfully. The specific information falling within each category is described next.

Content. When gathering information about tasks, the job analyst seeks to determine what the worker does, the purpose of the action, and the tools, equipment, or machinery used in the process. The analyst may also gather additional information about tasks, such as their relative importance, the expected performance levels, and the type of training needed by a new worker to perform tasks satisfactorily. Job content can be described in a number of ways, depending on how specific one wants (or needs) to be. The different types of job content information are described in Exhibit 1.

Context. Job context refers to the conditions under which work is performed and the demands such work imposes on employees. Specific types of job context information typically identified during a job analysis include reporting relationships, supervision received, judgment, authority, personal contacts, working conditions, and the physical and mental demands on the worker.

Requirements. Worker requirements refer to the knowledge, skill, ability, personal characteristics, and credentials needed for effective job performance. These terms are defined as:

- *Knowledge*—the body of information one needs to perform the job.

- *Skill*—the capability to perform a learned motor task, such as forklift operating skills and word-processing skills.

- *Ability*—the capability needed to perform a nonmotor task, such as communication abilities,

---

Exhibit 1

The Different Types of Job Content Information

Broad Level

Function or Duty
- Definition: The major areas of the job-holder's responsibility.
- Example: A professor's functions are teaching, research, and service to the university/community.

Intermediate Level

Task
- Definition: What a worker does when carrying out a function of the job; it is an activity that results in a specific product or service.
- Example: The function of teaching requires a professor to perform several tasks like lecturing, giving/grading exams, and meeting with students.

Work Behavior
- Definition: An important activity that is not task specific; such behavior is engaged in when performing a variety of tasks.
- Example: "Communicating"—a professor engages in this behavior when performing several tasks, such as lecturing and meeting with students.

Specific Level

Subtasks
- Definition: The steps carried out in the completion of a task.
- Example: The task of providing lectures consists of several subtasks, such as reading the text and other relevant materials, deciding on what information to convey, and determining how this information can be communicated in a clear and interesting manner.

Critical Incidents
- Definition: Specific activities that distinguish effective from ineffective job performance.
- Example: "The professor uses several examples when explaining difficult concepts."

---

mathematical abilities, and reasoning or problem-solving abilities.

- *Personal characteristics*—an individual's traits (e.g., tact, assertiveness, concern for others, objectivity, work ethic) or their willingness/ability to adapt to the circumstances in the environment (e.g., ability to withstand boredom, willingness to work overtime, willingness to treat others cordially).

- *Credentials*—proof or documentation that an individual possesses certain competencies, such as diplomas, certifications, and licenses.

The sheer amount of information that can be uncovered during a job analysis may be overwhelming, but it is usually unnecessary to gather all possible data. The purpose or intended use of the job analysis dictates the particular information to be gathered. Therefore, the analyst must decide how the job analysis will be used before deciding what information to seek.

For instance, if a job analysis were to be used to develop a technical training program for new employees,

the analyst should focus on information about subtasks (a step-by-step description of how the job is carried out) and the specific KSAs one would need to do well on that job. If the purpose were to develop a written employment test to assess applicants' knowledge of the job, the analyst should target information about the specific tasks of the job and the knowledge required to perform each task (i.e., the facts, theories, principles, etc., one must know to be able to perform tasks satisfactorily).

DETERMINING HOW TO COLLECT THE INFORMATION

HR professionals often gather job analysis information. However, because these individuals lack sufficient expertise in the jobs being analyzed, they must enlist the actual job incumbents and their supervisors to gather and interpret the pertinent information. Job analysis information may be gathered by interviewing these individuals, observing them at work, and/or having them complete job analysis questionnaires. The appropriateness of each approach depends, in part, on the type of information sought.

Interviews. Job analysis interviews are structured conversations between the job analyst and one or more subject-matter experts. Interviews are typically held with both job incumbents and their supervisors. Interviews with incumbents tend to focus on job content and job context information. That is, incumbents are asked to describe what they do, how they do it, and the conditions under which they perform their jobs.

The typical role of the supervisor is to review and verify the accuracy of the incumbents' responses, and to provide further information concerning task importance, expected performance levels, training needs of new workers, and worker requirements.

As the most frequently used job analysis method, interviews provide a potential wealth of information. However, one-on-one interviews can be quite time-consuming. An interview usually takes between one and eight hours, depending on the amount and depth of information sought. Thus, interviewing can take a great deal of time, especially when the analyst must interview several people. When time constraints pose a problem, the best alternative is to conduct a group interview, where several subject-matter experts are interviewed simultaneously.

Observations. Sometimes a job analyst will supplement interviews with job analysis observations. As the name suggests, observation means watching the incumbent perform the job. Observation is most useful when jobs are complex and difficult to accurately describe. When analyzing such jobs, the analyst observes or videotapes the job and then interviews the worker for clarification or explanation. The observation allows the analyst to gain a better understanding of how the work is done and the KSAs needed to perform it.

While observation is usually used as a supplement to the interview, HR professionals sometimes base job analysis solely on observation. Whether or not observation yields sufficient data for the analysis depends on the type of information being collected.

For instance, it is an excellent method for identifying subtasks performed in routine/repetitive types of jobs, such as assembly-line work. When using this approach, however, analysts should be alert to the possibility that some workers may behave atypically when observed. For instance, they may increase their speed to impress the observer, or slow down in an effort to demonstrate how difficult their jobs are.

Questionnaires. Job analysis questionnaires ask subject-matter experts—workers and/or supervisors—to record job information in writing. Job analysis questionnaires contain either open-ended or closed-ended questions. Open-ended questions ask respondents to provide their own answers to the questions. Closed-ended questions ask respondents to select an answer from a list provided on the questionnaire. Closed-ended questions are more commonly used because they provide greater uniformity of responses and are more easily scored.

A job analysis questionnaire containing only closed-ended questions is called a job analysis inventory. An inventory containing a list of task statements is called a task inventory; one containing a list of worker ability requirements is called an ability inventory. Job analysis inventories ask respondents to rate each item in terms of its importance to the job. Task inventories also request information regarding the frequency or time spent performing each task.

Companies use job analysis inventories when information is needed from several people (e.g., when many people hold the same job title). Compared to interviews, information can be collected much more quickly using this approach. Companies also use inventories as a means of grouping jobs. Grouping refers to categorizing jobs based on the similarity of tasks performed or skills needed; a group would consist of jobs in which all workers performed similar tasks or needed similar skills.

Once groups are established, the organization can determine selection criteria, training needs, and evaluation criteria applicable to all jobs within a group. Job analysis inventories are also used to determine workers' training needs. Workers are presented with a list of tasks or abilities and are asked to indicate those for which they

need training. A five-point rating scale, ranging from "great need" to "no need," is typically used.

DETERMINING HOW JOB ANALYSIS INFORMATION WILL BE RECORDED

Once HR professionals have collected job analysis information, it must be recorded in some systematic way to produce a job description (i.e., a summary of job analysis findings). The format of job descriptions may be general purpose or special purpose.

General Purpose Job Description. A general purpose job description is one that contains a variety of information that can be used for several purposes, such as communicating job responsibilities to employees and specifying minimum job requirements. For instance, a manager would pull out a job description to review essential functions and worker requirements prior to developing interview questions for a job applicant.

The particular information contained in the job description varies depending on company preference and the intended use of the instrument. A typical general purpose job description contains the following sections: job identification, job summary, essential functions, and worker requirements.

General purpose job descriptions used by most companies provide only a brief summary of job analysis information, and thus lack sufficient detail for some HRM applications. For instance, many fail to indicate subtasks, performance standards, and job context. Subtask information may serve as a basis for developing training programs, performance standards may serve as a basis for developing certain types of performance appraisal forms, and job context information may serve as a basis for making job evaluation ratings that are needed to establish pay rates.

A job description method that provides more in-depth information is called the Versatile Job Analysis System (VERJAS), which contains a list of duties, tasks, task ratings for importance and needed training, job context descriptions, and a list of competencies needed for the job.

Special Purpose Job Descriptions. Several special purpose job descriptions have been developed by a variety of HRM experts during the past thirty years. A key difference between general and special purpose job descriptions lies in the amount of detail they include. Special purpose formats cover fewer topics, but the topics covered are analyzed in more depth. Some of the more commonly used special purpose approaches are described next.

Functional job analysis (FJA) focuses primarily on recording job content information. Each task is analyzed separately on a worksheet that contains a task statement (specifying what the worker does, how it is done, and the results or final product of the worker's actions), the performance standards and training needs associated with the task, and seven rating scales. Three of the scales are known as worker function scales, indicating the level of worker involvement with data, people, and things. The other four scales indicate the level of ability needed in the areas of reasoning, mathematics, language, and following instructions.

Another special purpose method of job analysis is called the critical incident technique (CIT). It originated in the military during World War II and was used to identify critical factors in human performance in a variety of military situations. Critical factors are those that have been demonstrated to make the difference between success and failure in performing a job.

The critical incident technique requires the job analyst to collect critical incidents from people familiar with the job. The incidents are usually collected in the form of stories or anecdotes that depict successful and unsuccessful job behaviors. The stories are then condensed to a single statement that captures the essence of the story. The CIT has several useful HRM applications. For instance, it is a good tool for identifying selection criteria and training needs and for developing performance appraisal forms.

Almost all human resources policies can be linked to job analysis. For example, each time a job function is changed, the competencies have the potential to change. This impacts skills required for new hires, as well as the training required, and how the organization will reward and recognize the competencies. Ultimately, this ties into performance management, which impacts job analysis. The impact of one simple change in the job analysis has a domino effect on many subprocesses within HRM. In fact, most HR policies identify the frequency with which job analysis must be completed.

HR professionals are challenged to keep abreast of changes in their workforce. They must make complex decisions using job data and facilitate communication across jobs, job families, or departments in their organization. In the twenty-first century, new technology had been introduced that offers easier ways to collect, store, analyze, and configure data. Metrics applied to that job data can aid decision making in areas such as recruitment, selection, transferability, promotion, training, and development—all things that link to the job analysis.

It's easy to see that job analysis is a key component of the HRM process. While the performance of comprehensive job analyses can be time consuming, ultimately employers will benefit from the many uses that a thorough job analysis can provide. From hiring and training to salary justification to remedial uses, job analysis will

make the HR manager's job easier, protect an organization from claims of discrimination, and can give the overall organization a competitive advantage.

JOINT VENTURES AND STRATEGIC ALLIANCES

As economies become more globalized, more and more firms are participating in foreign markets. The most popular participation strategies include exporting, licensing, outsourcing, strategic alliances, joint ventures, and direct foreign investment. Each of these involves different levels of risk, capital, and returns.

The use of strategic alliances and joint ventures is rapidly becoming popular with a growing number of multinational firms. According to Cullen in his 1999 book, an international strategic alliance is an "agreement between two or more firms from different countries to cooperate in any value-chain activity from R&D to sales". A strategic alliance, as differentiated from a joint venture, is a collaboration designed to achieve an isolated objective and involves no equity stake from the partners. Hitt, Ireland, and Hoskisson offered this definition: "joint venture is when an independent firm is created by at least

two other firms." A strategic alliance is a less rigid agreement than a joint venture. These cooperative strategies offer many potential advantages to the participant, but they are also pitted with special problems.

ADVANTAGES

Firms may have many motivations to form strategic alliances, and most of these reasons are based on the logic that each partner can bring complementary strengths to the table, resulting in a competitive advantage for the participants collectively. Partners in a strategic alliance can benefit from many aspects of a cooperative relationship: access to unfamiliar or untapped markets, risk sharing, economies of scale, shared technology, and decreased costs.

A partner's knowledge of the local market can be invaluable to a firm if it wants to get its services and products into a new market. This advantage is most easily achieved when the local firm is in a related industry with related products. The local partner knows the buying habits and preferences of the local buyers and suppliers, and he should also have knowledge of the existing channels of distribution. These relationships with others in the value chain may be otherwise unobtainable to an outside firm.

Consider a company that is contemplating entering foreign markets. Local governments often require, as a condition of entry, that entering companies allow some local ownership. This stipulation is found more often in developing countries than in more developed nations because the developing countries are trying to avoid being exploited for their resources. Through a joint venture the outside company can meet this requirement; in fact, the government of a developing country is often the partner in a joint venture.

Joint ventures and strategic alliances force companies to share revenues and profits, but they also share the risk of loss and failure. Thus, the popularity of the cooperative strategies increases as projected risk increases, because joint ventures allow firms to take on projects that are otherwise too risky or too costly.

Economies of scale can be achieved when two or more firms pool their resources together, maximizing efficiency based on the project's needs. Cooperative strategies also allow small companies to join together to compete against an industry giant. Companies of different sizes may also benefit from joining together. The large company offers its capital and resources in exchange for the efficiencies or innovations found at the smaller company. An article by Shafer describes how Abrakadoodle—a company that offers creative art classes for children in schools, day care centers, and community programs—established a strategic alliance with Binney and Smith, known for its Crayola brand art products. Abrakadoodle founder Mary Rogers was seeking products of high quality that would be safe for children and that would be available

nationally, so all locations could use the same materials in their classes. Since she was already using Crayola products in her classes, she states, "We realized that once we started franchising, the number of Crayola products used in Abrakadoodle classes would grow enormously." After months of negotiation, agreement was reached between the two companies. Crayola products will be featured exclusively in Abrakadoodle classes, Abrakadoodle will be allowed to use the Crayola trademark for advertising purposes and will be eligible for discounts on Crayola products. Both companies are benefiting from their shared vision for encouraging children's artistic creativity.

In cases where firms do not have the same strengths, creating alliances can allow them to share technology. This, in turn, can help firms produce more efficiently or at a higher quality. Firms must learn to recognize which other companies can offer complementary skills or technology.

When companies from developed countries cooperate with companies in less developed countries, they usually realize huge cost savings by seeking cheaper labor and untapped reserves of material. The company from the less-developed country benefits from advanced technology and increased access to capital. Both companies benefit from the cooperative alliance. Many U.S. firms have been attacked for taking their manufacturing plants "south of the border" to Mexico and thereby harming American workers. The firms are criticized because they join with governments in developing nations so that they can obtain cheaper labor in less-developed countries, thus lowering their production costs. Many argue that it harms American workers, but opponents often overlook the advantages that the developing country receives. Often, the large American company provides jobs to areas with alarmingly high unemployment rates and offers them infrastructure and support that they never had before.

SELECTING AN ALLIANCE PARTNER

In order to realize such benefits, many considerations must go into choosing a partner for a joint venture or a strategic alliance. Choosing a strategic alliance or joint venture partner is very important and can prove to be very difficult. Inherent in partner selection is the understanding of potential partners' goals. For one thing, a potential partner must have complementary strategic objectives. A venture will not succeed if the objectives are in conflict, but the objectives do not need to be identical. For example, the alliance between Yahoo and eBay provides Yahoo with an advertising client and gives eBay (as well as its subsidiaries, like PayPal and Skype) access to Yahoo's large customer base. Together, the two companies possess a market share to rival Google's domination of the Internet advertising market. The strategic alliance is mutually beneficial for both parties. It is important that each partner understand and accept the other's objectives.

Potential partners should also possess complementary skills. Each partner must contribute more than capital to the project, bringing other competencies into the venture. One firm may bring technical skills and another may bring knowledge of the market. There are many skills that a firm can bring into the relationship: managerial expertise, production facilities, or access to limited resources. Skills are most easily meshed when partners have similar, but not identical, products. If both produce an identical product it may be difficult for them to work together. Even if skills are complementary, competition may drive them apart and cause the venture to fail.

While the partners must offer complementary objectives and skills, both partners must believe that they can trust each other and that mutual commitment is a reality. As Cullen explained, "A common theme among managers from both failed and successful strategic alliances is the importance of building mutual trust and commitment among partners. No matter how mutually beneficial and logical the venture may seem . . . without trust and commitment the alliance will fail entirely, or it will fail to reach its strategic potential." There are a variety of ways that a company can attain and sustain commitment and trust in cooperative ventures. Goal and intent revelation is a crucial step toward building trust. The partners in a joint venture will outline their duties and goals. Both parties share in the right to manage the enterprise, the right to the profits and the duty to share the losses. The contract also determines when the joint venture will be terminated.

MANAGEMENT STRUCTURE

The management structures that control cooperative efforts are varied, and they are usually unique to each relationship. Cullen identified five typical management structures used by companies for their joint ventures and strategic alliances: dominant parent, shared management structure, split-control management structure, independent management structure, and rotating management.

The dominant parent is generally the majority owner of a joint venture. In cases where there is no majority owner, the dominant parent may be the company that contributes the most valuable resources. When there is a dominant parent, this company makes more operational

---

Table 1
Cullen's Five Management Structures

1. Dominant Parent
2. Shared Management Structure
3. Split-Control Management Structure
4. Independent Management Structure
5. Rotating Management

and strategic decisions. In many instances, a joint venture is treated as a subsidiary of the dominant parent. Often when large multinational firms have cooperative alliances with firms in small countries, the multinational firm comes in as the dominant parent.

The shared management structure and the split-control management structure are very similar. In these structures, both parent companies share decision-making responsibilities. In the shared structure, there are an equal number of managers in controlling positions from each company (board of directors, top management, and functional management). In split-control structures, there are not equal numbers of managers from each company at the functional level. In areas of expertise, one company may hold most or all of these positions. This can be because of differences in expertise or because one firm may insist on this type of arrangement if they do not want to share their knowledge or technology.

Independent management structures are found when the management of a joint venture acts independently of either parent firm. Because a joint venture is a separate legal entity, this is possible, but it is highly unlikely with new joint ventures. It is more common to see the independent management structure as a joint venture matures and begins to act as an independent firm. If the independent management structure is found in a young joint venture, it is often because the parents agreed to recruit externally for management positions.

In a rotating management structure, key positions of the hierarchy rotate between firms. Each firm assigns a person for their term. This structure is popular when an alliance partner is from a less-developed country. With this type of management, local management can be trained so that technology and expertise are transferred to the community, according to Cullen.

DOMESTIC JOINT VENTURES AND ALLIANCES

Not all joint ventures and strategic alliances cross international boundaries. Companies in the same country can achieve many of the same benefits found in an international cooperative agreement. For instance, in 2007, SABMiller and Coors entered a joint venture that combined their U.S. operations. The two companies merged their brand portfolio to consolidate their position in the beer market. According to SABMiller, the large scale and increased resources will enable the companies to invest more in brands and product innovation. The company predicts that lower operating costs will result in $500 million in cost synergies per year.

Just as the companies that come together are quite varied, so are their reasons for doing so. There is, how-

ever, one best reason for bringing two firms together: synergy. Synergy is the realization that the whole may be greater than the sum of the parts, according to Hitt et al. Often, when two firms are combined, they find that their new venture is greater than the sum of what each could have done independently. Many of the reasons presented create synergy, but one must analyze the venture to make sure that it creates something greater than the two companies could have been on their own. When there is synergy, new products are created for the market quicker or better than they would have been if the companies had kept their resources to themselves. If there is synergy, everyone benefits.

K

KNOWLEDGE-BASED VIEW OF THE FIRM

Knowledge-based view of the firm (KBV) is a management concept of organizational learning that provides firms with strategies for achieving competitive advantage. This is achieved through increased employee involvement in the formulation and administration of the operational goals and long-term transformational objectives of the firm. The continuous acquisition and transfer of knowledge within business organizations is necessitated by such factors as ever-changing competitive conditions in markets initiated by globalization, frequent deregulations, and technical advancements.

KBV is an important approach towards organizational learning that forms the basis for establishing human capital involvement in the structural and routine activities of the firm. KBV proposes the establishment of heterogeneous knowledge structures across the management hierarchies of a firm as a prerequisite condition for achieving sustainable knowledge-based competitive advantage. This is because knowledge-based resources are always characterized by difficulties of transmission, imitation, and social complexities.

As much as KBV is a relatively contemporary management concept, it draws much impetus and reference from classical theories of management such as the theory of the firm, the organizational theory, and the resource-based view of the firm. In fact, the fundamental assumptions of the knowledge-based theory of the firm are particularly believed to have stemmed from the resource-based view of the firm. However, the resource-based view of the firm does not give knowledge adequate recognition and, in fact, categorizes knowledge among the simple generic resources of the firm. Knowledge-based theory of the firm makes amends of these shortfalls by expounding on the strategic significance and distinctive characteristics of the different types of knowledge-based resources that portend competitive advantage for the firm, as demonstrated by the following assumptions:

- Knowledge-based resources hold the most strategic significance in firms.

- Production activities and processes in firms involve knowledge application.

- Individuals rather than organizations are responsible for creating, holding, and sharing knowledge.

- The incapability of markets to coordinate specialized knowledge necessitated the existence of firms, with management playing the coordination roles within the firms.

- Knowledge-based resources are characterized by difficulty of imitation and social complexities.

- Knowledge draws strategic significance from its appreciative value as opposed to other traditional factors of production, which depreciate.

The broad-based nature of knowledge can be analyzed through two major fronts: knowledge as an independent idiosyncratic characteristic of the firm and knowledge management as a determinant activity in the firm.

IDIOSYNCRATIC VIEWS OF KNOWLEDGE

Knowledge is a strategic management resource that initiates competitive advantage in the firm through value addition to

business data, information processes, and system operations. Knowledge is an important tool for change management that managers can use to respond to issues of staff retention. Explicit knowledge and tacit knowledge are the two major types of knowledge that firms can observe when seeking to achieve competitive advantage.

Explicit knowledge is the generalized knowledge that can easily be expressed and identified within the organization's routines, records, and information systems. Explicit knowledge defines industry trends that are generally practiced by competing firms rather as response to market demands and requirements than specific strategies for achieving competitive advantage. As such, the market value of explicit knowledge within a firm is more or less equivalent to its market value.

Firms utilize tacit knowledge to draw competitive advantage from the individual or firm-specific capabilities that are difficult to transmit or encapsulate. In a journal article titled "Knowledge-Based View of the Firm and Its Precursor," Carla Curado and Nick Bontis acknowledge that the intangible and dynamic nature of tacit knowledge creates the need for an idiosyncratic approach toward organizational learning and dependency. Firms apply tacit knowledge whenever responding to changes in market structures (such as the launch of new products by a competitor) or changes in market regulations that open up the market to competitors. Acquisition of tacit knowledge by individuals within the firm heavily depends on the ability of employees to share skills as well as the resolve to conduct education and research beyond the firm's boundaries.

KNOWLEDGE MANAGEMENT

Firms formulate knowledge management (KM) strategies so as to create and employ appropriate individual and collective knowledge resources in the pursuit of competitive advantage. Identifying, creating, storing, sharing, and applying knowledge are the main activities that define knowledge management.

Identifying Knowledge. The process of knowledge management begins with the review and appraisal of the existing resources as well as identifying any resource gaps that may need to be filled to increase the organizations competitive capacity.

Creating New Knowledge. This involves introducing new ways of conducting and managing business processes both at individual and team levels. The process of creating new knowledge may be achieved through training, brainstorming sessions, or internal and external consultancy. Training can be enhanced through job rotations, participation of employees in committee assignments, outdoor training, process simulations, lecture courses, and seminars.

Firms adopt knowledge creation strategies with the objective of fostering long-term innovative practices and developing strong performance foundation. Japanese companies are particularly known to apply the principles of *Kaizen* to motivate the creation of knowledge through organizational cultures that embolden vision of services and products alongside other strategies that promote transparency, sharing of information, and active utilization of knowledge. For example, Toyota has based its success through the Toyota Production System which focuses on the creation of idiosyncratic and tacit knowledge. The pervasiveness of the orientations of the different types of knowledge in the cultural contexts of organizations serves as the benchmark for companies that pursue knowledge creation and innovation. Companies can excel in knowledge creation by not only developing capabilities for collecting and organizing information about knowledge, but also by providing adequate channels for accessing and distributing knowledge across organizational structures.

Applying Knowledge. Applying knowledge is the stage where the organization emphasizes the continuous transformation of information into skills and knowledge with the objective of achieving competitive advantage. The value of knowledge-based resources can be realized only if relevant knowledge is applied purposefully to enhance business decisions and actions. Although many companies work diligently to acquire shelves of knowledge repositories, they fail to dedicate adequate attention to transformation of the repositories into information resources through which employees can apply the knowledge in running the current business activities and generating new ideas for future use. This is because the application of knowledge is a complex issue that encompasses different organizational dimensions such as organizational culture and process designs.

Sharing Knowledge. Relevant knowledge should always be made available and accessible at all times to all interested parties within the organization. In the book titled *Human Resource Management for Tourism, Hospitality and Leisure: An International Perspective*, Tom Baum identifies two methods of distributing knowledge: the stock method that involves distributing knowledge through information databases, and the flow method which involves direct knowledge distribution through individual and group collaborations and mentoring.

Managers can employ various strategies to incorporate knowledge distribution in work processes. Creation of specific roles for importing and exporting knowledge is one such strategy. This practice is evident in consulting firms such as Deloitte & Touche and PricewaterhouseCoopers, which allocate specialized responsibilities of managing knowledge transfer within both the organizations and client organizations. Another strategy involves

designing knowledge-oriented analytical procedures within work processes or projects. For example, the Japanese Toyota manufacturers rely on the Toyota Production System to insert reviews of knowledge already gained and knowledge that is still required among the key points of the quality improvement processes.

Storing Knowledge. Organizations store knowledge either in the form of tacit or explicit knowledge. Managers can overcome the challenges of storing knowledge by adopting the strategy of integrating knowledge use into the IT systems that support processes among knowledgeable workers. For example, General Motors designs new motor vehicle models using a "knowledge-based engineering" system that embeds a set of design rules into the computer-aided design system. The main objective of systematic knowledge integration is to provide continuous access to the organization's knowledge structures while providing room for individual creativity and innovation. Managers can further perfect the storing of knowledge by implementing continuous improvement programs that allow frequent revision of core organizational processes that constitute team routines and procedures.

CHALLENGES

Leading proponents of KBV such as R.M. Grant acknowledge that hurdles that usually emerge from divergence of interests between employee conditions and owner expectations can hamper smooth coordination of specialized knowledge. As such, firms that seek to entrench uniformity of interests should pursue coordination of specialized knowledge by encouraging cooperation among all employees in the organization. However, the pursuit of cooperation may lead to bureaucratic imposition of coordination objectives through hierarchical structures, a situation that can be avoided through incorporation of other administrative and enforcement tools such as recognition of organizational culture and process designs.

Organizational culture. Organizational culture basically involves the unique norms, shared values, and assumptions that define an organization alongside the practices that all groups and individuals share within the organization. KBV perceives the organizational culture in terms of the organization's reward structures for the decisions and actions of employees in regard to utilization and sharing of knowledge. Firms hire employees with expectations that employees will apply knowledge in their actions and decisions regarding their assigned responsibilities, an objective that should never be taken for granted and should always be highlighted and emphasized during hiring processes in organizations because it would be a difficult task for the firm to inculcate basic intellectual curiosity among new employees. KM thrives in organiza-

tional cultures that portray flexible orientations such as the human relations orientation.

Firms that observe a human relations cultural orientation operate more or less like family, with a flat internal structure that emphasizes employee empowerment, interpersonal relations, and staff development (as opposed to hierarchical structures and reporting channels). As much as hierarchies provide the convenience of processing knowledge, they present challenges to knowledge integration, especially in situations where decision making on the higher levels depends on the knowledge of employees in the lower levels of hierarchical structures. It is for this reason that KBV emphasizes organizational structures that are not only participative in nature, but also motivational, so as to create appropriate conditions for decentralization, spreading, and sharing of both idiosyncratic and tacit knowledge throughout the firm.

Process designs. Knowledge determines the key processes in the firm such as administration, marketing, product development and design, planning, and resource allocation. Therefore, knowledgeable workers should practice their skills in the course of their duties and experience the convenience of doing so, for they are the best knowledge repositories to be utilized in organizations. Firms can achieve this through creation of adequate links between work processes and knowledge, as well as through continuous evaluation of all key processes in the firm to ascertain the acquisition of knowledge by human brains and information sources.

Greater value-addition can be achieved through knowledge if managers explore ways of exporting and sharing knowledge acquired by employees in the course of their duties in the firm. Appropriate process designs emphasize adherence to routines, slotting of responsibilities, communication of new policies, issuance of directives, use of systems and documentations, and a consultative approach when seeking solutions to problems.

THE TECHNOLOGICAL PERSPECTIVE OF KBV

Technological business applications play an important role in advancing knowledge capabilities in organizations. Organizations are increasingly adopting IT applications to execute transactions, customer relations management, asset management, and total quality management, as well as to enhance competency and innovation among the workforce. Organizations can use IT applications to create a collaborative work environment by empowering employees with the capacity to share knowledge through publishing tools that are interactive in nature such as chats, e-mails, discussion groups, intranets, and video conferencing.

KNOWLEDGE CENTERS

A knowledge center is an Internet-based community or system designed to help people remotely share information. Knowledge centers offer a variety of tools and accessories that enable the immediate or delayed sending and receiving of information. This can include online chat rooms, discussion boards, downloadable texts and other materials, and sometimes even the ability to chat with multiple users via videoconferencing. A knowledge center is usually set up within a community where its advantages are far-reaching and utilitarian, offering the ability to "information swap" among groups of people who otherwise could not communicate due to geographic or time constraints.

Usually, knowledge centers are highly specialized and niched, designed with a very specific audience in mind. Most knowledge centers fall under categories that fit within the realm of education (the center facilitates the needs of educators and students) or within the realm of a particular industry or even corporation. There are knowledge centers for those in the medical sciences, for example, who use the knowledge centers to further the reach of their own research while simultaneously catching up on new research, events, and findings of other colleagues. In this way, a knowledge center promotes the rapid progression of an industry or particular subject matter and allows for faster solutions by way of synergy. An online community of experts and highly interested parties in a constant state of contribution are the life force of successful knowledge centers in every thinkable genre.

WHAT MAKES A KNOWLEDGE CENTER?

A knowledge center must implement some method by which people can communicate and swap important information. The methods for doing this must be efficient and either free or very economical to ensure their use; if they are not, like-minded people with a particular interest will access another knowledge center.

There must be constant updates to a knowledge center, and therefore there is a need for an administrator who can update the online content of the site, ensure that users are playing by the rules, check that live content does not violate any copyrights, and make sure the center is as efficient as it can be. For a university or corporate knowledge center, an administrator may be its own paid position or part of an existing position.

Other resources should be available through the knowledge center, including links to pertinent Web sites, training or study materials, and a member center where free or paid members can check the status of messages sent and received, bulletins, and more. It is imperative that a knowledge center have its information updated as regularly as possible to keep content fresh, accurate, and of universal interest.

KNOWLEDGE CENTER AND WHITE PAPERS

Some entities that have white papers, especially publicly traded companies, will create a knowledge center as a platform to host, among other things, its white papers. For most, white papers are used to aid in the marketing process for a new product or service offered by a firm. Prospective clientele and proponents of the new product or service can be the captive audience of a knowledge center, so placing white papers in this type of Internet forum can have phenomenal results. Bringing white papers to the same place where discussions about the new product or service are facilitated and where potential customers can engage industry experts via chat rooms or bulletins is good business sense and an expert use of the Internet.

A knowledge center representing a business endeavor or any other entity should always exist as a repository for useful information that will help those with full mastery of the subject matter as well as novices. Using the knowledge center as a place to post and catch up on useful, current, industry information should always be the central goal; using the knowledge center to promote outside causes or as a means to network in a social manner should always be discouraged by the administrator. The offering of useful Internet links, articles, and tools for communication are the assets that any knowledge center will need as its fundamental foundation.

KNOWLEDGE MANAGEMENT

Knowledge management (KM) refers to an organization's strategic efforts to gain a competitive advantage by capturing and using the intellectual assets held by its employees and customers. Efforts to archive best practices and lessons learned, and to make better use of information stored in databases, also fall under the rubric of knowledge management. Advocates of knowledge management believe that capturing, storing, and distributing knowledge will help employees work smarter, reduce duplication, and ultimately produce more innovative products and services that meet the customers' needs and offer a good value.

If a company knows something (e.g., changing tastes of the customers, innovative solutions to international tax issues, or how to use information systems to better monitor production processes) that its competitors do not, then that company has an opportunity to offer a distinguishing product or service. Knowledge management, as a business practice, impacts the entire organization by helping employees, managers, and executives share information and best practices that positively impact collective performance. Unlike downsizing, which emphasizes the reduction and control of costs (often through attrition and layoffs), knowledge management is a value-adding practice that seeks to enhance profits, innovation, and decision making by providing more and better information to every member of the organization.

To better understand why knowledge has become a critical factor in businesses, we need to understand that the United States and many other industrial countries are moving toward a knowledge economy. A knowledge economy is one where a majority of workers spend their day applying know-how to the production of goods and delivery of services. In a knowledge economy, employees work to improve decision-making, design, and delivery processes, while only a limited number of people are involved with the actual manufacturing of goods. Important questions that we might ask about a knowledge economy include:

- How many people now spend their day applying knowledge?

- How did the change to a knowledge economy come about?

- How do organizations go about managing knowledge?

American labor trends indicate that the percentage of people working in an information-intensive capacity is increasing while the number of people working in agriculture, manufacturing, and nonprofessional service industries is decreasing.

The rapid increase in knowledge-intensive work is often attributed to communication technologies, and espe-

cially digital technologies, that allow employees to transfer or access large amounts of data in minutes. Since the end of World War II, the world has seen the invention of the first programmable computer, satellite technology, fax machines, microprocessors, floppy disks, portable computers, cellular telephones and pagers, and the World Wide Web. All of these technologies are historically important because they allow great quantities of information to be shared with partners who are geographically separated from us and who, using earlier technologies, might have had to wait hours, days, or even weeks to receive information. Technology has, in effect, brought people closer together by allowing voice, text, and images to be rapidly transmitted across great distances.

Recognizing that knowledge systems are usually based on local area network (LAN) or Internet technology, several critical questions arise when an organization attempts to implement a knowledge management system. First, how do you measure the value of a knowledge management system? Like soft-skills training, many organizations and experts are struggling to measure the value added by a knowledge management system. For example, the value of new technology in a manufacturing plant can be measured with relative accuracy and be said to decrease production costs by a certain amount per unit. Knowledge management systems, however, commonly do not have such a direct impact on operations. How can we accurately measure value of having immediate access to information that improves decision-making or strategy?

Another problem is, how do you create an organizational culture that values sharing? The old adage "Information is power" exemplifies the cultural reasons why knowledge management systems can be challenging to implement. Traditionally in the United States, employees have been recognized and rewarded for individual effort and achievement. Collaborative effort and cooperation have not traditionally been rewarded. Consequently, implementing a knowledge management system may likely require that an organization reassess the values by which business is conducted, the performance evaluation instruments, and the pay/bonus structures so that employees see ample incentive to share knowledge and cooperate throughout the organization.

How much information is too much? Information overload is a concern in organizations that are developing a knowledge management system. What information do we attempt to capture and make available? What information do we overlook? In large organizations, the answers to such questions can have a dramatic impact on the quantity and quality of information available to employees.

TACIT AND EXPLICIT KNOWLEDGE

Many knowledge management activities in business involve finding sources of tacit and explicit knowledge, and changing

tacit knowledge to more useful, explicit forms. *Tacit knowledge* is static: it consists of ideas, experiences, and data that reside in particular sources and are not often communicated. Usually, tacit knowledge is contained by employees; it is knowledge that workers have but do not share, either because the worker does not think their knowledge is important or because there is not an available communication channel to move that knowledge along to other members of the company. Other forms of tacit information may include unaccessed files or third-party analysis that has not been reviewed. Tacit knowledge is considered especially important in innovation, where latent talents and ideas that employees have can have great impact on new products or processes the company is seeking.

Explicit knowledge is available to other people: this type of knowledge, rather than residing in specific employees, has been integrated into the company as a whole. It can be accessed by anyone who requires the knowledge for their activities, and it is usually vital to the success of the company. Examples of explicit knowledge include manuals, presentations, and company reports. Databases and all data-compounding techniques deal with extracting explicit knowledge from information reservoirs. This type of knowledge is much more useful than tacit knowledge because it is available for application.

How can a company make tacit knowledge into explicit knowledge and gain competitive advantage from it? There are many methods. Some companies, especially prospector-types, willingly ask for employees' knowledge and opinions to better innovate new business techniques. Other companies, more defender based, hold all knowledge in higher management and work to collect and distribute executive knowledge. Most businesses are a combination of the two. However, some types of tacit knowledge cannot be expressed to multiple people. Employees may have a certain know-how or various insights or intuitions that cannot be quantified. For this type of tacit knowledge, the best employers can do is develop strong communication channels and highlight skilled employees who have a wealth of the more intangible knowledge assets.

The most difficult step in transforming tacit knowledge to explicit knowledge is collecting it from employees. Companies can set up collaboration initiatives at regular intervals to give their employees a chance to share their experiences and make collection easier. In service-related businesses, a step can be put into place to gather and submit employee opinions every time a transaction is carried through (this could also be done at timed intervals). Once tacit knowledge is collected, it is categorized, streamlined, and turned into explicit knowledge available to the entire company.

KM AND INTRANETS

One of the most common ways for businesses to distribute explicit information is through the company intranet.

The efficiency of the information channels in the intranet depends on how the knowledge is filed and shared. There are two primary schools of thought concerning the management of intranet knowledge. The first, more common belief proposes that the company intranet should be structured with a clear center, a hub of information that employees can access based on need and position. The second school of thought believes that knowledge is healthier and more naturally updated when it is available to everyone. These analysts propose that company intranet systems are more functional when information is available to everyone and freely accessed from any level.

Since employees spend so much time using the intranet system to trade knowledge, companies should be careful in how they categorize and manage intranet information. Is intranet knowledge well-organized, easy to find, and based on employee need? Do employees know about all the sources of knowledge on their company's intranet? Is there a training program in place for using all intranet systems? A 2008 study by Chaudhry, Ali, and Abadi in the *Journal of Knowledge Management Practice* gives several suggestions to improve intranets as a knowledge management tool, including:

- Redesign the user interface. Switching colors, fonts, and font sizes can aid readability for employees and help them absorb information more quickly.

- Conduct spring cleaning initiatives for the company intranet. Studies have shown that many documents are duplicated or refiled unnecessarily. Cleaning exercises also allow companies a chance to be sure that all files are formatted correctly and standardized according to company policy.

- Allow more online transactions. Employees can benefit by exchanging knowledge with each other, and transferring information over the intranet can be a much more efficient tool than using instant messaging or e-mail.

- Consistently update information. Some employees find their intranet systems to be filled with extra information they did not need. Updating information should include not only filing new information but cleaning out outdated information as well.

- Improve search systems. Most employees search the intranet systems by keyword. This can lead to complicated results, and companies can increase efficiency by creating better keyword search engines.

- Appoint a manager to be in charge of the intranet, so that they can implement changes, design regulations, and oversee necessary organizations.

KNOWLEDGE MAPS

KM strategies have long made use of knowledge maps, or visual representations of the pools of knowledge within

companies, who has access to them, and what other groups they affect. KM workers find knowledge maps useful for giving overviews of explicit knowledge, and finding particular pieces of information faster. There are a number of different types of knowledge maps, used for different purposes. The top four types of maps are:

- **Concept maps**. The concept map is a simple version of knowledge mapping, dividing the information groups into clear categories and showing relevant connections with circles and lines. These are usually made with a main body of knowledge and several branching groups, and are used in teaching and presentation formats. Unfortunately, it can be difficult to show processes with several related steps in concept mapping.

- **Mind maps**. These flexible, intuitive-based maps are used to express tacit knowledge for the benefit of other people, or for review. These can be more than one color and consist of interlaced connection with multiple central headings. These connections are often based on semantics or hierarchal structures. Mind maps can be developed into more structured maps further on in development.

- **Conceptual diagram**. These maps are one of the most complicated, involving many titles with textual definitions. Conceptual diagrams are most often used when there is a predetermined topic that needs extensive explanation.

- **Visual metaphor**. Visual metaphors use some sort of preexisting structure—a story, graphic, animal, or identifiable object—to communicate meaning in an easy way to understand. Visual metaphors help people remember key connections for certain topics. Visual metaphors should be chosen carefully for their association value.

KNOWLEDGE WORKERS

Knowledge workers, alternatively termed knowledge entrepreneurs, free agents, or human capital, constitute the fastest growing sector of the workforce in the world. In 2006, knowledge workers in North America outnumbered all other workers four to one. In his 1995 book, *Managing in a Time of Great Change*, Peter Drucker, the eminent management writer credited with coining the term "knowledge worker," defines these individuals as "high level employees who apply theoretical and analytical knowledge, acquired through formal education, to develop new products or services". Knowledge workers are those who acquire, manipulate, interpret, and apply information in order to perform multidisciplinary, complex and unpredictable work. They analyze information and apply expertise in a variety of areas to solve problems, generate ideas, or create new products and services.

Examples of knowledge workers include professionals, scientists, educators, and information system designers. Knowledge work is characterized by the use of information, by unique work situations, and by creativity and autonomy. Knowledge workers make decisions rather than physical items and work with ideas rather than with objects. Their work focuses on mental rather than muscle power and is characterized by non-repetitive tasks. Knowledge workers use different methods and techniques to solve problems and have the authority to decide what work methods to use in order to complete their varying job tasks.

CATEGORIZATION OF KNOWLEDGE WORKERS

Knowledge workers can be grouped into various categories, based on the amount of time spent on individual tasks or on the type of information or skills possessed. The fact that knowledge workers can be classified in different ways is indicative of the variety of jobs they hold.

Knowledge workers can be categorized according to the amount of time they are engaged in routine versus innovative

behaviors. On one end of the scale, workers perform tasks that are primarily repetitive and routine in nature but occasionally use complex information to make independent decisions, often with regard to customer service issues. Employees at the spectrum's opposite end spend most of their time accessing information and making independent decisions with regard to that information.

A second way to categorize those whose work focuses on information and ideas is as follows: specialty knowledge workers, portable knowledge workers, and creation of knowledge workers. Specialty knowledge workers possess a significant amount of knowledge related to a specific company's products or services. These individuals can be thought of as housing vital corporate assets in their heads. Portable knowledge workers possess information of wide and immediate utility. They are familiar with knowledge that is in demand by a variety of organizations. Software programmers, librarians, and persons with business degrees are examples of portable knowledge workers. Creation of knowledge workers focuses the majority of their efforts on innovative behaviors, such as product design and development. Examples of creation of knowledge workers include scientists and information systems designers.

KNOWLEDGE WORKER CHARACTERISTICS

Knowledge work is complex, and those who perform it require certain skills and abilities as well as familiarity with actual and theoretical knowledge. These persons must be able to find, access, recall, and apply information, interact well with others, and possess the ability and motivation to acquire and improve these skills. While the importance of one or more of these characteristics may vary from one job to the next, all knowledge workers need these basic qualifications. More jobs now require college degrees than ever before and a shortage of knowledge workers is imminent. Another future concern is the retirement of experienced plant managers, research scientists, and other knowledge workers that will lead to reduced capacity to innovate and pursue growth strategies as well as increase costly operational errors and decrease efficiency in the management of resources and productivity.

Possessing Factual and Theoretical Knowledge. Knowledge workers are conversant with specific factual and theoretical information. Schoolteachers possess information regarding specialized subject matter, teaching strategies, and learning theories. The sales representative commands factual knowledge concerning the product he or she sells and theoretical knowledge about how to interest customers in that product. Prospective knowledge workers may need years of formal education to master the information needed to enter a particular field of work. Because knowledge is

always being created, this type of employee will be acquiring additional information on a continual basis.

Finding and Accessing Information. At a time when the operations of today's information society depends on knowledge that is continually growing and changing, distribution of information within organizations has become problematic due to the massive amount of information with which employees need to be familiar. Knowledge workers must therefore know how to independently identify and find such material. Such employees need to know which sources provide the information they need and how to use these sources in order to locate information successfully.

Ability to Apply Information. Knowledge workers use information to answer questions, solve problems, complete writing assignments, and generate ideas. Use of analogical reasoning and relevance judgment enables employees to successfully address personal and customer service-related issues. Analogical reasoning is a knowledge-based problem-solving process in which persons apply information from precedents to new situations. Relevance judgment is the process by which individuals decide whether or not a precedent is applicable to the problem at hand. The non-repetitive nature of knowledge workers' jobs makes crucial the ability to apply information to new situations.

Communication Skills. Knowledge work is characterized by close contact with customers, supervisors, subordinates, and teammates. Successful knowledge workers present clearly, in spoken and written word, both factual and theoretical information. These employees listen with understanding and ask for clarification when they do not understand what is being said to them.

Knowledge workers must be able to speak, read, write, and listen in one-on-one and group settings. Emphasis on quality customer service and customization of goods and services to meet individual customer needs and wants brings knowledge workers into close contact with customers. The goals of organizational effectiveness and continual improvement of products, together with the need to continually consider new information in order to accomplish work, require communication between supervisor and supervised and among teammates or colleagues. Knowledge workers possess communications skills that enable them to collaborate with one another for goal-setting, decision-making, and idea-generating purposes.

Motivation. The nature of knowledge work requires continual growth, in terms of mastery of information and skill development, on the part of those who do this type of work. Knowledge workers must become and remain interested in finding information, memorizing that information, and applying it to their work. Because new technological

developments call on knowledge workers to change continuously the way they accomplish their work, these individuals must maintain a desire to apply their talents toward incorporating new information and new technologies into their work.

Intellectual Capabilities. Knowledge workers must have the intellectual capabilities to acquire the skills discussed above. Such intellectual capacities include those concerned with the understanding, recall, processing and application of specialized information. Persons who perform knowledge work must possess the abilities needed to acquire appropriate communication skills and to learn how to figure out where and how information can be located. Knowledge workers are able to learn how to read and write at post-secondary levels and to perform abstract reasoning. They also have the intellectual capacity to understand the value of acquiring and maintaining the knowledge and skills needed to accomplish their work.

HISTORICAL BACKGROUND

Some occupations have always centered on the use of specialized information. Only recently, however, have persons employed in these types of occupations begun to outnumber those employed in jobs that do not require intensive use of specialized knowledge. In the late 1950s and early 1960s, writers such as Fritz Machlup and Peter Drucker first identified and described the reasons behind this phenomenon. Today the increase in knowledge work professions concerns business administrators, professors, management consultants and others interested in learning how to increase business profits or improve life's quality.

Recently, the number of persons employed in traditional types of knowledge work professions has escalated while new types of knowledge work have appeared. Throughout history, people such as writers, teachers, and ministers, for example, have engaged themselves in intellectual activity. Their numbers grew as the population of Europeans in North America increased in the eighteenth century and early nineteenth century. Industrialization then fostered the creation of new categories of employees who used information to make their livings: inventors, consultants, and managers. As the population continued to grow, so did the economy, which became able to support greater numbers of knowledge workers.

In the 1950s, computer science and other knowledge-based professions rapidly expanded. Economist Fritz Machlup examined the distribution, use, and creation of information in the United States. He used statistical information to show that manual workers' share of the labor force was decreasing while the white-collar share was increasing. He tried to differentiate among various types of knowledge workers. Machlup showed that knowledge-producing occupations were growing much faster than manual labor occupations, and he redefined the word "work" in terms of a way to manage and use knowledge.

Peter Drucker wrote extensively on the subject of the knowledge worker. Drucker identified and described the reasons for the decline of the blue collar worker and the rise of the knowledge worker, and he made what are now considered accurate predictions about the knowledge worker's future place in society. He described how knowledge-based positions evolved from manufacturing and agricultural jobs as automation changed the way these jobs were accomplished. Drucker argued that service sector activities had increased, expanded, and diversified, causing the number of knowledge workers to grow. He explained how emphasis on and developments in science and technology fostered the creation of new knowledge professions while an expanding economy enabled their growth.

Information continues to influence work and alter the way it is accomplished. Technology makes possible computerized databases to manage and access such information. In turn, the introduction of new technologies creates jobs for those who design, manage, and utilize these technologies. Organizational expansion, brought on by the use of new knowledge, also creates this type of work, as employees turn their attention toward coordinating additional work. Information's importance in the workplace continues to make crucial its accessibility.

KNOWLEDGE WORKER SHORTAGE

The information society requires a highly qualified workforce. As compared to the past, a larger proportion of the population should attend college and participate in formal training programs designed to teach specialized information and specific skills associated with knowledge work. The fact that traditional blue-collar workers cannot acquire easily the knowledge and skills needed to become knowledge workers will create a shortage of these types of workers. Although colleges and universities may adapt their curriculums to prepare students for various types of knowledge work, it is unlikely that significantly greater percentages of the population will attend college. The American Society for Training and Development maintains that, while nine-tenths of all new jobs now require post-secondary levels of reading, writing, and math, only half of those entering the workforce for the first time have attained these skills. When the traditional blue-collar worker cannot make the transition to knowledge work, society will face problems caused by both unemployment and understaffing. According to the 2007 Talent Shortage Survey conducted by Manpower Inc., human capital will become increasingly scarce as the demographic bulge known as the baby boomers—the generation born between 1945 and 1960—begin to retire. The Generation Xers, those born between 1961 and 1970, are

expected to replace the retiring workforce, but they are only half in number of the boomer generation.

HIRING AND RETAINING THE KNOWLEDGE WORKER

The shortage of knowledge workers makes employers concerned with attracting and retaining these employees. In order to hire and retain knowledge workers, employers may offer higher salaries, attractive work environments, and continuing educational opportunities. Employers take actions designed to attract and retain knowledge workers by creating a free-agent community, respecting knowledge workers as new bosses, and providing growth opportunities. In a free-agent community, employees have the freedom to choose their work methods and work in the environments in which they function best. Treating knowledge workers as the new bosses means that management operates as a facilitator rather than as a controller of work. This gives knowledge workers the autonomy they need to complete their work as they see fit. Employers make work attractive and rewarding by providing growth opportunities, such as those that are associated with ongoing training and development, special assignments, and rotation of jobs and job responsibilities. In such ways, employers attempt to address the knowledge worker shortage.

IMPROVING KNOWLEDGE WORKER PRODUCTIVITY

Knowledge worker productivity influences success in today's competitive work economy, and businesses are focusing on increasing this productivity. Management facilitates the knowledge worker's job performance by providing access to relevant information; environments that promote this information's desired use, continuing educational opportunities, and a balance between guidance and autonomy.

Employers use costly technologies to facilitate access to and manipulation of information. The term information technology refers to computer equipment and programs used to access, process, store, and disseminate information. Examples of information technologies include word processing, spreadsheet, and electronic mail programs, and a variety of other software programs designed to process information in specific ways. Information technologies are designed to reduce the amount of time employees spend on information access, management and manipulation, and to increase the accuracy of these processes. Information technology is important because it helps make information accessible and manageable in a time when accessibility and manipulation of information are crucial to the world economy.

THE WORKPLACE

The characteristics of each individual knowledge worker's workplace depend on the type of work accomplished and what the employer is willing and able to provide. Workplace arrangements range from traditional physical office space occupied by employees between the hours of 9:00 A.M. to 5:00 P.M. each workday to virtual office space which can exist just about anywhere.

Knowledge workers who work exclusively with ideas and information may operate in a non-traditional workplace situated anywhere that employees have access to needed computer and communication equipment. Individuals who work in such "virtual offices" may utilize physical office space as necessary or use "hoteling" to visit customers. Hoteling is a process by which those who work out of virtual offices schedule physical office space for meetings with colleagues, customers, clients, and sales representatives. Writers, researchers, outside sales representatives, and product designers are examples of knowledge workers who might utilize non-traditional workspaces.

CHALLENGES AND OPPORTUNITIES

The increasing demand for employees who use their skills and talents to perform complex and non-repetitive work presents both challenges and opportunities. The challenges include attainment and maintenance of a well educated, highly skilled, and efficient workforce. Opportunities include chances for greater numbers of working age people to hold more rewarding jobs than previously possible and for employees to be judged according to their unique talents and abilities rather with regard to how quickly they complete repetitive tasks or how well they conform to pre-established work standards.

Education of a properly skilled workforce will take special effort. Society will need to convince its members to pursue educational and training opportunities that will qualify them for knowledge work. Businesses and educational institutions may work together to determine exactly what skills and knowledge students need to enter the workforce and how to educate students accordingly. Educators and employers will need to ensure that those who need to know how to use certain technologies are able to do so and will not become disconnected because they are unable to use advanced computer programs or telecommunications equipment. While potential knowledge workers will require familiarity with specialized information related to the type of work they plan to undertake, it will be important that their educational backgrounds give them a common basis for understanding one another.

Hiring, retention, and productivity of knowledge workers will remain important issues. As the shortage of persons qualified to perform knowledge work increases, employers will be challenged to find more effective ways to hire and retain these individuals. In order to improve productivity, employers will try to figure out how to promote teamwork among knowledge workers, how to best design the workplace, and

how to keep knowledge workers from becoming overwhelmed with the information they need to do their jobs.

The use of information technology to manage and manipulate information presents a series of challenges. Employers will need to find ways to fund these technologies and to provide training on their use. Corporate universities are increasingly popular in large businesses as a means of providing job-specific training to employees. Walt Disney, Boeing, and Motorola are three major companies that have a corporate university branch. In the article "Education in the Workplace: An Examination of Corporate University Models," Denise Heam lists a number of reasons why a business might set up an education department. These include:

1. Organize training

2. Start and support change in the organization

3. Get the most out the investment in education

4. Bring a common culture, loyalty, and sense of belonging to a company

5. Remain competitive in today's economy

6. Retain employees

In the current Information Age, an important use of corporate universities is to educate staff about the information technology systems used by the company.

In order to maximize the value of information technologies, employers will want to determine how and when information technologies increase knowledge worker productivity and performance, how to best match a particular technology with a specific job, and how computer programs can be best used to locate, process, and create information. Employers will also need to know how to evaluate employee use of information technologies and how to cope with underutilization, of and resistance to, these technologies. With this user-oriented infrastructure, mission critical business news and financial and research data is now available upon demand to the user's desktop. In fact, the availability of critical information via the web has created a new breed of telecommuting knowledge workers with anytime/anyplace capabilities.

The shift from blue-collar jobs to knowledge work presents new opportunities. Greater numbers of people will be able to hold jobs that enable them to develop their talents and use their creativity. These new knowledge workers will have greater job mobility. Employers will respect them as individuals who bring unique talents and abilities to their jobs as opposed to workers who perform repetitive tasks. Leadership opportunities will be open to increasingly greater numbers of people.

The twenty-first century has brought a new challenge in the form of outsourcing knowledge workers in several sectors of the economy. Business process outsourcing

(BPO) is the transfer of business operations, such as the production of an automotive component, to a third party. In the past, BPO was primarily used in manufacturing as a way of taking advantage of inexpensive labor and supplies; now everything from human resources to information technology is being outsourced. Contracting the services of BPO vendors outside of a company's home country is termed "offshore outsourcing." Use of BPO rather than an application service provider suggests that some of the risk associated with running the business segment is also being transferred to the third party. Services are now flowing to countries such as India, the Philippines, Morocco, and Egypt. According to the management consulting firm McKinsey the global BPO market is worth $122 to $154 billion. However, concern about high costs and poor quality (resulting from cultural and communication issues) due to outsourcing has been expressed on more than one occasion.

Under-utilization and cost demands of business worldwide are influencing the changes in knowledge-worker skills, requirements, and work location. Identifying and utilizing the knowledge worker in an effective and cost-efficient manner is a challenge for business and for the economy today.

L

LAYOUT

In manufacturing, facility layout consists of configuring the plant site with lines, buildings, major facilities, work areas, aisles, and other pertinent features such as department boundaries. While facility layout for services may be similar to that for manufacturing, it also may be somewhat different—as is the case with offices, retailers, and warehouses. Because of its relative permanence, facility layout probably is one of the most crucial elements affecting efficiency. An efficient layout can reduce unnecessary material handling, help to keep costs low, and maintain product flow through the facility. Types of layouts include process, product, fixed-position, combination, cellular, and certain types of service layouts.

PROCESS LAYOUT

Process layouts are found primarily in job shops, or firms that produce customized, low-volume products that may require different processing requirements and sequences of operations. Process layouts are facility configurations in which operations of a similar nature or function are grouped together. As such, they occasionally are referred to as functional layouts. Their purpose is to process goods or provide services that involve a variety of processing requirements. A manufacturing example would be a machine shop. A machine shop generally has separate departments where general-purpose machines are grouped together by function (e.g., milling, grinding, drilling, hydraulic presses, and lathes). Therefore, facilities that are configured according to individual functions or processes have a process layout. This type of layout gives the firm the flexibility needed to handle a variety of routes and process requirements. Services that utilize process layouts include hospitals, banks, auto repair, libraries, and universities.

Improving process layouts involves the minimization of transportation cost, distance, or time. To accomplish this some firms use what is known as a Muther grid, where subjective information is summarized on a grid displaying various combinations of department, work group, or machine pairs. Each combination (pair), represented by an intersection on the grid, is assigned a letter indicating the importance of the closeness of the two (A = absolutely necessary; E = very important; I = important; O = ordinary importance; U = unimportant; X = undesirable). Importance generally is based on the shared use of facilities, equipment, workers or records, work flow, communication requirements, or safety requirements. The departments and other elements are then assigned to clusters in order of importance.

Advantages of process layouts include:

- **Flexibility.** The firm has the ability to handle a variety of processing requirements.

- **Cost.** Sometimes, the general-purpose equipment utilized may be less costly to purchase and less costly and easier to maintain than specialized equipment.

- **Motivation.** Employees in this type of layout will probably be able to perform a variety of tasks on multiple machines, as opposed to the boredom of performing a repetitive task on an assembly line. A process layout also allows the employer to use some type of individual incentive system.

- **System protection.** Since there are multiple machines available, process layouts are not particularly vulnerable to equipment failures.

Disadvantages of process layouts include:

- **Utilization.** Equipment utilization rates in process layout are frequently very low, because machine usage is dependent upon a variety of output requirements.

- **Cost.** If batch processing is used, in-process inventory costs could be high. Lower volume means higher per-unit costs. More specialized attention is necessary for both products and customers. Setups are more frequent, hence higher setup costs. Material handling is slower and more inefficient. The span of supervision is small due to job complexities (routing, setups, etc.), so supervisory costs are higher. Additionally, in this type of layout accounting, inventory control, and purchasing usually are highly involved.

- **Confusion.** Constantly changing schedules and routings make juggling process requirements more difficult.

PRODUCT LAYOUT

Product layouts are found in flow shops (repetitive assembly and process or continuous flow industries). Flow shops produce high-volume, highly standardized products that require highly standardized, repetitive processes. In a product layout, resources are arranged sequentially, based on the routing of the products. In theory, this sequential layout allows the entire process to be laid out in a straight line, which at times may be totally dedicated to the production of only one product or product version. The flow of the line can then be subdivided so that labor and equipment are utilized smoothly throughout the operation.

Two types of lines are used in product layouts: paced and unpaced. Paced lines can use some sort of conveyor that moves output along at a continuous rate so that workers can perform operations on the product as it goes by. For longer operating times, the worker may have to walk alongside the work as it moves until he or she is finished and can walk back to the workstation to begin working on another part (this essentially is how automobile manufacturing works).

On an unpaced line, workers build up queues between workstations to allow a variable work pace. However, this type of line does not work well with large, bulky products because too much storage space may be required. Also, it is difficult to balance an extreme variety of output rates without significant idle time. A technique known as assembly-line balancing can be used to group the individual tasks performed into workstations so that there will be a reasonable balance of work among the workstations.

Product layout efficiency is often enhanced through the use of line balancing. Line balancing is the assignment of tasks to workstations in such a way that workstations have approximately equal time requirements. This minimizes the amount of time that some workstations are idle due to waiting on parts from an upstream process. It also avoids the problem of building up an inventory queue in front of a downstream process.

Advantages of product layouts include:

- **Output.** Product layouts can generate a large volume of products in a short time.

- **Cost.** Unit cost is low as a result of the high volume. Labor specialization results in reduced training time and cost. A wider span of supervision also reduces labor costs. Accounting, purchasing, and inventory control are routine. Because routing is fixed, less attention is required.

- **Utilization.** There is a high degree of labor and equipment utilization.

Disadvantages of product layouts include:

- **Motivation.** The system's inherent division of labor can result in dull, repetitive jobs that can prove to be quite stressful. Also, assembly-line layouts make it very hard to administer individual incentive plans.

- **Flexibility.** Product layouts are inflexible and cannot easily respond to required system changes—especially changes in product or process design.

- **System protection.** The system is at risk from equipment breakdown, absenteeism, and downtime due to preventive maintenance.

FIXED-POSITION LAYOUT

A fixed-position layout is appropriate for a product that is too large or too heavy to move. For example, battleships are not produced on an assembly line. For services, other reasons may dictate the fixed position (e.g., a hospital operating room where doctors, nurses, and medical equipment are brought to the patient). Other fixed-position layout examples include construction (e.g., buildings, dams, and electric or nuclear power plants), shipbuilding, aircraft, aerospace, farming, drilling for oil, home repair, and automated car washes. In order to make this work, required resources must be portable so that they can be taken to the job for "on the spot" performance.

Due to the nature of the product, the user has little choice in the use of a fixed-position layout. Disadvantages include:

- **Space.** For many fixed-position layouts, the work area may be crowded so that little storage space is available. This also can cause material handling problems.

- **Administration.** Oftentimes, the administrative burden is higher for fixed-position layouts. The span of control can be narrow, and coordination difficult.

COMBINATION LAYOUTS

Many situations call for a mixture of the three main layout types. These mixtures are commonly called combination or hybrid layouts. For example, one firm may utilize a process layout for the majority of its process along with an assembly in one area. Alternatively, a firm may utilize a fixed-position layout for the assembly of its final product, but use assembly lines to produce the components and subassemblies that make up the final product (e.g., aircraft).

CELLULAR LAYOUT

Cellular manufacturing is a type of layout where machines are grouped according to the process requirements for a set of similar items (part families) that require similar processing. These groups are called cells. Therefore, a cellular layout is an equipment layout configured to support cellular manufacturing.

Processes are grouped into cells using a technique known as group technology (GT). Group technology involves identifying parts with similar design characteristics (size, shape, and function) and similar process characteristics (type of processing required, available machinery that performs this type of process, and processing sequence).

Workers in cellular layouts are cross-trained so that they can operate all the equipment within the cell and take responsibility for its output. Sometimes the cells feed into an assembly line that produces the final product. In some cases a cell is formed by dedicating certain equipment to the production of a family of parts without actually moving the equipment into a physical cell (these are called virtual or nominal cells). In this way, the firm avoids the burden of rearranging its current layout. However, physical cells are more common.

An automated version of cellular manufacturing is the flexible manufacturing system (FMS). With an FMS, a computer controls the transfer of parts to the various processes, enabling manufacturers to achieve some of the benefits of product layouts while maintaining the flexibility of small batch production.

Some of the advantages of cellular manufacturing include:

- **Cost.** Cellular manufacturing provides for faster processing time, less material handling, less work-in-process inventory, and reduced setup time, all of which reduce costs.

- **Flexibility.** Cellular manufacturing allows for the production of small batches, which provides some degree of increased flexibility. This aspect is greatly enhanced with FMSs.

- **Motivation.** Since workers are cross-trained to run every machine in the cell, boredom is less of a factor. Also, since workers are responsible for their cells' output, more autonomy and job ownership is present.

In the twenty-first century, companies are taking advantage of software simulation capabilities to cut the cost of building new production facilities. Such software enables three-dimensional visualization of building and work cell layouts. For example, a German truck manufacturer used simulation software when developing an initial draft plan of its new manufacturing facility. The trucks manufactured consisted of about 6,500 parts delivered in containers to the workstations. Each container of parts was required to be available at the right time and the right place to keep production flowing. The facility simulation revealed how the original plans would have led to the concentration of materials at certain locations and rendered feasible work processes impossible. The company used the software to configure alternative manufacturing designs, systems layouts, material handling, tests for usability, and the supply concept. Additionally, line balancing and cycle periods were all placed in the facility, then visualized and optimized. The software helped the truck manufacturer minimize costs and reduce production problems.

OTHER LAYOUTS

In addition to the aforementioned layouts, there are others that are more appropriate for use in service organizations. These include warehouse/storage layouts, retail layouts, and office layouts.

With warehouse/storage layouts, order frequency is a key factor. Items that are ordered frequently should be placed close together near the entrance of the facility, while those ordered less frequently remain in the rear of the facility. Pareto analysis is an excellent method for determining which items to place near the entrance. Since 20 percent of the items typically represent 80 percent of the items ordered, it is not difficult to determine which 20 percent to place in the most convenient location. In this way, order picking is made more efficient.

While layout design is much simpler for small retail establishments (shoe repair, dry cleaner, etc.), retail stores, unlike manufacturers, must take into consideration the presence of customers and the accompanying opportunities to influence sales and customer attitudes. For example, supermarkets place dairy products near the rear of the store so that customers who run into the store for a quick gallon of milk must travel through other sections of the store. This increases the chance of the customer seeing an item of interest and making an impulse buy. Additionally, expensive items such as meat are often placed so that the

customer will see them frequently (e.g., pass them at the end of each aisle). Retail chains are able to take advantage of standardized layouts, which give the customer more familiarity with the store when shopping in a new location.

Office layouts must be configured so that the physical transfer of information (paperwork) is optimized. Communication also can be enhanced through the use of low-rise partitions and glass walls.

A number of changes taking place in manufacturing have had a direct effect on facility layout. One apparent manufacturing trend is to build smaller and more compact facilities with more automation and robotics. In these situations, machines need to be placed closer to each other in order to reduce material handling. Another trend is an increase in automated material handling systems, including automated storage and retrieval systems (AS/AR) and automated guided vehicles (AGVs). There also is movement toward the use of U-shaped lines, which allow workers, material handlers, and supervisors to see the entire line easily and travel efficiently between workstations. So that the view is not obstructed, fewer walls and partitions are incorporated into the layout. Finally, thanks to lean manufacturing and just-in-time production, less space is needed for inventory storage throughout the layout.

LEADERSHIP IN ENERGY AND ENVIRONMENTAL DESIGN (LEED)

Leadership in Energy and Environmental Design (LEED) is a rating system developed by the U.S. Green Building Council (USGBC), which awards points to buildings that satisfy environmentally responsible criteria. The USGBC is a nonprofit organization that was created in 1993 to promote sustainable building. The Council has grown to include more that 14,500 member organizations and companies. Since the first rating system was put into effect in 1998, LEED has expanded to review six environ-

mental categories, which include sustainable sites, water efficiency, energy and atmosphere, materials and resources, indoor environmental quality, and innovation and design. The rating systems have come to be recognized as the international benchmark for green building and development. Projects that are eligible for LEED certification include new construction, commercial interiors, core and shell developments, as well as existing buildings, homes, schools, retail facilities, and healthcare facilities.

LEED serves as a guide for the design, construction, and operations of environmentally sustainable buildings. Verified projects receive a LEED plaque demonstrating that the building has been certified by the USGBC. To earn LEED certification, a building must meet a set of prerequisites. The project then earns points by using sustainable strategies and documenting the building's environmental performance. Buildings are rated as Certified, Silver, Gold, or Platinum.

DEVELOPMENT

LEED rating systems are developed by volunteer committees made up of people from the building industry in cooperation with technical advisory groups. The consensus process involves stakeholder comment and review, and a member ballot. Finally, the rating system is open to the appeals process.

As of 2008, LEED professional accreditation has been granted to 43,000 building professionals since the program's inception in 2001. These individuals display extensive knowledge of green building practices and the LEED rating systems. In 2008, the Green Building Certification Institute (GBCI) was created to administer this program.

BENEFITS

In 2008, two studies by the New Buildings Institute (NBI) and the CoStar Group found that LEED-certified buildings outperform non-LEED-certified buildings in terms of energy use, occupancy rates, sale value, and rental rates. According to the NBI, LEED-certified buildings use 25 to 30 percent less energy than non-certified buildings. Gold and Platinum LEED-certified buildings have average energy savings of some 50 percent. Additionally, incentives for buildings to be certified by LEED are granted at state and local levels.

Since there are obvious advantages to owning an energy-efficient household, many would assume that most new construction would be "green" building. Unfortunately, this is not yet the case. The problem stems from the fact that many developers, while realizing the benefits of LEED designs, are reluctant to increase the initial cost of the house in order to build in this manner. To put it another way, the developer does not reap any of the benefits of the energy-efficient construction, and since putting in these

types of devices often increases the cost, there is the danger of building a green home that is more expensive than the regular home and therefore does not sell.

OVERCOMING RELUCTANCE FOR GREEN BUILDING

There are two major ways in which this obstacle to LEED-designed construction can be overcome. One is through better marketing; many people would be excited about lower monthly energy costs (especially in the late 2000s, as these costs move ever upward), and so they could be convinced to pay more upfront for a house that was energy efficient with the understanding that over time, their initial monetary outlay would be recouped via lower bills.

A second way to overcome higher initial prices for green construction is through legislation, particularly that of a local nature. For example, a city council has an interest in having energy-efficient houses within its domain, for such energy-saving units should allow the city's utilities (electricity, water) to manage growth and demand for these services better. In other words, a huge increase in new housing would typically mean a proportional increase would be needed for gas, electricity, and other utilities, but if the new housing is energy-efficient, this spike in utility demand is mitigated. To achieve this, then, local governments can modify local building codes to offer rebates to developers on various forms of green building, thereby encouraging more new construction be LEED certified.

LEADERSHIP STYLES AND BASES OF POWER

Studies of leadership styles are diverse in nature and multiple definitions have been offered. However, leadership style can be defined broadly as the manner and approach of providing direction, implementing plans, and motivating people.

Bases of power refer to the methods that managers and leaders utilize to influence their employees. When examining bases of power, the concept of authority must also be considered. These two are interconnected attributes tied to the behavior of superiors over subordinates. In their article, "Are There No Limits To Authority?", David Knights and Darren McCabe explain that "power should be understood to be a condition of social relations. Thus, it is erroneous to ask who has power. Instead, it is necessary to explore how power is exercised."

In turn, the nature of how power is exercised is a workable definition for authority. In short, authority and power are intertwined, with power being the ability to do things or have others do what one has ordered, while authority is the foundation on which that power is built.

STYLES OF LEADERSHIP

Three different styles of leadership were identified by Kurt Lewin, renowned social scientist, in 1939: authoritarian, democratic, and laissez-faire. His results indicated that the democratic style is superior to the other two styles. Attributes of each style are outlined below.

- The *authoritarian* makes all decisions, independent of member's input. The authority figure dictates direction, leaving members in the dark about future plans. The authority figure selects which members will work collaboratively and determines solely the work tasks for the teams. This leader type is very personal in his praise and criticisms of each member, but does not actively participate with the group, unless demonstrating to the group. The authority figure is unfriendly and/or impersonal, but not openly hostile.

- The *democratic* leader welcomes team input and facilitates group discussion and decision making. This leader type shares plans with the group and offers multiple options for group consideration. The democratic leader encourages members to work freely with each other and leaves division of tasks to the group. This leader is objective in praise and criticism, and joins group activities without over-participating.

- The *laissez-faire* leader allows the group complete freedom for decision-making, without participating himself. This leader type provides materials and offers to assist only by request. The laissez-faire leader does not participate in work discussions or group tasks. This leader does not offer commentary on members' performance unless asked directly, and does not participate or intervene in activities.

Since 1939, Lewin's research has been the basis for many further research studies and articles on organizational behavioral in theory and in action. Each leadership style can be appropriate depending on the environment within which it is implemented, the members of the group (employees), and the goals or tasks that are being undertaken by the group. Leaders may adjust their style of leadership to fit certain tasks, groups, or settings.

An authoritarian leadership style can be effective when a situation calls for expedited action or decision-making. Group members who are not self-motivated, who prefer structure, and appreciate significant direction and monitoring may thrive under this style.

A democratic leadership style allows for multiple viewpoints, inputs, and participation, while still maintaining control and the leadership role. A quality democratic leader recognizes each member's strengths and effectively elicits the best performance from each member, all the while guiding and leading effectively. A challenge for the democratic leader is to recognize that not all tasks need to be handled by the group; that the leader should appropriately address some issues alone.

A laissez-faire leadership style works best when group members are highly skilled and motivated, with a proven track record of excellence. This hands-off approach can allow these capable members to be productive and effective. The laissez-faire style is interpreted by the members as a sign of confidence and trust in their abilities and further empowers them to be successful and motivated.

BASES OF POWER

Five bases of power were identified by French and Raven in 1960, which laid the groundwork for most discussions of power and authority in the latter half of the twentieth century. These five types of power are coercive, legitimate, reward, referent, and expert. Power can be manifested through one or more of these bases.

Coercive Power. Coercive power rests in the ability of a manager to force an employee to comply with an order through the threat of punishment. Coercive power typically leads to short-term compliance, but in the long-run produces dysfunctional behavior.

Coercion reduces employees' satisfaction with their jobs, leading to lack of commitment and general employee withdrawal. In the United States, Canada, and Western Europe, coercive power has seen a decline in the last fifty years. Several reasons contribute to this, ranging from the legal erosion of employment-at-will and the awareness of employee violence or other forms of retaliatory behavior.

Equally important as an effect on the receding popularity of coercion as a basis of power has been the influence of quality management theorists, such as Philip Crosby and W. Edwards Deming. They suggested that there is a decline in productivity and creativity when coercive power is employed. The use of coercive power results in an atmosphere of insecurity or fear. In spite of this insight, coercion as a base of power continues to play a role even in those organizations influenced by theories of quality management.

In times of economic crisis or threats to the survival of the organization at large, coercion may come to the forefront. Coercive power may also materialize as organizations attempt to streamline their operations for maximum efficiency. If employees must be fired, those who fail to conform to the organizational goals for survival will be the most likely candidates for termination. The threat of termination for failure to comply, in turn, is coercive power.

Legitimate Power. Legitimate power rests in the belief among employees that their manager has the right to give orders based on his or her position. For example, at the scene of a crime, people usually comply with the orders of a uniformed police officer based simply on their shared belief that he or she has the predetermined authority to give such orders. In a corporate setting, employees comply with the orders of a manager who relies on legitimate power based on the position in the organizational hierarchy that the manager holds. Although employees may comply based on legitimate power, they may not feel a sense of commitment or cooperation.

Reward Power. Reward power, as the name implies, rests on the ability of a manager to give some sort of reward to employees. These rewards can range from monetary compensation to improved work schedules. Reward power often does not need monetary or other tangible compensation to work when managers can convey various intangible benefits as rewards.

When reward power is used in a flexible manner, it can prove to be a strong motivator, as Crosby, Deming, and others have shown. Still, when organizations rely too rigidly on rewards, the system can backfire. Employees may be tempted to unethically or even illegally meet the quotas to which overly rigid reward systems may be tied.

Another problem associated with rewards as a base for power is the possibility that the rewards will divert employees' attention from their jobs and focus their attention instead on the rewards dangled before them.

Referent Power. Referent power derives from employees' respect for a manager and their desire to identify with or emulate him or her. In referent power, the manager leads by example. Referent power rests heavily on trust. It often influences employees who may not be particularly aware that they are modeling their behavior on that of the manager and using what they presume he or she would do in such a situation as a point of reference.

The concept of empowerment in large part rests on referent power. Referent power may take considerable time to develop and thus may not prove particularly effective in a workforce with a rapid turnover of personnel.

One common error in applying referent power in cross-cultural situations, however, comes in misunderstanding the ways in which employees identify with their superiors. Since identification with one's superior in the United States is hampered by symbols of legitimate power (for example, titles or dress), those who advocate its use encourage managers to

dress down to the level of their employees and use terms such as "facilitator" and "coach" coupled with "associates" and "group members" rather than "boss" and "subordinates."

In societies such as Argentina or Mexico, symbols of legitimate power may not readily hamper identification, whereas American-style egalitarianism may diminish the respect employees feel for the manager. In short, U.S. employees are likely to identify with managers by personally liking them and feeling liked in return, whereas Argentine and Mexican employees are likely to identify with managers by respecting them and feeling respected in return. Thus, referent power may be more cross-culturally variable than the other four bases of power laid out by French and Raven.

Imberman describes how specialized training is now used in the grocery industry to train Latino immigrants in the democratic supervisory techniques of U.S. managers. In the past, when these men and women were promoted to supervisory positions, they tended to rely heavily on the Latino model of authoritarianism under which they were raised. The managerial style hindered their ability to effectively supervise employees or to garner the respect they were seeking. To remedy this situation, specialized training programs are now utilized. The end result is effective and confident supervisors, motivated workers, higher productivity, less waste, and better customer service.

Expert Power. Expert power rests on the belief of employees that an individual has a particularly high level of knowledge or highly specialized skill set. Managers may be accorded authority based on the perception of their greater knowledge of the tasks at hand than their employees.

Interestingly, in expert power, the superior may not rank higher than the other persons in a formal sense. Thus, when an equipment repair person comes to the CEO's office to fix a malfunctioning piece of machinery, no question exists that the CEO outranks the repair person; yet regarding the specific task of getting the machine operational, the CEO is likely to follow the orders of the repair person.

Expert power has within it a built-in point of weakness: as a point of power, expertise diminishes as knowledge is shared. If a manager shares knowledge or skill instruction with his or her employees, in time they will acquire a similar knowledge base or skill set. As the employees grow to equal the manager's knowledge or skills, their respect for the superiority of his expertise diminishes.

The result is either that the manager's authority diminishes or that the manager intentionally chooses not to share his or her knowledge base or skill set with the employees. The former choice weakens the manager's authority over time, while the latter weakens the organization's effectiveness over time.

MULTIDIMENSIONAL POWER

Traditional theories such as those of French and Raven, as well as the empowerment advocates of the 1980s, such as Crosby and Deming, have tended to approach power and authority as one-dimensional. By contrast, several experts have more recently begun to reconfigure how power is viewed to a more multidimensional interweaving of relations or conflicting needs.

For example, Grant, Shani, and Krishnan described TQM's consumer-focused goals and traditional management's economic model of the firm as two inherently opposed paradigms. Because these two paradigms are grounded in two independent sources of authority, they produce different but coexisting dimensions of power.

It has also been argued that authority is culturally based. Geert Hofstede, in one of the most thorough empirical surveys on cross-cultural influences on work-related values, delineated marked differences in what he called "power distance."

For Hofstede, power distance is the degree to which members of a culture feel comfortable with inequalities in power within an organization; that is, the extent to which one's boss is seen as having greater power than oneself. Thus, views regarding both power and leadership shape the conception of authority within an organization. And because both these facets of authority conception differ drastically from culture to culture, authority itself is conceived of differently from society to society.

Consequently, no single dimension of authority and power is likely to hold equally for all managers and employees in a multicultural domestic setting or in the multicultural milieu of the multinational corporation.

Finally, one can also argue against the one-dimensional view of authority and power when they are viewed not as independent elements in the abstract, but as intrinsically derived from relations within the organization. Power and authority are multidimensional because relationships are by nature multidimensional.

Theorists believe that leadership is a function influenced by the leader, the followers, and the situation. Fred Fiedler presented this in the Leadership Contingency Model in the early 1970s, and it is still studied nearly four decades later. Fiedler suggested that the most successful leadership outcome is a result of matching the leader to the situation. Therefore, most valuable leadership in an organization may be those leaders who have proven they are able to adapt and lead successfully in a variety of situations. The optimal organization/leadership style, therefore, is contingent upon various internal and external constraints.

The ways in which managers influence their employees and encourage them to be productive depend on many variables, including the personality of the leader,

the skills of the group/employees, the task or assignment at hand, or the group dynamics and personalities of group members. As with leadership styles, each base of power has its place in management and can prove effective in the right setting and right circumstances.

While most literature on leadership emphasizes the influence of the leader on the group, the opposite is also true. Groups can influence leader behavior by selectively responding to specific leader behaviors. External factors—such as organizational policies, group norms, and individual skills and abilities—also influence leaders. The followers' skills and abilities and the nature of the task itself affect the leader's influence.

Along with leadership styles, there is much similarity and terminology crossover in the study of leadership theories; researchers should examine both terms in the available literature to access the full spectrum of knowledge on the topic of leadership.

LEADERSHIP THEORIES AND STUDIES

Leadership can be defined as a process by which one individual influences others toward the attainment of group or organizational goals. Three points about the definition of leadership should be emphasized. First, leadership is a social influence process. Leadership cannot exist without a leader and one or more followers. Second, leadership elicits voluntary action on the part of followers. The voluntary nature of compliance separates leadership from other types of influence based on formal authority. Finally, leadership results in followers' behavior that is purposeful and goal-directed in some sort of organized setting. Many, although not all, studies of leadership focus on the nature of leadership in the workplace.

Leadership is probably the most frequently studied topic in the organizational sciences. Thousands of leadership studies have been published and thousands of pages on leadership have been written in academic books and journals, business-oriented publications, and general-interest publications. Despite this, the precise nature of leadership and its relationship to key criterion variables such as subordinate satisfaction, commitment, and performance is still uncertain, to the point where Fred Luthans, in his book *Organizational Behavior* (2005), said that "it [leadership] does remain pretty much of a 'black box' or unexplainable concept."

Leadership should be distinguished from management. Management involves planning, organizing, staffing, directing, and controlling, and a manager is someone who performs these functions. A manager has formal authority by virtue of his or her position or office. Leadership, by contrast, primarily deals with influence. A manager may or may not be an effective leader. A leader's ability to influence others may be based on a variety of factors other than his or her formal authority or position.

In the sections that follow, the development of leadership studies and theories over time is briefly traced. Table 1 provides a summary of the major theoretical approaches.

Table 1

Leadership Perspectives

Historical Leadership Theories

Leadership Theory	Time of Introduction	Major Tenets
Trait Theories	1930s	Individual characteristics of leaders are different than those of nonleaders.
Behavioral Theories	1940s and 1950s	The behaviors of effective leaders are different than the behaviors of ineffective leaders. Two major classes of leader behavior are task-oriented behavior and relationship-oriented behavior.
Contingency Theories	1960s and 1970s	Factors unique to each situation determine whether specific leader characteristics and behaviors will be effective.
Leader-Member Exchange	1970s	Leaders from high-quality relationships with some subordinates but not others. The quality of leader-subordinates relationship affects numerous workplace outcomes.
Charismatic Leadership	1970s and 1980s	Effective leaders inspire subordinates to commit themselves to goals by communicating a vision, displaying charismatic behavior, and setting a powerful personal example.
Substitutes for Leadership	1970s	Characteristics of the organization, task, and subordinates may substitute for or negate the effects of leadership behaviors.

HISTORICAL DEVELOPMENT

Three main theoretical frameworks have dominated leadership research at different points in time. These included the trait approach (1930s and 1940s), the behavioral approach (1940s and 1950s), and the contingency or situational approach (1960s and 1970s).

Trait Approach. The scientific study of leadership began with a focus on the traits of effective leaders. The basic premise behind trait theory was that effective leaders are born, not made, thus the name sometimes applied to early versions of this idea—the "great man" theory. Many leadership studies based on this theoretical framework were conducted in the 1930s, 1940s, and 1950s.

Leader trait research examined the physical, mental, and social characteristics of individuals. In general, these studies simply looked for significant associations between individual traits and measures of leadership effectiveness. Physical traits such as height, mental traits such as intelligence, and social traits such as personality attributes were all subjects of empirical research.

The initial conclusion from studies of leader traits was that there were no universal traits that consistently separated effective leaders from other individuals. In an important review of the leadership literature published in 1948, Ralph Stogdill concluded that the existing research had not demonstrated the utility of the trait approach.

Several problems with early trait research might explain the perceived lack of significant findings. First, measure-ment theory at the time was not highly sophisticated. Little was known about the psychometric properties of the measures used to operationalize traits. As a result, different studies were likely to use different measures to assess the same construct, which made it very difficult to replicate findings. In addition, many of the trait studies relied on samples of teenagers or lower-level managers.

Early trait research was largely atheoretical, offering no explanations for the proposed relationship between individual characteristics and leadership.

Finally, early trait research did not consider the impact of situational variables that might moderate the relationship between leader traits and measures of leader effectiveness. As a result of the lack of consistent findings linking individual traits to leadership effectiveness, empirical studies of leader traits were largely abandoned in the 1950s.

Leader Behavior Approach. Partially as a result of the disenchantment with the trait approach to leadership that occurred by the beginning of the 1950s, the focus of leadership research shifted away from leader traits to leader behaviors. The premise of this stream of research was that the behaviors exhibited by leaders are more important than their physical, mental, or emotional traits. The two most famous behavioral leadership studies took place at Ohio State University and the University of Michigan in the late 1940s and 1950s. These studies sparked hundreds of other leadership studies and are still widely cited.

The Ohio State studies utilized the Leader Behavior Description Questionnaire (LBDQ), administering it to samples of individuals in the military, manufacturing companies, college administrators, and student leaders. Answers to the questionnaire were factor-analyzed to determine if common leader behaviors emerged across samples. The conclusion was that there were two distinct aspects of leadership that describe how leaders carry out their role.

Two factors, termed consideration and initiating structure, consistently appeared. Consideration involves showing concern for subordinates, being supportive, recognizing subordinates' accomplishments, and providing for subordinates' welfare. Initiating structure, sometimes called task-oriented behavior, involves planning, organizing, and coordinating the work of subordinates.

The Michigan leadership studies took place at about the same time as those at Ohio State. Under the general direction of Rensis Likert, the focus of the Michigan studies was to determine the principles and methods of leadership that led to productivity and job satisfaction. The studies resulted in two general leadership behaviors or orientations: an employee orientation and a production orientation. Leaders with an employee orientation showed genuine concern for interpersonal relations. Those with a production orientation focused on the task or technical aspects of the job.

The conclusion of the Michigan studies was that an employee orientation and general, instead of close, supervision yielded better results. Likert eventually developed four "systems" of management based on these studies; he advocated System 4 (the participative-group system, which was the most participatory set of leader behaviors) as resulting in the most positive outcomes.

One concept based largely on the behavioral approach to leadership effectiveness was the Managerial (or Leadership) Grid, developed by Robert Blake and Jane Mouton. The grid combines "concern for production" with "concern for people" and presents five alternative behavioral styles of leadership. An individual who emphasized neither method was practicing "impoverished management" according to the grid. If a person emphasized concern for people and placed little emphasis on production, he was termed a "country-club" manager.

Conversely, a person who emphasized a concern for production but paid little attention to the concerns of subordinates was a "task" manager. A person who tried to balance concern for production and concern for people was termed a "middle-of-the-road" manager.

Finally, an individual who was able to simultaneously exhibit a high concern for production and a high concern for people was practicing "team management." According to the prescriptions of the grid, team management was the best leadership approach. The Managerial Grid became a

major consulting tool and was the basis for a considerable amount of leadership training in the corporate world.

The assumption of the leader behavior approach was that there were certain behaviors that would be universally effective for leaders. Unfortunately, empirical research has not demonstrated consistent relationships between task-oriented or person-oriented leader behaviors and leader effectiveness. Like trait research, leader behavior research did not consider situational influences that might moderate the relationship between leader behaviors and leader effectiveness.

Contingency (Situational) Approach. Contingency or situational theories of leadership propose that the organizational or work group context affects the extent to which given leader traits and behaviors will be effective. Contingency theories gained prominence in the late 1960s and 1970s. Four of the more well-known contingency theories are Fiedler's contingency theory, path-goal theory, the Vroom-Yetton-Jago decision-making model of leadership, and the situational leadership theory. Each of these approaches to leadership is briefly described in the paragraphs that follow.

Introduced in 1967, Fiedler's contingency theory was the first to specify how situational factors interact with leader traits and behavior to influence leadership effectiveness. The theory suggests that the "favorability" of the situation determines the effectiveness of task- and person-oriented leader behavior.

Favorability is determined by (1) the respect and trust that followers have for the leader; (2) the extent to which subordinates' responsibilities can be structured and performance measured; and (3) the control the leader has over subordinates' rewards. The situation is most favorable when followers respect and trust the leader, the task is highly structured, and the leader has control over rewards and punishments.

Fiedler's research indicated that task-oriented leaders were more effective when the situation was either highly favorable or highly unfavorable, but that person-oriented leaders were more effective in the moderately favorable or unfavorable situations. The theory did not necessarily propose that leaders could adapt their leadership styles to different situations, but that leaders with different leadership styles would be more effective when placed in situations that matched their preferred style.

Fiedler's contingency theory has been criticized on both conceptual and methodological grounds. However, empirical research has supported many of the specific propositions of the theory, and it remains an important contribution to the understanding of leadership effectiveness.

Path-goal theory was first presented in a 1971 *Administrative Science Quarterly* article by Robert House. Path-goal

theory proposes that subordinates' characteristics and characteristics of the work environment determine which leader behaviors will be more effective. Key characteristics of subordinates identified by the theory are locus of control, work experience, ability, and the need for affiliation. Important environmental characteristics named by the theory are the nature of the task, the formal authority system, and the nature of the work group. The theory includes four different leader behaviors, which include directive leadership, supportive leadership, participative leadership, and achievement-oriented leadership.

According to the theory, leader behavior should reduce barriers to subordinates' goal attainment, strengthen subordinates' expectancies that improved performance will lead to valued rewards, and provide coaching to make the path to payoffs easier for subordinates. Path-goal theory suggests that the leader behavior that will accomplish these tasks depends upon the subordinate and environmental contingency factors.

Path-goal theory has been criticized because it does not consider interactions among the contingency factors and also because of the complexity of its underlying theoretical model, expectancy theory. Empirical research has provided some support for the theory's propositions, primarily as they relate to directive and supportive leader behaviors.

The Vroom-Yetton-Jago decision-making model was introduced by Victor Vroom and Phillip Yetton in 1973 and revised by Vroom and Jago in 1988. The theory focuses primarily on the degree of subordinate participation that is appropriate in different situations. Thus, it emphasizes the decision-making style of the leader.

There are five types of leader decision-making styles, which are labeled AI, AII, CI, CII, and G. These styles range from strongly autocratic (AI), to strongly democratic (G). According to the theory, the appropriate style is determined by answers to up to eight diagnostic questions, which relate to such contingency factors as the importance of decision quality, the structure of the problem, whether subordinates have enough information to make a quality decision, and the importance of subordinate commitment to the decision.

The Vroom-Yetton-Jago model has been criticized for its complexity, for its assumption that the decision makers' goals are consistent with organizational goals, and for ignoring the skills needed to arrive at group decisions to difficult problems. Empirical research has supported some of the prescriptions of the theory.

The situational leadership theory was initially introduced in 1969 and revised in 1977 by Hersey and Blanchard. The theory suggests that the key contingency factor affecting choice of leadership style is the task-related maturity of the subordinates. Subordinate maturity is defined as the ability of subordinates to accept responsibility for their own task-related behavior. The theory classifies leader behaviors into the two broad classes of task-oriented and relationship-oriented behaviors. The major proposition of situational leadership theory is that the effectiveness of task and relationship-oriented leadership depends upon the maturity of a leader's subordinates.

Situational leadership theory has been criticized on both theoretical and methodological grounds. However, it remains one of the better-known contingency theories of leadership and offers important insights into the interaction between subordinate ability and leadership style.

RECENT DEVELOPMENTS

Although trait, behavioral, and contingency approaches have each contributed to the understanding of leadership, none of the approaches have provided a completely satisfactory explanation of leadership and leadership effectiveness. Since the 1970s, several alternative theoretical frameworks for the study of leadership have been advanced. Among the more important of these are leader-member exchange theory, transformational leadership theory, the substitutes for leadership approach, and the philosophy of servant leadership.

Leader-Member Exchange Theory. Leader-member exchange (LMX) theory was initially called the vertical dyad linkage theory. The theory was introduced by George Graen and various colleagues in the 1970s and has been revised and refined in the years since. LMX theory emphasizes the dyadic (i.e., one-on-one) relationships between leaders and individual subordinates, instead of the traits or behaviors of leaders or situational characteristics.

The theory's focus is determining the type of leader-subordinate relationships that promote effective outcomes and the factors that determine whether leaders and subordinates will be able to develop high-quality relationships.

According to LMX theory, leaders do not treat all subordinates in the same manner, but establish close relationships with some (the in-group) while remaining aloof from others (the out-group). Those in the in-group enjoy relationships with the leader that are marked by trust and mutual respect. They tend to be involved in important activities and decisions. Conversely, those in the out-group are excluded from important activities and decisions.

LMX theory suggests that high-quality relationships between a leader-subordinate dyad will lead to positive outcomes such as better performance, lower turnover, job satisfaction, and organizational commitment. Empirical research supports many of the proposed relationships.

Transformational Leadership Theories. Beginning in the 1970s, a number of leadership theories emerged that focused on the importance of a leader's charisma to

leadership effectiveness. Included within this class of theories are House's theory of charismatic leadership, Bass's transformational leadership theory, and Conger and Kanungo's charismatic leadership theory.

These theories have much in common. They all focus on attempting to explain how leaders can accomplish extraordinary things against the odds, such as turning around a failing company, founding a successful company, or achieving great military success. The theories also emphasize the importance of leaders inspiring subordinates' admiration, dedication, and unquestioned loyalty through articulating a clear and compelling vision.

Transformational leadership theory differentiates between the transactional and the transformational leader. Transactional leadership focuses on role and task requirements and utilizes rewards contingent on performance. By contrast, transformational leadership focuses on developing mutual trust, fostering the leadership abilities of others, and setting goals that go beyond the short-term needs of the work group.

Bass's transformational leadership theory identifies four aspects of effective leadership, which include charisma, inspiration, intellectual stimulation, and consideration. A leader who exhibits these qualities will inspire subordinates to be high achievers and put the long-term interest of the organization ahead of their own short-term interest, according to the theory. Empirical research has supported many of the theory's propositions.

Substitutes for Leadership Theory. Kerr and Jermier introduced the substitutes for leadership theory in 1978. The theory's focus is concerned with providing an explanation for the lack of stronger empirical support for a relationship between leader traits or leader behaviors and subordinates' satisfaction and performance. The substitutes for leadership theory suggests that characteristics of the organization, the task, and subordinates may substitute for or negate the effects of leadership, thus weakening observed relationships between leader behaviors and important organizational outcomes.

Substitutes for leadership make leader behaviors such as task-oriented or relationship-oriented unnecessary. Characteristics of the organization that may substitute for leadership include formalization, group cohesiveness, inflexible rules, and organizational rewards not under the control of the leader. Characteristics of the task that may substitute for leadership include routine and repetitive tasks or tasks that are satisfying. Characteristics of subordinates that may substitute for leadership include ability, experience, training, and job-related knowledge.

The substitutes for leadership theory has generated a considerable amount of interest because it offers an intuitively appealing explanation for why leader behavior impacts subordinates in some situations but not in others. However, some of its theoretical propositions have not been adequately tested. The theory continues to generate empirical research.

Servant Leadership. This approach to leadership reflects a philosophy that leaders should be servants first. It suggests that leaders must place the needs of subordinates, customers, and the community ahead of their own interests in order to be effective. Characteristics of servant leaders include empathy, stewardship, and commitment to the personal, professional, and spiritual growth of their subordinates. Servant leadership has not been subjected to extensive empirical testing but has generated considerable interest among both leadership scholars and practitioners.

Entrepreneurial Leadership. The entrepreneurship theory of leadership, which started developing in the 1970s, is a dynamic process of vision, change, and creation. Entrepreneurial leaders are able to create visionary scenarios to assemble and mobilize a team committed to discovering strategic value creation. These leaders aim to improve performance, adaptability, and long-term potential, particularly in highly competitive and invariably changing business environments. The entrepreneurial leader aims to drive employees to higher levels of achievement by utilizing inventive organizational strategies.

Essential ingredients of the entrepreneurial leader are the willingness to take calculated risks—in terms of time, equity, or career; the ability to form an effective venture team; the creative skill to organize the needed resources; the fundamental skill of building a solid business plan; and, finally, the vision to recognize opportunity where others see chaos, contradiction, and confusion.

Regardless of the type of leadership employed, leaders everywhere have similarities. Wharton Business School professor, Robert J. House, created the Global Leadership and Organization Effectiveness (GLOBE) research program in the early 1990s to determine what defined leaders around the world and to compare their styles and values. GLOBE has demonstrated that effective leaders have similarities; they are charismatic, dynamic, optimistic, and socially adept, and are expected to be trustworthy and have foresight. Most leaders rely on team performance and have developed styles for dealing and operating with leaders from different cultures.

Leadership continues to be one of the most written about topics in the social sciences. Although much has been learned about leadership since the 1930s, many avenues of research, such as the GLOBE program, still remain to be explored.

LEAN MANUFACTURING AND JUST-IN-TIME PRODUCTION

Associated with Japanese management techniques, just-in-time production (JIT) is a set of principles and practices based on the philosophy that firms should hold little or no inventory beyond that required for immediate production or distribution. That is, a manufacturer should receive raw materials or parts from its suppliers perhaps just hours before they will be used in production, and the firm's output should be shipped to its customers as soon after completion as possible—without holding onto a stock of either raw goods or finished products.

In practice, JIT has often been expressed as a holistic management system aimed at reducing waste, maximizing cost efficiency, and securing a competitive advantage. Thus, a number of additional conditions are considered necessary for the successful implementation of JIT. These include small lot sizes, short setup and changeover times, efficient and effective quality controls, and perhaps most of all, designing the whole production process to minimize back-ups and maximize the efficiency of human and machine labor.

Lean manufacturing encompasses a number of things. It essentially is a Westernized version of JIT and Japanese *kaizen*, or continuous improvement. Lean manufacturing is a process for measuring and reducing inventory and streamlining production. It is a means for changing the way a company measures plant performance. A knowledge-based system, lean manufacturing takes years of hard work, preparation, and support from upper management. Lean manufacturing is so named because it purports to use much less of certain resources (space, inventory, workers, etc.) than is used by normal mass-production systems to produce comparable output. The term came into widespread use with the 1990 publication of the book *The Machine That Changed the World* by James P. Womack, Daniel T. Jones, and Daniel Roos. The book is based on the MIT five-year International Motor Vehicle Program's study of the auto industry in fourteen countries. This seminal study of the automobile industry explains the concept of lean production to a North American audience for the first time.

The *APICS Dictionary* defines lean manufacturing as a philosophy of production that emphasizes minimizing the amount of all resources (including time) used in various enterprise activities. It involves identifying and eliminating non-value-adding activities in design, production, supply chain management, and customer relations. Lean producers employ teams of multi-skilled workers at all levels of the organization and use highly flexible, increasingly automated machines to produce volumes of products in potentially enormous variety. In effect, they

incorporate the advantages of both mass production (high volume, low unit cost) and craft production (variety and flexibility). Quality is higher than in normal mass production. Compensation and rewards are based on meeting the total cost equation rather than on labor, overhead, or individual quality measures.

Lean manufacturing and JIT (lean/JIT) share most of the same characteristics, goals, and philosophy. In fact, the terms are often used interchangeably.

HISTORY OF LEAN MANUFACTURING/JIT

Since Japan is a physically small country with minimal resources and a large population, the Japanese have always been careful not to waste resources such as time, labor, and space. Waste is seen as abhorrent to the Japanese because they have so little space and so few natural resources. Hence, it has been necessary for the Japanese to maximize the yield from minimally available resources. Also, dense population has made it necessary for the Japanese people to maintain mutual respect in order to work and live together.

Under this *wa* (harmony) culture, everyone tries to maintain the best possible human relationship and is reluctant to be involved in any confrontations. Additionally, most Japanese firms have a *rentai* relationship, which entails maintaining a "joint responsibility" between management and workers. Under this relationship, management should treat all workers equally. In exchange, each worker respects management's leadership position and follows orders exactly without mistakes, cooperates with coworkers, and generates ideas and creativity to improve the firm's competitiveness. This type of culture reinforces the basic tenets of lean/JIT: waste minimization, continuous improvement, and respect for all workers.

This concept was originally developed in Japan in the mid-1970s by the Toyota Motor Corporation. In fact, many firms continue to refer to lean/JIT as the Toyota system. The concept emphasized the avoidance of waste of materials, space, and labor. Significant attention was paid to identifying and correcting potential problems that could lead to any form of waste. Operations were constantly being improved and fine-tuned so as to further eliminate waste and thereby increase productivity and yield. In addition, equal respect was paid to all workers, while minimizing the trappings of status. As a result, by using lean/JIT, Toyota was able to reduce the time needed to produce a car from fifteen days to one day.

In the June 2008 issue of the *Harvard Business Review*, Hirotaka Takeuchi, Emi Osono, and Norihiko Shimizu examine "The Contradictions That Drive Toyota's Success." Two characteristics of the Toyota Corporation that are thought to be germane to the company's success are the setting of vague goals and the company's eagerness to experiment. Toyota President Katsuaki Watanabe tells his employees that his goal is to "build a car that makes the air cleaner, prevents accidents, makes people happier and healthier when they drive it, and gets you from coast to coast on one tank of gas." The philosophy is that by assigning broad goals, researchers are allowed the freedom to explore innovative paths to improve the product. Toyota's commitment to constantly improving their operations requires a steady stream of new ideas and concepts. By encouraging employees to try new things in order to gain knowledge from their successes and failures, Toyota has turned the management process of Plan-Do-Check-Act process into the Toyota Business Practices (TBP), which outlines a routine for experimentation that encompasses eight steps:

- Clarify the problem
- Break down the problem
- Set a target
- Analyze the root cause
- Develop countermeasures
- See countermeasures through
- Monitor both results and processes
- Standardize successful processes

Vague goals and routine experimentation are two of the ways in which Toyota has been able to implement the principle of continuous improvement successfully.

United States. In 1924 Henry Ford's Highland Park plant, and later the River Rouge operation, mass-produced Model T parts just-in-time for assembly while assembly lines pulled work forward to the next assembly stations just-in-time. One hundred freight cars of material were unloaded daily, with materials flowing through fabrication, subassembly, final assembly, and back onto the freight cars. The production cycle was twenty-one days. At River Rouge the cycle was only four days, and that included processing ore into steel at the on-site steel mill.

Unfortunately, this "just-in-time" type manufacturing soon gave way to the large lot sizes and lengthy cycle times dictated by the economies of scale of mass production, mass markets, and standard designs with interchangeable parts. U.S. manufacturers held on to this paradigm until the early 1980s, when the development of the Toyota production system caused it to shift. U.S. manufacturers initially greeted lean/JIT with a great deal of ambivalence, thinking that the concept would never work in the United States due to its reliance on the cultural aspects of the Japanese work environment. However, this view changed when firms such as Hewlett-Packard and Harley-Davidson yielded significant benefits from its use.

MANUFACTURING

The idea behind lean/JIT is a concept called ideal production. Simply produce and deliver finished goods just in time to be sold, subassemblies just in time to go into subassemblies, and purchased materials just in time to be transformed into fabricated parts. The goal of lean/JIT is to find practical ways to create the effect of an automated industry that will come as close as possible to this concept of ideal production.

While the prevailing view of lean/JIT is that of an inventory control system, lean/JIT goes much further. It is an operational philosophy that incorporates an improved inventory control system in conjunction with other systems. These systems include:

- A setup improvement system

- A maintenance improvement system

- A quality improvement system

- A productivity improvement system

Inventory Control System. When larger quantities are ordered or produced, average inventory obviously is larger. This larger inventory results in increased inventory-carrying charges. If a reduction in carrying costs is desired, smaller quantities should be ordered and orders should be placed more often. However, the practice of ordering smaller quantities can have the side effect of increasing ordering costs. To balance these two costs, the concept of economic order quantity (EOQ) was developed. The EOQ formula derives the point, or order quantity, where inventory carrying costs and ordering or setup costs are the same. An order of this quantity will minimize the sum of the two costs.

However, the EOQ formula is flawed. While carrying costs and ordering/setup costs are obvious, other costs that can significantly affect lot size are not considered. The user of the formula often fails to consider quality, scrap, productivity, and worker motivation and responsibility. In addition, the EOQ formula user frequently fails to consider that even though setup costs are significant, they are not unalterable. American manufacturing managers traditionally considered setup costs as a necessary evil and made little or no effort to reduce them.

The lean/JIT philosophy suggests that a firm should eliminate any reliance upon the EOQ formula and seek the ideal production quantity of one. Of course, a lot size of one is not always feasible, but it is a goal used to focus attention on the concept of rapid adjustments and flexibility. Naturally, a reduction in inventory levels means an increase in setups or orders, so the responsibility rests with production to make every effort to reduce setup time and setup costs. It should be noted that this assumes setup time and cost are positively related. This is not always true

because the cost to reduce setup time could be very high if retooling or equipment redesign are involved.

Setup Cost Reduction System. Toyota began a campaign to reduce setup times in 1971. Five years later, the time required to set up presses to form fenders and hoods had fallen from 1 hour to 12 minutes, while U.S. manufacturers needed 6 hours to perform the same task. As the company continued to emphasize reduction of setup times, its operations became capable of "one-touch" setups, which take less than 1 minute.

Setup time can be divided into two phases: external time and internal time. External time includes activities that can take place while the machine is running, such as transporting dies between storage and the machines. These items are external to the run time and do not interrupt it. Internal time includes activities that can only be conducted when the machine is stopped, such as mounting and removing dies. These are items that will interrupt the run time. Ensuring that appropriate tools are ready before changeover begins can eliminate external time. Internal time can be reduced by addressing the question, "How can operations be quickened?" Appropriate responses could include the use of locating pins and hand levers to replace bolts, the standardization of any remaining bolts, permanent installation of wrenches for adjusting nuts, and the use of an air driver instead of a ratchet.

Management tends to analyze the large, obvious costs such as direct labor, but then treats setup as an inherent cost that must be accepted. However, only by reducing setup time and costs can lot sizes be reduced toward the ideal lot size of one.

Preventive Maintenance System. Most arguments against preventive maintenance (PM) suggest that PM programs are more expensive than programs that only repair broken equipment. The flaw in this line of thought arises from the unpredictable nature of equipment breakdown. This reaction mode of maintenance usually means that the maintenance personnel must temporarily patch the equipment and defer the substantive repair until time allows. Unfortunately, since the equipment already has suffered lost time due to the initial breakdown, the likelihood of finding repair time decreases. The result often is a circular process of "adjust and tinker," with an increased risk of unexplained defects in the output.

A proposed requirement for lean/JIT is that machinery be in top running condition at all times. When using small lot sizes, management can ill afford unexpected downtime in production flow. Equipment must be in condition to produce whatever is needed, whenever it is needed. Therefore, a little time should be scheduled each

day to ensure that machinery is capable of producing top quality results. Preventive maintenance is necessary for continuous, long-term improvement in the quality of the production process.

Quality Improvement System. In order for companies to successfully produce goods while receiving only minimum deliveries, no room can be allowed for poor quality. This requires an overhaul in the thinking of management, which traditionally sought the so-called acceptable quality level (AQL). After receipt, delivered goods are randomly inspected to see how many defective parts there are within a predetermined sample size. If the number of defects exceeds a certain amount (the AQL), the entire batch is rejected. No such provision is made under lean/JIT; all parts must be good. The Japanese use the term *zero defects* to describe this philosophy.

Zero defects certainly cannot be obtained overnight, nor can it be expected from all of a firm's current suppliers. To facilitate the receipt of high quality goods, a firm must offer more than the usual short-term contract or purchase order to the lowest bidder. A firm also may have to eliminate or decrease the use of multiple sourcing, or purchasing the same part from several sources as a backup in case one source experiences quality or delivery problems. By issuing long-term contracts to a single source, the lean/JIT firm gives its supplier the confidence and incentive to spend time and money on ensuring near perfect quality while constantly improving the product. Frequently, this makes for a captive supplier who must maintain the required quality in order to survive. The lean/JIT firm should then work constantly and directly with the supplier to monitor quality and provide technical support.

The use of lean/JIT improves the quality of suppliers, as well as the lean/JIT firm's internal quality. When lot sizes are drastically reduced, defect discovery is naturally enhanced. If a worker produces a lot size of one and passes it to the next station, the quality of feedback will be immediate. In this way, defects are discovered quickly and their causes can be corrected immediately. Production of large lots with high defect rates is avoided.

U.S. manufacturers traditionally allowed lot sizes and inventory levels to remain high "just in case" a quality problem, an equipment problem, or a delivery problem should arise. This "just in case" inventory, commonly called buffer stock, allowed the firm to maintain its production flow while the problem was being corrected. When a quality problem emerged and inventory was ample, the search for the source of the problem was postponed until a more suitable time. This suitable time may have never occurred. When lot sizes are minimal, one worker's problem threatens to bring subsequent processes to a halt. This

means that all production workers and management must collaborate to find an immediate solution. The benefits here are twofold. First, the firm avoids the production of large quantities of defective parts. Secondly, good managers will be able to use this as motivation for unity of purpose within the workforce.

Productivity Improvement System. Productivity can be defined as good output divided by required input. The productivity facet of lean/JIT has been described as nothing sitting idle, which wastes time. If equipment is operated only for productive purposes, then energy waste is eliminated. If all inventory is converted into product, then material waste is eliminated. If errors are not allowed, then rework is eliminated.

A number of productivity improvements may result from lean/JIT implementation. Among these are lower inventory levels, lower scrap rates, reductions in rework costs, reductions in inventory carrying costs, smaller floor space requirements, reduced material handling, simpler inventory accounting, and more positive inventory control. All of these lower the input component or increase the good output of the productivity ratio.

Reductions in idle inventories allow the firm to reduce internal lead times—from the purchase of raw materials to the shipping of finished goods—allowing quicker changes in product mix and production quantities. Furthermore, the firm's ability to forecast is enhanced because the forecast horizon is shortened.

TEN STEPS TO LEAN/JIT PRODUCTION

Steve L. Hunter lists ten steps to implement a lean/JIT production system:

1. Reengineer the manufacturing system
2. Reduce setup
3. Integrate quality control
4. Integrate preventive maintenance
5. Level and balance the system
6. Integrate a pull system
7. Control inventory
8. Implement a vendor program
9. Utilize computer integrated manufacturing (CIM) benefits

SIX SIGMA AND LEAN SIX SIGMA

Six Sigma is a management process that shares many characteristics with just-in-time manufacturing and lean production. Developed by Motorola in the 1980s, the strategy encompasses a set of practices inspired by other

management methods such as quality control and zero defects. Six Sigma aims to identify and correct constraints on manufacturing and other business processes in order to achieve a specific financial objective. In Six Sigma, defects include any attribute of the business that could result in customer dissatisfaction.

The term "Sigma" refers to a scale for measuring quality. Processes that operate at "Six Sigma quality" produce fewer than 3.4 defects per million opportunities (DPMO). The management system aims to reduce the frequency of defects in all processes to this level. According to the Motorola University, the Six Sigma improvement methodology has four focuses:

1. Understanding and managing customer requirements

2. Aligning key business processes to achieve those requirements

3. Utilizing rigorous data analysis to minimize variation in those processes

4. Driving rapid and sustainable improvement to business processes

The Six Sigma management system is a framework for creating clear objectives and aligning improvement efforts with the overall business strategy. Six Sigma is applied from the top down of an organization. Martial arts rankings—from green belts through to champion black belts, who work directly under the executive leadership—are used to establish a hierarchy of business functions.

When principles of Six Sigma and lean manufacturing are used together, it is called Lean Six Sigma. This methodology yields process improvement through the use of quantitative analysis and rigorous cost reduction through the elimination of waste.

Lean Six Sigma has been used to streamline IT operations at Bank of America Corporation, Sara Lee Corporation, Xerox Corporation, General Electric, and Seagate Technology. Sara Lee required that all of its IT employees become certified in Lean Six Sigma before the company began the implementation of SAP software. By making Lean Six Sigma the educational standard in the IT department, Sara Lee was able to obtain strategic alignment. CIO Mark Brewer of Seagate used Six Sigma to solve what was believed to be a bandwidth problem. Six Sigma processes were used to calculate server response times, and when the discrepancies between them were analyzed, the IT department realized that the problem was not with the bandwidth. This discovery ended up saving the company from a huge expense that would not have addressed the initial problem. Brewer claims that once he began thinking of IT operations as a factory, Six Sigma immediately became relevant.

BENEFITS OF LEAN/JIT PRODUCTION

While it was noted that inventory reduction is not the sole goal of lean/JIT implementation, it is a very obvious benefit. Less workspace is now needed due to the use of smaller lot sizes and reduced inventory levels. Much of this inventory was stored between and within work centers. By reducing inventory, firms have been able to actually move work centers closer together, freeing up space and reducing material handling distances. This results in a neater, more organized facility that provides for speedy identification of bottlenecks and fewer lost parts.

Additionally, this reduction in inventory and lot sizes promotes rapid feedback from downstream work centers when there is a quality problem. This feedback results in a reduction in scrap and rework, and ultimately a higher level of overall quality.

Reduced inventory and lot sizes also result in increased inventory turns. Inventory turn increases have been noted at Haworth, Hewlett-Packard, Richardson-Vicks Homecare Products, IBM, Raleigh (a fourfold increase), and Harley-Davidson.

The introduction of preventive maintenance and the use of smaller, more flexible machinery combine to yield increased equipment utilization. One major firm was able to change from three lines running three shifts to two lines running one shift with no change in output.

The next phase of lean manufacturing is lean product development, where companies seek a competitive advantage by shortening the time-to-market cycle. At Toyota, engineers and manufacturers collaborate in the development process with the goal of designing a product that facilitates lean manufacturing.

The lean/JIT producer combines the advantages of craft and mass production, while avoiding the high cost of the former and the rigidity of mass production. Lean/JIT producers set their sights explicitly on perfection: continually declining costs, zero defects, zero inventories, and endless product variety. Lean/JIT manufacturing is the new paradigm for manufacturing, replacing a mass-production system that has existed for more than seventy years.

LEVERAGED BUYOUTS

A leveraged buyout (LBO) is a restructuring of the capitalization and ownership of a company. The term *leveraged* refers to the use of debt as the primary method of financing the restructuring. The *buyout* portion refers to the fact that the method is often used to transform a publicly held company into one that is privately held. There are a number of reasons why this type of transaction might take place. These include cost savings, managerial incentives, and tax benefits.

A private equity firm is an investment manager that buys up companies using one of a number of strategies referred to as private equity; one of these strategies is the LBO. When an investor uses debt to acquire a company, the investor does not have to put down all of the capital required to make the acquisition. Once the company has been acquired, its cash flows are used to repay the debt. The investor makes large returns when the company is sold because the investor only put up a fraction of the original purchasing price. In other cases, the group pursuing the buyout might include the publicly held firm's upper management. This type of action is known as a management buyout (MBO).

Among the multiple parties involved when a public firm is taken private, there normally are both winners and losers. Existing shareholders who have their shares purchased in the buyout often win big. This is because most LBOs involve the payment of a premium over the market price at which the shares were trading prior to the announcement of the takeover. Similarly, the parties taking control of the firm gain managerial control and the enhanced flexibility normally associated with privately run

firms. The new owners also have access to the firm's assets and cash flows, which formerly were part of the public corporation.

The biggest losers in an LBO are the firm's existing creditors. Because the buyout is financed primarily with debt capital, existing bondholders become creditors of a much riskier firm. This drives down the market value of outstanding bonds and makes future debt service much more uncertain. During the 1980s, a number of institutional investors who held large bond positions in firms that were the subject of MBOs sued the management of the firms. They claimed that managers knowingly engaged in activities that harmed their economic investment as creditors of the corporation. These suits resulted in settlements and damage awards in several instances.

HISTORY OF LEVERAGED BUYOUTS

When a public firm experiences an LBO, its entire equity is purchased by a small group of investors. In order to entice existing shareholders to sell the firm's outstanding shares, the group often offers a premium above the stock's prevailing market value. The capital they need to purchase the shares is obtained by issuing debt, in the form of bonds, against the firm's assets and cash flows. From a balance-sheet perspective, the action all takes place on the right-hand side. That is, the transaction involves the exchange of debt for equity. The result is that creditors have a larger claim, and owners a smaller claim, on the firm's assets. Note that the assets on the left-hand side of the firm's balance sheet do not change. Instead, what changes is how they are financed.

During the 1980s, leveraged buyouts became a huge part of America's corporate landscape. This largely was the result of a single investment banking firm, Drexel Burham Lambert, and the efforts of one of its principals, Michael Milken. It was Milken who determined that high-yield bonds could fill an existing funding gap in corporate financing. The bonds, commonly referred to as *junk bonds* because of their riskiness, would be enticing to investors who otherwise might not be willing to take an equity position in high-risk firms. Drexel developed a market for junk bonds and served as the investment bank for corporate raiders and management groups interested in taking over existing corporations. The market flourished for several years, before Milken was prosecuted and convicted of securities violations. Drexel Burham Lambert ultimately went bankrupt, but the firm's legacy lives on in the active market for high-yield debt and private equity firms.

REASONS FOR TAKING
A FIRM PRIVATE

The junk bond market enabled small investor groups to raise large sums of money in order to take public companies

private. A number of reasons motivated managers and investors to pursue LBOs.

One advantage that a private firm has over a public one is administrative cost savings. A publicly traded company must produce annual reports, 10-K reports, comply with numerous regulations required by the Securities and Exchange Commission, hold annual shareholder meetings, and respond to shareholder requests. The management of publicly held firms must meet regularly with security analysts who follow the firm's stock, and maintain a shareholder relations department to deal with investor concerns. These costs are not required of a privately held firm.

In a private firm, managers no longer have to answer to the shareholder constituency. Lack of public accountability translates into greater management flexibility, since managers no longer have to focus as strongly on short-term operating results. The intense interest in reported quarterly earnings can bias managers in public firms to devote a great amount of effort and resources on short-term performance. Thus, managers of private firms have the luxury of being able to engage in investment activity that takes longer to produce tangible rewards. This greater flexibility and freedom from having to answer to shareholders is very enticing to upper-level management.

In addition, the process of buying up existing shares of the firm's stock severely diminishes the absolute number of shareholders. Because of their large capital investment and the fact that they now answer to themselves, the shareholders that remain after an LBO are highly interested in the firm's operations. These shareholders play an active role in the firm's management, as opposed to the hundreds of thousands of passive investors that hold a publicly traded firm's common stock.

The new entity's management has enhanced incentives to operate efficiently and profitably. This is because the high amount of debt service resulting from an LBO leaves little room for corporate perks and excess. The combination of having to pay the large interest expense on the debt and, in the case of MBOs, working for themselves as opposed to anonymous shareholders, results in much greater motivation for management to perform. Equity holders remaining after an LBO often have some special expertise or talent that they bring to the firm, such as access to additional capital sources. Shareholders in the new private firm who are not part of active management also have much greater incentive to monitor active management, since their personal stake in the firm is typically high.

Corporate tax shields are another potential advantage of restructuring with debt financing. The corporate tax code in the United States allows companies to deduct the interest paid on debt as an expense for tax purposes. No such deduction is allowed for dividends paid on equity shares. Thus, increased use of debt results in lower tax obligations owed to the Internal Revenue Service. Firms facing large tax liabilities may reap considerable benefits from the tax savings that result from debt financing.

Finally, large publicly held corporations in mature industries typically have access to large amounts of free cash flow. These dollars are valuable, because they can be used to develop new products and markets or invest in other firms. In a public corporation, these cash flows may be used for perquisites such as corporate travel to conventions and trade shows, company cars, membership in clubs, and other types of non-monetary rewards. By taking the firm private, remaining shareholders gain access to the firm's free cash flow and can put it to use, thereby reaping direct benefits.

THE 1990s

With the demise of Drexel Burnham Lambert and the default on several prominent junk bond issues associated with 1980s restructurings, leveraged buyout activity slowed considerably in the 1990s. The appetite of investors for new junk bond issues decreased, and some of the firms that had previously gone private subsequently were recapitalized as public corporations.

THE 2000s

After a lull in the 1990s, leveraged buyouts began to regain some of their charm in the early part of the twenty-first century. According to Dealogic, a New York-based deal tracker, LBO firms accounted for 10 percent of the $540 billion in mergers and acquisitions announced in the United States, double the average of 5 percent over the previous 10 years. Europe also showed a significant increase in LBO activities throughout the early 2000s. By 2004 and 2005, leveraged buyouts of large companies were becoming common again. The next eighteen months would see a buyout frenzy fuelled by the low cost of debt. From the beginning of 2006 to the middle of 2007, nine of the ten largest buyouts were announced. Kohlberg Kravis Roberts (KKR), TPG, and Goldman Sachs Capital Partners completed a massive buyout in the United States in October 2007 when they acquired TXU CORP for $31.8 billion. In September 2007, a huge leveraged buyout occurred when shareholders approved the acquisition of Canadian phone company BCE by Teachers Private Capital, Madison Dearborn, and Providence Equity for $32.6 billion. According to Dow Jones, private equity firms acquired 654 companies in the United States for $375 billion in 2006. This was eighteen times the value of deals closed in 2003.

In July 2007, problems in the mortgage markets began to impact the leveraged finance and high-yield debt markets. By September, the credit crunch became widely publicized with high-profile writedowns by major banks such as Citigroup and UBS. LBOs petered out as the credit markets

dried up, and it became apparent that another cycle of the private equity boom had come to an end.

LICENSING AND LICENSING AGREEMENTS

A license provides the legal authority to engage in certain acts. Some licenses are required for the protection of the public. For example, a physician is licensed to assure professional competence, and the owner of a bar and restaurant is licensed to prove moral fitness. Some licenses are designed to raise government revenue (e.g., automobile licenses) or to grant some other party permission to make use of land (e.g., land easement). In business, a license is the granting of permission to use a property right in a limited capacity, while still allowing the licensor to retain ownership. For example, under a licensing agreement a U.S. clothing manufacturer may allow a foreign producer to use its designs and specifications to make clothes.

For a license to exist, there must be a contract between two or more parties giving an explanation as to what property rights the licensor is agreeing to give up to the licensee. This agreement or contract is known as the licensing agreement. These agreements have been in existence since the first copyrights and patents were issued in the late eighteenth century.

The licensing agreement is a complex legal document that begins by identifying parties to the agreement, as well as the dates of the agreement. It specifies the subject matter to be licensed, including patents and trade secrets. Also specified are the provisions or rights of the license, such as whether it grants exclusive rights or is subject to other agreements. Any limitations, such as territorial and quantity restrictions, are also specified. A final section can specify duration, termination, and related provisions of the agreement.

In business, licensing agreements or arrangements are mutually beneficial. The licensor provides his or her property right and the licensee contributes expertise in the particular industry or territory covered by the license. The resulting relationship becomes much the same as a joint venture or partnership. There are several types of licensing agreements, including copyright licensing, patent licensing, merchandise licensing, trademark licensing, and software licensing.

BENEFITS OF LICENSING

Typically, a trademark owner will grant a license in order to exploit the trademark rights in areas where he or she does not have the appropriate expertise, infrastructure, or capital resources to maximize the value of the right. While the licensor is exploiting the trademark right, the licensee is betting that the name or symbol recognition of the property will influence consumers and motivate them to buy a particular item. Characters that have enjoyed popularity from trademark licensing relationships include Mickey Mouse, Barbie, and King Mufasa from the Lion King. A major trend has been for manufacturers and retailers to build the core of their business with trademark-licensed products.

When granting a license, copyright owners are motivated by the prospect of receiving royalties for each product, performance, or copy of their work. In the case of a publication, the copyright is an exclusive right given to an author of an original work. Books, plays, magazines, photography, paintings, sculpture, articles, musical compositions, and radio and television programs are additional commodities that can be copyrighted. The exclusive right also allows copyright owners to reproduce their own work or allow others to do so.

LICENSING AS A GLOBALIZATION STRATEGY

In its most general sense, licensing is a key mode of entry for firms considering international expansion. A licensing agreement gives a foreign company the rights to produce and/or sell another firm's goods in their country. The agreement also may include production and sales in more than one country. The licensee takes the risks and makes the investment in facilities for handling the manufacturing of the goods, as well as managing other supply chain

linkages to deliver and even sell the goods to the final consumer. The licensor is normally paid a royalty on each unit produced and sold. Because there is little investment for the licensor, this method is seen as an easier way to become an international or global company.

Licensing is growing as manufacturers and retailers build their core businesses and change their strategies to include more licenses. For example, Merck and Upjohn have licensed organizations in other parts of the world to manufacture and sell their pharmaceutical products. Other firms using licensing agreements in this way include McDonald's, Nestlé, Anheuser-Busch, and KFC.

The release of hot movies like the *Lord of the Rings* trilogy also triggers many license agreements and ties between mass merchandisers and licensors for toys, games, and children's apparel. Some retailers go so far as to demand exclusive agreements for licensed apparel and movie tie-in products in order to pursue marketplace differentiation strategies.

Service-based businesses also can benefit from licensing arrangements. Within the airline industry, many of the code-sharing arrangements that allow airlines to sell each other's seats are much like licensing agreements. Airlines and other firms enter such agreements when they need help commercializing a new technology, expanding a brand franchise globally, or building a marketing image. Rather than entering a new or international market alone, licensing is a faster way to grow a market and achieve market-share dominance. It also may allow firms to gain a larger market for their nonlicensed products.

In the early twenty-first century, a growing number of technology companies began launching intellectual property (IP) licensing programs in order to turn dormant projects into revenue, penetrate new markets, and evaluate potential business partners. These firms conducted inventories of their knowledge bases and patent families, and identified technologies that were outside the core business yet still offered some potential for development. They then sought to license these technologies to other firms.

In *Licensing Journal,* George A. Frank explained: "Patents that some corporations had obtained for reasons not directly related to the development or transfer of technology were proving to be a vast untapped resource. IP licensing has now become a tremendous income source, and indeed is now an important benchmark by which a corporation's success is measured." IBM, for example, earns more than $1 billion per year from its IP licensing program.

As human embryonic stem cell research increases during the twenty-first century, medical companies and research facilities are developing numerous licensing agreements. Several high level committees have been formed throughout the world to create guidelines to resolve intellectual property issues that will be critically important in this research area. These guidelines attempt to consider all legal issues that will arise. In 2005 the National Institutes of Health recommended that "whenever possible, non-exclusive licensing should be pursued as a best practice. A non-exclusive licensing approach favors and facilitates making broad enabling technologies and research uses of inventions widely available and accessible to the scientific community."

In the United States, the Wisconsin Alumni Research Foundation (WARF) has been a leader in stem cell licensing and agreements. WARF, the patent and licensing arm of the University of Wisconsin-Milwaukee, signed its twenty-fourth human embryonic stem cell licensing agreement in 2008; it allows biotech firms to use its human embryonic stem cells for the development of new research technology.

RISKS TO LICENSING

There are some risks and disadvantages to licensing. The firm may lose control over the manufacture and marketing of its goods in other countries. As a mode of international market entry, licensing also may be less profitable than other choices because returns must be shared between two parties. There even is a risk that the foreign licensee may sell a similar competitive product after the license agreement expires. Other risks and issues involve selecting a partner, as well as all of the general uncertainties in doing business with an international partner, including language, culture, political risk, and currency fluctuations. Alternatives to licensing include exporting, acquisitions, establishing a wholly owned international subsidiary, franchising, and forming strategic alliances.

LIFELONG LEARNING TRENDS

SEE *Continuing Education and Lifelong Learning Trends*

LINE-AND-STAFF ORGANIZATIONS

In addition to task organizational boundary considerations, organizational structure involves the designation of jobs within an organization and the relationships among those jobs. There are numerous ways to structure jobs within an organization, but two of the most basic forms include simple line structures and line-and-staff structures.

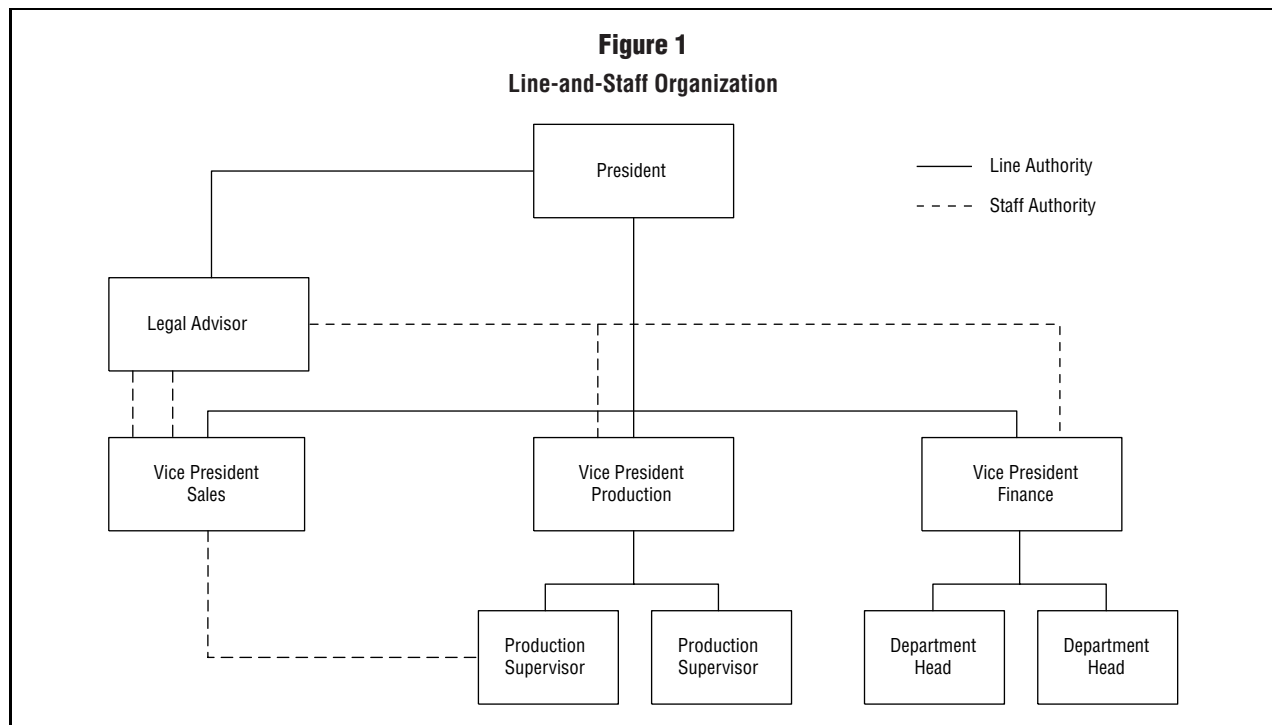
In a line organization, top management has complete control and the chain of command is clear and simple. Examples of line organizations are small businesses in which the top manager, often the owner, is positioned at the top of the organizational structure and has clear "lines" of distinction between him and his subordinates.

The line-and-staff organization combines the line organization with staff departments that support and advise line departments. Most medium and large-sized firms exhibit line-and-staff organizational structures. The distinguishing characteristic between simple line organizations and line-and-staff organizations is the multiple layers of management within line-and-staff organizations. The following sections refer primarily to line-and-staff structures, although the advantages and disadvantages discussed apply to both types of organizational structures.

Several advantages and disadvantages are present within a line-and-staff organization. An advantage of a line-and-staff organization is the availability of technical specialists. Staff experts in specific areas are incorporated into the formal chain of command. A disadvantage of a line-and-staff organization is conflict between line and staff personnel.

LINE-AND-STAFF POSITIONS

A wide variety of positions exist within a line-and-staff organization. Some positions are primary to the company's mission, whereas others are secondary—in the form of support and indirect contribution. Although positions within a line-and-staff organization can be differentiated in several ways, the simplest approach classifies them as being either line or staff.

Figure 1
Line-and-Staff Organization


A line position is directly involved in the day-to-day operations of the organization, such as producing or selling a product or service. Line positions are occupied by line personnel and line managers. Line personnel carry out the primary activities of a business and are considered essential to the basic functioning of the organization.

Line managers make the majority of the decisions and direct line personnel to achieve company goals. An example of a line manager is a marketing executive. Although a marketing executive does not actually produce the product or service, he or she directly contributes to the firm's overall objectives through market forecasting and generating product or service demand. Therefore, line positions, whether they are personnel or managers, engage in activities that are functionally and directly related to the principal workflow of an organization. In his book *Leadership: How to Lead, How to Live*, Harvard business professor D. Quinn Mills notes that "Line positions often provide invaluable learning of a type not easily obtained in school or even in staff positions. A line manager learns how to respond to customers when they are pressuring him from all sides; how to energize employees who aren't motivated by money or promotions and who don't care who you are or what you learned in school. . ."

Staff positions serve the organization by indirectly supporting line functions. Staff positions consist of staff personnel and staff managers. Staff personnel use their technical expertise to assist line personnel and aid top management in various business activities. Staff managers provide support, advice, and knowledge to other individuals in the chain of command.

Although staff managers are not part of the chain of command related to direct production of products or services, they do have authority over personnel. An example of a staff manager is a legal adviser. He or she does not actively engage in profit-making activities, but does provide legal support to those who do. Therefore, staff positions, whether personnel or managers, engage in activities that are supportive to line personnel. Dr. Mills offers, "There is no better place to learn about an organization than from a key staff position. A person has the responsibility of learning how things are done; of determining the major trends in the marketplace and among competitors; or deciding courses of action. In a sense it is the staff person who often decides what to do; the line manager who carries out the plan."

LINE-AND-STAFF AUTHORITY

Authority within a line-and-staff organization can be differentiated. Three types of authority are present: line, staff, and functional. Line authority is the right to carry out assignments and exact performance from other individuals.

Line Authority. Line authority flows down the chain of command. For example, line authority gives a production supervisor the right to direct an employee to operate a particular machine, and it gives the vice president of finance the right to request a certain report from a department head. Therefore, line authority gives an individual a certain degree of power relating to the performance of an organizational task.

Two important clarifications should be considered, however, when discussing line authority: (1) line authority does not ensure effective performance, and (2) line authority is not restricted to line personnel. The head of a staff department has line authority over his or her employees by virtue of authority relationships between the department head and his or her directly-reporting employees.

Staff Authority. Staff authority is the right to advise or counsel those with line authority. For example, human resource department employees help other departments by selecting and developing a qualified workforce. A quality control manager aids a production manager by determining the acceptable quality level of products or services at a manufacturing company, initiating quality programs, and carrying out statistical analysis to ensure compliance with quality standards. Therefore, staff authority gives staff personnel the right to offer advice in an effort to improve line operations.

Functional Authority. Functional authority is referred to as limited line authority. It gives a staff person power over a particular function, such as safety or accounting. Usually, functional authority is given to specific staff personnel with expertise in a certain area. For example, members of an accounting department might have authority to request documents they need to prepare financial reports, or a human resource manager might have authority to ensure that all departments are complying with equal employment opportunity laws. Functional authority is a special type of authority for staff personnel, which must be designated by top management.

LINE-AND-STAFF CONFLICT

Due to different positions and types of authority within a line-and-staff organization, conflict between line and staff personnel is almost inevitable. Although minimal conflict due to differences in viewpoints is natural, conflict on the part of line and staff personnel can disrupt an entire organization. There are many reasons for conflict. Poor human relations, overlapping authority and responsibility, and misuse of staff personnel by top management are all primary reasons for feelings of resentment between line and staff personnel. This resentment can result in various departments viewing the organization from a narrow stance instead of looking at the organization as a whole.

Fortunately, there are several ways to minimize conflict. One way is to integrate line and staff personnel into a work team. The success of the work team depends on how well each group can work together in efforts to increase productivity and performance. Another solution is to ensure that the areas of responsibility and authority of both line and staff personnel are clearly defined. With clearly defined lines of authority and responsibility, each group may better understand their role in the organization. A third way to minimize conflict is to hold both line and staff personnel accountable for the results of their own activities. In other words, line personnel should not be entirely responsible for poor performance resulting from staff personnel advice.

Line-and-staff organizations combine the direct flow of authority present within a line organization with staff departments that offer support and advice. A clear chain of command is a consistent characteristic among line-and-staff organizational structures. Problems of conflict may arise, but organizations that clearly delineate responsibility can help minimize such conflict.

LOCATION STRATEGY

Being in the right location is a key ingredient in a business's success. If a company selects the wrong location, it may not have adequate access to customers, workers, transportation, materials, and so on. Consequently, location often plays a significant role in a company's profit and overall success. A location strategy is a plan for obtaining the optimal location for a company by identifying company needs and objectives, and searching for locations with offerings that are compatible with these needs and objectives. Generally, this means the firm will attempt to maximize opportunity while minimizing costs and risks.

A company's location strategy should conform with, and be part of, its overall corporate strategy. Hence, if a company strives to become a global leader in telecommunications equipment, for example, it must consider establishing plants and warehouses in regions that are consistent with its strategy and that are optimally located to serve its global customers. A company's executives and managers often develop location strategies, but they may select consultants (or economic development groups) to undertake the task of developing a location strategy, or at least to assist in the process, especially if they have little experience in selecting locations.

Formulating a location strategy typically involves the following factors:

1. **Facilities.** Facilities planning involves determining what kind of space a company will need given its short-term and long-term goals.

2. **Feasibility.** Feasibility analysis is an assessment of the different operating costs and other factors associated with different locations.

3. **Logistics.** Logistics evaluation is the appraisal of the transportation options and costs for the prospective manufacturing and warehousing facilities.

4. **Labor.** Labor analysis determines whether prospective locations can meet a company's labor needs given its short-term and long-term goals.

5. **Community and site.** Community and site evaluation involves examining whether a company and a prospective community and site will be compatible in the long term.

6. **Trade zones.** Companies may want to consider the benefits offered by free-trade zones, which are closed facilities monitored by customs services where goods can be brought without the usual customs requirements.

7. **Political risk.** Companies considering expanding into other countries must take political risk into consideration when developing a location strategy. Since some countries have unstable political environments, companies must be prepared for upheaval and turmoil if they plan long-term operations in such countries.

8. **Governmental regulation.** Companies also may face government barriers and heavy restrictions and regulation if they intend to expand into other countries. Therefore, companies must examine governmental—as well as cultural—obstacles in other countries when developing location strategies.

9. **Environmental regulation.** Companies should consider the various environmental regulations that might

affect their operations in different locations. Environmental regulation also may have an impact on the relationship between a company and the community around a prospective location.

10. **Incentives.** Incentive negotiation is the process by which a company and a community negotiate property and any benefits the company will receive, such as tax breaks. Incentives may play a significant role in a company's selection of a site.

Depending on the type of business, companies also may have to examine other aspects of prospective locations and communities. Based on these considerations, companies are able to choose a site that will best serve their needs and help them achieve their goals.

COMPANY REQUIREMENTS

The initial part of developing a location strategy is determining what a company will require of its locations. These needs then serve as some of the primary criteria a company uses to evaluate different options. Some of the basic requirements a company must consider are:

- **Size.** A company must determine what size property or facility it needs.

- **Traffic.** If it is in the service business, a company must obtain statistics on the amount of traffic or the number of pedestrians that pass by a prospective location each day.

- **Population.** Whether a service or manufacturing operation, a company must examine the population of prospective locations to ensure that there is a sufficient number of potential customers (if a service business) or a sufficient number of skilled or trainable workers. In addition, manufacturers also benefit from being close to their customers, because proximity to customers reduces shipment time and increases company responsiveness to customers.

- **Total costs.** Companies must determine the maximum total costs they are willing to pay for a new location. Total costs include distribution, land, labor, taxes, utilities, and construction. More obscure costs also should be considered, such as transportation costs to ship materials and supplies, and the loss of customer responsiveness if moving further away from the customer base.

- **Infrastructure.** Companies must consider what their infrastructure requirements will be, including what modes of transportation they will need and what kinds of telecommunications services and equipment they will need.

- **Labor.** Companies must establish their labor criteria and determine what kind of labor pool they will need, including the desired education and skill levels.

- **Suppliers.** Companies must consider the kinds of suppliers they will need near their locations. In addition, having suppliers nearby can help companies reduce their production costs.

Besides these basic requirements, companies must consider their unique requirements of prospective locations. These requirements may correspond to their overall corporate strategy and corporate goals and to their particular industries.

LOCATION SELECTION TECHNIQUES

Manufacturing. Several techniques exist that can be used as part of a location strategy to determine the merits of prospective sites. Location strategists often divide assessment of prospective locations into macro analysis and micro analysis. Macro analysis encompasses the evaluation of different regions and communities, whereas micro analysis includes the evaluation of particular sites. The main macro analysis techniques are factor-rating systems, linear programming, and center of gravity.

Factor-rating systems are among the most commonly used techniques for choosing a location, because they analyze diverse factors in an easily comprehensible manner. Factor-rating systems simply consist of a weighted list of the factors a company considers the most important and a range of values for each factor (see Table 1). A company can rate each site with a value from the range based on the costs and benefits offered by the alternative locations, and multiply this value by the appropriate weight. These numbers are then summed to get an overall "factor rating." Then a company can compare the overall ratings of alternative sites. This technique enables a company to choose a location systematically based on the best rating.

Linear programming provides a method for evaluating the cost of prospective locations within a production/distribution network. This technique uses a matrix of production facilities and warehouses that shows the unit shipping costs from a manufacturing location designated by a variable, such as *X*, to prospective destinations, such as warehouses designated by other variables—*E, F,* and *G*—and the total amount of goods the prospective manufacturer, *X*, could produce. Other prospective manufacturing locations and the same information for each are also included in the matrix. After computing the total costs for each prospective location, a company can determine which one has lower total costs in terms of the entire production/distribution network.

Table 1			
Sample Factor-Rating System			
Factor	Rating (1-100)	Weight	Factor-Rating
Energy availability	60	.3	18
Labor availability	80	.2	16
Transportation	40	.2	8
Supplies	90	.1	9
Taxes and regulations	70	.1	7
Infrastructure	70	.1	7
Overall Factor-Rating	—	—	65

The center of gravity method is useful for identifying an individual location by considering existing locations, the distances between them, and the volume of products to be shipped. Companies use this method mostly for locating distribution warehouses. To use this technique, companies plot their existing locations on a grid with a coordinate system (the particular coordinate system used does not matter). The idea behind this technique is to identify the relative distances between locations. After the existing locations are placed on the grid, the center of gravity is determined by calculating the X and Y coordinates that would have the lowest transportation costs.

Services. Since service businesses generally must maintain a number of sites to remain close to customers, the location selected should be close to the targeted segment of the market. The market also can influence the number of new locations, as well as their size and features.

A simple technique for determining service locations is to establish a set of minimum criteria for opening new outlets. These criteria should be developed so that the locations selected have strong chances of success. A company could assess the potential of prospective locations based on primary criteria such as:

- The population of the community should be more than 100,000.

- The annual per capita income should be more than $35,000.

After selecting locations that satisfy these criteria, a company might further evaluate the potential locations based on a set of criteria that considers the location's industrialization, person/car ratio, labor availability, population density, and infrastructure.

For example Wal-Mart keeps its stores close to each other so it can economize on shipping. This relative prox-

imity enables one truck to make numerous shipments—a benefit the store loses if stores are more spread out. Wal-Mart's dense network of stores, therefore, facilitates the delivery logistics. Another benefit of this strategy is the easy transfer of experienced managers and personnel to new stores opening near existing stores.

Sometimes, more often in the case of franchises, stores can be placed too close together. This practice—referred to as cannibalization—can affect a company's earnings. In theory, franchises should be placed closely enough to ensure an effective market presence, but not so close that specific locations are battling over the same group of consumers.

TRENDS IN LOCATION STRATEGY

Globalization and technology have been the biggest drivers of change in the location decision process over the last thirty years. Location activity has been very high in recent decades as a result of technology improvements, economic growth, international expansion and globalization, and corporate restructuring, mergers, and acquisitions.

The top five location factors for global companies are costs, infrastructure, labor characteristics, government and political issues, and economy. Key sub-factors are the availability and quality of the labor force, the quality and reliability of modes of transportation, the quality and reliability of utilities, wage rates, worker motivation, telecommunication systems, record of government stability, and industrial relations laws. Other sub-factors—protection of patents, availability of management resources and specific skills, and system and integration costs—are of increasing importance.

Whereas wages and the industrial relations environment are significant factors in multinational location decisions, by far the main determinant is the host country market size. Furthermore, global economic considerations have become paramount in location strategy as companies contemplate the advantages afforded by various locations in terms of positioning in international markets and against competitors.

When companies seek new sites they generally strive to keep operating and start-up costs low, and so they often choose locations in collaboration with economic development groups to achieve these goals. Companies also now expect to move into new facilities more quickly than in the past, so they tend to focus more on leasing facilities than purchasing land and building new facilities. Also, by leasing facilities, companies can relocate every few years if the market requires it.

Technology, especially communications technology, has not only been a driver of change, but has facilitated the site selection process. Managers can obtain initial information on alternative locations via the Internet and promotional software. Site selection agencies increasingly

use geographical information system (GIS) technology, and e-mail has become a dominant mode of communication in location research and negotiation.

Location databases have enabled companies to do initial screening themselves, hence reducing their need to rely on economic developers to provide only very specific information and details on locations—such as commuting patterns and workforce characteristics.

Telecommunications technology has created the "virtual office" of employees working from remote locations. The growth of the virtual office has impacted location strategy in that some companies no longer need as much workspace because many employees work from remote sites. When these employees need to work at the office, they can call and reserve office space for themselves. The decrease in facility size can lead to millions of dollars worth of savings each year, while increasing productivity.

LOGISTICS AND TRANSPORTATION

According to the Council of Supply Chain Management Professionals (CSCMP), logistics management can be defined as "that part of supply chain management that plans, implements, and controls the efficient, effective forward and reverse flow and storage of goods, services, and related information between the point of origin and the point of consumption in order to meet customers' requirements."

The history of logistics is rooted in its military application. Since WWII it has developed into an important function of business as it became evident that logistics and transportation add place and time value to products and enhance the form and possession value added by manufacturing and marketing.

The concept of logistics as a business discipline began to appear in the business-related literature in the 1960s when it was called physical distribution. At that time its focus was on the outbound side of the logistics system. With the emerging importance of Supply Chain Management, logistics and transportation has become even more crucial as supply chain managers realize that the coordination and integration of the logistics systems of all organizations with the supply chain are requirements for success.

According to Coyle, Bardi, and Langley, there are four subdivisions of logistics:

- Business logistics—this is the same as the definition from the CSCMP and is the approach adopted in this essay.

- Military logistics—all that is necessary to support the operational capability of military forces and their equipment in order to ensure readiness, reliability, and efficiency.

- Event logistics—management of all involved (activities, facilities, and personnel) in organizing, scheduling, and deploying the resources necessary to ensure the occurrence of an event and efficient withdrawal afterwards.

- Service logistics—acquisition, scheduling, and management of facilities, personnel, and materials need to support and sustain a service operation.

This essay addresses the concept of business logistics. Business logistics systems can be classified into four categories:

1. *Balanced System.* Firms with a balanced system have reasonably balanced inbound and outbound flows.

2. *Heavy inbound.* These firms have a very heavy inbound flow but a very simple outbound flow. Firms with heavy inbound flow typically do not warehouse their finished goods (for example, aircraft manufacturers).

3. *Heavy outbound.* These firms have a complex outbound flow and a very simple inbound flow. Their inbound flow is usually raw material from a relatively short distance. Typically their outbound shipments are a wide variety of packaged finished goods requiring storage and transportation to the final consumer.

4. **Reverse system.** Reverse supply chain logistics systems have reverse flows on the outbound side of their system. Durable products are returned for credit, trade-in, repair, salvage, or disposal, or the firm-utilized returnable or reusable containers.

Coyle, Bardi, and Langley list a number of activities that lie within the realm of logistics:

- Order fulfillment—activities involved with completing customer orders. Transportation and logistics would be an integral part of completing the orders since they directly impact delivery.

- Traffic and transportation—the physical movement of goods.

- Warehousing and storage—a number of warehousing decisions directly impact logistics and transportation. For example, how many warehouses are needed, where should they be located, how large should they be, how much inventory should be held in each?

- Plant and warehouse site location—location can alter time and place relationships between the warehouse and the customer. Frequently transportation cost is a major factor in plant and warehouse location.

- Materials handling—the placement of goods and the movement of goods within a warehouse, factory, or other facility. This includes incoming movement of goods and the movement of goods from storage to order-picking areas to dock areas for shipment.

- Industrial packaging—transportation directly impacts the type of packaging needed. Fast methods of transport, such as air, generally require little in the way of packaging while the slower modes, such as water or rail, require substantial packaging expenditures to ensure safe shipment.

- Purchasing—quantities purchased directly affect transportation costs. Also, transportation relates directly to the distance or location of goods purchased by the firm. Purchasing and logistics are increasingly integrated in many major firms.

- Demand forecasting—accurate and reliable forecasting is essential for effective inventory control purposes, especially within firms utilizing lean manufacturing and just-in-time (JIT) production.

- Inventory control—this is directly related to transportation and warehousing. If transportation is slow, higher levels of inventory are needed, therefore more warehouse capacity is needed.

- Production planning—production planning must operate in close coordination with logistics in order to ensure adequate market coverage. Production

planning and logistics are increasingly integrated within large corporations.

- Parts and service support—the effectiveness of parts and service support depend upon speed of transportation, location of warehouses, and forecasting of support function needs. Thus, parts and service support have a direct impact on customer service levels.

- Return goods handling—reverse supply chain logistics is an increasingly important but frequently overlooked dimension in logistics.

- Salvage and scrap disposal—disposal is an integral part of the reverse supply chain. There is an increasing interest, as seen in the logistics literature, in the impact of the location of evaluation and disposal facilities for returned goods.

- Customer service levels—logistics plays an extremely important role in ensuring that customers get the right products at the right place at the right time. Transportation, warehousing, forecasting, inventory control, and production planning all have a direct impact on customer satisfaction.

The two most obvious aspects of logistics are warehousing and transportation.

Warehousing and Storage. Warehousing is defined as the storage of goods: raw materials, semi-finished goods, or finished goods. This includes a wide spectrum of facilities and locations that provide warehousing. Since this is a point in the logistics system where goods are held for varying amounts of time, the flow is interrupted or stopped, thereby creating additional costs to the product.

In a macroeconomic sense, warehousing creates time utility for raw materials, industrial goods, and finished products. It also increases the utility of goods by broadening their time availability to prospective customers.

Transportation. Transportation involves the physical movement or flow of goods. The transportation system is the physical link that connects customers, raw material suppliers, plants, warehouses, and channel members. These are the fixed points in a logistics supply chain.

The basic modes of transportation are water, rail, motor carrier, air, and pipeline. Water is the slowest mode, with rail, motor carrier, and air following in order of speed of delivery. Generally, the order is reversed when looking at costs.

Selection of the appropriate carrier has several steps. First the firm selects a transportation mode. The shipper must compare the service desired with the rate or cost of service. Service usually means transit time or the time that elapses from the time the consignor makes the goods

available for dispatch until the carrier delivers to the consignee. Pickup and delivery, terminal handling, and movement between origin and destination account for the time involved in transporting goods.

The firm must balance the need for quick delivery with the costs inherent in the mode of transport. This includes the rate charged for the service, minimum weight requirements, loading and unloading facilities, packaging, possible damage in transit, and any special services that may be desired or required. If next day delivery is imperative, the shipper will utilize an air freight carrier but will pay a premium price for such rapid service. If time is not a particularly critical element the shipper may elect to use rail or a motor carrier, or may even utilize a water carrier if time is inconsequential. Water-based modes of transportation are the least expensive and are used for commodity type products such as grain, coal, and ore. Some firms even utilize more than one mode of transportation, called intermodal transport, to move their goods.

Once a mode is selected, the shipper must decide the legal classification or type of carrier they wish to utilize: common, regulated, contract, exempt, or private.

Common carriers serve the general public at reasonable prices and without discrimination. They cannot refuse to carry a particular commodity or refuse to serve a particular point with the scope of the carrier's operation. Common carriers are liable for all goods lost, damaged, or delayed unless caused by an act of God, an act of a public enemy, an act of public authority, an act of the shipper, or some defect within the good itself.

Regulated carriers are required to provide safe and adequate service and facilities upon reasonable request and are liable for damage up to limits established by the carrier. Regulated carriers can be motor carriers or water carriers and are subject to minimal federal controls.

A contract carrier does not serve the general public, but rather serves one or a limited number of contracted customers. They have no legal service obligation. They often provide a specialized service and usually have lower rates than common or regulated carriers.

Exempt carriers are exempt from regulation regarding rates and services. Exempt status comes from the type of commodity hauled or the nature of the carrier's operation. Exempt motor carriers are usually local and typically transport such items as agricultural goods, newspapers, livestock, and fish. Exempt water carriers transport bulk commodities such as coal, ore, grain, and liquid. Exempt rail carriers transport piggyback shipments and exempt air carriers haul cargo.

A firm's own transportation is termed a private carrier. Private carriers are not "for-hire" and not subject to the same federal regulations as other types of transport.

However, the carrier's primary business must be something other than transportation.

Once the mode and type of carrier is determined a final decision can be made based on other factors. Accessibility is one such factor. Some firms have geographic limits to their routing network. Others may not possess physical access to needed facilities or have the ability to provide the equipment and facilities that movement of a particular commodity may require. Reliability—the consistency of the transit time a carrier provides—is also a key factor. Finally, convenience and communication are other important considerations when selecting a carrier.

Measures that a transportation firm would use to judge its performance include: orders shipped on time, orders shipped complete, order preparation time, product availability, and transit time. From the customer perspective performance can be gauged from orders received on time, orders received complete, orders received damage free, orders filled accurately, and orders billed accurately.

GLOBAL LOGISTICS

The expansion of the global marketplace puts the concept of global logistics into the limelight. Logistics experts must now manage all of the aforementioned logistics activities within a worldwide arena spanning a multitude of countries, languages, cultures, governments, and regulations. Along with this expansion of the marketplace comes the need for global channel intermediaries. Today's global logistics manager would be familiar with the role of each of the following:

- Foreign freight forwarders—handlers of myriad foreign freight services such as rate quotes, vessel chartering, booking of vessel space, handling of documentation and cargo insurance, tracing and expediting, arranging inland transportation, and providing translation services.

- Export management companies—suppliers of expertise to those wishing to sell products overseas but lacking the necessary resources.

- Export trading companies—locaters of overseas buyers. They also handle export documentation, transportation, and the meeting of foreign government requirements.

- Customs house brokers—overseers of the movement of goods through customs. They also ensure that accompanying documents are complete and accurate.

- Ship brokers—sales representatives for ship owners and purchasing representatives for the shipper.

- Ship agents—local representative of the ship operator that handles the ship's arrival, berthing, clearance, loading, and unloading.

- Export packers—suppliers of export packaging services.

- Port authorities—owner and operator of the port. They provide wharf, dock, and other terminal facilities at port locations.

As the global market continues to expand, there is an increasing need for real-time logistics data in order to make decisions across the supply chain. Thus, a number of software companies now offer products designed specifically for the logistics and transportation industry. These products provide information like GPS tracking, automatic vehicle routing, and instantaneous updates on route progress. One such product, TerritoryPro by Appian Logistics, creates maps of optimal sales and delivery territories based on information about volume, workload, and other constraints. As the market for more sophisticated global logistics software continues to grow, the logistics and transportation industry is sure to continue its trend toward increased automation of tasks formerly performed by human beings.

LONG TAIL

Long tail is a type of business strategy which focuses on lowering distribution costs and marketing a wide variety of goods to a large consumer group, an approach made easier by the rise of e-commerce and e-retailers. The term *long tail* comes from a reference to a mathematical graph in which the concentration of a particular item or occurrence is shown, from a short, high head (the concentrated occurrence) to a sloping, drawn-out tail (the area of lower occurrence).

In business statistics, a bell curve is created to illustrate the probability of markets and the results of surveys, polls, averages, and so forth. A symmetrical curve will have two identical tails, both descending away from the highest middle point (the mode, the highest concentration of occurrence or the most popular answer). However, most statistical graphs will show a skewed, unsymmetrical frequency, meaning that the line of the graph will tend more toward one range, creating a long tail. A skewed curve can tend either toward the left, making a positive distribution, or toward the right, giving the graph a negative distribution. The graph in the example below has a positive long tail, the most common example of skewed distributions. Analysts use such graphs to determine what products are most popular, what types of marketing are most effective with customers, and what companies are most effective at selling in their industry, among other types of information.

While many companies attempt to fall within the head of a product distribution (the most popular, best-selling section), other businesses have tried to make money by appealing to a broader audience of consumers with a wider range of goods that, though less popular, can be sold successfully in lower quantities to many niche markets. One of the most famous types of broad-market companies in the early twentieth century was Sears Roebuck. Sears Roebuck produced a famous catalog advertising furniture, appliances, clothing items, houses, and other items to customers across America. The business was run as a mail-order company, so Sears Roebuck was able to concentrate on storage and distribution. Customers could order nearly any item they wanted through the catalog, and have it shipped straight to them. A century later, the Internet revolutionized the same system for many other companies.

Calling such business strategies "long tail" began in 2004, when Chris Anderson wrote a revolutionary article in *Wired* Magazine describing long tail effects and abilities. He later followed this with a 2006 book, *The Long Tail: Why the Future of Business Is Selling Less of More*, which has recently been updated in a 2008 edition. In his original article, Anderson questioned the techniques of companies selling only on the steep head of the graph, the few items statistically proven to be bestselling. He suggested that customers had more individuality than companies gave them credit for, and that nearly any item could find a perfect market if given the right opportunity.

A TALE OF TWO BOOKS

Anderson's first example for his long tail theory involved two popular mountain-climbing books published a decade apart, first *Touching the Void* in 1988 and then the bestselling *Into Thin Air* a decade later. Although *Touching the Void* was nearly out of print, Amazon.com began to suggest the book in their online store as a possible interest for those purchasing *Into Thin Air*. However, customer reviews and online recommendations for the earlier book soon escalated exponentially, leading to new

enthusiasm. Before long, *Touching the Void* was outselling *Into Thin Air* and stayed on the *New York Times* best-selling list for weeks, all due to the fact that Amazon.com still carried the nearly out of print book for those possibly interested in it. This, according to Anderson, was a perfect example of how selling in the long tail can pay off.

The long tail theory applies to much more than books. Any online company with strong distribution abilities can and often does make use of the myriad niche markets available in today's interconnected world. Anderson also applied the theory to the music industry, which he considered especially open due to the song-by-song basis on which music could be sold. Song lovers, able to find and pick out their favorite tracks, tend to gravitate to their favorite bands regardless of popularity, so that no matter what albums online music stores offer, there is likely to be a group of consumers, somewhere, who will buy songs from that album. Movie distributors over the Internet, such as Netflix, demonstrate a similar advantage.

There are several common marketing theories which Anderson disagreed with in his groundbreaking article, among them the continuance of the hit-driven market and the 80-20 rule. Hit-driven economics occurs in a wealthy, profitable market where there is a varied supply and not enough shelf space. Businesses must choose what products to display, so they choose the hits (the products society has chosen, goods surrounded by the most buzz). Hit-driven economics creates profit, but Anderson suggests that it fails to meet the needs of consumers and is outdated with today's technology. He proposes that businesses now operate in an abundant market where many specific goods, not only the hits, can be made available through the Internet. The 80-20 rule is similar, stating that only 20 percent of available title products—such as music or book releases—will become bestsellers and therefore will be worthy of attention. However, Anderson argues that nearly all the titles will sell at least a minimal number of copies, and that the 80-20 rule blinds businesses to sales outside the mainstream.

Fortunately, selling outside the mainstream in online trade is much easier than in space-limited, brick-and-mortar establishments. Cost savings are found through several different methods. Since there is no shelf space, there is no need to pay for anything other than product storage. Since most interfaces are digital, money can be saved by limited personnel and smaller office space. Distribution fees are also either lower or nonexistent, and manufacturing costs can often be lowered.

STEPS IN UTILIZING THE LONG TAIL

Anderson describes three driving forces in his book, three technological innovations recently developed that enable companies to access the long tail in a profitable way. These advances have changed the business market in fundamental ways, according to Anderson, allowing successful strategies to be centered away from mainstream items:

1. ***Tools of production.*** Certain tools of production have been developed in recent years that enable nearly anyone to create certain kinds of goods. Camcorders have become smaller and of higher quality, and they are available at lower costs. Software creation programs have become more common, and the number of those trained in computer programming has also increased. Along with the open source perspective many online businesses are taking, this allows nearly anyone with proper skills to make improvements and innovations to online structures. Many new software packages enable users to create their own music, publish their own articles, or form their own blogs. As a result of these changes, a vast number of small, niche products has risen with their own marketing possibilities. The key, naturally, is to locate and distribute the high quality products that others will be interested in.

2. ***The Internet aggregators***. Internet aggregators include most online e-retailers, Internet stores that are able to gather a large number of products or services to sell. There are many types of aggregation. Some online stores, such as Amazon, offer many different types of products in one centralized location, much as the Sears catalog did a century ago. Others, such as eBay, gather not products but potential long tail sellers, making money off the services they offer. Some aggregators specialize in a particular good, such as iTunes and their wide variety of music. The key attribute of Internet aggregators is their ability to offer the long tail items all from a single, virtual store. These are the businesses which can follow long tail strategies.

3. ***Software connecting supply and demand***. These are the necessary players that help connect small-time producers using tools of production, Internet aggregators with the ability to offer all their products in one online store, and consumers who have particular demands and interests. All types of Internet systems can function as connectors of long tail supply and demand. Social networking sites provide a platform where people can share knowledge and interests, increasing the size of many niche markets. Blogs spread information concerning cultural fads, hobbies, and various pastimes that can also affect long tail markets. Many search engines and e-mail providers, such as Google, also provide necessary connections between consumers looking for certain goods and companies offering them.

In addition to these three driving forces of long tail strategies, Anderson also gave three general rules for

companies trying to profit by their long tail business. These rules apply mostly to entertainment industries, where niche markets are the most widespread, but can be used in any situation where long tail sales are a goal:

- **Make everything available.** An online aggregate should attempt to offer every type of its product line possible. If the e-retailer is selling movies, or renting them as Netflix does, they should offer every type of movie they can, especially those marketed to a small audience (such as documentaries, independent movies, and foreign films that buyers would not be able to find in an average video or retail store). "Almost anything is worth offering on the off chance it will find a buyer," Anderson says, and when accessing the long tail this is a necessary step. Every genre and subgenre should have representation, and the more esoteric it is, the better the chances are that the product will have a particular niche market.

- **Cut the price in half—now lower it**. Anderson's second step is to lower prices to the point where they accurately reflect the costs involved in distribution. Since long tail distribution costs are naturally low, long tail e-retailers should have naturally low prices for their products. Anderson uses the music industry as an example: as of 2008, iTunes allows customers to download song tracks for 99 cents. The music industry could offer songs at lower prices—Anderson estimates about 79 cents instead—but stay away from lowering prices too much for fear that CD manufactures and distributors would be displaced, causing ramifications throughout the record industry. However, this might not be the case. The music industry, especially in the long tail, may be elastic enough to increase in demand equal to lowered prices. E-retailers, in other words, can sell more by dropping prices, and many niche markets depend on such low prices. Anderson also points out that the older tracks (or movies, or books), already invested in, can easily stand price cuts that make them more noticeable to possible customers.

- **Aid customers looking into the long tail**. Long tail businesses must avoid the tempting problem of only offering products lying within the long tail part of statistical graphs. This is not a successful strategy, since customers are not drawn to the smaller business niches in a direct process, but rather through a series of introductory steps, often beginning with more popular items closer to the head of the graph and progressing down to less significant products closer to the consumers' taste. This is often done through a series of recommendations. When a customer accesses an online store to search for a popular item—the new release of a book or movie, for instance—the e-retailer gives them several recommendations of similar, lesser known products that curious customers can inspect. These recommendations in turn lead to other, even rarer product recommendations the customer can search through until he or she finds the right good, possibly located far down the long tail. Without offering popular products and recommendations in the first place, e-retailers cannot attract consumers to lesser known items.

THE LONG TAIL DEBATE

In 2008, Professor Anita Elberse wrote an article in the *Harvard Business Review* that sparked a series of debating posts between her and Chris Anderson over the applicability of the long tail theory. Elberse began by proposing that Anderson's ideas, while sound, were not nearly as effective as he theorized. Her own research led her to downplay the effectiveness of a long tail strategy and suggest that the long tail is too flat and extended to be useful, that profitable business is not moving toward niche markets but is instead staying firmly in place near the head, where the bestselling products are. Since Anita Elberse had both collaborated with Anderson in his book research and conducted detail analysis of the music industry herself, her argument attracted a large amount of attention in the business world.

Chris Anderson replied with an article refining his definition of long tail and head, and he challenged Elberse's interpretation of music industry percentages. According to his view, the prominent head of Elberse's argument technically counted as only a small portion of available products, the few percentage points of successful goods found on the shelves in brick-and-mortars. The total of other goods, what Anderson referred as the tail, sold overall more copies (and made a higher profit) than the total of the head, which still confirmed his theory. Anderson used the same logic on the other studies conducted by Elberse, splitting the head and tail into percentages that agreed with his views.

Elberse responded to Anderson's retort with another article, in which she agreed with his main tenets but underlined two of her beliefs. First, she emphasized the increasing flatness of the long tail, proposing that the more online retailers offered goods to niche markets, the flatter the tail would become, until businesses would begin struggling to cover all possible products. Second, Elberse pointed out that all "light hitters," or infrequent shoppers, preferred the bestsellers by far, and that bestsellers were rated higher by all customers than the rarer tracks—showing that quality counted more than quantity. Her efforts were directed toward moving away from defining all sales as either head or tail, and toward an empirical view of strategic effectiveness.

SMALL BUSINESSES

Although Elberse's argument is based on careful analysis, her points concern mostly large corporations who have the ability to reach across the full length of the long tail. Smaller businesses can make use of long tail strategy to find successful markets for their goods. Anita Campbell explores the long tail advantages of small businesses in her 2008 article, "Is it Time to Chuck the Long Tail Theory?" and comes to the conclusion that large corporation can afford to concentrate on making and marketing bestsellers, but small businesses cannot afford to pick and choose products. What they can do, according to Campbell, is use the power of distribution to access possible long tail buyers.

In the exhibit shown above, large corporations have the resources to use legal distribution, supply and demand, and capitalism to utilize long tails, while small businesses need to work with independent production and let the long tail market find them. For them, the distribution power and online representation today's technology offers is a step toward introducing their creations up the tail toward the head. Small business's lesser known goods can find niche markets through the online availability (long tail software) and work upward, creating their own popularity.

LONG TAIL EXAMPLES

Amazon.com: With their innovative recommendations list and vast variety of products, Amazon typifies the online retailer making use of long tail strategies.

Netflix: Making a point to carry all titles, not just those for sale in local video rental stores, Netflix has revolutionized online DVD rental services.

Rhapsody: Chris Anderson notes that online music seller Rhapsody dared to attempt his second long tail step of drastically reducing song track prices in an experiment, selling some tracks at both 79 and 49 cents; though Rhapsody lost money on the endeavor, the company made it up by selling triple the number of usual songs.

eBay: The famous online C2C seller allows customers to search for a vast variety of products and, more importantly, provides the services necessary for niche markets to function successfully.

Google: The Internet giant gives consumers the ability to search for whatever particular products they want.

ISSUES WITH LONG TAIL STRATEGY

As Anita Elberse countered in her articles, no matter how much discussion centers around maximizing profit through appeal to the long tail, the statistics show that the money still lies in bestsellers. While long tail products may be able to find a market somewhere in the world, businesses must choose what strategy to invest in, and most find it easier to focus on the head rather than the tail. Consumers simply prefer the blockbuster titles, and no matter how available other products become, the bestsellers appear to receive the best reviews, the highest accolades, and the most interest. For companies with limited resources, investing in the head goods is easier and more profitable, unless an entire long tail system is already in place.

Others predict a failing in long tail markets that will arrive when the costs of communicating and maintaining ever-increasing availability outweigh the profits of appealing to countless niche markets. For instance, social networking sites collect and provide many kinds of content (such as video and audio clips only a step away from entering niche markets as a possible source of profit), which users can share with their friends and create a buzz about. However, as the number of users, the number of generated pieces, and the number possible markets increases, the costs of maintaining the social networking sites also rise. More employees are needed to secure the data and more servers are needed to hold the information, which often leads to a need for more office space and more system updates. Eventually, these rising costs will eat away at the profitability of the social networks, and some content will have to be dropped to save space. Who decides what content will be dropped? The social networking companies will most likely choose some of the oldest information—but when users discover their shared information is being deleted, they will lose interest in sharing, and the niche markets will disperse, beginning a cycle of loss. This same danger applies to all long tail strategies, although it remains to be seen whether the niche markets will actually dry up in this manner.

M

MACROECONOMICS

SEE *Economics*

MACROENVIRONMENTAL FORCES

An organization's macroenvironment consists of nonspecific aspects in the organization's surroundings that have the potential to affect the organization's strategies. When compared to a firm's task environment, the impact of macroenvironmental variables is less direct, and the organization has a more limited impact on these elements of the environment.

Macroenvironmental variables include sociocultural, technological, political-legal, economic, and international variables. A firm considers these variables as part of its environmental scanning to better understand the threats and opportunities created by the variables and how strategic plans need to be adjusted so the firm can obtain and retain competitive advantage.

The macroenvironment consists of forces that originate outside of an organization and generally cannot be altered by actions of the organization. In other words, a firm may be influenced by changes within this element of its environment, but cannot itself influence the environment. The curved lines in Figure 1 indicate the indirect influence of the environment on the organization.

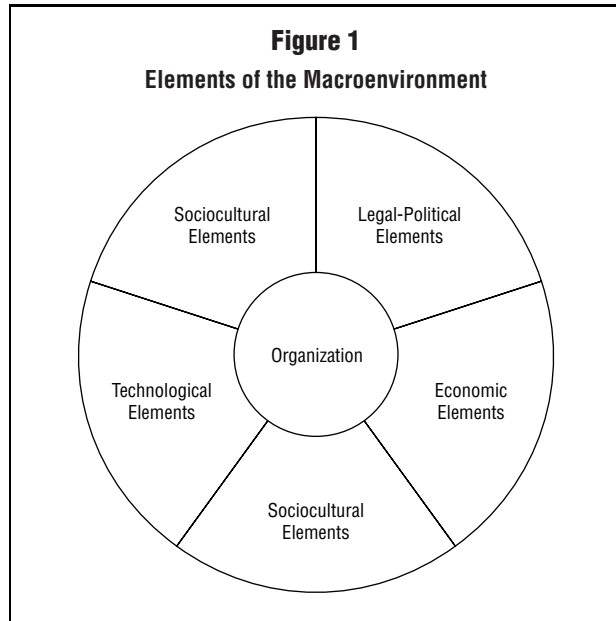
SOCIOCULTURAL FACTORS

The sociocultural dimensions of the environment consist of customs, lifestyles, and values that characterize the society in which the firm operates. Sociocultural components of the environment influence the ability of the firm to obtain resources, make its goods and services, and function within the society. Sociocultural factors include anything within the context of society that has the potential to affect an organization. Population demographics, rising educational levels, norms and values, and attitudes toward social responsibility are examples of sociocultural variables.

Population Changes. Changes in population demographics have many potential consequences for organizations. As the total population changes, the demand for products and services also changes. For instance, the decline in the birthrate and improvement in health care have contributed to an increase in the average age of the population in the United States.

Many firms that traditionally marketed their products toward youth are developing product lines that appeal to an older market. Clothing from Levi Strauss & Co. was traditionally popular among young adults. While its popularity in this market has waned, the firm has been able to develop a strong following in the adult market with its Dockers label. (In 2008, the company attempted to attract a younger market for Dockers with a viral marketing campaign.)

Other firms are developing strategies that will allow them to capitalize on the aging population. Firms in the health-care industry and firms providing funeral services are expected to do well, given the increasing age of the U.S. population. They are projected as a growth segment of U.S. industry simply because of the population demographics.

Figure 1
Elements of the Macroenvironment


Rising Educational Levels. Rising educational levels also have an impact on organizations. Higher educational levels allow people to earn higher incomes than would have been possible otherwise. The increase in income has created opportunities to purchase additional goods and services, and to raise the overall standard of living of a large segment of the population. The educational level has also led to increased expectations of workers, and has increased job mobility. Workers are less accepting of undesirable working conditions than were workers a generation ago. Better working conditions, stable employment, and opportunities for training and development are a few of the demands businesses confront more frequently as the result of a more educated workforce.

Norms and Values. Norms (standard accepted forms of behavior) and values (attitudes toward right and wrong) differ across time and between geographical areas. Lifestyles differ as well among different ethnic groups. As an example, the application in the United States of Japanese-influenced approaches to management has caused firms to reevaluate the concept of quality. Customers have also come to expect increasing quality in products. Many firms have found it necessary to reexamine production and marketing strategies to respond to changes in consumer expectations.

Social Responsibility. Social responsibility is the expectation that a business or individual will strive to improve the welfare of society. From a business perspective, this translates into the public expecting businesses to take active steps to make society better by virtue of the business being in existence. Like norms and values, what is considered

socially responsible behavior changes over time. In the 1970s affirmative action was a high priority. During the early part of the twenty-first century, prominent social issues were environmental quality (most prominently, recycling and waste reduction) and human rights, in addition to general social welfare. More than just philanthropy, social responsibility looks for active participation on the part of corporations to serve their communities.

Corporate responsibility has become an increasingly important issue as concerns about the environment grow, compelling large organizations to address the topic or risk public scorn. Search engine giant Google, for example, provides grants to projects aimed at developing renewable energy, while Starbucks has several programs devoted to sustainable coffee research.

The stakeholder approach to social responsibility demonstrates some of the complexities of incorporating socially-responsible issues into a firm's strategies. Stakeholders are anyone with a stake in the organization's existence. Highly visible stakeholders are stockholders, employees, customers, and the local community. Decisions to be responsible and maximize the return to stockholders may require closing an unprofitable plant. However, employees and members of the local community could view this move as socially irresponsible since the move would not benefit the community.

TECHNOLOGICAL FACTORS

Technology is another aspect of the environment a firm should consider in developing strategic plans. Changing technology may affect the demand for a firm's products and services, its production processes, and raw materials. Technological changes may create new opportunities for the firm, or threaten the survival of a product, firm, or industry. Technological innovation continues to move at an increasingly rapid rate.

Demand. Technology can change the lifestyle and buying patterns of consumers. Developments in the field of personal computers have dramatically expanded the potential customer base and created innumerable opportunities for businesses to engage in business via the Internet. Whereas computers were traditionally used only by large organizations to handle data processing needs, personal computers are commonly used by smaller firms and individuals for uses not even imagined in the past. Similarly, new developments in technology led to a reduction in prices for computers and expanded the potential market. Lower prices allow computers to be marketed to the general public rather than to business, scientific, and professional users—the initial market.

Technology may also cause certain products to be removed from the market. Asbestos-related illnesses have

severely limited asbestos as a resource used in heat-sensitive products such as hair dryers. Further, a number of chemicals that have been commonly used by farmers to control insects or plants are prohibited from use or require licensure as a consequence of those chemicals appearing in the food chain.

Production Processes. Technology also changes production processes. The introduction of products based on new technology often requires new production techniques; further, new production technology may alter production processes. Robotics represents one of the most visible challenges to existing production methods. Robots may be used in positions considered hazardous for people or that require repetitive, detailed activities.

The consequences for other jobs currently occupied by people are not clear. When production was first automated, although some workers were displaced, new jobs were created to produce and maintain the automated equipment. The impact of robotics on jobs is in large part a function of the uses made of the technology and the willingness of workers to learn to use new technology.

In some industries, use of robots during the early 2000s increased production and efficiency but resulted in significant numbers of job losses. However, technological innovation can also result in increased job growth. For example, Ford Motor Company's $375-million technology update to its Norfolk assembly plant to build its 2004 F-150 resulted in the ability to build more models on its assembly line and consequently created about 270 new jobs, an 11 percent increase.

Evaluating Technological Changes. There is little doubt that technology represents both potential threats and potential opportunities for established products. Products with relatively complex or new technology are often introduced while the technology is being refined, making it hard for firms to assess their market potential. When ballpoint pens were first introduced, they leaked, skipped, and left large blotches of ink on the writing surface. Fountain pen manufacturers believed that the new technology was not a threat to existing products and did not attempt to produce ballpoint pens until substantial market share had been lost.

Another technology, the electric razor, has yet to totally replace the blade for shaving purposes. Perhaps the difference is that the manufacturers of blades have innovated by adding new features to retain customers. Manufacturers of fountain pens did not attempt to innovate until the ballpoint pen was well established.

It is quite difficult to predict the impact of a new technology on an existing product. Still, the need to monitor the environment for new technological developments is obvious. Attention must also be given to developments in industries that are not direct competitors, since new tech-

nology developed in one industry may impact companies and organizations in others.

POLITICAL AND LEGAL FACTORS

The political-legal dimension of the general environment also affects business activity. The philosophy of the political parties in power influences business practices. The legal environment serves to define what organizations can and cannot do at a particular point in time.

ATTITUDES TOWARD BUSINESS

A pro-business attitude on the part of government enables firms to enter into arrangements that would not be allowed under a more anti-business philosophy. The numerous joint ventures between U.S. and Japanese automobile manufacturers could have been termed anti-competitive by a less pro-business administration. The release of many acres of government land for business use (logging, mining) angered many environmentalists who had been able to restrict business use of the land under previous administrations.

Changes in sentiments toward smoking and its related health risks have altered the public's attitude toward the tobacco industry. These changes have been reflected in many organizations by limiting smoking to designated areas or completely prohibiting it at work. The transformation in attitude has also caused firms within the tobacco industry to modify marketing strategies, encouraging many to seek expansion opportunities abroad.

Legislation. The legal environment facing organizations is becoming more complex and affecting businesses more directly. It has become increasingly difficult for businesses to take action without encountering a law, regulation, or legal problem. A very brief listing of significant laws that affect business would include legislation in the areas of consumerism, employee relations, the environment, and competitive practices.

Many of the laws also have an associated regulatory agency. Powerful U.S. regulatory agencies include the Environmental Protection Agency (EPA), the Occupational Safety and Health Administration (OSHA), the Equal Employment Opportunity Commission (EEOC), and the Securities and Exchange Commission (SEC).

Estimates of the cost of compliance vary widely, but could well exceed $100 billion annually. Many of these costs are passed to consumers. However, costs of legal expenses and settlements may not be incurred for years and are not likely to be paid by consumers of the product or owners of the company when the violation occurred. Still, potential legal action often results in higher prices for consumers and a more conservative attitude by business executives.

Levels of Government Influence. In discussion, the term "the government" is generally meant to refer to the federal government. It is the federal government that passes and enforces legislation concerning the entire country. Actions by the federal government affect a large number of firms and are consistent across state boundaries. Environmental analysis, however, should not overlook actions by both state and local governments.

Regulations concerning many business practices differ between states. Tax rates vary widely. Laws regarding unionization (e.g., right-to-work states) and treatment of homosexual workers differ between states.

Local governments have the potential to affect business practices significantly. Some local governments may be willing to provide incentives to attract business to the area. Some may build industrial parks, service roads, and provide low-interest bonds to encourage a desirable business to move into the community.

Regulatory measures such as building codes and zoning requirements differ significantly between communities. Infrastructure such as electric and sewer services, educational facilities, and sewage treatment capabilities may not be able to accommodate the increased demand associated with certain industries, making that locale unsuitable for establishing some businesses.

ECONOMIC FACTORS

Economic factors refer to the character and direction of the economic system within which the firm operates. Economic factors include the balance of payments, the state of the business cycle, the distribution of income within the population, and governmental monetary and fiscal policies. The impact of economic factors may also differ between industries.

Balance of Payments. The balance of payments of a country refers to the net difference in value of goods bought and sold by citizens of the country. To decrease the dollar value of goods imported into a country, it is common practice to construct barriers to entry for particular classes of products. Such practices reduce competition for firms whose products are protected by the trade barriers.

Mexico has limited the number of automobiles that can be imported. The purpose of this practice is to stimulate the domestic automobile market and to allow it to become large enough to create economies of scale and to create jobs for Mexican workers. A side effect of the import restriction, however, has been an increase in the price and a decrease in the quality of automobiles available to the public.

Another potential consequence of import restrictions is the possibility of reciprocal import restrictions. Partially in retaliation to import restriction on Japanese televisions and automobiles by the United States, the Japanese have limited imports of agricultural goods from the United States.

Lowering trade restrictions as a means of stimulating the economy of a country may meet with mixed results. The North American Free Trade Agreement (NAFTA) has opened the borders between the United States, Canada, and Mexico for the movement of many manufacturers. Government officials in the United States argue the results have been positive, but many local communities that have lost manufacturing plants question the wisdom of the agreement.

As discussed in an article by Susan Schmidt in *World Trade* magazine, issues that stemmed from regulatory agencies and national security measures were barriers to free trade during the early part of the twenty-first century, demonstrating that NAFTA alone could not clear the path for companies and countries to take advantage of free trade benefits.

Business Cycle. The business cycle is another economic factor that may influence the operation of a firm. Purchases of many durable goods (appliances, furniture, and automobiles) can be postponed during periods of recession and depression, as can purchases of new equipment and plant expansions. Economic downturns result in lower profits, reductions in hiring, increased borrowing, and decreased productivity for firms adversely affected by the recession. Positive consequences of recessions may include reductions in waste, more realistic perceptions of working conditions, exit of marginally efficient firms, and a more efficient system.

Some organizations may benefit from an economic downturn. Postponed purchases may result in the need to service existing products. An owner electing to keep a used automobile rather than buying a new one may need to have it repaired, thus creating an increased demand for automobile mechanics and replacement parts. Limited job opportunities during downturns also encourage individuals unable to get satisfactory jobs to consider going to college or joining the armed services.

Income Distribution. The distribution of income may differ between economic systems. Two countries with the same mean (per capita) income levels may have dramatically different distributions of income. The majority of persons in the United States are considered middle income, with only a relatively small number of persons having exceptionally high or low incomes.

Many developing countries have citizens who are either extremely wealthy or extremely poor. Only a few persons would qualify as middle class. Therefore, although both countries had the same mean income, opportunities to market products to the middle class would be greater in the United States.

Transfer Payments. Transfer payments (e.g., welfare, social security) within the United States change the distribution of income. Transfer payments provide money to individuals in the lower income brackets and enable them to purchase goods and services they otherwise could not afford. Such a redistribution of income may not be the practice in other economic systems. Thus, large numbers of people in need of basic goods and services do not assure that those people will be able to purchase such goods and services.

Monetary and Fiscal Policies. Monetary and fiscal policies utilized by the federal government also influence business operations. Monetary policies are controlled by the Federal Reserve System and affect the size of the money supply and interest rates. Fiscal policies represent purchases made by the federal government.

For example, allocation of funds to defense means expenditures for weapons and hardware. If appropriations had gone to the Health and Human Services and Education Departments instead, much of the money would have constituted transfer payments. The primary beneficiaries of such a fiscal policy would be firms in the basic food and shelter businesses. No matter how government expenditures are reallocated, the result is lost sales and cut budgets for some companies, and additional opportunities for others.

Though unpopular in the United States, another aspect of government fiscal policy is deficit spending, which may allow government expenditures to rise, but can also influence interest rates, exchange rates, and other economic trends.

INTERNATIONAL FACTORS

A final component of the general environment is actions of other countries or groups of countries that affect the organization. Governments may act to reserve a portion of their industries for domestic firms, or may subsidize particular types of businesses to make them more competitive in the international market.

Some countries may have a culture or undergo a change in leadership that limits the ability of firms to participate in the country's economy. As with the other elements of the macroenvironment, such actions are not directed at any single company, but at many firms.

Economic Associations. As described previously, one joint effort by governments to influence business practices was NAFTA. The agreement between the United States, Canada, and Mexico was intended to facilitate free trade between the three countries. The result has been a decrease in trade barriers between them, making it easier to transport resources and outputs across national boundaries. The move has been beneficial to many businesses, and probably to the economies of all three countries. In most economic associations, preference is also given to products from member countries at the expense of products from nonmembers.

Probably the best-known joint effort by multiple countries to influence business practices is the Organization of Petroleum Exporting Countries (OPEC). The formation of OPEC, an oil cartel including most major suppliers of oil and gas, led to a drastic increase in fuel prices. Rising fuel prices had a significant effect on the demand for automobiles worldwide. The increases in oil prices also contributed to inflation all over the world. OPEC's early success encouraged countries producing other basic products (coffee beans, sugar, bananas) to attempt to control the prices of their products.

A more recent example of an economic association serving multiple countries was the International Coffee Organization (ICO). The United States rejoined the ICO in 2004 in hopes of fostering sustainability and competition across countries and the industry. The United States works with the Honduras, Mexico, and Nicaragua, among others, as part of this organization.

Intergovernmental Relations. Changing relationships between the United States and other countries may alter the ability of firms to enter foreign markets. The United States' establishment of trade relations with China in the 1970s created opportunities for many firms to begin marketing their products in China.

The rise of Ayatollah Ruhollah Khomeini to power in Iran altered the lives of many Iranian citizens. Wine, vodka, music, and other forms of entertainment were prohibited. Black markets provided certain restricted items. Other products, such as wine, began to be produced at home. Anti-American sentiments throughout the country showed the hostility of many citizens. Non-American firms thus had an opportunity to capitalize on the anti-American sentiments and to provide goods and services formerly provided by U.S. firms.

Cultural Differences. In different countries and sometimes even within a country, there are substantial differences in attitudes, beliefs, motivation, morality, superstition, and perception, as well as other characteristics. Geert Hofstede (b. 1928) developed a model in which worldwide differences in culture are categorized according to five dimensions. These dimensions include:

- Power distance—the degree of inequality among people which the population of a country considers normal.
- Individualism vs. collectivism—the degree to which people in a country prefer to act as individuals or as members of a group.

- Masculinity vs. femininity—the degree to which values like assertiveness, performance, success, and competitiveness are used to guide decisions versus values like the quality of life, warm personal relationships, service, and solidarity.

- Uncertainty avoidance—the degree to which citizens of a country prefer structured over unstructured situations, rigidity of procedures, or willingness to accept risk and potential failure.

- Time orientation—the extent to which decisions are based on long-term orientation versus short-term orientation, past versus present versus future, and punctuality.

Hofstede argues that U.S. management theories contain a number of idiosyncrasies that are not necessarily shared by managers in other cultures. Approaches to motivation and leadership, for example, differ widely throughout the world. Citizens of Japan tend to put greater importance on collective effort and working as a team member. Individual recognition is not desired. It is viewed as contradictory to being a good team member.

Similarly, in other countries, high tax rates may make bonuses and other forms of monetary compensation less attractive and less motivating than in the United States. Hofstede argues that employees and products are more readily transferred between countries sharing similar cultures.

The macroenvironment consists of forces that originate outside of an organization and generally cannot be altered by actions of the organization. Dimensions of the macroenvironment consist of sociocultural factors, technological factors, political-legal elements, economic factors, and international elements. A firm needs to study these elements of its environment, as they have the potential to affect how the organization should operate to attain and maintain its competitive advantage.

MAINTENANCE

Maintenance is the combination of all technical and associated administrative actions intended to retain an item in, or restore it to, a state in which it can perform its required function. Many companies seek to gain competitive advantage with respect to cost, quality, service, and on-time deliveries. The effect of maintenance on these variables has prompted increased attention to the maintenance area as an integral part of productivity improvement. Maintenance is rapidly evolving into a major contributor to the performance and profitability of manufacturing systems. In fact, some see maintenance as the "last frontier" for manufacturing.

In their article "Make Maintenance Meaningful," P.K. Kauppi and Paavo Ylinen describe the bulk of maintenance procedures as being:

- Preventive maintenance—the prevention of equipment breakdowns before they happen. This includes inspections, adjustments, regular service, and planned shutdowns.

- Repair work—repairing equipment and troubleshooting malfunctions in an effort to return the equipment to its previous condition. These repairs may be reactive or preventive.

- Improvement work—searching for better materials and improved designs to facilitate equipment reliability. Repair work is often a part of improvement work.

As shown in Figure 1, six maintenance programs are identified within the maintenance hierarchy, each representing an increased level of sophistication.

Figure 1

Maintenance Hierarchy

Reliability-Centered Maintenance

Total Productive Maintenance

Preventative Maintenance

Predictive Maintenance

Scheduled Maintenance

Reactive Maintenance
REACTIVE MAINTENANCE

Reactive maintenance (also known as corrective maintenance) involves all unscheduled actions performed as a result of system or product failure. Basically, it is an attempt to restore the system/product to a specified condition. The spectrum of activities within this level is (1) failure identification, (2) localization and isolation, (3) disassembly, (4) item removal and replacement or repair in place, (5) reassembly, and (6) checkout and condition verification.

This approach is mainly a response to machine breakdowns. Unfortunately, many manufacturers are still in a reactive mode of operation, since their main objective is to ship the product. If their manufacturing equipment breaks down, they fix it as quickly as possible and then run it until it breaks down again—an extremely unreliable process and not the best way to maximize the useful life span of assets. It leaves machine tools in a state of poor repair and can cause the production of out-of-tolerance parts and scrap. Because of its unpredictable nature it can easily cause disruptions to the production process.

SCHEDULED MAINTENANCE

Scheduled maintenance utilizes a previously developed maintenance schedule for each machine tool. While this is a broadly practiced technique in many manufacturing organizations, it does possess some distinct disadvantages. The scheduled maintenance may take place too soon, while the machine still operates well (15–20 percent of all components fail after a predictable time), or it may come too late if the machine fails before the scheduled maintenance time. In some cases, the machine may still be running but producing unacceptable parts. Scheduled maintenance can be considered a part of preventive maintenance (discussed later) known as fixed-time maintenance (FTM).

PREDICTIVE MAINTENANCE

Predictive maintenance involves performing maintenance on a machine in advance of the time a failure would occur if the maintenance were not performed. This means that one must calculate when a machine is predicted to fail. In order to do this, the firm must collect data on variables that can be used to indicate an impending failure (vibration, temperature, sound, color, etc.). This data is analyzed to approximate when a failure will occur and maintenance is then scheduled to take place prior to this time. By seeking the correct level of maintenance required, unplanned downtime is minimized.

PREVENTIVE MAINTENANCE

Preventive maintenance encompasses activities, including adjustments, replacement, and basic cleanliness, that forestall machine breakdowns. Preventive activities are primarily condition based. The condition of a component, measured when the equipment is operating, governs planned/scheduled maintenance.

Typical preventive maintenance activities include periodic inspections, condition monitoring, critical item replacements, and calibrations. In order to accomplish this, blocks of time are incorporated into the operations schedule. The purpose of preventive maintenance is to ensure that production quality is maintained and that delivery schedules are met. In addition, a machine that is well cared for will last longer and cause fewer problems.

Current trends in management philosophy such as just-in-time (JIT) and total quality management (TQM) incorporate preventive maintenance as key factors in their success. JIT requires high machine availability, which in turn requires preventive maintenance. Also, TQM requires equipment that is well maintained in order to meet required process capability.

Preventive maintenance is also seen as a measure of management excellence. It requires a long-term commitment, constant monitoring of new technology, a constant assessment of the financial and organizational tradeoffs in contracting out versus in-house maintenance, and an awareness of the impact of the regulatory and legal environment.

The resulting benefits of preventive maintenance are many. Some of them are listed below:

- **Safety.** Machinery that is not well maintained can become a safety hazard. Preventive maintenance increases the margin of safety by keeping equipment in top running condition.

- **Lower cost.** A modern and cost-effective approach to preventive maintenance shows that there is no maintenance cost optimum. However, maintenance costs will decrease as the costs for production losses decreases. No preventive maintenance action is performed unless it is less costly than the resulting failure.

- **Reduction in failures and breakdowns.** Preventive maintenance aims to reduce or eliminate unplanned

downtime, thereby increasing machine efficiency. Downtime is also reduced when the preventive maintenance process gives maintenance personnel sufficient warning so repairs can be scheduled during normal outages.

- **Extension of equipment life.** Equipment that is cared for will last longer than equipment that is abused and neglected.

- **Improved trade-in/resale value of equipment.** If the equipment is to be sold or traded in, a preventive maintenance program will help keep the machine in the best possible condition, thereby maximizing its used value.

- **Increased equipment reliability.** By performing preventive maintenance on equipment, a firm begins to build reliability into the equipment by removing routine and avoidable breakdowns.

- **Increased plant productivity.** Productivity is enhanced by the decrease in unexpected machine breakdown. Also, forecast shutdown time can allow the firm to utilize alternate routings and scheduling alternatives that will minimize the negative effect of downtime.

- **Fewer surprises.** Preventive maintenance enables users to avoid the unexpected. Preventive maintenance does not guarantee elimination of all unexpected downtime, but empirically it has proven to eliminate most downtime caused by mechanical failure.

- **Reduced cycle time.** If process equipment is incapable of running the product, then the time it takes to move the product through the factory will suffer. Taninecz found, from an *Industry Week* survey, that there is a strong correlation between preventive maintenance and cycle-time reductions as well as near-perfect on-time delivery rates. Also, approximately 35 percent of the surveyed plants who widely adopted preventive maintenance achieved on-time delivery rates of 98 percent, compared to only 19.5 percent for non-adopters.

- **Increased service level for the customer and reduction in the number of defective parts.** These have a positive direct effect on stockouts, backlog, and delivery time to the customer.

- **Reduced overall maintenance.** By not allowing machinery to fall into a state of disrepair, overall maintenance requirements are greatly decreased.

TOTAL PRODUCTIVE MAINTENANCE

Total productive maintenance (TPM) is preventive maintenance plus continuing efforts to adapt, modify, and refine equipment to increase flexibility, reduce material handling, and promote continuous flows. It is operator-oriented maintenance with the involvement of all qualified employees in all maintenance activities.

TPM has been described as preventive maintenance with these three factors added: (1) involving machine operators in preliminary maintenance activities by encouraging them to keep machines clean and well lubricated; (2) encouraging operators to report indications of incipient distress to the maintenance department; and (3) establishing a maintenance education and training program.

Developed in Japan, TPM places a high value on teamwork, consensus building, and continuous improvement. It is a partnership approach among organizational functions, especially production and maintenance. TPM means total employee involvement, total equipment effectiveness, and a total maintenance delivery system. In order to achieve this, machine operators must share the preventive maintenance efforts, assist mechanics with repairs when equipment is down, and work on equipment and process improvements within team activities.

Tennessee Eastman found that another employee, such as an equipment operator, with minimal training, could do 40 percent of the traditional maintenance mechanic's work. Another 40 percent could be performed with additional training, but still below the certified level. Only 20 percent of the maintenance tasks actually required a certified mechanic's skills. They also reported that as much as 75 percent of maintenance problems can be prevented by operators at an early stage. This frees maintenance personnel to be responsible for the tasks that require their critical skills, such as breakdown analysis, overhaul, corrective maintenance, and root cause analysis. This places maintenance personnel in a "consultant" role with the operators allowing them to:

- Help the operator diagnose problems and restore equipment to like-new condition.

- Use appropriate technologies and standards to verify that the equipment is in like-new condition after repair, overhaul, or replacement.

- Use this knowledge to assess the root cause of the problem so that changes may be made to the design, operation, or maintenance practices in the future.

- Work with purchasing, engineering, operations, and maintenance to modify procurement standards to assure maximum reliability in future equipment.

In order for this to work, the firm must have an organizational culture which supports a high level of employee involvement. Businesses must be willing to provide the necessary training in order to allow production personnel to perform the required tasks.

TPM's focus is on elimination of the major losses or inefficiencies incurred in production activities. These

losses include those due to obstruction of equipment efficiency, manpower efficiency, and material and energy efficiency. Based on their link to corporate goals, targets for eliminating or reducing these losses are developed.

Just as in activity-based cost accounting where cost drivers are identified, the objective of TPM is to identify variables that can demonstrate improved performance. All major equipment losses are functionally related to availability, performance, efficiency, and/or quality rate so the improvement resulting from the maintenance system can be measured by its impact on overall equipment effectiveness (see below).

Beneficial results of TPM include:

- It maximizes overall equipment effectiveness and overall efficiency.
- It takes the guesswork out of determining which machine needs major repairs or rebuilding.
- It provides objectivity by converting the operator's intuition into quantifiable values.
- It pinpoints exact maintenance requirements. The operator carries out only the needed corrective actions, so no unnecessary work, beyond routine maintenance, is done.
- It rapidly verifies the effectiveness of major corrective work.
- It helps operators improve their job skills.
- It motivates operators by involving them in maintenance of their own machines and in team-based concepts.
- It gives operators ownership of making the project a success by involving them in the process.
- It enables the development of a preventive maintenance program for the lifecycle of the equipment.
- It gets everyone involved in equipment design and selection, resulting in a better understanding of why certain decisions and trade-offs are necessary.
- It results in equipment and maintenance management (inherent in a reliability strategy).
- It maximizes capacity.
- It minimizes costs.
- It improves product quality.
- It improves safety.
- It continually improves the manufacturing process.

As a final note on TPM, another school of thought holds that TPM can be adopted by continuous diagnostic monitoring of a machine's conditions and establishing a trend line for it. Trend lines approaching or veering into the domain that identifies poor operating conditions will trigger maintenance action.

RELIABILITY-CENTERED MAINTENANCE

It has been assumed that preventive maintenance programs help to ensure reliability and safety of equipment and machinery. However, tests performed by airlines in the mid-1960s showed that scheduled overhaul of complex equipment had little or no positive effect on the reliability of the equipment in service. These tests revealed the need for a new concept of preventive maintenance, which later became known as reliability-centered maintenance (RCM).

The concept of RCM is rooted in a 1968 working paper prepared by the Boeing 747 Maintenance Steering Group. A refined version appeared in 1970. Continued studies at the Department of Defense led to the 1986 publication of the "Reliability Centered Maintenance Requirements for Naval Aircraft, Weapons Systems and Support Equipment," a set of maintenance standards and procedures that certain military maintenance personnel were expected to follow. The RCM methodology was further developed and found application not only in the military and aviation, but also in the energy, manufacturing, foundry, and transport industries.

According to Bulmer, the RCM process can be considered as three separate but associated analyses: failure mode and effects analysis, consequence analysis, and task analysis. These analyses consider the specific characteristics and consequences of a failure and attempt to arrive at the optimal solution based on this information.

OVERALL EQUIPMENT EFFECTIVENESS

Total productive maintenance provides a systematic procedure for linking corporate goals to maintenance goals. This procedure calls for the consideration of external and internal corporate environments, and then the development of a basic maintenance policy congruent with the environments. Next key points for maintenance improvement are identified, which result in the definition of target values for maintenance performance. These values, referred to as overall equipment effectiveness (OEE), are a function of equipment availability, quality rate, and equipment performance efficiency, and provide a starting point for developing quantitative variables for relating maintenance measurement and control to corporate strategy.

Essentially, OEE offers a measurement tool that helps identify the real areas of opportunity within an operation. These areas have been termed the "six big losses." OEE

allows the firm to break these losses into smaller components to better evaluate the impact the maintenance program is making on the operation. The six losses are:

1. Breakdowns from equipment failure (unplanned downtime)

2. Setup and adjustments from product changes and minor adjustments necessary to get the equipment operating properly after the line change

3. Idling and minor stoppages due to abnormal operation of the equipment causing momentary lapses in production, but not long enough to track as downtime

4. Reduced speeds, the discrepancy between design and actual speed the equipment operates

5. Process defects due to scrapped production and defects needing rework

6. Reduced yield and lost materials during the manufacturing process, from start-up to end of production run

If a company has an OEE of 85 percent or more, then it is considered to be a world-class company.

TRENDS IN MAINTENANCE

Two major trends in the development of maintenance management research have been identified: (1) emerging developments and advances in maintenance technology, information and decision technology, and maintenance methods; and (2) the linking of maintenance to quality improvement strategies and the use of maintenance as a competitive strategy.

The first major trend has to do with the impact of artificial intelligence techniques, such as expert systems and neural networks, on the formation of maintenance knowledge in industrial organizations. There is a diverse application of expert systems within the maintenance area. A number of these systems and their applications are listed below:

- CATS—an expert maintenance system for detecting sudden failures in diesel-electric locomotive systems.

- INNATE—an expert system used for electronic circuit diagnosis.

- FSM—an expert system used by Boeing for continuous condition monitoring of aircraft alarms.

- RLA—an expert system developed by Lockheed for repair-level analysis for major parts in an aerospace system.

- GEMS-TTS—an expert system used by AT&T maintenance specialists to isolate faults in communication links.

- TOPAS—an expert system that diagnoses transmission and signaling problems in real time that may arise on switched circuits.

- CHARLEY—an expert system used by General Motors to diagnose problems with broken machine tools and to instruct less experienced individuals by providing explanations.

- XCON—an expert system developed by Digital Equipment Corporation (now part of Compaq) for product configuration.

The second major trend is typified by the emergence of total productive maintenance, which must be incorporated into the firm's strategy. In the quest for world-class manufacturing standards, many industries are appreciating the need for efficient maintenance systems that have been effectively integrated with corporate strategy. It is vital that maintenance management becomes integrated with corporate strategy to ensure equipment availability, quality products, on-time deliveries, and competitive pricing. Managerial attitudes have changed toward maintenance because of the emergence of new management philosophies. In addition, social trends such as lack of capital, fluctuations in currencies, competition, quality, and environmental consciousness have also encouraged a new focus on maintenance.

Maintenance continues to be a major area of concern for manufacturers and other forms of business. A study of some seventy manufacturing plants found that over 50 percent of the maintenance work performed by these firms was reactive (run to failure, emergency breakdown). The balance of maintenance work was preventive or period based (25%), predictive or condition based (15%), and proactive or root-caused based (10%). A strong correlation has been found to exist between manufacturing cost reduction and preventive/predictive maintenance. Over a five-year period a study group of companies found that productivity improvements correlated strongly with a number of variables, one of which was preventive/predictive maintenance.

Maintenance Repairs and Inventory Management. Maintenance repair and operations (MRO) inventory handling is one of the most important maintenance processes in business organizations because it is a liability that must be accounted for in management reports of the organization. Since MRO inventory management is an expense (rather than an investment) to business organizations, managers do not give much attention towards supervision of the movements of products that are consumed internally within the organization. However, failure to track the in-house inventory activities leads to mismatch between stocking estimates and the actual types and quantities of stock items required to sustain the short-term and long-term operations of a business organization.

There are various strategies that can be applied to ensure efficiency in the management of MRO inventory. The most commonly used strategy involves assigning stocked products in the MRO inventory into different functional categories. For example, the management can split the MRO inventory into routine maintenance products, non-routine maintenance products which are used on regular predetermined schedules, and unpredictable products of emergency nature. Proper MRO inventory management enables business organizations to control repair and maintenance costs by stocking and tracking only those items that are required by the company.

The continued advancement of information technology has led to increased use of automated systems in (MRO) inventory handling practices in business organizations. Both large scale and small scale manufacturers are gradually optimizing the use of Computer Maintenance Management System (CMMS), a software program that facilitates the automation of logistical procedures in the management of operations and maintenance activities in manufacturing firms. CMMS adoption is a transformational function that involves software installation, system configuration, training of end users, and system implementation.

The implementation phase of CMMS in the organization requires the management to develop appropriate oversight measures to ensure that all personnel who are affected by the system have deep understanding of the procedures that concern changes introduced in the routine work flows, data-capturing processes, report processing requirements, and performance logistics by the aided planning of maintenance. Successful incorporation of CMMS into the MRO inventory practices of a firm leads to efficiency in the performance of a firm's maintenance procedures including preventive maintenance, repair work, and improvement work, as well as routine activities such as inventory control and asset management.

Mike Laskiewicz recommends that organizations recognize maintenance as a key department that needs to be well managed. In addition, the maintenance department should be led by a strong-minded individual who is a good motivator, technically competent, experienced and familiar with advanced industry practices. Finally Laskiewicz notes that maintenance planning must be a top priority.

MAKE-OR-BUY DECISIONS

The make-or-buy decision is the act of making a strategic choice between producing an item internally (in-house) or buying it externally (from an outside supplier). The buy side of the decision also is referred to as outsourcing. Make-or-buy decisions usually arise when a firm that has developed a product or part—or significantly modified a product or part—is having trouble with current suppliers, or has diminishing capacity or changing demand.

Make-or-buy analysis is conducted at the strategic and operational level. The strategic level is the more long-range of the two. Variables considered at the strategic level include analysis of the future, as well as the current environment.

Issues like government regulation, competing firms, and market trends all have a strategic impact on the make-or-buy decision. Of course, firms should make items that reinforce or are in-line with their core competencies. These are areas in which the firm is strongest and which give the firm a competitive advantage.

The increased existence of firms that utilize the concept of lean manufacturing has prompted an increase in outsourcing. Manufacturers are tending to purchase subassemblies rather than piece parts, and are outsourcing activities ranging from logistics to administrative services.

In their 2003 book *World Class Supply Management,* David Burt, Donald Dobler, and Stephen Starling present a rule of thumb for outsourcing. It prescribes that a firm

outsource all items that do not fit one of the following three categories: (1) the item is critical to the success of the product, including customer perception of important product attributes; (2) the item requires specialized design and manufacturing skills or equipment and the number of capable and reliable suppliers is extremely limited; and (3) the item fits well within the firm's core competencies, or within those the firm must develop to fulfill future plans. Items that fit under one of these three categories are considered strategic in nature and should be produced internally if at all possible.

Make-or-buy decisions also occur at the operational level. Analysis in separate texts by Burt, Dobler, and Starling, as well as Joel Wisner, G. Keong Leong, and Keah-Choon Tan, suggest these considerations that favor making a part in-house:

- Cost considerations (less expensive to make the part)
- Desire to integrate plant operations
- Productive use of excess plant capacity to help absorb fixed overhead (using existing idle capacity)
- Need to exert direct control over production and/or quality
- Better quality control
- Design secrecy is required to protect proprietary technology
- Unreliable suppliers
- No competent suppliers
- Desire to maintain a stable workforce (in periods of declining sales)
- Quantity too small to interest a supplier
- Control of lead time, transportation, and warehousing costs
- Greater assurance of continual supply
- Provision of a second source
- Political, social, or environmental reasons (union pressure)
- Emotion (e.g., pride)

Factors that may influence firms to buy a part externally include:

- Lack of expertise
- Suppliers' research and specialized know-how exceeds that of the buyer
- Cost considerations (less expensive to buy the item)
- Small-volume requirements
- Limited production facilities or insufficient capacity

- Desire to maintain a multiple-source policy
- Indirect managerial control considerations
- Procurement and inventory considerations
- Brand preference
- Item not essential to the firm's strategy

The two most important factors to consider in a make-or-buy decision are cost and the availability of production capacity. Burt, Dobler, and Starling warn that "no other factor is subject to more varied interpretation and to greater misunderstanding."

Cost considerations should include all relevant costs and be long-term in nature. Obviously, the buying firm will compare production and purchase costs. Burt, Dobler, and Starling provide the major elements included in this comparison. Elements of the "make" analysis include:

- Incremental inventory-carrying costs
- Direct labor costs
- Incremental factory overhead costs
- Delivered purchased material costs
- Incremental managerial costs
- Any follow-on costs stemming from quality and related problems
- Incremental purchasing costs
- Incremental capital costs

Cost considerations for the "buy" analysis include:

- Purchase price of the part
- Transportation costs
- Receiving and inspection costs
- Incremental purchasing costs
- Any follow-on costs related to quality or service

It should be noted that six of the costs to consider are incremental. By definition, incremental costs would not be incurred if the part were purchased from an outside source.

If a firm does not currently have the capacity to make the part, incremental costs will include variable costs plus the full portion of fixed overhead allocable to the part's manufacture. If the firm has excess capacity that can be used to produce the part in question, only the variable overhead caused by production of the parts are considered incremental. That is, fixed costs, under conditions of sufficient idle capacity, are not incremental and should not be considered as part of the cost to make the part.

While cost is seldom the only criterion used in a make-or-buy decision, simple break-even analysis can be an

effective way to quickly surmise the cost implications within a decision. Suppose that a firm can purchase equipment for in-house use for $250,000 and produce the needed parts for $10 each. Alternatively, a supplier could produce and ship the part for $15 each. Ignoring the cost of negotiating a contract with the supplier, the simple break-even point could easily be computed:

$$\$250,000 + \$10Q = \$15Q$$
$$\$250,000 = \$15Q - \$10Q$$
$$\$250,000 = \$5Q$$
$$50,000 = Q$$

Therefore, it would be more cost effective for a firm to buy the part if demand is less than 50,000 units, and make the part if demand exceeds 50,000 units. However, if the firm had enough idle capacity to produce the parts, the fixed cost of $250,000 would not be incurred (meaning it is not an incremental cost), making the prospect of making the part too cost efficient to ignore.

Stanley Gardiner and John Blackstone's 1991 paper in the *International Journal of Purchasing and Materials Management* presented the contribution-per-constraint-minute (CPCM) method of make-or-buy analysis, which makes the decision based on the theory of constraints. They also used this approach to determine the maximum permissible component price (MPCP) that a buyer should pay when outsourcing. In 2005 Jaydeep Balakrishnan and Chun Hung Cheng noted that Gardiner and Blackstone's method did not guarantee a best solution for a complicated make-or-buy problem. Therefore, they offered an updated, enhanced approach using spreadsheets with built-in liner programming (LP) capability to provide "what if" analyses to encourage efforts toward finding an optimal solution.

Firms have started to realize the importance of the make-or-buy decision to overall manufacturing strategy and the implication it can have for employment levels, asset levels, and core competencies. In response to this, some firms have adopted total cost of ownership (TCO) procedures for incorporating non-price considerations into the make-or-buy decision.

MANAGEMENT: ART VS. SCIENCE

SEE *The Art and Science of Management*

MANAGEMENT AUDIT

Typically, a *management audit* is used to examine and appraise the efficiency and effectiveness of management in carrying out its activities. Areas of auditor interest include the nature and quality of management decisions, operating results achieved, and risks undertaken.

The management audit focuses on results, evaluating the effectiveness and suitability of controls by challenging underlying rules, procedures, and methods. Management audits, which are generally performed internally, are both compliance reviews and goals-and-effect analyses. When performed correctly, they are potentially the most useful of evaluation methods because they result in change.

The management audit is a process of systematically examining, analyzing, and appraising management's overall performance. The appraisal is composed of ten categories, examined historically and in comparison with other organizations. The audit measures a company's quality of management relative to those of other companies in its particular industry, as well as the finest management in other industries. The ten categories of the management audit are: (1) economic function, (2) corporate structure, (3) health of earnings, (4) service to stockholders, (5) research and development, (6) directorate analysis, (7) fiscal policies, (8) production efficiency, (9) sales vigor, and (10) executive evaluation. These categories do not represent single functions of management.

ECONOMIC FUNCTION

The economic function category in the management audit assigns to management the responsibility for the company's importance to the economy. In essence, the public value of the company is determined. The value is based on what the company does, what products or services it sells, and how it goes about its business in a moral and ethical sense. It

Exhibit 1

Replacement Chart for the Position of District Manager

Candidates	S. Jones	B. Smith	H. Johnson
Performance in present job	4	3	5

Advancement potential score	85	78	87
Rank	2	3	1

includes the company's reputation as well as management's view of the purpose of the company.

The public is defined in this sense not only as the consumers of the company's products or services and its shareholders, but also a number of groups that the company must seek to satisfy. These groups include its employees, suppliers, distributors, and the communities in which it operates. A company cannot have achieved maximum economic function unless it has survived trade cycles, met competition, developed and replaced management, and earned a reputation among its various publics.

CORPORATE STRUCTURE

The corporate structure review evaluates the effectiveness of the structure through which a company's management seeks to fulfill its aims. An organization's structure must strengthen decision-making, permit control of the company, and develop the areas of responsibility and authority of its executives. These requirements must be met regardless of the type of company. Companies that have established product divisions or other forms of organization have maximized the delegation of authority, but have not reduced the need for a clear understanding of authority.

Companies are generally decentralized after the lines of authority have been established; but even large companies have endured conflicts as the result of a breakdown in the acceptance of authority. An example of this is General Motors in the early 1920s, when the company endured an $85 million inventory loss because division leaders did not accept the authority of principal executives.

HEALTH OF EARNINGS

The health of earnings function analyzes corporate income in a historical and comparative aspect. The question this function seeks to answer is whether assets have been employed for the full realization of their potential. This can be assessed by a study of the risk assumed in the employment of resources, in the profit returns upon employment, and the distribution of assets among various categories. The actual value of the assets may not be able to be determined, but a company can trace the cost of

acquisitions, rate of depreciation, and the extent to which assets have been fully profitable or not. The information needed for this category can usually be found within the company's annual reports.

SERVICE TO STOCKHOLDERS

The evaluation of a company's service to its shareholders can be assessed in three areas: (1) the extent to which stockholders' principal is not exposed to unnecessary risks; (2) whether the principal is enhanced as much as possible through undistributed profits; and (3) whether stockholders receive a reasonable rate of return on their investment through the form of dividends.

The evaluation also covers the quality of service provided by the company to its stockholders, mainly in the form of information and advice about their holdings. Although companies and industries vary widely on the amount of earnings they can pay out in the form of dividends, the rate of return and capital appreciation are the most important indicators of fairness to stockholders.

RESEARCH AND DEVELOPMENT

The evaluation of research and development is essential because it is often responsible for a company's growth and improvement in its industry. Analyzing research results can show how well research dollars have been utilized, but it does not show whether management has realized the maximum from its potential. Just like health of earnings, research should be examined from a historical and comparative standpoint in dollars expended; the number of research workers employed; the ratio of research costs and staff to total expenses; and new ideas, information, and products turned out. The examination of these figures compared with past results show management's willingness to employ research for future growth and health.

The American Institute of Management's evaluation attempts to determine what part of the company's past progress can properly be credited to research and how well research policies are preparing the company for future progress.

DIRECTORATE ANALYSIS

Directorate analysis covers the quality and effectiveness of the board of directors. Three principal elements are considered in the evaluation of the board. First, the quality of each director is assessed along with the quality and quantity of the contributions he or she makes to the board. Second, how well the directorate works together as a team is evaluated. Third, the directors are assessed to determine if they truly act as trustees for the company and act in the shareholders' best interest. This can best be examined in areas where a conflict of interest exists between a company's executives and its owners and public. One of the best areas to evaluate is corporate incentives. The manner in which a board handles conflicts of compensation provides a good key to its value.

FISCAL POLICY

The fiscal policy function of the management audit expresses the past and present financial policies. This function includes the company's capital structure, its organizations for developing fiscal policies and controls, and the application of these policies and controls in different areas of corporate activity.

PRODUCTION EFFICIENCY

Production efficiency is an important function for manufacturing companies as well as non-manufacturing companies. Production efficiency is divided into two parts. The first part, machinery and material management, evaluates the mechanical production of the company's products. The second aspect, manpower management, includes all personnel policies and practices for non-sales and non-executive employees developed by management. Only when both parts are analyzed can an overall evaluation of production be effectively performed.

SALES VIGOR

Sales vigor can be evaluated even though sales practices vary widely among industries. This can be accomplished after marketing goals have been determined and assessed. The goals must be assessed in terms of the overall goals of the company. Historical and comparative data are then analyzed to evaluate how well past sales potential has been realized and how well present company sales policies prepare the organization to realize future potential.

EXECUTIVE EVALUATION

Executive evaluation is the most important function of the management audit. The other nine functions indirectly evaluate the organization's management, since they represent the results of management's decisions and actions. This function addresses the quality of the executives and their management philosophy.

The American Institute of Management has found that the three essential elements in a business leader are ability, industry, and integrity. These elements provide a framework for the executive's evaluation in the management audit and should also be the criteria used in selecting and advancing executives. As a group, executives must regard the continuity of the organization as an important goal, assuring it by sound policies of executive selection, development, advancement, and replacement.

The most important management audit activity is an internal audit function. Each enterprise must have an independent source for developing and verifying controls, above and beyond what the external auditors might do in a financial audit. The internal audit function provides managers with the most appropriate avenue for evaluating the achievements of an organization in terms of operational efficiency, regulatory compliance, and financial success. Kaggerman, Kinney, and Kuting note that as a key component of the internal monitoring systems in organizations, an internal audit consists of predetermined measures aimed at securing assets and guaranteeing efficiency of the accounting systems of organizations.

The importance of the internal audit function in organizations is further demonstrated by the formulation of standards and regulatory frameworks for implementing internal controls in business organizations in the United States. The Sarbanes-Oxley Act and the New York Stock Exchange Listing Standards are some of the regulatory standards for internal controls designed to protect the financial interests of the organizations and investors.

The Sarbanes-Oxley Act provides a regulatory benchmark against which managers can compare the results of the internal policies of organizations. The Act was enacted by the U.S. Congress following the unearthing of grand accounting scandals in major U.S companies in the beginning of the twenty-first century. The internal audit section of the Sarbanes-Oxley Act requires managers to validate financial statements as well as ascertain and report the validity of internal controls over the organization's financial records. The internal audit function is also a compulsory prerequisite requirement for all companies listed in the New York Stock Exchange.

The functions of the management audit remain the same regardless of the type of business. Management audit is a very important exercise that managers can use to analyze the successes and failures of the overall objectives of a business organization. Regular and clearly defined management audits enable managers to identify risk factors that inhibit productivity in the organization and develop appropriate strategies for intervening against such risks. In order to get good results, companies must

observe principles of sound management; the degree to which they succeed can be appraised by systems such as the one outlined here.

MANAGEMENT AWARDS

One indicator of the growing recognition of management as a field of great importance has been the proliferation of prizes that various governments award their most outstanding organizations. Such official recognition of management practice, quality, and contribution to business reflects the belief at the highest levels that good management practice can be learned and nurtured through promoting awareness of best practices and innovative techniques.

THE FIVE MAJOR AWARDS

The five most prestigious management awards are Japan's Deming Prize, the United States' Malcolm Baldrige National Award, the EFQM Excellence Award (formerly the European Quality Award), the Canada Awards for Excellence, and the Akao Prize.

The first widely esteemed management award, Japan's Deming Prize, was only established in 1950. For nearly three decades, the Deming Prize stood essentially alone as a major prize for business management practice.

With the enormous success of Japanese industry in the late twentieth century, interest in Japanese business practices grew, including Japan's recognition of business successes. By the 1980s, Japan's success at international trade was admired worldwide, and Japanese business began to find emulators. Subsequently, the United States and Europe set up their own equivalents to the Deming

Prize to honor their own businesses. The United States established the Malcolm Baldrige National Quality Award in 1989, and soon after the twelve nations of the European Community (now the European Union) jointly created the European Quality Awards in 1990, awarding the first recipient in 1992.

The Deming Prize. The Japanese Union of Scientists and Engineers (JUSE) created the first major management award, the Deming Prize, to recognize "contributions to quality and dependability of product." The award is still generally held as the most prestigious of all management awards and is generally recognized as the most highly esteemed business award offered in Japan. The JUSE instituted the award in 1950 and began awarding the prize annually in 1951.

Interestingly, this most significant of Japan's business awards honors an American, Dr. W. Edwards Deming. Many Japanese government and academic leaders credit Deming with revolutionizing Japanese postwar industry through his advocacy in Japan of quality control and managerial efficiency.

The JUSE's Deming Prize Committee administers two types of awards honoring Deming: the Deming Prize and the Deming Application Prize. The Deming Prize is given to a person or group of people who have advanced the practice and furthered awareness of total quality control (TQC). The Deming Application Prize, in turn, goes only to companies based on successes attributable to implementing TQC.

Beginning in 1970, the JUSE began to offer the Japan Quality Control Medal. Only those who have formerly won a Deming Application Prize five years or more earlier are eligible for the Quality Control Medal. The medal is intended to upgrade the quality control of former prize recipients. To this end, the criteria for the Quality Control Medal remain the same as those for the Deming Application Prize, and the medal is awarded at the same time as the other Deming Prize awards. The current aim of the examination is to find out how well a company implements total quality control by assessing its quality-assurance policies and activities, and by measuring the company's results in the areas of productivity improvement, quality improvement, cost reduction, expanded sales, and increased profits.

The Deming Institute also offers a Quality Control Award for specific parts of an organization. Originally titled the Quality Control Award for Factories, it was later renamed the Quality Control Award for Operations Business Units. Mitsubishi's Fobe shipyard won the first award in 1973. Historically, this award has gone to manufacturing operations, such as specific plants of companies like Nissan or the Japan Steel Works. However, Suntory's Yamanashi Winery won in 1990, and in 2002 and 2003, Indian operations won the award.

Non-Japanese companies were allowed to apply for and receive the Deming Prize starting in 1984; the categories that remain unavailable to non-Japanese companies include the individual prize and the factory award. In 1989, Florida Light and Power became the first U.S. company to be named.

Though historically Japanese companies have been winners of the Deming prizes, a slight, though growing, presence of international winners hints at the growing globalization of the business scene. In 2002, the Sanden Corporation's Sundaram-Clayton Brakes Division in India won the Japan Quality Medal. Since then, a Thai company as well as another Indian company have won the award.

Malcolm Baldrige National Quality Award. The U.S. Congress created the Malcolm Baldrige National Quality Award in 1987 largely as a counterpart to Japan's Deming Prize. The specific goal of the Baldrige Award is to heighten U.S. awareness of TQM and to formally recognize successful quality management systems. The award is named for the U.S. Secretary of Commerce from 1981 to 1987. Baldrige was actually helping draft the creation of the award at the time of his death in a rodeo accident.

The U.S. Commerce Department's National Institute of Standards and Technology (NIST) administers the Baldrige Award. The NIST presents up to two awards each in three divisions: manufacturing, service, and small business. The NIST gave its first awards in 1988.

The Baldrige Award judges results companies have shown through management practices in seven specific areas. These are (1) leadership, (2) information and analysis, (3) strategic planning, (4) human resource focus, (5) process management, (6) business results and company performance, and (7) customer focus and satisfaction.

In addition to evaluating traditional for-profit businesses in the United States, the Baldrige Award features several different categories for judging, each with their own award. They are: (1) small business, (2) healthcare, and (3) nonprofit organizations. Like the Deming Prize, the award may be won by a foreign-owned company, but unlike the Deming Prize only those foreign-owned companies with more than 50 percent of their employees or physical assets located in the United States are eligible.

In addition to its more parochial focus, the Baldrige differs from the Deming Prize in three significant ways. First, the Baldrige Award emphasizes customer perceptions and the bottom line emphasizing clear-cut results through its seven specific areas. This makes the Baldrige more objective-oriented than the more systemic focus of the Deming Prize.

Second, while the NIST is an independent agency, the Baldrige relies on a wide array of professional groups to decide on its winners, while from its inception the Deming Prize has relied solely on the JUSE. The Baldrige is consequently able to draw on a wider range of expertise among its judges than the Deming Prize, but may be more open to charges of conflict of interest among the reviewers.

Finally, the Baldrige Award has a stated objective of sharing information while the Deming Prize does not. Consequently, the Baldrige is more likely to make known to other companies how the winners have achieved their success so that others may emulate them; the Deming Prize is more proprietary, allowing winners more readily to keep company secrets if they wish, thus widening the field of companies that may wish to participate but simultaneously limiting the benefit to other companies and to the dissemination of TQM principles in general.

The EFQM Excellence Awards. By 1990, the European Community (now the European Union) felt that it had fallen behind Japan and the United States in the recognition of quality management. In that year, the European Foundation for Quality Management (EFQM), with support from the European Organization for Quality and the European Commission, set about to create its own Deming or Baldrige equivalent, The European Quality Awards. The first winners were announced in October 1992. The award was later renamed the EFQM Excellence Award.

The initial awards favored larger, for-profit companies, so by 1996 the European Commission began to give out additional awards for public sector organizations and for small- to mid-sized enterprises. The awards also have a category for operational units of companies, such as factories, research units, or assembly plants.

The EFQM Excellence Awards, regardless of category, judges applicants on nine criteria: (1) leadership, (2) people management, (3) policy and strategy, (4) resource management, (5) process management, (6) customer satisfaction, (7) people satisfaction (defined as the perception of people toward the organization), (8) impact on society, and (9) business results.

While the categories essentially copy those of the Baldrige Award, the emphasis on people's perceptions of the organization and of the organization's impact on society are unique to the European Quality Awards and add a societal element lacking in either the Deming or Baldrige Awards. The EFQM Excellence Awards also differ from the Deming and Baldrige, as noted earlier, in the various categories for eligible organizations. The EFQM Excellence Awards also differ in the nature of their awards jury, which is made up of business leaders as well as academics. Finally, by its nature, the European Union is more international than either Japan or the United States, and from the start, the award has been open to companies outside the European Union. Still, the

Chart 1
The European Model for Small and Medium Sized Enterprises

People Management 90 Points (9%)		People Satisfaction 90 Points (9%)
Leadership 100 Points (10%)	Strategy & Planning 80 Points (8%)	Quality System & Processes 140 Points (14%)	Customer Satisfaction 200 Points (20%)	Business Results 150 Points (15%)
	Resources 90 Points (9%)		Impact on Society 60 Points (6%)

Enablers - 500 points, 50% ←→ Results - 500 points, 50%

award is limited to those companies that have at least 50 percent of their activities in Europe. 2007 winners included companies from Northern Ireland, Spain, and Italy.

Applications to the program are examined by a team of six assessors, each of whom undergo training to ensure a high level of consistency in scoring. Assessors include some academics and quality professionals, but most are drawn from the ranks of experienced practicing managers from European countries. The application is assessed and scored on a scale from 0 to 1,000 points. Chart 1 illustrates the scoring system for the small- and medium-sized company award. The awards committee also looks for systematic change throughout an organization. The award's brochure states that an organization should demonstrate "systematic improvement" for a minimum of five years.

The Canada Awards for Excellence. After Japan established the Deming Prize, Canada was the next major industrialized nation to establish an award honoring managerial practice. Even then, it was not until 1983 that the federal government of Canada created the Canada Awards for Excellence. For the first ten years, the Canada Awards for Excellence were administered by the Canadian government directly. In 1993, Canada handed the administration of the award over to the National Quality Institute, a Canadian nonprofit organization.

From the beginning, the Canada Awards for Excellence differed from the Deming Prizes in significant ways that in some respects laid the foundation of the Baldrige and European Quality Awards. The Canada Awards for Excellence were from their inception more results-oriented than the Deming Prize and in this respect served as a blueprint for the Baldrige Award's results orientation. Indeed, the Canada Awards for Excellence have been judging nominees on their "Seven Drivers" as the criteria for excellence six years before the first Baldrige Award was given for its seven factors. Indeed, most of the Canadian Awards' Seven Drivers are the same as what the Baldrige Award would later adopt. The Canadian Seven Drivers are (1) leadership, (2) planning, (3) customer focus, (4) people focus, (5) process management, (6) supplier focus, and (7) organizational performance.

Similarly, the Canada Awards for Excellence foreshadowed the broader reach of the European award program. From their beginning, the Canadian Awards have been open to both public and private sector organizations that contribute to the nation's economic success. In this respect, the Canada Awards for Excellence foreshadow the decision in Europe over a decade later to expand the scope of the European Quality Awards from solely for-profit companies to include public sector organizations.

In many respects, the Canada Awards for Excellence are as significant as their better known counterparts in Japan, the United States, and Europe, but remain more limited in scope simply because of Canada's relatively small population. Still, the Canada Awards for Excellence are highly

Figure 1
Major Management Prizes

Prize	Year Established	Administering Organization
Deming Prize	1951	Japanese Union of Scientists and Engineers (JUSE)
Franze Edelman Award for Management Science Achievement	1975	Institute for Operations Research and the Management Sciences
Canada Quality Awards for Excellence	1983	National (Canadian) Quality Institute (since 1993)
Shingo Prize for Excellence in Manufacturing	1988	National (US) Association of Manufacturers
Malcolm Baldridge National Quality Award	1989	National Institute of Standards and Technology (NIST); US Department of Commerce
European Quality Awards	1990	European Foundation for Quality Management
ESCAP Human Resources Development Award	1990	United Nations Economic and Social Commissions for Asia and the Pacific (ESCAP)
INFORMS Award	1991	Institute for Operations Research and the Management Sciences
EUCUSA Award	1997	European Customer Satisfaction Association
Canada Healthy Workplace Award	1999	National (Canadian) Quality Institute

regarded within Canada itself, and since their founding over 300 people and organizations have received the award.

Until 1999, Canada offered only one Award for Excellence: the Quality Award. Beginning in 1999, Canada broke new ground by offering a second award previously unprecedented elsewhere in national awards, the Healthy Workplace Award. The Healthy Workplace Award recognizes organizations that "promote, encourage, support and offer exemplary health-related programs in the workplace," judging the organization in five areas: (1) leadership, (2) planning, (3) people focus, (4) process management, and (5) outcomes.

Akao Prize. In 1996, the QFD (or Quality Function Deployment) Institute established the Akao Prize to recognize individuals who have made an "outstanding contribution to the advancement of QFD." The award roughly follows the pattern of the Deming award but differs from other quality awards not only in focusing exclusively on QFD, but in recognizing only individuals, and not organizations as a whole. The prize was named for Dr. Yoji Akao, himself a Deming Award winner and one of the seminal developers of the field of QFD. Dr. Akao sits on the awards committee and personally hands out the award at the annual ceremony.

Unlike other prominent management awards, the Akao Prize has had an international character since its inception. The first recipients were from both Japan and the United States. Since 1996, the prize has been awarded to individuals from countries such as Sweden, Germany, Australia, and Mexico.

OTHER QUALITY AWARDS

The success of the major awards in attracting attention to management excellence in Japan, the United States, the European nations, and Canada has promoted widespread interest in other nations as well as state awards within the United States, provincial awards within Canada, and individual national awards within Europe (as shown in Figure 1).

Australia. Australia established its Australian Quality Awards for Business Excellence in 1991. The award is somewhat unique in that it has four tiers of recognition, nurturing companies to maintain ongoing quality management excellence. The first tier is the Business Improvement Level, giving first-level recognition for Progress or Foundation in Business Excellence. The next level, The Australian Quality Award for Business Excellence, is a best practices achievement award. The third level is the Australian Quality for Business Excellence Gold Award, open only to past award winners and intended to demonstrate ongoing improvement. The highest level is the Australian Quality Prize,

which is also open only to former winners and represents best practices internationally throughout the company.

At the awards, organizations can receive kudos via recognition either as a finalist or a winner. Figure 2 depicts the hierarchy of recognition. Winners gain the right to use the Australian Quality Awards for Business Excellence logo for three years.

New Zealand. The New Zealand Quality Foundation established the New Zealand Excellence Award in the late 1990s. Like its Australian counterpart, it is a tiered award, although with three rather than four tiers.

Europe. Several European countries have national prizes honoring business excellence and quality management in their nation. Among these are Denmark's *Den Danske Kvalitets Pris* (the Danish Quality Award), the Dutch *Nederlandse Kwaliteitprijs* (Netherlands Quality Award), Ireland's Business Excellence Award, and Switzerland's *Esprix* award, also known as the *Schweizer Qualitätspreis für Business Excellence* (Swiss Quality Award for Business Excellence). The United Kingdom Quality Award for Business Excellence, established in 1994 by the president of the U.K. Board of Trade, was extended beyond for-profit organizations in 1995 to include categories not only for public organizations but, somewhat uniquely, also for voluntary services.

Even some regions within European nations (for example, Northern Ireland within the United Kingdom, and Flanders within Belgium) have begun to offer their own quality management prizes. Most of these competitions use the same guidelines as those used in the European Quality Awards.

United States. Soon after the introduction of the Baldrige awards, a majority of the states began to offer their own awards. The oldest of these was the Connecticut Quality

Improvement Award, begun in 1987, and so actually preceding the Baldrige Award by a year. Yet within ten years, Connecticut was just one of forty-one states offering their own awards for excellence, most based at least in part on the Baldrige Award criteria. Several of these awards modified the Baldrige qualifications to include government, educational, or nonprofit organizations. Several awards from the larger states such as the Texas Quality Award and California's Eureka Award for Quality have tiered levels similar to the Australian Quality Awards described above.

Also notable is the Massachusetts Quality Award, established in 1992. The Massachusetts award is named for Armand Feigenbaum, the Massachusetts native whose book *Total Quality Control* (1951) founded the TQM movement. Most of the state awards are at least partially and usually entirely government funded. Maine's Margaret Chase Smith Maine State Quality Award, however, is unique in that it is entirely privately funded, which its organizers argue makes it freer from political considerations.

In addition to state-sponsored awards, several federal departments offer quality awards. For example, the U.S. Department of Energy Quality Accomplishment Award, begun in 1995, uses the Baldrige Award as its guidelines. The DOE Quality Accomplishment Award is administered by the Department of Commerce (and so independent of the DOE itself).

Similarly, the federal Office of Personnel Management annually offers the President's Award for Quality. The OPM's President's Award also uses the Baldrige Award criteria. The award recognizes federal agencies that have successfully implemented total quality management programs.

Canada. In addition to the national Canada Awards for Excellence, the provinces of Manitoba and British Columbia offer their own awards. Additionally, Ontario's Durham region also offers its own award.

OTHER COUNTRIES

The Singapore Productivity and Standards Board in 1994 began the Singapore Quality Award to recognize organizations in Singapore for outstanding quality management practices and to enhance Singapore's competitiveness in the global market. Its model uses seven categories for comparing best practices and performances.

In 1995 the Japan Productivity Center for Socio-Economic Development established the Japan Quality Award to be awarded to companies excelling through strong customer focus, competitiveness, employee orientation and social responsibility.

The Costa Rica Excellence Award, a joint effort of the Costa Rican Chamber of Industries and Baxter, Firestone, and Intel, evaluates companies using the parameters of ISO 9000 and ISO 14000 standards.

The South African Excellence Award focuses on companies attaining customer satisfaction and is awarded by the South African Excellence Foundation.

The Jordan's King Abdullah II Award for Excellence is the highest level recognition for companies in Jordan. It is aimed at increasing competitiveness by promoting quality awareness, performance, and achievement.

Other management national awards include the Dubai International Award for Best Practices and the Rajiv Gandhi National Quality Awards in India.

AWARDS FOR OTHER MANAGEMENT AREAS

Many awards exist for other areas besides quality management. These awards range from teamwork issues to customer satisfaction and from manufacturing excellence to operations research management.

AQP National Team Excellence Award. The Association for Quality and Participation annually awards teams within organizations for improving quality through participative teamwork for problem-solving, innovation, or improvement of an existing product, service, or process. The focus of the award is primarily for the United States.

The INFORMS Prize. Since 1991, The Institute for Operations Research and the Management Sciences (INFORMS) has annually awarded their INFORMS Prize to a selected organization for pioneering efforts in the innovation of operations research/management sciences. In 1994, the award took its present name; from 1991 to 1994 the prize had been known as the ORSA Prize.

Franz Edelman Award. In addition to the INFORMS Prize, the Institute for Operations Research and the Management Sciences has, since 1975, annually given out the Franz Edelman Award for Management Science Achieve-

ment to reward "outstanding examples of management science and operations research practice in the world." Though several Edelman Awards are given each year, the first-place prize carries a substantial $10,000 purse.

Frank P. Ramsey Medal. The Decision Analysis Society awards the Frank P. Ramsey Medal annually to recognize major contributions to the field of decision analysis. The medal is the most recognized decision-analysis award and takes its name from the Cambridge University probability expert who helped found the field.

Shingo Prize. In 1988, the National Association of Manufacturers established the Shingo Prize for Excellence in Manufacturing. The Shingo Prize is administered by the NAM through the Utah State University College of Business, but is not linked substantively to the state of Utah. Also, while the prize has traditionally been awarded to U.S. companies, it is open to Canadian and Mexican manufacturers as well. The prize honors manufacturers for excellence in productivity and process improvement, quality enhancement, and customer satisfaction. The Shingo Prize rewards "focused improvements in core manufacturing processes, implementing lean, just-in-time philosophies and systems, eliminating waste, and achieving zero defects, while continuously improving products and costs."

EUCUSA Award. The European Customer Satisfaction Association (EUCUSA) began in 1997 to give awards annually to recognize European organizations and companies for achievements in improving customer satisfaction. The award categories are for large and small enterprises, nonprofit organizations, and cities or communities.

Ishikawa Prize. The Ishikawa Prize has been awarded annually since 1970 to recognize companies that have applied new methods or systems of management. The award is given by the same organization that gives the Deming Prize, the JUSE. Ichiro Ishikawa, for whom the award is named, was the first chairman of the JUSE's Board of Directors.

ESCAP Award. The United Nations Economic and Social Commission for Asia and the Pacific (ESCAP), in accordance with the Jakarta Plan of Action on Human Resources Development, created the ESCAP Human Resources Development Award in 1990. The award is open to organizations in over fifty Asian or Pacific Island nations or territories belonging to the United Nations. The award annually recognizes exceptional work in the field of human resources development (HRD). In addition to the annual honoring ceremony in Bangkok, the winner receives $30,000 for the continuance of their project.

The ESCAP HRD Award has a theme each year. Some years the theme is less closely related to business

initiatives than in others. For example, the theme in 1990 emphasized environmental management; the theme in 1992, drug abuse management; and the theme in 1998, education. Still, in most years, the award has recognized HRD for business initiatives. For example, the theme in 1994 was for "Human Resource Development for Women in Extreme Poverty," which was won by the Dhaka Ahsania Mission of Bangladesh. Similarly, the theme in 1995 had a primarily business focus, "HRD for Productive Employment of Youth," and was won by the "Barefoot College" of India's Social Work and Research Centre. In 1996 the theme was "People's Participation in Community Development," won by the Sungi Development Foundation of Pakistan; and in 1997, the theme was "Empowering the Urban Poor," won by Thailand's Human Development Centre.

SHRM Awards for Professional Excellence. The Society for Human Resource Management annually gives out four Awards for Professional Excellence. The four categories are for educators and for large, medium, and small organizations.

ASTD Awards. The American Society for Training and Development offers several awards in three different categories annually. The three categories are (1) Advancing Workplace Learning and Performance; (2) Excellence in Practice; and (3) Advancing ASTD's Vision.

The Advancing Workplace Learning and Performance Awards category includes awards for Distinguished Contribution, for Lifetime Achievement, for Champion of Workplace Learning and Performance, for Research, for Dissertation, and for Public Policy. Recipients have been of very high caliber, including in 1997 alone such figures as management authors Peter Senge and Peter Drucker, General Electric CEO Jack Welch, Senator Patrick Moynihan (New York), Senator William Roth (Delaware), Congressman Clay Shaw (Florida), and Congressman Sander Levin (Michigan).

The Excellence in Practice Awards category covers contributions in applied training in development in different areas including learning technologies, performance improvement, managing change, valuing differences, career development, organizational learning, and technical training. The Vision Awards category covers contributions to the ASTD as an organization.

MANAGEMENT CONTROL

Management control describes the means by which the actions of individuals or groups within an organization are constrained to perform certain actions while avoiding other actions in an effort to achieve organizational goals. Management control falls into two broad categories—regulative and normative controls—but within these categories are several types.

The following section addresses regulative controls including bureaucratic controls, financial controls, and quality controls. The second section addresses normative controls including team norms and organization cultural norms.

Table 1
Types of Control

Regulative Controls	Normative Controls
Bureaucratic Controls	Team Norms
Financial Controls	Organizational Cultural Norms
Quality Controls	

<div style="border:1px solid">

Table 2

Definition and Examples of Regulative Controls

Type of Regulative Control	Definition	Example
Bureaucratic Controls	Policies and operating procedures	Employee handbook
Financial Controls	Key financial targets	Return on investment
Quality Controls	Acceptable levels of product or process variation	Defects per million

</div>

REGULATIVE CONTROLS

Regulative controls stem from standing policies and standard operating procedures, leading some to criticize regulative controls as outdated and counterproductive. As organizations have become more flexible in recent years by flattening organizational hierarchies, expanding organizational boundaries to include suppliers in inventory management and customers in new product development, forging cooperative alliances with competitors, and developing virtual organizations in which employees are geographically dispersed and may meet only a few time each year, critics point out that regulative controls may prevent rather than promote goal attainment.

There is some truth to this. Customer service representatives at Holiday Inn are limited in the extent to which they can correct mistakes involving guests. They can move guests to a different room if there is excessive noise in the room next to the guest's room. In some instances, guests may get a gift certificate for an additional night at another Holiday Inn if they have had a particularly bad experience. In contrast, customer service representatives at Tokyo's Marriott Inn have the latitude to take up to $500 off a customer's bill to solve complaints.

The actions of customer service representatives at both Holiday Inn and Marriott Inn must follow policies and procedures, yet those at Marriott are likely to feel less constrained and more empowered by Marriott's policies and procedures compared to Holiday Inn customer service representatives. The key in terms of management control is matching regulative controls such as policies and procedures with organizational goals such as customer satisfaction. Each of the three types of regulative controls discussed in the next few paragraphs has the potential to align or misalign organizational goals with regulative controls. The challenge for managers is striking the right balance between too much control and too little.

BUREAUCRATIC CONTROLS

Bureaucratic controls stem from lines of authority and this authority comes with one's position in the organizational hierarchy. The higher up the chain of command, the more an individual will have authority to dictate policies and procedures. Bureaucratic controls have gotten

a bad name and often rightfully so. Organizations placing too much reliance on chain of command authority relationships inhibit flexibility to deal with unexpected events. However, there are ways managers can build flexibility into policies and procedures that make bureaucracies as flexible and as able to quickly respond to customer problems as any other form of organizational control.

Consider how hospitals, for example, are structured along hierarchical lines of authority. The Board of Directors is at the top, followed by the CEO and then the Medical Director. Below these top executives are vice presidents with responsibility for overseeing various hospital functions such as human resources, medical records, surgery, and intensive care units. The chain of command in hospitals is clear; a nurse, for example, would not dare increase the dosage of a heart medication to a patient in an intensive care unit without a physician's order. Clearly, this has the potential to slow reaction times—physicians sometimes spread their time across hospital rounds for two or three hospitals and also their individual office practice. Yet, it is the nurses and other direct care providers who have the most contact with patients and are in the best position to rapidly respond to changes in a patient's condition.

The question bureaucratic controls must address is: How can the chain of command be preserved while also building flexibility and quick response times into the system? One way is through standard operating procedures that delegate responsibility downward. Some hospital respiratory therapy departments, for example, have developed standard operating procedures (in health care terms, therapist-driven protocols or TDPs) with input from physicians.

TDPs usually have branching logic structures requiring therapists to perform specific tests prior to certain patient interventions to build safety into the protocol. Once physicians approve a set of TDPs, therapists have the autonomy to make decisions concerning patient care without further physicians' orders as long as these decisions stay within the boundaries of the TDP. Patients need not wait for a physician to make the next set of rounds or patient visits, write a new set of orders, enter the orders on the hospitals intranet, and wait for the manager of respiratory therapy to schedule a therapist to perform the intervention. Instead, therapists can respond

immediately because protocols are established that build in flexibility and fast response along with safety checks to limit mistakes.

Bureaucratic control is thus not synonymous with rigidity. Unfortunately, organizations have built rigidity into many bureaucratic systems, but this need not be the case. It is entirely possible for creative managers to develop flexible, quick-response bureaucracies.

FINANCIAL CONTROLS

Financial controls include key financial targets for which managers are held accountable. These types of controls are common among firms that are organized as multiple strategic business units (SBUs). SBUs are product, service, or geographic lines having managers who are responsible for the SBU's profits and losses. These managers are held responsible to upper management to achieve financial targets that contribute to the overall profitability of the corporation.

Managers who are not SBU executives often have financial responsibility as well. Individual department heads are typically responsible for keeping expenses within budgeted guidelines. These managers, however, tend to have less overall responsibility for financial profitability targets than SBU managers.

In either case, financial controls place constraints on spending. For SBU managers, increased spending must be justified by increased revenues. For departmental managers, staying within budget is typically one key measure of periodic performance reviews. The role of financial controls, then, is to increase overall profitability as well as to keep costs in line. To determine which costs are reasonable, some firms will benchmark other firms in the same industry. Such benchmarking, while not always direct comparison, provides at least some evidence to determine whether costs are in line with industry averages.

QUALITY CONTROLS

Quality controls describe the extent of variation in processes or products that is considered acceptable. For some companies, zero defects–no variation at all–is the standard. In other companies, statistically insignificant variation is allowable.

Quality controls influence the ultimate product or service outcome offered to customers. By maintaining consistent quality, customers can rely on a firm's product or service attributes, but this also creates an interesting dilemma. An overemphasis on consistency where variation is kept to the lowest levels may also reduce response to unique customer needs. This is not a problem when the product or service is relatively standardized such as a McDonald's hamburger, but may pose a problem when customers have nonstandard situations for which a one-size-fits-all solution is inappropriate. Wealth managers, for example, may create investment portfolios tailored to a single client, but the process used to implement that portfolio, such as stock market transactions, will be standardized. Thus, there is room within quality control for both creativity (such as wealth portfolio solutions), and standardization (such as stock market transactions).

NORMATIVE CONTROLS

Rather than relying on written policies and procedures as in regulative controls, normative controls govern employee and managerial behavior through generally accepted patterns of action. One way to think of normative controls is in terms of how certain behaviors are appropriate and others are less appropriate. For instance, a tuxedo might be the appropriate attire for an American business awards ceremony, but totally out of place at a Scottish awards ceremony, where a formal kilt may be more in line with local customs. However, there would generally be no written policy regarding disciplinary action for failure to wear the appropriate attire, thus separating formal regulative controls from the more informal normative controls.

TEAM NORMS

Teams have become commonplace in many organizations. Team norms are the informal rules that make team members aware of their responsibilities to the team. Although the task of the team may be formally documented and

Table 3
Definition and Examples of Normative Controls

Type of Normative Control	Definition	Example
Team Norms	Informal team rules and responsibilities	Task delegation based on team member expertise
Organizational Cultural Norms	Shared organizational values, beliefs, and rituals	Collaboration may be valued more than individual "stars"

communicated, the ways in which team members interact are typically developed over time as the team goes through phases of growth. Even team leadership must be informally agreed upon; at times, an appointed leader may have less influence than an informal leader. If, for example, an informal leader has greater expertise than a formal team leader, team members may look to the informal leader for guidance requiring specific skills or knowledge. Team norms tend to develop gradually, but once formed, can be powerful influences over behavior.

ORGANIZATIONAL CULTURE NORMS

In addition to team norms, norms based on organizational culture are another type of normative control. Organizational culture involves the shared values, beliefs, and rituals of a particular organization. The Internet search firm, Google, Inc. has a culture in which innovation is valued, the belief that the work of the organization is important is shared among employees, and teamwork and collaboration are common. In contrast, the retirement specialty firm, VALIC, focuses on individual production for its sales agents, de-emphasizing teamwork and collaboration in favor of personal effort and rewards. Both of these examples are equally effective in matching norms with organizational goals; the key is thus in properly aligning norms and goals.

The broad categories of regulative and normative controls are present in nearly all organizations, but the relative emphasis of each type of control varies. Within the regulative category are bureaucratic, financial, and quality controls. Within the normative category are team norms and organization cultural norms. Both categories of norms can be effective and one is not inherently superior to the other. The managerial challenge is to encourage norms that align employee behavior with organizational goals.

MANAGEMENT AND EXECUTIVE DEVELOPMENT

Manager effectiveness has an enormous impact on a firm's success. Therefore, companies must provide instruction for managers and high-potential management candidates in order to help them perform current and future jobs with the utmost proficiency. Management development has long been an important component of corporate strategic planning. In fact, many companies consider the identification and development of next-generation managers to be their top human resource challenge.

Management development is important for new managers because these individuals need instruction on how to perform their new supervisory jobs. Even so, companies often allow employees to make the transition to management with little or no training, leaving them with feelings of frustration, inadequacy, and dismay. More experienced managers also benefit from management development. A majority of first-line managers have their sights set on higher-level management jobs. Given these ambitions, companies need to provide lower-level and mid-level managers with formal development programs in order to help them climb the corporate ladder.

Effective management instruction programs are able to bridge gaps between what individuals already know and what they need to know for their new positions. Managers need different skills at each managerial level. The instructional programs needed to produce these skills are shown in Table 1.

A variety of approaches are used to teach these subjects. Some are in traditional classroom-type settings, while others

---

Table 1

Instructional Needs at Different Managerial Levels

First-line managers need training in
- basic supervision
- motivation
- career planning
- performance feedback

Middle managers need training in
- designing and implementing effective group and intergroup work and information systems
- defining and monitoring group-level performance indicators
- diagnosing and resolving problems within and among work groups
- designing and implementing reward systems that support cooperative behavior

Executives need training in
- broadening their understanding of how factors such as competition, world economies, politics, and social trends influence the effectiveness of the organization

---

are taught outside of the classroom via career resource centers, job rotation, mentoring, and special projects.

CLASSROOM INSTRUCTION

Classroom training takes place within the organization or outside at seminars and universities. The subjects typically covered in these programs are briefly described in Table 2.

Lecture. Most training experts criticize lectures because they are passive learning devices, focusing on one-way communication to learners who do not have the opportunity to clarify material. Lectures generally fail to gain and maintain learner attention unless they are given by someone who is able to make the material meaningful and promote questions and discussions. Lectures are most appropriate for situations where simple knowledge acquisition is the goal (e.g., describing company history during a new employee orientation session). However, lectures are not well suited to serve as the sole training method for teaching management skills, because the format does not provide trainees with feedback or the opportunity for practice.

Case Method. As the name suggests, the case method requires management trainees to analyze cases or scenarios depicting realistic job situations. Cases often are structured like a play that opens in the middle of a story and uses flashbacks to describe the action that led up to the opening scene, where an employee has just made a key decision. The rest of the case lays out the documentation and data available to the decision maker at the time of the decision. Questions are posed at the end of the case that ask the trainees to analyze the situation and recommend a solution. For instance, trainees may be asked to state the nature of the problem, identify the events that led to the problem, and indicate what the individual should do to resolve the problem.

The case method rests on the assumption that people are most likely to retain and use what they learn if they reach an understanding through "guided discovery." Trainers act as guides or facilitators. Cases typically do not have right or wrong answers. Therefore, the aim of the method is not to teach trainees the "right" answer, but rather to teach them how to identify potential problems and recommend realistic actions.

Critics of this method balk at the lack of direction trainees receive when analyzing a case. What if they arrive at a poor decision? Moreover, trainees do not get the opportunity to practice their skills. For instance, after analyzing a case involving a subordinate who has repeatedly arrived at work late, the trainees may conclude that the manager should have said something sooner and must now provide counsel. However, the case method does not afford trainees the opportunity to practice their counseling skills.

Role-playing. As an instructional technique, role-playing presents a hypothetical problem involving human interaction. Trainees spontaneously act out that interaction face-to-face. Participants are then given feedback by the trainer and the rest of the group on their performance so they may gain insight regarding the impact of their behavior on others. The issues addressed during feedback typically revolve around these types of questions:

- What was correct about the participant's behavior?
- What was incorrect about the participant's behavior?
- How did the participant's behavior make the other participants feel?
- How could the trainee have handled the situation more effectively?

Role-playing may be used to develop skill in any area that involves human interaction. The method is most often used for teaching human relations skills and sales techniques. Role-playing provides management trainees with an opportunity to practice the skill being taught, thus going beyond the case method, which merely requires the trainee to make a decision regarding how to handle a situation. These two methods are often used in

---

Table 2

Content Areas of Classroom Instruction

Job Duties and Responsibilities. Trainees learn what they must do to fulfill the company's expectations of them.

Policies and Procedures. Trainees learn company policies and procedures.

Employee Familiarization. Trainees become familiar with the job functions of their employees. The training provides specific instructions on how to review job descriptions, performance standards, personnel files, and so forth.

Attitudes and Confidence. The training attempts to establish new attitudes toward the job employees, and the manager, and to build the confidence necessary for managers to be effective on the job.

Handling Employee Interactions. Trainees are taught how to handle interpersonal problems effectively through such techniques as behavior modeling.

Career Development. Trainees learn about career opportunities in higher levels of management and how they may advance in the future.

General Management Training. These courses typically cover labor relations, management theory and practice, labor economics, and general management functions.

Human Relations/Leadership Programs. These topics are narrower than general management programs. They focus on the human relations problems of leadership, supervision, attitude toward employees, and communication.

Self-Awareness Program. The content of these programs is understanding one's own behavior and how that behavior is viewed by others, identifying the so-called games people play, and learning about one's strengths and weaknesses.

Problem-Solving/Decision-Making Programs. The emphasis is on teaching generalized problem-solving and decision-making skills that would be applicable to the wide range of work problems that managers encounter.

---

conjunction with one another. That is, after analyzing a case and recommending a solution, trainees are asked to act out the solution in the form of a role-play.

Critics of the role-playing method point out that role-players are often given little guidance beforehand on how to handle transactions. This may cause them to make mistakes, resulting in embarrassment and a loss of self-confidence. When their mistake-ridden role-play is finished, they sit, never getting the opportunity to do it correctly.

Behavior Modeling. Behavior modeling is based on the idea that workers learn best when they see how a task should be performed and then practice the task with feedback until they are competent. This method is similar to role-playing in that the trainees act out situations playing certain roles. However, the methods differ in two important ways. First, behavior modeling teaches trainees a preferred way to perform a task. Second, the interactions occurring during behavior modeling are practice sessions, not role plays. The trainees practice only the right way. If the trainees make a mistake, the trainer immediately corrects them and asks them to repeat the step correctly.

A behavior modeling program typically consists of the following steps:

1. **Present an overview of the material.** This usually consists of a brief lecture that describes training objectives and the importance of the skill to be learned.

2. **Describe the procedural steps.** The trainee learns the one best way (or at least an effective way) to handle a situation. Case and role-playing methods, on the other hand, stress the variety of effective ways to handle a situation and do not emphasize any one particular approach.

3. **Model or demonstrate the procedural steps.** The trainee is shown a "model" of how the task is to be performed correctly. The model usually is presented in the form of a videotape or live demonstration.

4. **Allow guided practice.** Trainees then practice the modeled behaviors. As previously stated, these sessions are similar to role-plays, except that trainees are given feedback by the instructor (or classmates) during the skill practice session, rather than after. This procedure forces trainees to correct mistakes as soon as they are made, assuring them an opportunity to practice the correct way of performing the task. Practice sessions start with simple problems similar to those depicted in the model. Later practice sessions are made more realistic by adding complexity to the situation.

5. **Provide on-the-job reinforcement.** Participants' managers often go through identical training programs to ensure that they will understand what their employees are learning and, hence, support these new behaviors on the job.

Behavior modeling, first introduced in the mid-1970s, was very popular by the mid-1990s and continues to be widely used in the twenty-first century. Research examining its effectiveness has consistently shown favorable outcomes. Behavior modeling works because it successfully incorporates each of the aforementioned learning principles: it captures and maintains trainees' attention and provides ample opportunity for practice and feedback.

Recent developments in behavior modeling have led to more action-oriented approaches that synthesize formal training programs and on-the-job learning. Action learning emphasizes learning by doing. It involves bringing together trainers and trainees to analyze actual work problems; they continue meeting as actions are implemented, learning from the results and making mid-course corrections. In their 2007 book on action learning, authors Judy O'Neil and Victoria J. Marsick point out, "As much as adult learners can absorb in a classroom, they learn and retain a lot more on the job."

NONCLASSROOM METHODS

Nonclassroom methods include career resource centers, job rotation, coaching and mentoring, and special assignments.

Career Resource Centers. Some organizations make learning opportunities available to interested candidates by establishing career resource centers, which usually include an in-house library with relevant reading material along with computer and Internet resources for additional materials. In some companies, candidates simply are given recommended readings lists. Other companies provide management candidates with comprehensive career-planning guides that contain company-related information about available resources, career options, and counseling contacts. These individuals also may be given workbooks that provide written assignments.

Job Rotation. Job rotation exposes management trainees to various organizational settings by rotating them through a number of departments. Thus, trainees have an opportunity to gain an overall perspective of the organization and learn how various parts interrelate. Additionally, they face new challenges during these assignments that may foster new skill development.

Trainees usually have full management responsibility during these assignments. For example, in one hospital new department supervisors rotate through all major departments on a monthly basis, serving in a managerial capacity during their "tours." Although they often learn a lot from such training, they also may make harmful mistakes during their learning period because they lack knowledge of the functional area that they are supervising.

Coaching and Mentoring. Coaching is a method of management development that is conducted on the job, in which experienced managers or peers advise and guide trainees in solving managerial problems. Typically, less experienced managers are coached by their direct supervisor or a coworker on their specific performance of managerial tasks. An upper-level manager is likely to coach several lower-level managers at once, offering feedback, helping them to find expert advice, and providing resources.

Mentoring is different from coaching in several ways. Mentors are experienced supervisors who establish close, one-on-one relationships with new managers, called protégés. A mentor usually is someone two or three levels higher in the organization than the protégé who teaches, guides, advises, counsels, and serves as a role model; the mentor is not necessarily the protégé's direct supervisor. Mentoring can help the protégé to form common values with the organization's senior leadership and better understand his or her role in the company. Additionally, protégés are often advocated for and protected by a mentor. A mentor may ensure that the protégé is assigned high-visibility projects, or even change negative opinions about the protégé that may be held by others in the company. While a coach focuses on job-specific advice, a mentor is likely to give advice on a broader range of topics related to the protégé's career success.

Special Assignment. Companies sometimes assign special, nonroutine job duties to trainees in order to prepare them for future assignments. One such special project is called action learning, which derives its name from the fact that the trainees can learn by doing. Candidates are given real problems generated by management. Trainees might be given a written assignment that specifies objectives, action plans, target dates, and the name of the person responsible for monitoring the completion of the assignment. For instance, trainees might be asked to study the company's budgeting procedures and submit a written critique.

Another type of special project is the task force, where trainees are grouped together and asked to tackle an actual organizational problem. For example, the task force may be asked to develop a new performance appraisal form, solve a quality problem, or design a program to train new employees. Trainees not only gain valuable experience by serving on a task force, they also have the opportunity to improve their visibility to others within the organization.

MANAGEMENT SUCCESSION PLANNING

Most organizations base their management development and training efforts on succession planning, a systematic process of defining future management requirements and identifying the candidates who best meet them. Unfortu-

nately, many companies take a very informal approach to succession planning. Identification of high-potential candidates is largely subjective, based on the opinions of the nominating managers, who choose "fast-track" or "superstar" employees with little consideration of the actual requirements of future positions. Research has found that promotions within the management ranks are often based on employee behaviors that have no bearing on managerial effectiveness. Typically, networking had the greatest influence on managerial promotions, even though networking made no contribution to actual performance. Additionally, ill-conceived succession planning activities can have disastrous consequences; as many as 30 percent of all newly placed executives are unprepared for their jobs and ultimately fail to meet company expectations.

Elements of an effective succession planning program involve human resource planning, defining qualifications for positions, identifying career paths, and developing replacement charts. The first step in succession planning is human resource planning, in which forecasting is used to determine projected staffing needs for the next several years. Based on these needs, management succession plans should specify key management positions for which staffing should be targeted. Succession plans should next define pertinent individual qualifications needed for each targeted position, which are based on information derived from a job analysis. A firm then identifies individuals with high potential for promotion into or through the management ranks. This is accomplished by assessing employee abilities and career interests through records of career progress, experience, past performance, and self-reported interests regarding future career steps.

Following the above steps, an organization identifies a career path for each high-potential candidate (i.e., those who have the interest and ability to move upward in the organization). A career path typically appears as a flow chart, indicating the sequencing of specific jobs that may lead one up the organizational ladder to a targeted job. The final step is to develop replacement charts that indicate the availability of candidates and their readiness to step into the various management positions. Such charts usually are depicted as diagrams superimposed onto the organizational chart. These show possible replacement candidates, in rank order, for each management position. Rank orders are often based on the candidates' overall potential scores, derived on the basis of their past performance, experience, test scores, and so on.

MANAGEMENT FUNCTIONS

The functions of management uniquely describe managers' jobs. The most commonly cited functions of management are planning, organizing, leading, and controlling, although some identify additional functions. The functions of management define the process of management as distinct from accounting, finance, marketing, and other business functions. These functions provide a useful way of classifying information about management, and most basic management texts since the 1950s have been organized around a functional framework.

DEVELOPMENT OF THE FUNCTIONAL APPROACH TO MANAGEMENT

Henri Fayol was the first person to identify elements or functions of management in his classic 1916 book *Administration Industrielle et Generale.* Fayol was the managing director of a large French coal-mining firm and based his book largely on his experiences as a practitioner of management. Fayol defined five functions, or elements of management: planning, organizing, commanding, coordinating, and controlling. Fayol argued that these functions were universal, in the sense that all managers performed them in the course of their jobs, whether the managers worked in business, military, government, religious, or philanthropic undertakings.

Fayol defined planning in terms of forecasting future conditions, setting objectives, and developing means to attain objectives. Fayol recognized that effective planning must also take into account unexpected contingencies that might arise and did not advocate rigid and inflexible plans. Fayol defined organizing as making provision for the structuring of activities and relationships within the firm and also the recruiting, evaluation, and training of personnel.

According to Fayol, commanding as a managerial function concerned the personal supervision of subordinates and involved inspiring them to put forth unified effort to achieve objectives. Fayol emphasized the importance of managers understanding the people who worked for them, setting a good example, treating subordinates in a manner consistent with firm policy, delegating, and communicating through meetings and conferences.

Fayol saw the function of coordination as harmonizing all of the various activities of the firm. Most later experts did not retain Fayol's coordination function as a separate function of management but regarded it as a necessary component of all the other management functions. Fayol defined the control function in terms of ensuring that everything occurs within the parameters of the plan and accompanying principles. The purpose of control was to identify deviations from objectives and plans and to take corrective action.

Fayol's work was not widely known outside Europe until 1949, when a translation of his work appeared in the United States. Nevertheless, his discussion of the practice of management as a process consisting of specific functions had a tremendous influence on early management texts that appeared in the 1950s.

Management pioneers such as George Terry, Harold Koontz, Cyril O'Donnell, and Ralph Davis all published management texts in the 1950s that defined management as a process consisting of a set of interdependent functions. Collectively, these and several other management experts became identified with what came to be known as the process school of management.

According to the process school, management is a distinct intellectual activity consisting of several functions. The process theorists believe that all managers, regardless of their industry, organization, or level of management, engage in the functions of management. The process school of management became a dominant paradigm for studying management and the functions of management became the most common way of describing the nature of managerial work.

CRITICISM OF THE FUNCTIONAL APPROACH TO MANAGEMENT

By the early 1970s, some experts suggested that the functions of management as described by Fayol and others of the process school of management were not an accurate description of the reality of managers' jobs. Chief among the critics of the functional approach was Henry Mintzberg.

Mintzberg argued that the functional or process school of management was "folklore" and that functions of management such as planning, organizing, leading, and controlling did not accurately depict the chaotic nature of managerial work. He felt that the functional approach to the managerial job falsely conveyed a sense that managers carefully and deliberately evaluated information before making management decisions.

Based upon an observational study of five executives, Mintzberg concluded that the work managers actually performed could best be represented by three sets of roles,

or activities: interpersonal roles, informational roles, and decision-making roles. He described the interpersonal roles as consisting of figurehead, leader, and liaison. He identified three informational roles: monitor, disseminator, and spokesperson. Finally, he described four decision-making roles that included entrepreneur, disturbance handler, resource allocator, and negotiator.

Mintzberg's challenge to the usefulness of the functions of management and the process school attracted a tremendous amount of attention and generated several empirical studies designed to determine whether his or Fayol's description of the managerial job was most accurate. While this research did indicate that managers performed at least some of the roles Mintzberg identified, there was little in the findings that suggested that the functions of management were not a useful way of describing managerial work.

Scholars continue to debate this question. Research by David Lamond suggests that both approaches had some validity, with Fayol's approach describing the ideal management job and Mintzberg describing the day-to-day activities of managers. Thus, the general conclusion seems to be that while Mintzberg offered a genuine insight into the daily activities of practicing managers, the functions of management still provides a very useful way of classifying the activities managers engage in as they attempt to achieve organizational goals.

PLANNING

Planning is the function of management that involves setting objectives and determining a course of action for achieving these objectives. Planning requires that managers be aware of environmental conditions facing their organization and forecast future conditions. It also requires that managers be good decision-makers.

Planning is a process consisting of several steps. The process begins with environmental scanning, which simply means that planners must be aware of the critical contingencies facing their organization in terms of economic conditions, their competitors, and their customers. Planners must then attempt to forecast future conditions. These forecasts form the basis for planning.

Planners must establish objectives, which are statements of what needs to be achieved and when. They must then identify alternative courses of action for achieving objectives. After evaluating the various alternatives, planners must make decisions about the best courses of action for achieving objectives. They must then formulate necessary steps and ensure effective implementation of plans. Finally, planners must constantly evaluate the success of their plans and take corrective action when necessary.

There are many different types of plans and planning.

Strategic Planning. Strategic planning involves analyzing competitive opportunities and threats, as well as the strengths and weaknesses of the organization, and then determining how to position the organization to compete effectively in their environment. Strategic planning has a long time frame, often three years or more. Strategic planning generally includes the entire organization and includes formulation of objectives. Strategic planning is often based on the organization's mission, which is its fundamental reason for existence. An organization's top management most often conducts strategic planning.

Tactical Planning. Tactical planning is intermediate-range planning that is designed to develop relatively concrete and specific means to implement the strategic plan. Middle-level managers often engage in tactical planning. Tactical planning often has a one- to three-year time horizon.

Operational Planning. Operational planning generally assumes the existence of objectives and specifies ways to achieve them. Operational planning is short-range planning that is designed to develop specific action steps that support the strategic and tactical plans. Operational planning usually has a very short time horizon, from one week to one year.

ORGANIZING

Organizing is the function of management that involves developing an organizational structure and allocating human resources to ensure the accomplishment of objectives. The structure of the organization is the framework within which effort is coordinated. The structure is usually represented by an organization chart, which provides a graphic representation of the chain of command within an organization. Decisions made about the structure of an organization are generally referred to as "organizational design" decisions.

Organizing also involves the design of individual jobs within the organization. Decisions must be made about the duties and responsibilities of individual jobs as well as the manner in which the duties should be carried out. Decisions made about the nature of jobs within the organization are generally called "job design" decisions.

Organizing at the level of the organization involves deciding how best to departmentalize or cluster jobs into departments to effectively coordinate effort. There are many different ways to departmentalize, including organizing by function, product, geography, or customer. Many larger organizations utilize multiple methods of departmentalization. Organizing at the level of job involves how best to design individual jobs to most effectively use human resources.

Traditionally, job design was based on principles of division of labor and specialization, which assumed that the more narrow the job content, the more proficient the individual performing the job could become. However, experience has shown that it is possible for jobs to become too narrow and specialized. When this happens, negative outcomes result, including decreased job satisfaction and organizational commitment and increased absenteeism and turnover.

Recently many organizations have attempted to strike a balance between the need for worker specialization and the need for workers to have jobs that entail variety and autonomy. Many jobs are now designed based on such principles as job enrichment and teamwork.

LEADING

Leading involves influencing others toward the attainment of organizational objectives. Effective leading requires the manager to motivate subordinates, communicate effectively, and effectively use power. If managers are effective leaders, their subordinates will be enthusiastic about exerting effort toward the attainment of organizational objectives.

To become effective at leading, managers must first understand their subordinates' personalities, values, attitudes, and emotions. Therefore, the behavioral sciences have made many contributions to the understanding of this function of management. Personality research and studies of job attitudes provide important information as to how managers can most effectively lead subordinates.

As a new generation of employees enter the workforce, managers must become familiar with the values and norms particular to the demographic. For example, much has been written about how to manage the 80 million workers under the age of 30 known as "millenials" or "Generation Y." Although the group has been stereotyped as self-absorbed and entitled, experts say that this generation is also passionate about teamwork and eager to take on challenges. Such generalizations may be a useful springboard for exploring the relationship between young employees and company culture, but they can easily be misused when relied on without supplemental information.

Studies of motivation and motivation theory provide important information about the ways in which workers can be energized to put forth productive effort. Studies of communication provide direction as to how managers can effectively and persuasively communicate. Studies of leadership and leadership style provide information regarding questions such as, "What makes a manager a good leader?" and "In what situations are certain leadership styles most appropriate and effective?"

CONTROLLING

Controlling involves ensuring that performance does not deviate from standards. Controlling consists of three steps, which include establishing performance standards, comparing actual performance against standards, and taking corrective action when necessary. Performance standards are often stated in monetary terms such as revenue, costs, or profits, but may also be stated in other terms, such as units produced, number of defective products, or levels of customer service. The measurement of performance can be done in several ways, depending on the performance standards, including financial statements, sales reports, production results, customer satisfaction, and formal performance appraisals. Managers at all levels engage in the managerial function of controlling to some degree.

The managerial function of controlling should not be confused with control in the behavioral or manipulative sense. This function does not imply that managers should attempt to control or manipulate the personalities, values, attitudes, or emotions of their subordinates. Instead, this function of management concerns the manager's role in taking necessary actions to ensure that the work-related activities of subordinates are consistent with and contributing toward the accomplishment of organizational and departmental objectives.

Effective controlling requires the existence of plans, since planning provides the necessary performance standards or objectives. Controlling also requires a clear understanding of where responsibility for deviations from standards lies. Two traditional control techniques are the budget and the performance audit. Although controlling is often thought of in terms of financial criteria, managers must also control production/operations processes, procedures for delivery of services, compliance with company policies, and many other activities within the organization.

The management functions of planning, organizing, leading, and controlling are widely considered to be the best means of describing the manager's job as well as the best way to classify accumulated knowledge about the study of management. Although there have been tremendous changes in the environment faced by managers and the tools used by managers to perform their roles, managers still perform these essential functions.

MANAGEMENT INFORMATION SYSTEMS

All businesses share one common asset, regardless of the type of business. It does not matter if they manufacture goods or provide services. It is a vital part of any business entity, whether a sole proprietorship or a multinational corporation. That common asset is information.

Information enables one to determine the need to create new products and services. Information tells companies to move into new markets or to withdraw from other markets. Without information, the goods do not get made, the orders are not placed, the materials are not procured, the shipments are not delivered, the customers are not billed, and the business cannot survive.

But information has far lesser impact when presented as raw data. In order to maximize the value of information, it must be captured, analyzed, quantified, compiled, manipulated, made accessible, and shared. In order to accomplish those tasks, an information system (IS) must be designed, developed, administered, and maintained.

INFORMATION SYSTEMS

An information system is a computer system that provides management and other personnel within an organization with up-to-date information regarding the organization's performance; for example, current inventory and sales. It usually is linked to a computer network, which is created by joining different computers together in order to share data and resources. It is designed to capture, transmit, store, retrieve, manipulate, and or display information used in one or more business processes. These systems output information in a form that is useable at all levels of the organization: strategic, tactical, and operational.

Systems that are specifically geared toward serving general, predictable management functions are sometimes called management information systems (MIS). A good example of an MIS report is the information that goes into an annual report created for the stockholders of a corporation (a scheduled report). The administration of an information system is typically the province of the MIS or information technology (IT) department within an organization.

Some applications have infringed on the familiar MIS landscape. Enterprise resource planning (ERP) software and executive information systems (EIS) both provide packaged modules and programs that perform the same functions as traditional MIS, but with greater functionality, flexibility, and integration capabilities.

Mainframes. The original computerized information systems were based on mainframes. "Mainframe" is a term originally referring to the cabinet containing the central processor unit or "main frame" of a room-filling computer. Firms such as IBM were instrumental in the mid-twentieth century in helping businesses integrate and operate information systems and technology into their business operations. After the emergence of smaller minicomputer designs in the early 1970s, the traditional large machines were described as "mainframe computers," or simply mainframes. The term carries the connotation of a machine designed for batch rather than interactive use, though possibly with an interactive time-sharing operating system retrofitted onto it. It has been conventional wisdom in most of the business community since the late 1980s that the mainframe architectural tradition is essentially dead, having been swamped by huge advances in integrated circuit design technology and low-cost personal computing. Despite this, in the twenty-first century there are still uses for mainframe systems that store vast amounts of data.

The Internet. The Internet has opened up further developments in information systems and the exchange of information via Web-based e-mail, intranets, and extranets. These technologies allow for much faster data and information exchange and greater access for more users. Web-casting and videoconferencing allow for real-time information exchanges. Mobile computing technologies accessed by handheld devices, such as multi-functional mobile phones, personal digital assistants, and podcasting (via iPods), are offering further modes of communication.

Information systems are also crucial if a firm decides to practice telecommuting, or teleworking. Telecommuting is defined as when employees can conduct full operations without being inside the business's office, instead working from a location such as an employee's home.

Telecommuting is seen as an asset both in improving employees' quality of life, and with allowing an organization more flexibility. A 2005 article in *Technovation* noted a firm's ability to adapt to telecommuting as a policy is directly linked to its information technology resources. As some scholars note, these advances in technology can fundamentally change the nature of management.

However, some have also argued that security of a company's data has increased in importance with the increase in information technology. A 2007 *Software World* article stated that such practices as telecommuting make information systems vulnerable to attack. Due to the range of threats to information systems (including viruses and hackers), information security—such as passwords, firewalls, and so forth—are crucial to an organization.

INFORMATION SYSTEM DESIGN AND ADMINISTRATION

The design of an information system is based on various factors. Cost is a major consideration, but there certainly are others to be taken into account, such as the number of users; the modularity of the system, or the ease with which new components can be integrated into the system, and the ease with which outdated or failed components can be replaced; the amount of information to be processed; the type of information to be processed; the computing power required to meet the varied needs of the organization; the anticipated functional life of the system and/or components; the ease of use for the people who will be using the system; and the requirements and compatibility of the applications that are to be run on the system.

There are different ways to construct an information system, based upon organizational requirements, both in the function aspect and the financial sense. Of course, the company needs to take into consideration that hardware that is purchased and assembled into a network will become outdated rather quickly. It is almost axiomatic that the technologies used in information systems steadily increase in power and versatility on a rapid time scale. Perhaps the trickiest part of designing an information system from a hardware standpoint is straddling the fine line between too much and not enough, while keeping an eye on the requirements that the future may impose.

Applying foresight when designing a system can bring substantial rewards in the future, when system components are easy to repair, replace, remove, or update without having to bring the whole information system to its knees. When an information system is rendered inaccessible or inoperative, the system is considered to be "down."

A primary function of maintaining an information system is to minimize downtime, or hopefully, to eradicate downtime altogether. The costs created by a department, facility, organization, or workforce being idled by an inoperative system can become staggering in a short amount of time. The inconvenience to customers can cost the firm even more if sales are lost as a result, in addition to any added costs the customers might incur.

Another vital consideration regarding the design and creation of an information system is to determine which users have access to which information. The system should be configured to grant access to the different partitions of data and information by granting user-level permissions for access. A common method of administering system access rights is to create unique profiles for each user, with the appropriate user-level permissions that provide proper clearances.

Individual passwords can be used to delineate each user and their level of access rights, as well as identify the tasks performed by each user. Data regarding the performance of any user unit, whether individual, departmental, or organizational can also be collected, measured, and assessed through the user identification process.

The open systems interconnection (OSI) seven-layer model attempts to provide a way of partitioning any computer network into independent modules from the lowest (physical/hardware) layer to the highest (application/program) layer. Many different specifications can exist at each of these layers.

A crucial aspect of administering information systems is maintaining communication between the IS staff, who have a technical perspective on situations, and the system users, who usually communicate their concerns or needs in more prosaic terminology. Getting the two sides to negotiate the language barriers can be difficult, but the burden of translation should fall upon the IS staff. A little patience and understanding can go a long way toward avoiding frustration on the part of both parties.

There is more to maintaining an information system than applying technical knowledge to hardware or software. IS professionals have to bridge the gap between technical issues and practicality for the users. The information system should also have a centralized body that functions to provide information, assistance, and services to the users of the system. These services will typically include telephone and electronic mail "help desk" type services for users, as well as direct contact between the users and IS personnel.

INFORMATION SYSTEM FUNCTIONS

Document and record management. Documenting and recording management may well be the most crucial aspect of any information system. Some examples of types of information maintained in these systems would be accounting, financial, manufacturing, marketing, and human resources. An information system can serve as a library. When properly collected, organized, and indexed in accordance

with the requirements of the organization, its stored data becomes accessible to those who need the information.

The location and retrieval of archived information can be a direct and logical process, if careful planning is employed during the design of the system. Creating an outline of how the information should be organized and indexed can be a very valuable tool during the design phase of a system. A critical feature of any information system should be the ability to not only access and retrieve data, but also to keep the archived information as current as possible.

Collaborative tools. Collaborative tools can consist of software or hardware, and serve as a base for the sharing of data and information, both internally and externally. These tools allow the exchange of information between users, as well as the sharing of resources. As previously mentioned, real-time communication is also a possible function that can be enabled through the use of collaborative tools.

Data mining. Data mining, or the process of analyzing empirical data, allows for the extrapolation of information. The extrapolated results are then used in forecasting and defining trends.

Query tools. Query tools allow the users to find the information needed to perform any specific function. The inability to easily create and execute functional queries is a common weak link in many information systems. A significant cause of that inability, as noted earlier, can be the communication difficulties between a management information systems department and the system users.

Another critical issue toward ensuring successful navigation of the varied information levels and partitions is the compatibility factor between knowledge bases. For maximum effectiveness, the system administrator should ascertain that the varied collection, retrieval, and analysis levels of the system either operate on a common platform, or can export the data to a common platform. Although much the same as query tools in principle, intelligent agents allow the customization of the information flow through sorting and filtering to suit the individual needs of the users. The primary difference between query tools and intelligent agents is that query tools allow the sorting and filtering processes to be employed to the specifications of management and the system administrators, and intelligent agents allow the information flow to be defined in accord with the needs of the user.

KEY POINTS

Managers should keep in mind the following advice in order to get the most out of an information system:

- Use the available hardware and software technologies to support the business. If the information system does not support quality and productivity, then it is misused.

- Use the available technologies to create and facilitate the flow of communication within your organization and, if feasible, outside of it as well. Collaboration and flexibility are the key advantages offered for all involved parties. Make the most of those advantages.

- Determine if any strategic advantages are to be gained by use of your information system, such as in the areas of order placement, shipment tracking, order fulfillment, market forecasting, just-in-time supply, or regular inventory. If you can gain any sort of advantage by virtue of the use of your information system, use it.

- Use the quantification opportunities presented by your information system to measure, analyze, and benchmark the performances of an individual, department, division, plant, or entire organization.

INFORMATION SYSTEMS AND OUTSOURCING

With companies outsourcing significant portions of their business operations (such as supply chain management), information systems can play an important role. General Motors (GM) is one company that outsourced many of its information technology operations in 2003. Doing so required coordinating operations and information systems among GM's internal IT operations and numerous other companies. One major task in this process has been standardizing information technology and other software processes.

Others note that globalization and, indeed, multinational operations would simply not be possible without sophisticated information systems.

An information system is more than hardware or software. The most integral and important components of the system are the people who design it, maintain it, and use it. While the overall system must meet various needs in terms of power and performance, it must also be usable for the organization's personnel. If the operation of day-to-day tasks is too daunting for the workforce, then even the most humble of aspirations for the system will go unrealized.

A company should not view information systems as ancillary. As management school professor Petter Gottschalk notes, information technology operations should be central to a company's management. The emergence of the CIO, or chief information officer, as a top management position also speaks to the importance of information systems and information technology.

A company will likely have a staff entrusted with the overall operation and maintenance of the system and that staff will be able to make the system perform in the manner expected of it. Pairing the information systems department with a training department can create a synergistic solution to the quandary of how to get non-technical staff to perform technical tasks. Oft times, the individuals staffing an information systems department will be as technical in their orientation as the operative staff is non-technical in theirs. This creates a language barrier between the two factions, but the communication level between them may be the most important exchange of information within the organization. Nomenclature out of context becomes little more than insular buzzwords.

If a company does not have a formal training department, the presence of staff members with a natural inclination to demonstrate and teach could mitigate a potentially disastrous situation. Management should find those employees who are most likely to adapt to the system and its operation. They should be taught how the system works and what it is supposed to do. Then they can share their knowledge with their fellow workers. There may not be a better way to bridge the natural chasm between the IS department and non-technical personnel. When the process of communicating information flows smoothly and can be used for enhancing and refining business operations, the organization and its customers will all profit.

MANAGEMENT LEVELS

Managers are organizational members who are responsible for the work performance of other organizational members. Managers have formal authority to use organizational resources and to make decisions. In organizations, there are typically three levels of management: top-level, middle-level, and first-level. These three main levels of managers form a hierarchy in which they are ranked in order of importance. In most organizations, the number of managers at each level is such that the hierarchy resembles a pyramid, with many more first-level managers, fewer middle managers, and the fewest managers at the top level. Each of these management levels is described below in terms of their possible job titles and their primary responsibilities and the paths taken to hold these positions. Additionally, there are differences across the management levels as to what types of management tasks each does and the roles that they take in their jobs. Finally, there are a number of changes that are occurring in many organizations that are changing the management hierarchies in them, such as the increasing use of teams, the prevalence of outsourcing, and the flattening of organizational structures.

The "Dean" of business history, Alfred Chandler, saw the managerial class as one of the great leaps forward in the business world. Chandler noted that managers and management levels arose from the need to further allocate responsibility and coordinate activities as large corporations emerged in the nineteenth century. For example, railroads were faced with the enormous task of coordinating activities (including scheduling) over wide geographic areas. Clear managerial roles helped this process. Chandler also reasoned that managers, because they had more specialized educational backgrounds, would tend to desire lifelong careers within a single corporation. As a result, managers favored long-range planning as opposed to short-term profits. Simply put, it is unlikely that the modern corporation

would have developed without the development of different and well-defined management levels.

TOP-LEVEL MANAGERS

Top-level managers, or top managers, are also called senior management or executives. These individuals are at the top one or two levels in an organization, and hold titles such as: chief executive officer (CEO), chief financial officer (CFO), chief operational officer (COO), chief information officer (CIO), chairperson of the board, president, vice president, corporate head.

Often, a set of these managers will constitute the top management team, which is composed of the CEO, the COO, and other department heads. Top-level managers make decisions affecting the entirety of the firm. Top managers do not direct the day-to-day activities of the firm; rather, they set goals for the organization and direct the company to achieve them. Top managers are ultimately responsible for the performance of the organization, and often, these managers have very visible jobs.

Top managers in most organizations have a great deal of managerial experience and have moved up through the ranks of management within the company or in another firm. An exception to this is a top manager who is also an entrepreneur; such an individual may start a small company and manage it until it grows enough to support several levels of management. Many top managers possess an advanced degree, such as a master's in business administration, but such a degree is not required.

Some CEOs are hired in from other top management positions in other companies. Conversely, they may be promoted from within and groomed for top management with management development activities, coaching, and mentoring. They may be tagged for promotion through succession planning, which identifies high potential managers.

MIDDLE-LEVEL MANAGERS

Middle-level managers, or middle managers, are those in the levels below top managers. Middle managers' job titles include: General manager, Plant manager, Regional manager, and Divisional manager.

Middle-level managers are responsible for carrying out the goals set by top management. They do so by setting goals for their departments and other business units. Middle managers can motivate and assist first-line managers to achieve business objectives. Middle managers may also communicate upward, by offering suggestions and feedback to top managers. Because middle managers are more involved in the day-to-day workings of a company, they may provide valuable information to top managers to help improve the organization's bottom line.

Jobs in middle management vary widely in terms of responsibility and salary. Depending on the size of the company and the number of middle-level managers in the firm, middle managers may supervise only a small group of employees, or they may manage very large groups, such as an entire business location. Middle managers may be employees who were promoted from first-level manager positions within the organization, or they may have been hired from outside the firm. Some middle managers may have aspirations to hold positions in top management in the future.

FIRST-LEVEL MANAGERS

First-level managers are also called first-line managers or supervisors. These managers have job titles such as: Office manager, Shift supervisor, Department manager, Foreperson, Crew leader, Store manager.

First-line managers are responsible for the daily management of line workers—the employees who actually produce the product or offer the service. There are first-line managers in every work unit in the organization. Although first-level managers typically do not set goals for the organization, they have a very strong influence on the company. These are the managers that most employees interact with on a daily basis, and if the managers perform poorly, employees may also perform poorly, may lack motivation, or may leave the company.

In the past, most first-line managers were employees who were promoted from line positions (such as production or clerical jobs). Rarely did these employees have formal education beyond the high-school level. However, many first-line managers are now graduates of a trade school, or have a two-year associates or a four-year bachelor's degree from college.

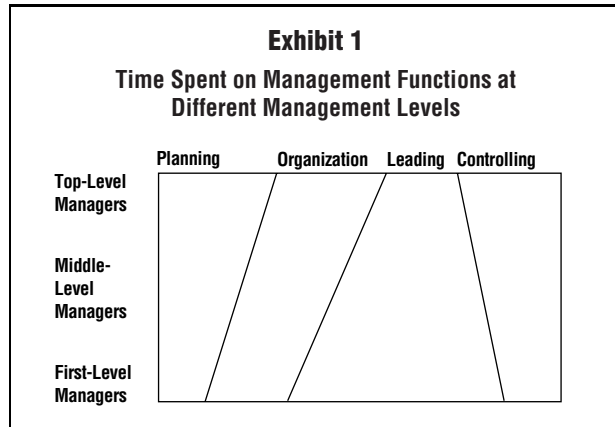
MANAGEMENT LEVELS AND THE FOUR MANAGERIAL FUNCTIONS

Managers at different levels of the organization engage in different amounts of time on the four managerial functions of planning, organizing, leading, and controlling.

Planning is choosing appropriate organizational goals and the correct directions to achieve those goals. Organizing involves determining the tasks and the relationships that allow employees to work together to achieve the planned goals. With leading, managers motivate and coordinate employees to work together to achieve organizational goals. When controlling, managers monitor and measure the degree to which the organization has reached its goals.

The degree to which top, middle, and supervisory managers perform each of these functions is presented in Exhibit 1. Note that top managers do considerably more planning, organizing, and controlling than do managers at any other level. However, they do much less leading. Most

Exhibit 1

Time Spent on Management Functions at Different Management Levels


of the leading is done by first-line managers. The amount of planning, organizing, and controlling decreases down the hierarchy of management; leading increases as you move down the hierarchy of management.

MANAGEMENT ROLES

In addition to the broad categories of management functions, managers in different levels of the hierarchy fill different managerial roles. These roles were categorized by researcher Henry Mintzberg, and they can be grouped into three major types: decisional, interpersonal, and informational.

Decisional Roles. Decisional roles require managers to plan strategy and utilize resources. There are four specific roles that are decisional. The *entrepreneur* role requires the manager to assign resources to develop innovative goods and services, or to expand a business. Most of these roles will be held by top-level managers, although middle managers may be given some ability to make such decisions. The *disturbance handler* corrects unanticipated problems facing the organization from the internal or external environment. Managers at all levels may take this role. For example, first-line managers may correct a problem halting the assembly line or a middle level manager may attempt to address the aftermath of a store robbery. Top managers are more likely to deal with major crises, such as requiring a recall of defective products. The third decisional role, that of *resource allocator*, involves determining which work units will get which resources. Top managers are likely to make large, overall budget decisions, while middle managers may make more specific allocations. In some organizations, supervisory managers are responsible for determining allocation of salary raises to employees. Finally, the *negotiator* works with others, such as suppliers, distributors, or labor unions, to reach agreements regarding products and services. First-level managers may negotiate with employees on issues of salary increases

or overtime hours, or they may work with other supervisory managers when needed resources must be shared. Middle managers also negotiate with other managers and are likely to work to secure preferred prices from suppliers and distributors. Top managers negotiate on larger issues, such as labor contracts, or even on mergers and acquisitions of other companies.

Interpersonal Roles. Interpersonal roles require managers to direct and supervise employees and the organization. The *figurehead* is typically a top or middle manager. This manager may communicate future organizational goals or ethical guidelines to employees at company meetings. A *leader* acts as an example for other employees to follow, gives commands and directions to subordinates, makes decisions, and mobilizes employee support. Managers must be leaders at all levels of the organization; often lower-level managers look to top management for this leadership example. In the role of *liaison*, a manager must coordinate the work of others in different work units, establish alliances between others, and work to share resources. This role is particularly critical for middle managers, who must often compete with other managers for important resources, yet must maintain successful working relationships with them for long time periods.

Informational Roles. Informational roles are those in which managers obtain and transmit information. These roles have changed dramatically as technology has improved. The *monitor* evaluates the performance of others and takes corrective action to improve that performance. Monitors also watch for changes in the environment and within the company that may affect individual and organizational performance. Monitoring occurs at all levels of management, although managers at higher levels of the organization are more likely to monitor external threats to the environment than are middle or first-line managers. The role of *disseminator* requires that managers inform employees of changes that affect them and the organization. They also communicate the company's vision and purpose.

Managers at each level disseminate information to those below them, and much information of this nature trickles from the top down. Finally, a *spokesperson* communicates with the external environment, from advertising the company's goods and services, to informing the community about the direction of the organization. The spokesperson for major announcements, such as a change in strategic direction, is likely to be a top manager. But, other, more routine information may be provided by a manager at any level of a company. For example, a middle manager may give a press release to a local newspaper, or a supervisor manager may give a presentation at a community meeting.

MANAGEMENT SKILLS

Regardless of organizational level, all managers must have five critical skills: technical skill, interpersonal skill, conceptual skill, diagnostic skill, and political skill.

Technical Skill. Technical skill involves understanding and demonstrating proficiency in a particular workplace activity. Technical skills are things such as using a computer word-processing program, creating a budget, operating a piece of machinery, or preparing a presentation. The technical skills used will differ in each level of management. First-level managers may engage in the actual operations of the organization; they need to have an understanding of how production and service occur in the organization in order to direct and evaluate line employees. Additionally, first-line managers need skill in scheduling workers and preparing budgets. Middle managers use more technical skills related to planning and organizing, and top managers need to have skill to understand the complex financial workings of the organization.

Interpersonal Skill. Interpersonal skill involves human relations, or the manager's ability to interact effectively with organizational members. Communication is a critical part of interpersonal skill, and an inability to communicate effectively can prevent career progression for managers. Managers who have excellent technical skill, but poor interpersonal skill are unlikely to succeed in their jobs. This skill is critical at all levels of management.

Conceptual Skill. Conceptual skill is a manager's ability to see the organization as a whole, as a complete entity. It involves understanding how organizational units work together and how the organization fits into its competitive environment. Conceptual skill is crucial for top managers, whose ability to see "the big picture" can have major repercussions on the success of the business. However, conceptual skill is still necessary for middle and supervisory managers, who must use this skill to envision, for example, how work units and teams are best organized.

Diagnostic Skill. Diagnostic skill is used to investigate problems, decide on a remedy, and implement a solution. Diagnostic skill involves other skills—technical, interpersonal, conceptual, and politic. For instance, to determine the root of a problem, a manager may need to speak with many organizational members or understand a variety of informational documents. The difference in the use of diagnostic skill across the three levels of management is primarily due to the types of problems that must be addressed at each level. For example, first-level managers may deal primarily with issues of motivation and discipline, such as determining why a particular employee's performance is flagging and how to improve it. Middle

managers are likely to deal with issues related to larger work units, such as a plant or sales office. For instance, a middle-level manager may have to diagnose why sales in a retail location have dipped. Top managers diagnose organization-wide problems, and may address issues such as strategic position, the possibility of outsourcing tasks, or opportunities for overseas expansion of a business.

Political Skill. Political skill involves obtaining power and preventing other employees from taking away one's power. Managers use power to achieve organizational objectives, and this skill can often reach goals with less effort than others who lack political skill. Much like the other skills described, political skill cannot stand alone as a manager's skill; in particular, though, using political skill without appropriate levels of other skills can lead to promoting a manager's own career rather than reaching organizational goals. Managers at all levels require political skill; managers must avoid others taking control that they should have in their work positions. Top managers may find that they need higher levels of political skill in order to successfully operate in their environments. Interacting with competitors, suppliers, customers, shareholders, government, and the public may require political skill.

CHANGES IN MANAGEMENT HIERARCHIES

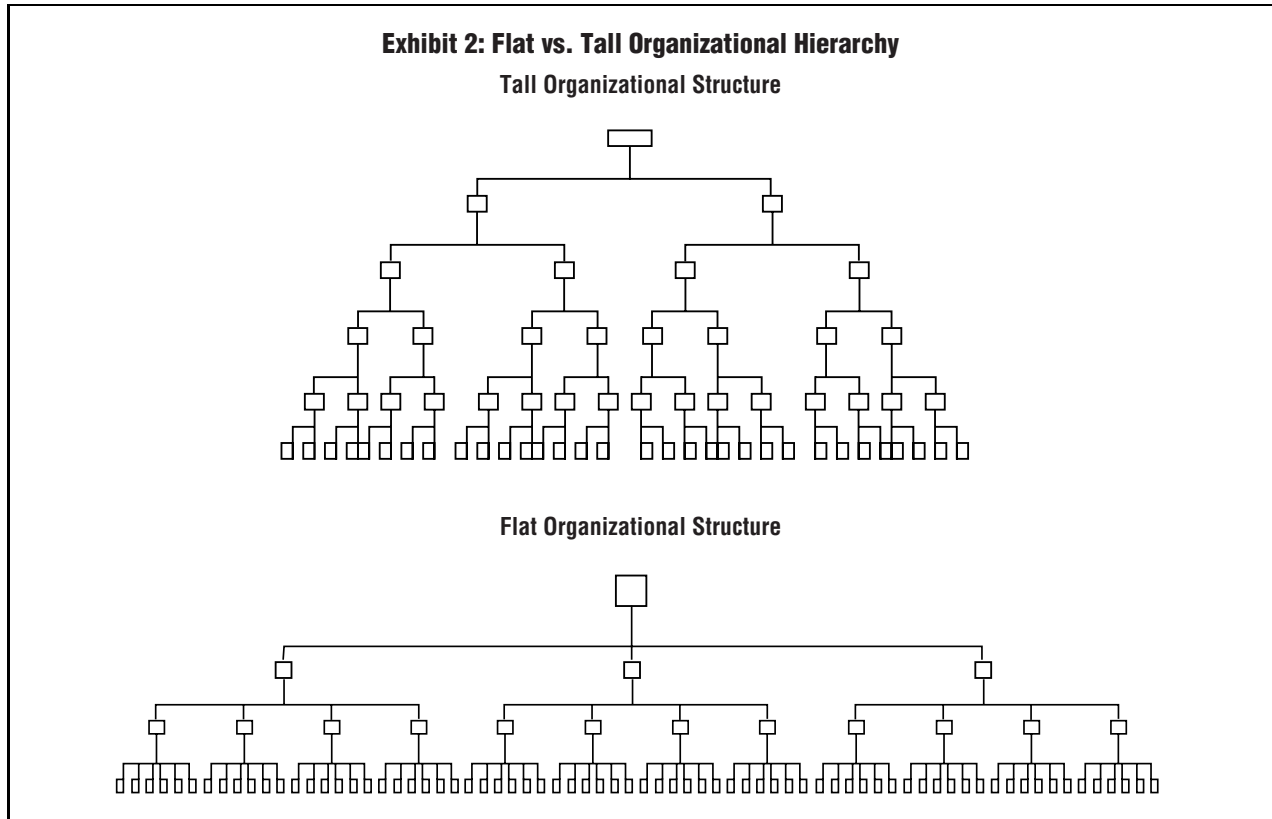
There are a number of changes to organizational structures that influence how many managers are at each level of the organizational hierarchy and what tasks they perform each day.

Flatter Organizational Structures. Organizational structures can be described by the number of levels of hierarchy; those with many levels are called "tall" organizations. They have numerous levels of middle management, and each manager supervises a small number of employees or other managers. That is, they have a small span of control. Conversely, "flat" organizations have fewer levels of middle management, and each manager has a much wider span of control. Examples of organization charts that show tall and flat organizational structures are presented in Exhibit 2.

Many organizational structures are now more flat than they were in previous decades. This is due to a number of factors. Many organizations want to be more flexible and increasingly responsive to complex environments. By becoming flatter, many organizations also become less centralized. Centralized organizational structures have most of the decisions and responsibility at the top of the organization, while decentralized organizations allow decision-making and authority at lower levels of the organization. Flat organizations that make use of decentralization are often

Exhibit 2: Flat vs. Tall Organizational Hierarchy

Tall Organizational Structure

Flat Organizational Structure


more able to efficiently respond to customer needs and the changing competitive environment.

As organizations move to flatter structures, the ranks of middle-level managers are diminishing. This means that there a fewer opportunities for promotion for first-level managers, but this also means that employees at all levels are likely to have more autonomy in their jobs, as flatter organizations promote decentralization. When organizations move from taller to flatter hierarchies, this may mean that middle managers lose their jobs, and are either laid off from the organization, or are demoted to lower-level management positions. This creates a surplus of labor of middle level managers, who may find themselves with fewer job opportunities at the same level.

Rosabeth Moss Kanter notes that hierarchical arrangements have eroded to make way for organizational structures that are more flexible. Specifically, she states that managers will be increasingly working in what she terms "peer networks." Ultimately, Kanter argues that these networks, and the network that a manager is a part of, may matter more than a manager's formal level in a hierarchy. However, she also notes that because of these changes, managers may feel a loss of power.

Increased Use of Teams. A team is a group of individuals with complementary skills who work together to achieve a common goal. That is, each team member has different capabilities, yet they collaborate to perform tasks. Many organizations are now using teams more frequently to accomplish work because they may be capable of performing at a level higher than that of individual employees. Additionally, teams tend to be more successful when tasks require speed, innovation, integration of functions, and a complex and rapidly changing environment.

Another type of managerial position in an organization that uses teams is the team leader, who is sometimes called a project manager, a program manager, or task-force leader. This person manages the team by acting as a facilitator and catalyst. He or she may also engage in work to help accomplish the team's goals. Some teams do not have leaders, but instead are self-managed. Members of self-managed teams hold each other accountable for the team's goals and manage one another without the presence of a specific leader.

Outsourcing. Outsourcing occurs when an organization contracts with another company to perform work that it previously performed itself. Outsourcing is intended to reduce costs and promote efficiency. Costs can be reduced through outsourcing, often because the work can be done in other countries, where labor and resources are less expensive than in the United States. Additionally, by

having an outsourcing company aid in production or service, the contracting company can devote more attention and resources to the company's core competencies. Through outsourcing, many jobs that were previously performed by American workers are now performed overseas. Thus, this has reduced the need for many first-level and middle-level managers, who may not be able to find other similar jobs in another company.

Telecommuting. Telecommuting is similar to outsourcing in that both involve work being performed for a company offsite. However, the major difference between the two is that telecommuters are still employees of a company. Because of this, they often have to report to a manager. However, this also means that the relationship between the manager and the employee will change, as will managerial responsibilities. *Technovation* observed that managers' roles will alter in that they will not be able to observe employees at work, and must focus on outcome with regards to telecommuting employees.

Insourcing. Insourcing is another business trend that came into its own in the early twenty-first century. Insourcing is when outside firms take over major parts of a company's internal process. The journalist and author Thomas Friedman uses UPS and Toshiba computers as an example. Toshiba has insourced its computer repair operations to UPS. Toshiba itself does not work on damaged computers, but UPS does the work instead. This practice has implications for management levels that are similar to outsourcing in that this practice can result in the elimination of some management positions inside an organization.

MANAGEMENT SCIENCE

Management science generally refers to mathematical or quantitative methods for business decision making. The term "operations research" may be used interchangeably with management science.

HISTORY

Frederick Winslow Taylor is credited with the initial development of scientific management techniques in the early twentieth century. In addition, several management science techniques were further developed during World War II. Some even consider the World War II period as the beginning of management science, as this global conflict posed many military, strategic, logistic, and tactical problems. Operations research teams of engineers, mathematicians, and statisticians were developed to use the scientific method to find solutions for many of these problems.

Nonmilitary management science applications developed rapidly after World War II. Based on quantitative methods developed during World War II, several new applications emerged. The development of the simplex method by George Dantzig in the 1940s made application of linear programming practical. C. West Churchman, Russell Ackoff, and Leonard Arnoff made management science even more accessible by publishing the first operations research textbook in the 1950s.

Computer technology continues to play an integral role in management science. Practitioners and researchers are able to use ever-increasing computing power in conjunction with management science methods to solve larger and more complex problems. In addition, management scientists are constantly developing new algorithms and improving existing algorithms; these efforts also enable management scientists to solve larger and more complex problems.

BREADTH OF MANAGEMENT SCIENCE TECHNIQUES

The scope of management science techniques is broad. These techniques include:

- Mathematical programming
- Linear programming
- Simplex method

- Dynamic programming
- Goal programming
- Integer programming
- Nonlinear programming
- Stochastic programming
- Markov processes
- Queuing theory/waiting-line theory
- Transportation method
- Simulation

Management science techniques are used on a wide variety of problems from a vast array of applications. For example, integer programming has been used by baseball fans to allocate season tickets in a fair manner. When seven baseball fans purchased a pair of season tickets for the Seattle Mariners, the Mariners turned to management science and a computer program to assign games to each group member based on member priorities.

In marketing, optimal television scheduling has been determined using integer programming. Variables such as time slot, day of the week, show attributes, and competitive effects can be used to optimize the scheduling of programs. Optimal product designs based on consumer preferences have also been determined using integer programming.

Similarly, linear programming can be used in marketing research to help determine the timing of interviews. Such a model can determine the interviewing schedule that maximizes the overall response rate while providing appropriate representation across various demographics and household characteristics.

In the area of finance, management science can be employed to help determine optimal portfolio allocations, borrowing strategies, capital budgeting, asset allocations, and make-or-buy decisions. In portfolio allocations, for instance, linear programming can be used to help a financial manager select specific industries and investment vehicles (e.g., bonds versus stocks) in which to invest.

With regard to production scheduling, management science techniques can be applied to scheduling, inventory, and capacity problems. Production managers can deal with multi-period scheduling problems to develop low-cost production schedules. Production costs, inventory holding costs, and changes in production levels are among the types of variables that can be considered in such analyses.

Workforce assignment problems can also be solved with management science techniques. For example, when some personnel have been cross-trained and can work in more than one department, linear programming may be used to determine optimal staffing assignments.

Airports are frequently designed using queuing theory (to model the arrivals and departures of aircraft) and simulation (to simultaneously model the traffic on multiple runways). Such an analysis can yield information to be used in deciding how many runways to build and how many departing and arriving flights to allow by assessing the potential queues that can develop under various airport designs.

MATHEMATICAL PROGRAMMING

Mathematical programming deals with models comprised of an objective function and a set of constraints. Linear, integer, nonlinear, dynamic, goal, and stochastic programming are all types of mathematical programming.

An objective function is a mathematical expression of the quantity to be maximized or minimized. Manufacturers may wish to maximize production or minimize costs, advertisers may wish to maximize a product's exposure, and financial analysts may wish to maximize rate of return.

Constraints are mathematical expressions of restrictions that are placed on potential values of the objective function. Production may be constrained by the total amount of labor at hand and machine production capacity, an advertiser may be constrained by an advertising budget, and an investment portfolio may be restricted by the allowable risk.

LINEAR PROGRAMMING

Linear programming problems are a special class of mathematical programming problems for which the objective function and all constraints are linear. A classic example of the application of linear programming is the maximization of profits given various production or cost constraints.

Linear programming can be applied to a variety of business problems, such as marketing mix determination, financial decision making, production scheduling, workforce assignment, and resource blending. Such problems are generally solved using the "simplex method."

Media Selection Problem. The local Chamber of Commerce periodically sponsors public service seminars and programs. Promotional plans are under way for this year's program. Advertising alternatives include television, radio, and newspaper. Audience estimates, costs, and maximum media usage limitations are shown in Exhibit 1.

If the promotional budget is limited to $18,200, how many commercial messages should be run on each medium to maximize total audience contact? Linear programming can find the answer.

Exhibit 1			
Constraint	**Television**	**Radio**	**Newspaper**
Audience per ad	100,000	18,000	40,000
Cost per ad	2,000	300	600
Maximum usage	10	20	10

SIMPLEX METHOD

The simplex method is a specific algebraic procedure for solving linear programming problems. The simplex method begins with simultaneous linear equations and solves the equations by finding the best solution for the system of equations. This method first finds an initial basic feasible solution and then tries to find a better solution. A series of iterations results in an optimal solution.

Simplex Problem. Assume that Georgia Television buys components that are used to manufacture two television models. One model is called High Quality and the other is called Medium Quality. A weekly production schedule needs to be developed given the following production considerations.

The High Quality model produces a gross profit of $125 per unit, and the Medium Quality model has a $75 gross profit. Only 180 hours of production time are available for the next time period. High Quality models require a total production time of six hours and Medium Quality models require eight hours. In addition, there are only forty-five Medium Quality components on hand.

To complicate matters, only 250 square feet of warehouse space can be used for new production. The High Quality model requires 9 square feet of space while the Medium Quality model requires 7 square feet.

Given the above situation, the simplex method can provide a solution for the production allocation of High Quality models and Medium Quality models.

DYNAMIC PROGRAMMING

Dynamic programming is a process of segmenting a large problem into a several smaller problems. The approach is to solve all the smaller, easier problems individually in order to reach a solution to the original problem.

This technique is useful for making decisions that consist of several steps, each of which also requires a decision. In addition, it is assumed that the smaller problems are not independent of one another given they contribute to the larger question.

Dynamic programming can be utilized in the areas of capital budgeting, inventory control, resource allocation, production scheduling, and equipment replacement. These applications generally begin with a longer time horizon, such as a year, and then break down the problem into smaller time units such as months or weeks. For example, it may be necessary to determine an optimal production schedule for a twelve-month period.

Dynamic programming would first find a solution for smaller time periods, for example, monthly production schedules. By answering such questions, dynamic programming can identify solutions to a problem that are most efficient or that best serve other business needs given various constraints.

GOAL PROGRAMMING

Goal programming is a technique for solving multi-criteria rather than single-criteria decision problems, usually within the framework of linear programming. For example, in a location decision a bank would use not just one criterion, but several. The bank would consider cost of construction, land cost, and customer attractiveness, among other factors.

Goal programming establishes primary and secondary goals. The primary goal is generally referred to as a priority level 1 goal. Secondary goals are often labeled priority level 2, level 3, and so on. It should be noted that trade-offs are not allowed between higher and lower level goals.

Assume a bank is searching for a site to locate a new branch. The primary goal is to be located in a five-mile proximity to a population of 40,000 consumers. A secondary goal might be to be located at least two miles from a competitor. Given the no trade-off rule, the bank would first search for a target solution of locating close to 40,000 consumers.

Blending Problem. The XYZ Company mixes three raw materials to produce two products: a fuel additive and a solvent. Each ton of fuel additive is a mixture of 2/5 ton of material A and 3/5 ton of material C. A ton of solvent base is a mixture of 1/2 ton of material A, 1/5 ton of material B, and 3/10 ton of material C. Production is constrained by a limited availability of the three raw materials. For the current production period XYZ has the following quantities of each raw material: 20 tons of material A, 5 tons of material B, and 21 tons of material C. Management would like to achieve the following priority level goals:

Goal 1. Produce at least 30 tons of fuel additive.

Goal 2. Produce at least 15 tons of solvent.

Goal programming would provide directions for production.

INTEGER PROGRAMMING

Integer programming is useful when values of one or more decision variables are limited to integer values. This

Table 1

Integer Programming Example

Project	Estimated Net Return	Year 1	Year 2	Year 3
New office	25,000	10,000	10,000	10,000
New warehouse	85,000	35,000	25,000	25,000
New branch	40,000	15,000	15,000	15,000
Available funds		50,000	45,000	45,000

is particularly useful when modeling production processes for which fractional amounts of products cannot be produced. Integer variables are often limited to two values—zero or one. Such variables are particularly useful in modeling either/or decisions.

Areas of business that use integer linear programming include capital budgeting and physical distribution. For example, faced with limited capital, a firm needs to select capital projects in which to invest. This type of problem is represented in Table 1.

As can be seen in the table, capital requirements exceed the available funds for each year. Consequently, decisions to accept or reject regarding each of the projects must be made and integer programming would require the following integer definitions for each of the projects.

$x1 = 1$ if the new office project is accepted; 0 if rejected

$x2 = 1$ if the new warehouse project is accepted; 0 if rejected

$x3 = 1$ if the new branch project is accepted; 0 if rejected

A set of equations is developed from the definitions to provide an optimal solution.

NONLINEAR PROGRAMMING

Nonlinear programming is useful when the objective function or at least one of the constraints is not linear with respect to values of at least one decision variable. For example, the per-unit cost of a product may increase at a decreasing rate as the number of units produced increases because of economies of scale.

STOCHASTIC PROGRAMMING

Stochastic programming is useful when the value of a coefficient in the objective function or one of the constraints is not known with certainty but has a known probability distribution. For instance, the exact demand for a product may not be known, but its probability distribution may be understood. For such a problem, random values from this distribution can be substituted into the problem formula-

tion. The optimal objective function values associated with these formulations provide the basis of the probability distribution of the objective function.

MARKOV PROCESS MODELS

Markov process models are used to predict the future of systems given repeated use. For example, Markov models are used to predict the probability that production machinery will function properly given its past performance in any one period. Markov process models are also used to predict future market share given any specific period's market share.

Computer Facility Problem. The computing center at a state university has been experiencing computer downtime. Assume that the trials of an associated Markov process are defined as one-hour periods and that the probability of the system being in a running state or a down state is based on the state of the system in the previous period. Historical data in Table 2 show the transition probabilities.

The Markov process would then solve for the following: if the system is running, what is the probability of the system being down in the next hour of operation?

QUEUING THEORY/WAITING-LINE THEORY

Queuing theory is often referred to as waiting-line theory. Both terms refer to decision making regarding the management of waiting lines (or queues). This area of management science deals with operating characteristics of waiting lines, such as:

- The probability that there are no units in the system
- The mean number of units in the queue
- The mean number of units in the system (the number of units in the waiting line plus the number of units being served)
- The mean time a unit spends in the waiting line
- The mean time a unit spends in the system (the waiting time plus the service time)
- The probability that an arriving unit has to wait for service
- The probability of n units in the system

Table 2

		To	
		Running	Down
From	**Running**	.9	.1
	Down	.3	.7

Table 3

Origin	Warehouse Location	3 month capacity
1	Houston	2,000
2	Dallas	2,500
3	San Antonio	2,800
	Total	**7,300**

Given the above information, programs are developed that balance costs and service delivery levels. Typical applications involve supermarket checkout lines and waiting times in banks, hospitals, and restaurants.

Bank Line Problem. XYZ State Bank operates a drive-in-teller window, which allows customers to complete bank transactions without getting out of their cars. On weekday mornings arrivals to the drive-in-teller window occur at random, with a mean arrival rate of twenty-four customers per hour or 0.4 customers per minute.

Delay problems are expected if more than three customers arrive during any five-minute period. Waiting line models can determine the probability that delay problems will occur.

TRANSPORTATION METHOD

The transportation method is a specific application of the simplex method that finds an initial solution and then uses iteration to develop an optimal solution. As the name implies, this method is utilized in transportation problems.

Transportation Problem. A company must plan its distribution of goods to several destinations from several warehouses. The quantity available at each warehouse is limited. The goal is to minimize the cost of shipping the goods. An example of production capacity can be found in Table 3. The forecast for demand is shown in Table 4.

Table 4

Destination	Location	3 month forecast
1	New Orleans	1,800
2	Little Rock	3,200
3	Las Vegas	2,300
	Total	**7,300**

The transportation method will determine the optimal amount to be shipped from each warehouse and determine the optimal destination.

SIMULATION

Simulation is used to analyze complex systems by modeling complex relationships between variables with known probability distributions. Random values from these probability distributions are substituted into the model and the behavior of the system is observed. Repeated executions of the simulation model provide insight into the behavior of the system that is being modeled.

The different arithmetic models of management science can be incorporated into the strategic operational functions of organizations—such as integrated product management—to achieve greater efficiency in resource allocation and utilization. Integrated product management defines the end-to-end production activities such as operational costs, ethical issues, social factors, and environmental constraints. The incorporation of the tools, models, techniques, and concepts of management science into the overall product life-cycle processes optimizes the utility functions of all the elements in the chain of production to the advantage of the firm.

Management science keeps evolving because of the continued inventions of automated technologies and information management systems. In the book titled *Programming Languages for Business Problem Solving*, Wang and Wang reckon that computer literacy has become a prerequisite requirement for managers wishing to adopt the use of information technology in advancing business strategies in their organizations. The complex concepts and logical processes of management science can easily be conquered by the use of automated information technology systems tailored to suit organization-specific needs.

MANAGEMENT STYLES

A manager's style is determined by the situation, the needs and personalities of his or her employees, and by the culture of the organization. Organizational restructuring and the accompanying cultural change has caused management styles to come in and go out of fashion. There has been a move away from an authoritarian style of management (in which control is a key concept) to one that favors teamwork and empowerment. Managerial styles that focus on managers as technical experts who direct, coordinate, and control the work of others have been replaced by those that focus on managers as coaches, counselors, facilitators, and team leaders.

Successful management styles involve building teams, networks of relationships, and developing and motivating others. There is a greater emphasis on participative management styles and people management skills. In an article titled "Types of Managers and Management Styles" published in the *Fascicle of Management and Technological Engineering,* Mircea and Delia point out that accommodative management styles that encourage teamwork and employee participation in decision-making processes motivate employees and promote long-term growth prospects of organizations

compared to authoritative management styles. Management theorists have repeatedly found evidence to support the advantages of management styles such as participative management; Theory Y versus Theory X; Theory Z; Total Quality Management (TQM); Management by Walking Around; Management by Objectives; and employee empowerment.

PARTICIPATIVE MANAGEMENT

Participative management involves sharing information with employees and involving them in decision-making. Employees are encouraged to run their own departments and make decisions regarding policies and processes. Participative management has often been promoted as the quick cure for poor morale and low productivity. It is not, however, appropriate in every organization and at every level. This is because employees must have the skills and abilities to participate, and they must have the technical background, communication skills, and intelligence to make decisions and communicate those decisions effectively. The organization's culture must support employee involvement and the issues in which employees get involved must be relevant to them.

Representative participation allows workers to be represented by a small group who actually participate. The goal of representative participation is to redistribute power within the organization. Employees' interests become as important as those interests of management and stockholders.

According to Stephen P. Robbins, author of *Essentials of Organizational Behavior,* the two most popular forms of representative participation are works councils and board representatives. Works councils are groups of employees who have been elected by their peers and who must be consulted by management when making personnel decisions. Board representatives are employees that sit on the board of directors and represent labor interests.

As with participative management, representative participation is a poor choice for improving performance or morale. Evidence suggests that the overall influence of representative participation is small. The employees involved in representing personnel receive more benefit than those they represent.

THEORY X AND THEORY Y

Douglas McGregor's Theory X assumes that people are lazy and do not want to work; it is the job of the manager to force or coerce them to work. McGregor's Theory X makes three basic assumptions: (1) The average human being dislikes work and will do anything to get out of it; (2) most people must be coerced, controlled, directed, and threatened or punished to get them to work toward organizational objectives; and (3) the average human being

prefers to be directed, wishes to avoid responsibility, has relatively little ambition, and places job security above ambition. According to this theory, responsibility for demonstrating initiative and motivation lies with the employee, and failure to perform is his or her fault. Employees are motivated by extrinsic rewards such as money, promotions, and tenure.

Theory Y suggests employees would behave differently if treated differently by managers. Theory Y assumes that higher-order needs dominate individuals. The set of assumptions for Theory Y is: (1) the average human does not dislike work, and it is as natural as play; (2) people will exercise self-direction and self-control in order to achieve objectives; (3) rewards of satisfaction and self-actualization are obtained from effort put forth to achieve organizational objectives; (4) the average human being not only accepts but also seeks responsibility; (5) human beings are creative and imaginative in solving organizational problems; and (6) the intellectual potential of the average human is only partially realized. If productivity is low and employees are not motivated, then it is considered failure on the manager's part.

THEORY Z

William Ouchi studied management practices in the United States and Japan and developed Theory Z. Theory Z combines elements of both U.S. and Japanese management styles and is sometimes called Japanese Management. It assumes that the best management style involves employees at all levels of the organization. Specific characteristics included in Theory Z are long-term employment, less specialized career paths, informal control, group decision making, and concern for the individual (beyond work-related issues). This theory satisfies both lower order and higher order needs. Looking out for employees' well-being satisfies the lower-level needs. Incorporating group processes in decision making satisfies middle-level needs and encouraging employees to take responsibility for their work and decisions satisfies higher-level needs.

TOTAL QUALITY MANAGEMENT

Total Quality Management (TQM) is a management style that integrates all functions of a business to achieve a high quality of product. The major hallmarks are customer satisfaction, quality as the responsibility of all employees, and teamwork. As an integrated method, it involves every aspect of the company. The entire workforce, from the CEO to the line worker, must be involved in a shared commitment to improving quality.

TQM encourages employees to grow and learn and to participate in improvements, so it exemplifies a participative management style. TQM also encourages an ever-changing or continuous process, and emphasizes the ideas of working constantly toward improved quality.

Americans W. Edward Deming and Joseph M. Juran were the pioneers of the quality movement. Both did their major work in post-World War II Japan, and are credited with the major turnaround in the quality of Japanese products by the 1970s. In the 1980s both men were highly influential in the quality management movement in the United States.

MANAGEMENT BY WALKING AROUND

Management by Walking Around (MBWA) is a classic technique used by good managers who are proactive listeners. Managers using this style gather as much information as possible so that a challenging situation does not turn into a bigger problem. Listening carefully to employees' suggestions and concerns will help evade potential crises. MBWA benefits managers by providing unfiltered, real-time information about processes and policies that is often left out of formal communication channels. By walking around, management gets an idea of the level of morale in the organization and can offer help if there is trouble.

A potential concern of MBWA is that the manager will second-guess employees' decisions. The manager must maintain his or her role as coach and counselor, not director. By leaving decision-making responsibilities with the employees, managers can be assured of the fastest possible response time.

According to Max Messmer, another mistake managers make is to inadvertently create more work for employees. By offering suggestions that may be interpreted as assignments, managers can increase the workload and slow down progress.

Messmer illustrates an example of a team working on a project that needs a supplier of plastic molding. When the manager shows up, the team has reviewed three companies and selected the best one. The manager also knows of a good company, and suggests that team members give this company a call. They may not feel comfortable in saying that the decision has already been made, and will take the extra time to call the company in order to please the manager.

MANAGEMENT BY OBJECTIVES

Management by Objectives (MBO) is a company-wide process in which employees actively participate in setting goals that are tangible, verifiable, and measurable. Management theorist Peter Drucker pioneered this style in his 1954 book titled *The Practice of Management.*

MBO provides a systematic method of assuring that all employees and work groups set goals that are in alignment with achieving the organization's goals. Xerox, Intel,

and Du Pont are just a few examples of companies that use MBO at all levels of the organization. Overall organizational objectives are converted into specific objectives for employees. Objectives at each level of the organization are linked together through a "bottom up" approach as well as a "top down" approach. In this manner, if each individual achieves his or her goals, then the department will achieve its goals and the organization objectives will in turn be met.

There are four steps involved in the MBO process: setting goals, participative decision-making, implementing plans, and performance feedback. Top managers work with middle managers and middle managers work with lower level managers to set goals for their departments. Each manager then works with employees in the department to set individual performance goals. The participative decision-making step allows managers and employees to jointly set goals, define responsibility for achieving those goals, and set the evaluation process.

Managers are allowed to implement their plans and control their own performance. This step of MBO utilizes every manager's expertise to benefit the organization and permits managers to continuously improve their skills.

The final step is to continuously provide feedback on performance and achievement of objectives. By periodically reviewing employees' performance, goals can be modified or new goals can be set. This step complements the formal appraisal system because the continuous feedback throughout the year keeps individuals informed of their progress.

As with any other management style, the organization's culture must be conducive for MBO to work. Top management must be committed and involved in the MBO program for it to be beneficial. This management style is not without its problems. Managers often set their departmental goals and objectives too narrowly at the expense of the organization's strategic goals or objectives.

Another problem arises when managers are not flexible in setting up the goal-setting and evaluation processes, and employees lose the ability to respond to issues quickly. Unrealistic expectations about results are often a problem with MBO programs as is the unwillingness of management to allocate rewards based on the accomplishment of individual goals.

EMPLOYEE EMPOWERMENT

Employee empowerment is a style of management that puts managers in the role of coach, adviser, sponsor, or facilitator. Empowerment involves delegating the decision-making authority regarding the action to be taken on a task that is considered to be important to both the manager and employee. The main reasons for implementing an empowerment program are to provide fast solutions to business problems, to provide growth opportunities for employees, and to lower organizational costs while allowing the manager to work on multiple projects.

Employee empowerment is the most effective when management has set clear obtainable goals and defined specific accountability standards. The success of employee empowerment relies on the ability of management to provide resources such as time and money, support by way of legitimacy, and relevant and factual information so employees can make educated decisions. Training employees to take responsibility and make sound decisions that are supported by upper management as well as lower level managers are other areas that are important to the success of empowerment programs.

Employees benefit from empowerment because they have more responsibility in their jobs. Employee empowerment increases the level of employee involvement and therefore creates a deeper sense of satisfaction and higher levels of motivation.

However, there are potential problems with empowerment programs that often result in unfavorable outcomes. Many times managers delegate trivial, unimportant and boring tasks to employees and they retain the complicated and important tasks for themselves. Empowerment will not work unless the authority and decision-making tasks are perceived as meaningful by the employee.

Another problem arises when managers not only assign meaningless tasks to their employees but also then expect the employee to continuously consult them for approval. Managers must evaluate their employees' skills and abilities and determine if the organization's culture can support an empowerment program before beginning.

SELF-MANAGED WORK TEAMS

Employee empowerment led to the development of self-managed work teams. This management style delegates the authority to make decisions such as how to spend money, whom to hire, and what projects to undertake. Self-managed work teams are generally composed of ten to fifteen people and require minimal supervision. Xerox, General Motors, PepsiCo, Hewlett-Packard, and M&M/Mars are just a few organizations that have implemented self-managed work teams. According to Stephen P. Robbins, one in every five companies uses self-managed work teams.

Managers must select a management style that is best suited for them, their department, their subordinates, and finally the organization they work for. The situations managers encounter may require varying management styles depending on a specific assignment, the employees being managed, or the manager's personality. Management style can ultimately determine the performance outcome of employees and a company's growth depends on the

management styles of its executives. Therefore, in order to determine the most appropriate management style, it is necessary to first review previous results produced as a result of a particular management approach.

For example, Toyota has registered unprecedented growth and success as a result of a radical shift in management policy from an authoritative management style to a uniquely tailored management style called Toyota Production System. This particular system allows employees to exercise their skills independently and utilize tools within their reach to perform their duties and solve problems as they arise. Toyota production system management style has enabled the company to benefit from continued innovation from all categories of its employees from managers to junior staff.

Management positions require a certain degree of authority and therefore managers may often find themselves in leadership positions. However, not all leaders are managers and not all managers are leaders. Managers who possess good leadership skills influence and motivate employees to achieve organizational goals. It is therefore noteworthy to mention that certain leadership styles lend themselves to effective management styles as well.

MANAGEMENT THOUGHT

The schools of management thought are theoretical frameworks for the study of management. Each of the schools of management thought are based on somewhat different assumptions about human beings and the organizations for which they work. Since the formal study of management began in the late nineteenth century, the study of management has progressed through several stages as scholars and practitioners working in different eras focused on what they believed to be important aspects of good management practice. Over time, management thinkers have sought ways to organize and classify the voluminous information about management that has been collected and disseminated. These attempts at classification have resulted in the identification of management schools.

Disagreement exists as to the exact number of management schools. Different writers have identified as few as three and as many as twelve. Those discussed below include (1) the classical school, (2) the behavioral school, (3) the quantitative or management science school, (4) the systems school, (5) and the contingency school. The formal study of management is largely a phenomenon that began in the twentieth-century, and to some degree the relatively large number of management schools of thought reflect a lack of consensus among management scholars about basic questions of theory and practice.

Table 1 provides a brief summary of five major schools of management thought, their approximate dates of origin, and their relative areas of emphasis. The following sections discuss each of the management schools in more detail. In addition, three contemporary management perspectives are discussed.

THE CLASSICAL SCHOOL

The classical school is the oldest formal school of management thought. Its roots pre-date the twentieth century. The classical school of thought generally concerns ways to manage work and organizations more efficiently. Three

Table 1

Five Major Schools of Management Thought

MANAGEMENT SCHOOLS	Beginning Dates	Emphasis
CLASSICAL SCHOOL		Managing workers and organizations more efficiently.
Scientific Management	1880s	
Administrative Management	1940s	
Bureaucratic Management	1920s	
BEHAVIORAL SCHOOL		Understanding human behavior in the organization.
Human Relations	1930s	
Behavioral Science	1950s	
QUANTITATIVE SCHOOL		Increasing quality of managerial decision-making through the application of mathematical and statistical methods.
Management Science	1940s	
Operations Management	1940s	
Management Information Systems	1950s—1970s	
SYSTEMS SCHOOL	1950s	Understanding the organization as a system that transforms inputs into outputs while in constant interaction with its environment.
CONTINGENCY SCHOOL	1960s	Applying management principles and processes as dictated by the unique characteristics of each situation.

areas of study that can be grouped under the classical school are scientific management, administrative management, and bureaucratic management.

Scientific Management. In the late nineteenth century, management decisions were often arbitrary, and workers often worked at an intentionally slow pace. There was little in the way of systematic management; workers and management were often in conflict. Scientific management was introduced in an attempt to create a mental revolution in the workplace. It can be defined as the systematic study of work methods to improve efficiency. Frederick W. Taylor was its main proponent; other major contributors were Frank Gilbreth, Lillian Gilbreth, and Henry Gantt.

Scientific management has several major principles. First, it calls for the application of the scientific method to work in order to determine the best method for accomplishing each task. Second, scientific management suggests that workers should be scientifically selected based on their qualifications and trained to perform their jobs in the optimal manner. Third, scientific management advocates genuine cooperation between workers and management based on mutual self-interest. Finally, scientific management suggests that management should take complete responsibility for planning the work and that workers' primary responsibility should be implementing management's plans. Other important characteristics of scientific management include the scientific development of difficult but fair performance standards and the implementation of a pay-for-performance incentive plan based on work standards.

Scientific management had a tremendous influence on management practice in the early twentieth century. Although it does not represent a complete theory of management, it has contributed to the study of management and organizations in many areas, including human resource management and industrial engineering. Many of the tenets of scientific management are still valid today.

Administrative Management. Administrative management focuses on the management process and principles of management. In contrast to scientific management, which deals largely with jobs and work at the individual level of analysis, administrative management provides a more general theory of management. Henri Fayol is the major contributor to this school of management thought.

Fayol was a management practitioner who brought his experience to bear on the subject of management functions and principles. He argued that management was a universal process consisting of functions, which he termed planning, organizing, commanding, coordinating, and controlling. Fayol believed that all managers performed these functions and that the functions distinguished management as a separate discipline of study apart from accounting, finance, and production. Fayol also presented fourteen principles of management, which included maxims related to the division of work, authority

and responsibility, unity of command and direction, centralization, subordinate initiative, and team spirit.

Although administrative management has been criticized as being rigid and inflexible and the validity of the functional approach to management has been questioned, this school of thought still influences management theory and practice. The functional approach to management is still the dominant way of organizing management knowledge, and many of Fayol's principles of management, when applied with the flexibility that he advocated, are still considered relevant.

Bureaucratic Management. Bureaucratic management focuses on the ideal form of organization. Max Weber was the major contributor to bureaucratic management. Based on observation, Weber concluded that many early organizations were inefficiently managed, with decisions based on personal relationships and loyalty. He proposed that a form of organization, called a bureaucracy—characterized by division of labor, hierarchy, formalized rules, impersonality, and the selection and promotion of employees based on ability—would lead to more efficient management. Weber also contended that managers' authority in an organization should be based not on tradition or charisma but on the position held by managers in the organizational hierarchy.

Bureaucracy has come to stand for inflexibility and waste, but Weber did not advocate or favor the excesses found in many bureaucratic organizations today. Weber's ideas formed the basis for modern organization theory and are still descriptive of some organizations.

THE BEHAVIORAL SCHOOL

The behavioral school of management thought developed, in part, because of perceived weaknesses in the assumptions of the classical school. The classical school emphasized efficiency, process, and principles. Some felt that this emphasis disregarded important aspects of organizational life, particularly as it related to human behavior. Thus, the behavioral school focused on trying to understand the factors that affect human behavior at work.

Human Relations. The Hawthorne Experiments began in the 1920s and continued through the early 1930s. A variety of researchers participated in the studies, including Clair Turner, Fritz J. Roethlisberger, and Elton Mayo, whose respective books on the studies are perhaps the best known. One of the major conclusions of the Hawthorne studies was that workers' attitudes are associated with productivity. Another was that the workplace is a social system and informal group influence could exert a powerful effect on individual behavior. A third was that the style of supervision is an important factor in increasing workers' job satisfaction. The studies also found that organizations should take steps to assist employees in adjusting to organizational life by fostering collaborative systems between labor and management. Such conclusions sparked increasing interest in the human element at work; today, the Hawthorne studies are generally credited as the impetus for the human relations school.

According to the human relations school, the manager should possess skills for diagnosing the causes of human behavior at work, interpersonal communication, and motivating and leading workers. The focus became satisfying worker needs. If worker needs were satisfied, wisdom held, the workers would in turn be more productive. Thus, the human relations school focuses on issues of communication, leadership, motivation, and group behavior. The individuals who contributed to the school are too numerous to mention, but some of the best-known contributors include Mary Parker Follett, Chester Barnard, Abraham Maslow, Kurt Lewin, Renais Likert, and Keith Davis. The human relations school of thought still influences management theory and practice, as contemporary management focuses much attention on human resource management, organizational behavior, and applied psychology in the workplace.

Behavioral Science. Behavioral science and the study of organizational behavior emerged in the 1950s and 1960s. The behavioral science school was a natural progression of the human relations movement. It focused on applying conceptual and analytical tools to the problem of understanding and predicting behavior in the workplace. However, the study of behavioral science and organizational behavior was also a result of criticism of the human relations approach as simplistic and manipulative in its assumptions about the relationship between worker attitudes and productivity. The study of behavioral science in business schools was given increased credence by the 1959 Gordon and Howell report on higher education, which emphasized the importance of management practitioners to understanding human behavior.

The behavioral science school has contributed to the study of management through its focus on personality, attitudes, values, motivation, group behavior, leadership, communication, and conflict, among other issues. Some of the major contributors to this school include Douglas McGregor, Chris Argyris, Frederick Herzberg, Renais Likert, and Ralph Stogdill, although there are many others.

THE QUANTITATIVE SCHOOL

The quantitative school focuses on improving decision making via the application of quantitative techniques. Its roots can be traced back to scientific management.

Management Science and MIS. Management science (also called operations research) uses mathematical and statistical approaches to solve management problems. It developed during World War II as strategists tried to apply scientific knowledge and methods to the complex problems of war. Industry began to apply management science after the war. George Dantzig developed linear programming, an algebraic method to determine the optimal allocation of scarce resources. Other tools used in industry include inventory control theory, goal programming, queuing models, and simulation.

The advent of the computer made many management science tools and concepts more practical for industry. Increasingly, management science and management information systems (MIS) are intertwined. MIS focuses on providing needed information to managers in a useful format and at the proper time. Decision support systems (DSS) attempt to integrate decision models, data, and the decision maker into a system that supports better management decisions.

Production and Operations Management. This school focuses on the operation and control of the production process that transforms resources into finished goods and services. It has its roots in scientific management but became an identifiable area of management study after World War II. It uses many of the tools of management science.

Operations management emphasizes productivity and quality of both manufacturing and service organizations. W. Edwards Deming exerted a tremendous influence in shaping modern ideas about improving productivity and quality. Major areas of study within operations management include capacity planning, facilities location, facilities layout, materials requirement planning, scheduling, purchasing and inventory control, quality control, computer integrated manufacturing, just-in-time inventory systems, and flexible manufacturing systems.

SYSTEMS SCHOOL

The systems school focuses on understanding the organization as an open system that transforms inputs into outputs. This school is based on the work of a biologist, Ludwig von Bertalanffy, who believed that a general systems model could be used to unite science. Early contributors to this school included Kenneth Boulding, Richard Johnson, Fremont Kast, and James Rosenzweig.

The systems school began to have a strong impact on management thought in the 1960s as a way of thinking about managing techniques that would allow managers to relate different specialties and parts of the company to one another, as well as to external environmental factors. The systems school focuses on the organization as a whole, its interaction with the environment, and its need to achieve equilibrium. General systems theory received a great deal of attention in the 1960s, but its influence on management thought has diminished somewhat. It has been criticized as too abstract and too complex. However, many of the ideas inherent in the systems school formed the basis for the contingency school of management.

CONTINGENCY SCHOOL

The contingency school focuses on applying management principles and processes as dictated by the unique characteristics of each situation. It emphasizes that there is no one best way to manage and that it depends on various situational factors, such as the external environment, technology, organizational characteristics, characteristics of the manager, and characteristics of the subordinates. Contingency theorists often implicitly or explicitly criticize the classical school for its emphasis on the universality of management principles; however, most classical writers recognized the need to consider aspects of the situation when applying management principles.

The contingency school originated in the 1960s. It has been applied primarily to management issues such as organizational design, job design, motivation, and leadership style. For example, optimal organizational structure has been theorized to depend upon organizational size, technology, and environmental uncertainty; optimal leadership style, meanwhile, has been theorized to depend upon a variety of factors, including task structure, position power, characteristics of the work group, characteristics of individual subordinates, quality requirements, and problem structure, to name a few. A few of the major contributors to this school of management thought include Joan Woodward, Paul Lawrence, Jay Lorsch, and Fred Fiedler, among many others.

CONTEMPORARY "SCHOOLS" OF MANAGEMENT THOUGHT

Management research and practice continues to evolve and new approaches to the study of management continue to be advanced. This section briefly reviews four contemporary approaches: total quality management (TQM), the learning organization, benchmarking, and core competencies. While none of these management approaches offer a complete theory of management, they do offer additional insights into the management field.

Total Quality Management. Total quality management (TQM) is a philosophy or approach to management that focuses on managing the entire organization to deliver quality goods and services to customers. This approach to management was implemented in Japan after World War II and was a major factor in Japan's economic renaissance. TQM has at least three major elements that

include employee involvement, customer focus, and a philosophy of continuous improvement. Employee involvement is essential in preventing quality problems before they occur. Customer focus means that the organization must attempt to determine customer needs and wants and deliver products and services that address them. Finally, a philosophy of continuous improvement means that the organization is committed to incremental changes and improvements over time in all areas of the organization. TQM has been implemented by many companies worldwide and appears to have fostered performance improvements in many organizations. Perhaps the best-known proponent of this school of management was W. Edwards Deming.

Benchmarking. Benchmarking means that the organization is always seeking out other organizations that perform a function or process more effectively and using them as a standard, or benchmark, to judge their own performance. The organization will also attempt to adapt or improve the processes used by other companies relative to the availability of technological resources and production skills.

Learning Organization. The contemporary organization faces unprecedented environmental and technological change. Thus, one of the biggest challenges for organizations is to continuously change in a way that meets the demands of this turbulent competitive environment. The learning organization can be defined as one in which all employees are involved in identifying and solving problems, which allows the organization to continually increase its ability to grow, learn, and achieve its purpose. The organizing principle of the learning organization is not efficiency, but problem solving. Three key aspects of the learning organization are a team-based structure, empowered employees, and open information. Peter Senge is one of the best-known experts on learning organizations.

Core Competencies. Core competencies is a strategy approach to management that focuses on optimizing definite organizational strengths. This approach to management allows organizations to pursue advantage by channeling technological and production resources towards enhancement of business objectives that have the potential to achieve sustained competitive advantage. The organizational culture and dedication among employees are the main components that facilitate the success of the core competencies in achieving corporate objectives. The concept of core competencies was floated by C.K Prahad and Gary Hemel in the early 1990s and it has since become a major reference point for management practices.

MANAGING CHANGE

Recently, one of the concepts discussed, written about, and analyzed most frequently has been organizational change and the related concepts of resistance to change and management of change. Change has been variously defined as making a material difference in something compared to an earlier state, transforming or converting something, or simply becoming different. All of these definitions can be applied to change as it occurs within organizations and businesses. Organizational change may mean changing

technological infrastructures (e.g., changing network file systems), marketing strategies (targeting a new customer base), or management and decision-making practices.

Organizational change is not new to the American business landscape. Since the nineteenth century and the Industrial Revolution, corporations have had to deal with change on an increasingly rapid scale. The greater the technological developments and the greater the amount of products and information generated, the more necessary it becomes for corporations to provide effective management and develop solid organizational practices. The most revered business professionals of the United States have been those who were best able to exploit changes in business and the economy. For example, in the late nineteenth century, Andrew Carnegie greatly expanded his empire by purchasing the very businesses he depended on for his steel business, making his company one of the first successful examples of vertical integration.

The economist Joseph Schumpeter saw change and dynamism at the root of capitalism. His term "creative destruction" described the effects of capitalism's change. While newer activities were acts of creation, they simultaneously destroyed older forms, businesses, and ways of doing things by rendering them obsolete or putting them at a severe competitive disadvantage. Schumpeter noted that large, successful concerns tended to "automate" their processes. However, while many companies conducted business as usual, both in services and in operations, there were other individuals and firms who were quietly innovating; he referred to this as the "entrepreneurial response." These entrepreneurial firms and people would then, and sometimes suddenly, introduce a change that would significantly shift the balance of power in a given market. Schumpeter's ultimate lesson for managers was that change is inevitable and can be ruinous to an organization if it is ignored.

Beginning in the 1990s, change came at an exponentially faster rate due to factors such as increased competition in a global economy, expanding markets, new ways of doing business (such as e-commerce), and the omnipresent task of keeping up with the latest technology. Management guru Peter F. Drucker devoted his book, *Management Challenges of the Twenty-First Century*, to that very topic. As a result, businesses had to revise (or devise) corporate missions and goals, management practices, and day-to-day business functions. Companies routinely began redesigning business strategies, often replacing traditional hierarchical organization charts with flatter structures centered around "empowered" teams.

The late 1990s also saw the rise of the Internet, which fueled a large amount of rethinking business processes and organizational structure. Kevin Kelley, in a widely read book, *New Rules for the New Economy*, echoes

Schumpeter's mantra of creative destruction, arguing, among other things, that change needed to be at the core of business strategy. This period also saw the rise of business consultants who referred to themselves as "change agents."

In their book, *Corporate Cultures*, Terrence Deal and Allan Kennedy assert that change is inevitable for an organization. However, they also note that there are specific circumstances requiring change that an organization must recognize. These include market changes, an underperforming company, and a rapidly growing organization.

INDICATORS OF CHANGE

There are four primary indicators of major workplace change. They are a change to the organizational structure, a new product or service, new management, and new technology. Organizational structure may change through major downsizing, outsourcing, acquisitions, or mergers. These actions are often accompanied by layoffs, particularly as certain positions become redundant. A new product or service has implications for changes in production, sales, and customer service. Additionally, by changing product or service the organization may face new competitors or new markets. New management, such as a change in chief executive officer or president, often brings a period of transition during which upper-level managers are likely to alter existing business processes and personnel policies. Finally, new technology can create vast changes to the organization. Technology can change the production process or the working conditions (i.e., telecommuting), and these changes may influence the skills that employees use on the job.

During a transition period, a company may bring in management consultants to help the business as it reinvents itself or some process. It can be argued that these management consultants are more or less in the business of change. Many of the modern consulting firms emerged in the mid-twentieth century specifically offering their services as agents of organizational and structural change. These firms' success and longevity are testaments to the importance of change in the business world.

ROUTINE VERSUS NON-ROUTINE CHANGE

There are changes in organizations that are routine (e.g., they are commonplace and often expected), and there are those that are not routine (e.g., unique and unexpected). Examples of routine changes are organizational turnover and staffing replacements, small changes to products or services, or changes in human resources policies. Routine changes are the easiest to manage, and employees are somewhat accustomed to routine changes. There is typically little concern over implementing such changes. However, if not handled properly by management, even

routine change can prove to be difficult. If changes are not implemented properly or are not well communicated, problems may arise. For example, a small change to the company vacation policy may seem insignificant to management, but if employees are not properly apprised of the change it could result in considerable difficulty if employees do not follow the new policy.

Non-routine change is much more difficult than routine change; it can be unpredictable, significant, or even radical, and employees are much less likely to adapt well to non-routine change. In general, a non-routine change is seen as threatening, and employees are likely to be resistant. For instance, if a company announces a merger with a former competitor, this non-routine change is very likely to create anxiety about compensation and job security.

TYPES OF CHANGE

In addition to some of the major indicators of organizational change and the broad distinction of routine versus non-routine change, change can be categorized even more specifically into four categories: structural change, cost change, process change, and cultural change.

Structural change occurs when there is an alteration to the company's organizational structure. This reorganization may occur due to a merger or acquisition, or it may be the result of a restructuring. For instance, an organization that is intent on increasing its innovation may reorganize its traditional functional structure into a more flexible matrix structure that uses small, self-managed teams. Or, an organization that is expanding into new markets may adopt a divisional structure in which different geographic locations operate nearly independently of one another.

Cost changes are those that occur when an organization attempts to reduce costs in order to improve efficiency or performance. Major adjustments may be made to departments to cut costs: reducing budgets, laying off employees in redundant positions, and eliminating non-essential activities may all be a result of cost change.

Process changes are implemented to improve efficiency or effectiveness of organizational procedures. This may occur in production settings; there may be changes to how a product is created, assembled, packaged, or shipped. Or, in a service organization, there may be changes to the procedures used to accomplish work; new computer systems may create the need to change how paperwork is completed, or a new manager may modify the process used to handle customer complaints.

Cultural changes are the least tangible of all the types of change, but they can be the most difficult. An organization's culture is its shared set of assumptions, values, and beliefs. A prototypical culture is the very bureaucratic,

top-down style in which stability and standard processes are valued. When such an organization tries to adopt a more participative, involved style, this requires a shift in many organizational activities. Primarily, manager-employee relations are altered with a change in culture. Chris McKenna notes that consulting firms such as McKinsey and Co. regarded cultural change as so important that they began to focus on it in the 1980s.

IMPLEMENTING CHANGE

To properly implement change, management must take a number of steps: involving key people, developing a plan, supporting the plan, and communicating often.

1. The first step in implementing change is involving the key people; this typically means upper-level management and other executives whose processes and employees will be affected by the change. For instance, if a new computer system is to be installed in all areas of a company, key people would be not only top managers, but also lower-level managers who supervise the employees' use of the new technology. A different set of key people would be involved in a cost-cutting change. If the company is reducing its operating budget in a specific division, the managers of that division and also human resources personnel should be involved. In any circumstance in which there is a change to personnel policies or in which demotions, transfers, or layoffs occur, the human resources department should be involved to manage this change.

2. After key personnel have been identified and properly involved, the second step in implementing change is to develop a plan for effective transformation. The plan should help to define the responsibilities of the key people involved while also laying out short-term and long-term objectives for the changes. Because change can be unpredictable, the plan should also be flexible enough to accommodate new occurrences.

3. The third step in implementing change is to support the plan; this means that management follows through on the plan it created. Key to this step is enabling employees to adapt to the change. Employees may need training, reward systems may need to be adapted, or hiring may be required. If the organization does not provide the support necessary for the plan to take effect, it is unlikely to succeed.

4. The final step in successful change implementation should occur throughout the change process. Communicating with employees about what is occurring, why the changes are being made, and how they will develop is critical. Because change can create a lot of fear, increased communication can be used to calm

employees and encourage their continued support. In addition to downward communication, managers should pay attention to any upward communication that occurs. They should be available to take suggestions or answer questions that employees might have. Creating opportunities for employee feedback, such as holding meetings or having an open-door management policy, may facilitate change more successfully.

Heart of Change authors John Kotter and Dan Cohen also note that achieving permanent organizational change is only possible when that organization's culture also changes. Deal and Kennedy also highlight the role that internal culture plays in implementing and managing successful change. For example, they argue that the role of rituals can help members of an organization cope with change.

RESISTANCE TO CHANGE

As a general rule, it is not the proposed changes that people resist, but the impact that the changes will have on them, personally. People become comfortable in their jobs, in their areas of expertise, and in their relationships with coworkers and managers. Even when personnel are not very satisfied with the current workplace and therefore welcome change, they may find change to be stressful. Helping employees anticipate difficulties and informing employees of how these challenges will be handled can be a source of comfort to them. When an organization proposes large-scale change, those affected begin to worry about how their jobs will change, what new skills they will need, if their responsibilities will change, how established lines of communication will be altered, and how working relationships will change. The most successful members of a company may feel threatened because they were able to perform so well under the old organizational structure. Some common employee reactions to change include confusion, denial, loss of identity, and anger. And this resistance is not limited to employees—managers and executives may be just as prone as employees to experiencing problems with radical organizational change.

In their article, "Challenging 'Resistance to Change,'" Eric B. Dent and Susan Galloway Goldberg discuss their research on the origins of this concept and the prevalent idea that managers must overcome this resistance or are doomed to failure. Kurt Lewin, the mid-twentieth-century social psychologist, introduced the term "resistance to change" as a systems concept affecting managers and employees equally. The term, and not its original context, was adopted and used as a psychological concept placing employees against managers. Dent and Goldberg feel that

letting go of the term and its associations could help more useful models of change dynamics move forward.

There are theories of handling resistance to change that are related to this idea. While not explicitly questioning the use of the term, changing how organizations view resistance allows change to become an opportunity and not just a potential threat. Change is a personally challenging issue for everyone affected, but it also carries with it new possibilities. How corporate management responds to employee resistance can determine the fate of the organization. For example, a sense of confusion—usually represented by constant questioning from management and/or employees—usually means that not enough information has been provided. This can become an opportunity to convey additional information to employees, such as reiterating the big picture and why the company is working so hard to redefine its corporate culture. This is also a good time to provide assurances that management is going to take the time to address concerns.

Another common reaction is doubt or denial that actual change will occur. This reaction occurs sometimes because employees do not want change, and at other times because they do not believe management is fully committed to the idea. In any case, these reactions can also represent an opportunity for management to identify issues that may be present across the organization and address them. They can also alert management and higher-ups that actual implementation is not consistent with the plan that was put forth. A possibly related reaction is anger, sometimes accompanied by attempts to sabotage the company's efforts to change. Again, there can be benefits to this type of behavior. Employees who so visually make their feelings known let organizational leaders in on which impediments to change are likely to occur, and management can then formulate ways to address them. It also opens up areas for negotiation.

Peter Senge and his co-authors identified ten "challenges of change" (preferring the term "challenges" to "resistance") in the 1999 work *The Dance of Change: The Challenges to Sustaining Momentum in Learning Organizations*. As reported in *Fast Company*, he formalized these challenges as common excuses that are offered as reasons for resistance. These excuses can then be countered by addressing the real concerns behind them. For example, "This stuff isn't relevant" indicates the need for continuous and open communication from people who can convince others of the driving need for change in an organization. "This stuff isn't working" indicates a need for management to provide measurable criteria for success and clear expectations. "They . . . never let us do this stuff" indicates that, while management may be claiming

to offer groups and teams more autonomy, they are really having trouble letting go of their control.

Another concern is the fact that people who consider themselves specialists or experts in a given area are often asked to start over (e.g., working in a different functional area or using different technology), sometimes more than once when companies make cross-training one of their goals. Again, this threatens the comfort zone for many people at all levels of an organization. Having proven themselves once, they are being asked to do so over again. In order to allay these fears, management needs to encourage people to ask questions, take initiative, and take risks. Fear of failure is possibly one of the strongest reasons for resisting change. Companies that hope change will be embraced need to view risks and failures as tools through which the organization can learn and grow.

Along these same lines, resistance need not be a dirty word. Whereas organizations once felt it was most important to put a positive spin on everything, corporate management is realizing that showing their own concerns about organizational change helps other personnel to deal with theirs. It also affords them the opportunity to teach others how to identify best practices under less than ideal circumstances, and to let employees know they empathize with their concerns.

Resistance to change, as put forth by Kurt Lewin, affects managers and employees equally when systems undergo change. As such, resistance is a naturally occurring phenomenon that can be dealt with in a constructive manner. In a sense, resistance is a sign that radical change is indeed occurring and that an organization is not just redefining the status quo. Management can help by anticipating common reactions and using them to their best advantage. For instance, if an employee is able to make requested changes to his or her performance but not willing to do so, some negotiation might be all that is required to convince that person to follow along with the company's new direction. For those who buy into the need for change but lack some of the necessary skills, targeted training could be all that is needed to quell the fears of those people. Whatever the resistance an organization encounters, it is almost a guaranteed part of change, which has become a constant in the business landscape. With the globalization of markets and speeding technological innovation, an organization cannot afford to rest on its laurels.

RECENT EXAMPLES

There are numerous recent examples of companies that have successfully managed change. In 2007, *T+D* ran a story on the Indian computer company, Satyam, offering it as one such example. Satyam was faced with the challenge of rapid growth. The company's response was to reorganize its structure; Satyam now has what it calls "full lifecycle businesses," with each unit trying to emulate a small business. The article points out that this dramatic change was successful because the company carefully managed the process.

MANUFACTURING CONTROL VIA THE INTERNET

Manufacturing control via the Internet (e-manufacturing) refers to the process of integrating information and communication networks as well as Internet-supported robotics into the production systems, processes, and structures of the firm. As such, the firm uses the Internet to link production equipments and control functions of its manufacturing systems through series of real-time monitoring gadgets such as computers and mobile communication devices. E-manufacturing comes with many advantages that include: ubiquitous accessibility, remote-controlled monitoring possibilities, real-time communications capabilities, and increased production efficiency as a result of information-integrated production systems.

The unlimited linkage of manufacturing operations to the global communication infrastructure is a phenomenon that relies heavily on the Internet's networking technology. The Internet consists of physically-networked servers and advanced communication linkages that relay information across Web-based servers and client computers. The advent of the Internet and the subsequent advancement of digital technologies have introduced new economic frontiers characterized by the emergence of revolutionary and information-driven economic institutions. The increased access to the global information and communication infrastructures has closed the gaps among consumers, manufacturers, and suppliers by eliminating the political, economic, and geographic barriers.

BRIEF HISTORY OF THE INTERNET

The origins of the Internet can be traced to the 1960s military research activities of the United States Army. In the book titled *Internet Literacy*, Fred Hofstetter credits the United States Department of Defense for developing the first ever viable Internet called ARPANET through the Advanced Research Projects Agency (ARPA) in 1969. The main objective of ARPANET was to provide the U.S. military with a communication network capacity that could withstand turbulence and obstructions that rose from enemy attacks. It would accomplish this by relying on sets of networked computers to transmit labeled and addressed packets of information to designated destinations, even if one or more of the computers along the way stopped functioning. Thus, in the event of enemy attacks (such as a massive bombing campaign), the packets of information would automatically be routed through alternative paths to their intended destinations.

Commercial use of the Internet has been evident ever since the early 1990s following the liberalization of the National Science Foundation Network (NSFNET) in the United States. The move opened up the routing of high-speed Internet traffic to different interconnected Internet service providers (ISPs), thereby providing easy access to pioneer online auction and commercial entities such as Amazon, eBay, and PayPal. The Internet has since become a powerful tool for trade, commerce, and manufacturing because of its formidable infrastructure that runs across the globe.

THE INTERNET AND MANUFACTURING PROCESSES

The use of computer-based networking in production activities is based on the materials and requirement planning (MRP) framework that is demand dependent and specifically geared to assembly operations in firms. MRP was developed in the 1960s and still remains an important component of industrial manufacturing processes. Computerized MRP has evolved into MRP II, which involves linking and streamlining operations in different departments such as marketing, purchasing, production planning and control, human-resource management, and financial accounting.

MRP II integrates different functions in the firm into a central monitoring and decision system by collecting and relaying data and additional production inputs. The advancements in MRP II have given rise to enterprise resource planning (ERP), which integrates different types of industrial data, processes, and functions into a unified database through comprehensive linkages of software and hardware systems. Unlike MRP and MRP II, ERP has the capacity to link organizational functionalities through multiple systems. Instead of functions such as human resource management, production control, customer relations, financial accounting, and supply chain management existing in independent software applications and individual databases, ERP brings all these functions under one roof to share a single database and software applications.

The ability for ERP to streamline workflows, track processes, and improve productivity makes it easy for manufacturing companies to integrate e-manufacturing in controlling and managing industrial production processes. The implementation of e-manufacturing strategies through the existing ERP systems definitely revolutionizes the monitoring and functioning of the engineering capacity of machines, quality control, material control, and workflow processes.

Firms can use either in-house teams and software applications or software vendors and consultants to implement customized e-manufacturing systems. For example, Jain has contracted Rockwell Automation, a leading industrial automation software and service provider in the United States, to manage its entire processes of real-time automation and track the company's manufacturing data.

Companies can also outsource the management of e-manufacturing to industrial automation and software companies that have global presence such as Oracle and IBM.

The twenty-first century has experienced unprecedented increase in the use of telephone modems, Ethernet wireless connections, cable modems, digital subscriber lines (DSL), and satellite communications to access Web-based services such as e-mails, newsgroups, chat rooms, real-time messaging, and list servers through either computers or mobile devices. Manufacturing companies are embedding digital devices and sensors that range from micro-scale to macro-scale sizes in all aspects of production. For example, as Kwon Yongjin and Rauniar Shreepud point out in their 2007 journal article titled "E-Quality Manufacturing (EQM) Within the Framework of Internet-Based System" and contained in the *IEEE Transactions on Systems, Man and Cybernetics, Part C: Application and Reviews,* manufacturers use advanced tools such as the Ethernet SmartImage sensor and the Internet Controllable Yamaha Scara robot to initiate continuous correspondence in production processes with the objective of monitoring and achieving sustained quality control.

Manufacturing companies are continuously taking advantage of the advancements in Internet tracking and communications technologies to entrench quality control and monitor daily production activities in firms. In addition to using the Internet to remotely monitor and track production processes, companies also use the Internet to diagnose faulty functionalities of equipment and processes in the entire production system. Remote and automated access to manufacturing systems enables operations managers and production line experts to sustain quality control and initiate instant responses to sudden changes in a firm's manufacturing environment.

The most common real-time solutions that companies employ in production control include chat rooms and instant messaging (IM), which allows the use of voice calls, file sharing, webcams, information-on-demand (such as news, weather, auctions, and stock trading), and online status reporting. Leading IM providers include AOL Instant Messaging (AIM), Microsoft's MSN Messenger, Yahoo Messenger, and Skype.

The twenty-first century has also experienced the increased use of Ethernet video on the floor of the manufacturing plants to monitor operations, streamline coordination, train workers, and control repairs and maintenance. In an Internet article titled *Video via Ethernet Now,* Martin T. Hoske acknowledges that in addition to enhancing security applications during production processes, Ethernet video applications have also proved to be effective time-saving tools.

SECURITY AND THREATS TO E-MANUFACTURING

Real-time manufacturing control via the Internet is prone to enforceable inconveniences that are beyond the control of the organizations. Such inconveniences include network failure of ISPs or time lag as a result of network congestions. Moreover, the unauthorized access to network systems by hackers, crackers, state intelligence agencies, and other types of intruders remains the biggest threat to Internet security. Internet security threats come in the form of Internet break-ins, Internet fraud, and message sniffing.

Internet break-ins. Internet break-ins are particularly committed by crackers who gain unauthorized access into Web sites to collect private information about individuals, companies, and organizations. Crackers can disastrously land on a firm's private information such as credit card numbers, bank account details of individuals, or classified company information such as production formulas, secret codes, and classified data. In the United States, Internet break-in is treated both as theft and trespassing by the federal laws; offenders can be handed up to a five-year prison sentence for stealing money and ten years for fraudulent acquisition of a company's classified information.

Internet fraud. Internet fraud involves the use of Web site tools such as chat rooms, e-mails, or newsgroups by fraudsters to offer services and products that do not exist with the aim of convincing unsuspecting Internet users to transfer money or goods to the fraudsters. The increased prevalence of Internet fraud, particularly in online auctions, has prompted regulatory authorities in the United States to respond by setting up the Internet Fraud Complaint Center (IFCC). Consisting of a partnership between the Federal Bureau of Investigation (FBI) and the National White Collar Crime Center, the IFCC controls and coordinates campaigns against Internet fraud by providing Internet fraud reporting structures and mechanisms for forwarding fraud cases to law enforcement agencies.

Message sniffing. Message sniffing involves intercepting e-mail communication messages on the Internet with the aim of gaining access to the content of the e-mail messages. Sniffing targets the routes and gateways that link the networks to the Information Superhighway. Incidentally, each computer on the network is a gateway prone to hacking by crackers. For example, the FBI scans both local and international Internet communications in the United States using a customizable electronic sniffing gadget called Carnivore.

Carnivore can be installed in one or more ISPs to monitor the Internet traffic in regard to transmissions of e-mail, instant messaging, chat rooms, and newsgroups, and it automatically forwards any suspect communications

to the FBI data repositories. Although the use of Carnivore by the FBI to spy on private and public communications in the United States raises major privacy concerns, the action is fully backed by the USA Patriot Act of 2001 and the USA Patriot Improvement and Reauthorization Act of 2005, which have broadened the authority of U.S. intelligence and counterintelligence agencies to apply Internet-based surveillance systems in investigations.

DATA PROTECTION MEASURES FOR E-MANUFACTURING

So many security threats lurk in the communication network systems that no company can afford to run an unprotected Internet network. There are several measures that a company can employ to protect its Internet network from unauthorized access by intruders. Use of password protection, data encryption, firewall, data filters, and employee training are some of the probable measures that companies can adopt as protection against Internet security risks.

Use of passwords. Use of passwords enables companies to limit Web site access to users with authorized passwords. However, password codes should never be fully trusted because crackers can use sophisticated software to break the codes and access the private content in the Web site and e-mail messages.

Data encryption. Data encryption protects data from crackers and sniffing gadgets during the process of transmitting information between computers and network servers. Encrypted messages do not allow access to people who do not have the keys to the encryption codes. Pretty Good Privacy (PGP) is one good example of encryption programs. Fred Hofstetter contends that PGP provides a reliable mode for encrypting messages because it can run on any brand of computer. Companies can acquire messaging software such as Mozilla Thunderbird and Microsoft Outlook which are equipped with built-in encryption abilities.

Firewalls. Firewalls stand out as reliable Internet-security-enhancing tools because they prevent a company's data from flowing beyond the domain restrictions, in addition to preventing users of other domains from accessing the company's domain. Companies implement firewall restrictions by combining software tools, hardware equipment, and relevant IT security policies that block the movement of restricted data across the company's network and computers.

Firewalls are particularly used to protect the company's intranet from unlimited public access through programming of the firewall software to regulate minimum and maximum access levels between the company's intranet and the public Internet.

Data filters. Companies can use data filters to scan and sift the outgoing and incoming data for certain types of Internet content. Data filters can be applied in situations where the company is seeking to block employees from accessing certain Web sites such as adult content and Internet gambling sites. Data filters can be set either on the user or client servers.

Employee training. Employee training through Internet education programs can tremendously improve safety of Internet use in the company apart from improving the capacities of employees to detect and handle fraud. Employees should always be discouraged from responding to everything that they read on the Internet. Employees should be made aware of the dangers of revealing their personal bank account and credit card information and the company's classified data to information seekers with concealed identities.

MANUFACTURING RESOURCES PLANNING

Manufacturing resource planning, also known as MRP II, is a method for the effective planning of a manufacturer's resources. MRP II is composed of several linked functions, such as business planning, sales and operations planning, capacity requirements planning, and all related support systems. The output from these MRP II functions can be integrated into financial reports, such as the business plan, purchase commitment report, shipping budget, and inventory projections. It has the capability of specifically addressing operational planning and financial planning, and has simulation capability that allows its users to conduct sensitivity analyses (answering "what if" questions).

The earliest form of manufacturing resource planning was known as material requirements planning (MRP). This system was vastly improved upon until it no longer resembled the original version. The newer version was so fundamentally different from MRP that a new term seemed appropriate. Oliver Wight coined the acronym MRP II for manufacturing resource planning.

A basic understanding of MRP is essential to understanding MRP II. The following paragraphs begin with a description of MRP before moving on to MRP II.

MATERIAL REQUIREMENTS PLANNING

Material requirements planning (MRP) is a computer-based, time-phased system for planning and controlling the production and inventory function of a firm from the purchase of materials to the shipment of finished goods. All MRP systems are computer based since the detail involved and the inherent burden of computation make manual use prohibitive. MRP is time phased because it not only determines what and how much needs to be made or purchased, but also when.

MRP first appeared in the early 1970s and was popularized by a book of the same name by Joseph Orlicky. Its use was quickly heralded as the new manufacturing panacea, but enthusiasm slowed somewhat when firms began to realize the difficulty inherent in its implementation.

The MRP system is composed of three primary modules, all of which function as a form of input. These are the master production schedule, the bill-of-materials, and the inventory status file. Each module serves a unique purpose that is inter-related with the purpose of the other modules, and produces several forms of usable output.

Master Production Schedule. The master production schedule (MPS) is basically the production schedule for finished goods. This schedule is usually derived from current orders, plus any forecast requirements. The MPS is divided into units of time called "buckets." While any time frame may be utilized, usually days or weeks is appropriate. The MPS is also said to be the aggregate plan "disaggregated." In other words, the plan for goods to be produced in aggregate is broken down into its individual units or finished goods.

Bill-of-Materials. The bill-of-materials is a file made up of bills-of-material (BOM). Each BOM is a hierarchical listing of the type and number of parts needed to produce one unit of finished goods. Other information, such as the routings (the route through the system that individual parts take on the way to becoming a finished good), alternate routings, or substitute materials may be also be contained with the BOM.

A tool known as a product structure tree is used to clarify the relationship among the parts making up each unit of finished goods. Figure 1 details how a product structure tree for a rolling cart might appear on a bill-of-material. This cart consists of a top that is pressed from a sheet of steel; a frame formed from four steel bars; and a leg assembly consisting of four legs, each with a caster attached. Each caster is made up of a wheel, a ball bearing, an axle, and a caster frame.

The BOM can be used to determine the gross number of component parts needed to manufacturer a given number of finished goods. Since a gross number is determined, safety stock can be reduced because component parts may be shared by any number of finished goods (this is known as commonality).

The process of determining gross requirements of components is termed the "explosion" process, or "exploding" the bill-of-material. Assuming 100 rolling carts are needed, the example product structure tree can be used to compute the gross requirements for each rolling cart component. In order to produce 100 rolling carts, 100 tops are needed, which would require 100 sheets of steel; 100 leg assemblies, which would require 400 legs and 400 casters (requiring 400 wheels, 400 ball bearings,

Figure 1

Cart

Top — Leg Assembly — Frame

sheet steel

bars (4)

legs (4) — casters (4)

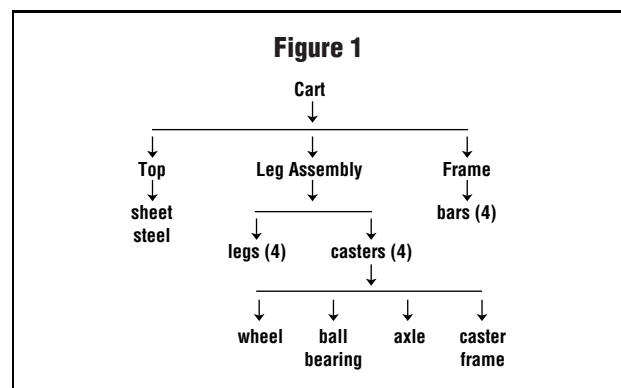
wheel — ball bearing — axle — caster frame


Figure 2

	1	2	3	4	5	6
Gross Requirements			100			250
Scheduled Receipts (open orders)			50		50	
On Hand (inventory balance)	25	25	25	0	0	50
Net Requirements			25			200
Planned Order Receipt			25			200
Planned Order Release	25			200		

400 axles, and 400 caster frames); and 100 frames, which would require 400 bars.

Inventory Status File. The inventory status file, or inventory records file, contains a count of the on-hand balance of every part held in inventory. In addition, the inventory status file contains all pertinent information regarding open orders and the lead time (the time that elapses between placing an order and actually receiving it) for each item.

Open orders are purchase orders (orders for items purchased outside the firm) or shop orders (formal instructions to the plant floor to process a given number of parts by a given date) that have not been completely satisfied. In other words, they are items that have been ordered, but are yet to be received.

The MRP Process. The MRP logic starts at the MPS, where it learns the schedule for finished goods (how many and when). It takes this information to the BOM where it "explodes" the gross requirements for all component parts. The MRP package then takes its knowledge of the gross requirements for all components parts to the inventory status file, where the on-hand balances are listed. It then subtracts the on-hand balances and open orders from the gross requirements for components yielding the net requirements for each component.

The process not only shows how many components are needed but when they are needed in order to complete the schedule for finished goods on time. By subtracting the lead time from the due date for each part, it is possible to see when an order must be placed for each part so that it can be received in time to avoid a delay in the MPS. A manual version of MRP for a part with requirements of 100 in period 3 and 250 in period 6 and with a two-period lead time is shown in Figure 2.

In order for the firm to meet demand on time (the MPS), it must place an order for 25 in period 1 and an order for 200 in period 4. Note that this is an overly simplified version of MRP, which does not include such relevant factors as lot sizing and safety stock.

EXPANDING INTO MRP II

With MRP generating the material and schedule requirements necessary for meeting the appropriate sales and inventory demands, more than the obvious manufacturing resources for supporting the MRP plan was found to be needed. Financial resources would have to be generated in varying amounts and timing. Also, the process would require varying degrees of marketing resource support. Production, marketing, and finance would be operating without complete knowledge or even regard for what the other functional areas of the firm were doing.

In the early 1980s MRP was expanded into a much broader approach. This new approach, manufacturing resource planning (MRP II), was an effort to expand the scope of production resource planning and to involve other functional areas of the firm in the planning process, most notably marketing and finance, but also engineering, personnel, and purchasing. Incorporation of other functional areas allows all areas of the firm to focus on a common set of goals. It also provides a means for generating a variety of reports to help managers in varying functions monitor the process and make necessary adjustments as the work progresses.

When finance knows which items will be purchased and when products will be delivered, it can accurately project the firm's cash flows. In addition, personnel can project hiring or layoff requirements, while marketing can keep track of up-to-the-minute changes in delivery times, lead times, and so on. Cost accounting information is gathered, engineering input is recorded, and distribution requirements planning is performed.

An MRP II system also has a simulation capability that enables its users to conduct sensitivity analyses or evaluate a variety of possible scenarios. The MRP II system can simulate a certain decision's impact throughout the organization, and predict its results in terms of customer orders, due dates, or other "what if" outcomes. Being able to answer these "what if" questions provides a firmer grasp of available options and their potential consequences.

As with MRP, MRP II requires a computer system for implementation because of its complexity and relatively large scale. Pursuit of MRP or MRP II in a clerical fashion would prove far too cumbersome to ever be useful. When MRP and MRP II were originally developed, hardware, software, and database technology were not sufficiently well advanced to provide the speed and computational power needed to run these systems in real time. Additionally, the cost of these systems was prohibitive. With the rapid advances in computer and information technology since the 1980s, these systems have become more affordable and widely available.

CLASSES OF FIRMS USING MRP AND MRP II

MRP and MRP II users are classified by the degree to which they utilize the various aspects of these systems. Class D companies have MRP working in their data processing area, but utilize little more than the inventory status file and the master production schedule, both of which may be poorly used and mismanaged. Typically, these firms are not getting much return for the expense incurred by the system.

Class C firms use their MRP system as an inventory ordering technique but make little use of its scheduling capabilities.

Class B companies utilize the basic MRP system (MPS, BOM, and Inventory file) with the addition of capacity requirements planning and a shop floor control system. Class B users have not incorporated purchasing into the system and do not have a management team that uses the system to run the business, but rather see it as a production and inventory control system.

Class A firms are said use the system in a closed loop mode. Their system consists of the basic MRP system, plus capacity planning and control, shop floor control, and vendor scheduling systems. In addition, their management uses the system to run the business. The system provides the game plan for sales, finance, manufacturing, purchasing, and engineering. Management then can use the system's report capability to monitor accuracy in the BOM, the inventory status file, and routing, as well as monitor the attainment of the MPS and capacity plans.

Class A firms have also tied in the financial system and have developed the system's simulation capabilities to answer "what if" questions. Because everyone is using the same numbers (e.g., finance and production), management has to work with only one set of numbers to run the business.

DEVELOPMENTS

A further extension of MRP and MRP II has been developed to improve resource planning by broadening the scope of planning to include more of the supply chain. The Gartner Group of Stamford, Connecticut, coined the term "enterprise resource planning" (ERP) for this system. Like MRP II systems, ERP systems rely on a common database throughout the company with the additional use of a modular software design that allows new programs to be added to improve the efficiency of specific aspects of the business.

With the improvement of lean manufacturing and just-in-time (JIT) systems that has occurred because of the same technological advances that made MRP and MRP II more accessible, some firms have come to feel that MRP, MRP II, and even ERP systems are obsolete. However, research has found that in certain environments with advance demand information, MRP-type push strategies yield better performance in term of inventories and service levels than did JIT's kanban-based pull strategies, and they continue to be used by big businesses and many medium and smaller businesses even today. In 2007, author Phil Robinson noted that "when properly implemented, an ERP package can be the most cost effective project a company has ever seen."

By the early twenty-first century, MRP and ERP systems were so entrenched in businesses that they no longer provided a source of competitive advantage. In 2005, the authors of *Manufacturing Planning and Control for Supply Chain Management* pointed out that sustaining competitive advantage would require that manufacturing planning and control (MPC) systems cross organizational boundaries to coordinate company units that have traditionally worked independently. They recommend that organizations need to begin working in pairs or dyads to develop jointly new MPC systems that allow integrated operations. Organizations will learn as much as possible from each dyad and then leverage what they have learned into other dyads. They termed this approach the "next frontier" for manufacturing planning and control systems.

MARKET SHARE

Firms are always concerned with the size of the potential market for their products or services and the proportion of that market they actually reach—often referred to as a company's market share. Market share is the percentage of the total market (or industry) sales made by one firm. As a formula, Market Share = Firm's Sales ÷ Total Market Sales. Share can be reflected as either percentage of sales dollars, percentage of units sold, or percentage of customers. Percentage of sales dollars is the most common reference.

Market share is one of the most commonly quoted measures of success in any industry. To correctly determine market share, one must clearly define the market. Having a small share of a large market can be as profitable as a large share of a small market. A producer of leather horse saddles must determine if his market is made up of saddle sales, equestrian sales, or all leather goods sales. Obviously, his market share in the saddle industry is much larger than his share in the leather goods market.

There are two sources for measuring market share: competitors and consumers. Surveying competitors gives a more accurate and reliable picture of market share. It is possible to interview 100 percent of competitors, but not all consumers. To get a reliable figure from consumers, a large number of people would have to be interviewed. For many industries, sales and market share figures may already be compiled by government agencies, trade associations, or private research firms.

MARKET PLAYERS

Market share defines the roles played by various firms in an industry. The firm with the largest market share is the market leader. The market leader usually has the highest marketing expenditures, distribution, price changes, and new product innovations. Market challengers are the firms working to increase their market share. Firms in an industry that are content with their share of the market or doing little to increase sales are considered the market followers. The market niche brand is the player that targets its business toward serving smaller, overlooked segments that are often ignored by the larger players. The niche marketer can be very profitable, opting for high margins over higher volume.

MARKET STRATEGIES

The leader must constantly monitor the market because the challenger is constantly trying to take away market share. The market leader has three options to keep its market position: expand the total market, protect market share, or expand market share. Markets can be expanded by creating more usage, new uses, or new users. Leaders can protect market share by monitoring their position and rushing to remedy any weaknesses.

Continuous innovation is the best way to protect market share. Another way to protect market share is to remove competitors through acquisition or merger. This strategy has become more and more popular among large firms, resulting in an increasing level of corporate consolidation since the mid-1990s.

Maintaining market share often requires constant innovation and change. When leaders become complacent with their products or services, it becomes easier for the challenger to make progress. A 2007 report indicated that both Coke and Pepsi were seeing their dominant market shares slip as health-conscious consumers switched to vitamin-infused energy drinks and bottled water. In response, both companies announced new products to chase that new trend. In large markets such as this, small increases or decreases in market share can translate into very large changes in sales; one point of market share can be worth hundreds of millions of dollars.

The market challenger must attempt to gain market share from the leader. The challenger must have some sustainable competitive advantage to attack the leader's market share. The challenger can attack other competitors through a direct attack by altering price, promotion, or distribution, or indirectly by diversifying or catering to underserved segments. Followers must keep quality high and prices low to maintain their positions. As Armstrong and Kolter point out in *Principles of Marketing*, the market follower must "find the right balance between following closely enough to win customers from the market leader but . . . at enough of a distance to avoid retaliation."

Niche marketers have many options available to them. The company must find a niche that is safe and profitable. It must be large enough to sustain growth but small enough that it does not look attractive to the market's larger players. Targeting multiple niches is an option that offers the niche marketer a higher chance of survival because the firm is not dependent on one segment.

Across segments, attempts to affect market share take place across the four "P's" of the marketing mix: product, price, place, and promotion. However, there are instances in which increasing market share is not necessarily desirable. The costs to increase production or improve the product may not be covered by the incremental profits.

Market share is easily understood by most managers, employees, and shareholders; therefore, it is often used as a primary measure of success. It is critical to understand market share, how it is used to identify market participants, and how the different participants use it to determine their market strategy.

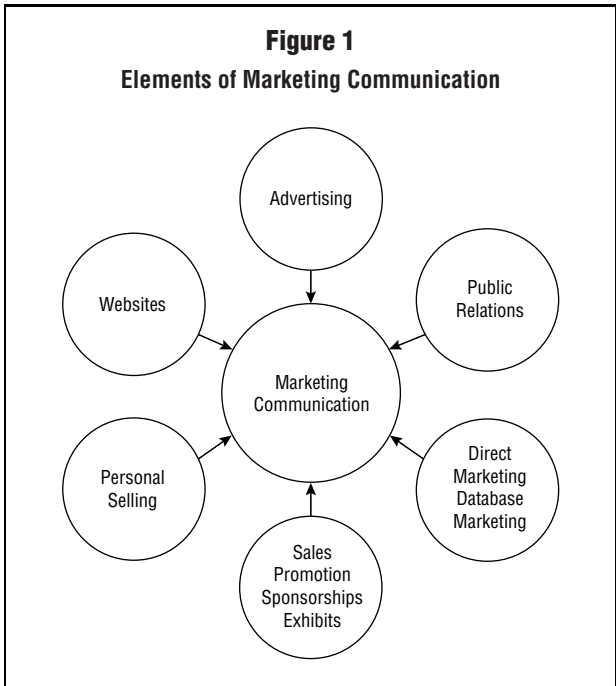
MARKETING COMMUNICATION

As the term suggests, marketing communication functions within a marketing framework. Traditionally known as the promotional element of the four Ps of marketing (product, place, price, and promotion), the primary goal of marketing communication is to reach a defined audience to affect its behavior by informing, persuading, and reminding. Marketing communication acquires new customers for brands by building awareness and encouraging trial. Marketing communication also maintains a brand's current customer base by reinforcing their purchase behavior by providing additional information about the brand's benefits. A secondary goal of marketing communication is building and reinforcing relationships with customers, prospects, retailers, and other important stakeholders.

Successful marketing communication relies on a combination of options called the promotional mix. These options include advertising, sales promotion, public relations, direct marketing, and personal selling. The role each element takes in a marketing communication program relies in part on whether a company employs a push strategy or a pull strategy. A pull strategy relies more on consumer demand than personal selling for the product to travel from the manufacturer to the end user. The demand generated by advertising, public relations, and sales promotion "pulls" the good or service through the channels of distribution. A push strategy, on the other hand, emphasizes personal selling to push the product through these channels.

For marketing communication to be successful, however, sound management decisions must be made in the other three areas of the marketing mix: the product, service, or idea itself; the price at which the brand will be offered; and the places at or through which customers may purchase the brand. The best promotion cannot overcome poor product quality, inordinately high prices, or insufficient retail distribution.


Likewise, successful marketing communication relies on sound management decisions regarding the coordination of the various elements of the promotional mix. To this end, a concept known as integrated marketing communication (IMC) has emerged; it seeks to orchestrate the use of all forms of the promotional mix to reach customers at different levels in new and better ways.

INTEGRATED MARKETING COMMUNICATION

The evolution of this perspective has two origins. Marketers began to realize that advertising, public relations, and sales were often at odds regarding responsibilities, budgets, management input, and a myriad of other decisions affecting the successful marketing of a brand. Executives in each area competed with the others for resources and a voice in decision making. The outcome was inconsistent promotional efforts, wasted money, counterproductive management decisions, and, perhaps worst of all, confusion among consumers.

Secondly, the marketing perspective itself began to shift from being market oriented to market driven. Marketing communication was traditionally viewed as an inside-out way of presenting the company's messages.

Figure 1
Elements of Marketing Communication

Advertising was the dominant element in the promotional mix because the mass media could effectively deliver a sales message to a mass audience. But then, the mass market began to fragment; consumers became better educated and more skeptical about advertising. A variety of sources, both controlled by the marketer and uncontrolled, became important to consumers. News reports, word-of-mouth, experts' opinions, and financial reports were just some of the "brand contacts" consumers began to use to learn about and form attitudes and opinions about a brand or company, or make purchase decisions. Advertising began to lose some of its luster in terms of its ability to deliver huge homogeneous audiences. In response, companies began to seek new ways to coordinate the multiplicity of product and company messages being issued and used by consumers and others.

Thus, two ideas permeate integrated marketing communication: relationship building and synergy. Rather than the traditional inside-out view, IMC is seen as an outside-in perspective. Customers are viewed not as targets but as partners in an ongoing relationship. Customers, prospects, and others encounter the brand and company through a host of sources and create from these various contacts ideas about the brand and company. By knowing the media habits and lifestyles of important consumer segments, marketers can tailor messages through media that are most likely to reach these segments at times when these segments are most likely to be receptive to these messages, thus optimizing the marketing communication effort.

Ideally, IMC is implemented by developing comprehensive databases on customers and prospects, segmenting these current and potential customers into groups with certain common awareness levels, predispositions, and behaviors, and developing messages and media strategies that guide the communication tactics to meet marketing objectives. In doing this, IMC builds and reinforces mutually profitable relationships with customers and other important stakeholders and generates synergy by coordinating all elements in the promotional mix into a program that possesses clarity, consistency, and maximum impact.

Practitioners and academics alike, however, have noted the difficulty of effectively implementing IMC. Defining exactly what IMC is has been difficult. For example, merely coordinating messages so that they speak "with one clear voice" in all promotional efforts does not fully capture the meaning of IMC. Also, changing the organization to accommodate the integrated approach has challenged the command and control structure of many organizations.

ADVERTISING

Advertising has four characteristics: it is persuasive in nature; it is non-personal; it is paid for by an identified sponsor; and it is disseminated through mass channels of communication. Advertising messages may promote the adoption of goods, services, persons, or ideas. Because the sales message is disseminated through the mass media—as opposed to personal selling—it is viewed as a much cheaper way of reaching consumers. However, its non-personal nature means it lacks the ability to tailor the sales message to the message recipient and, more importantly, actually get the sale. Therefore, advertising effects are best measured in terms of increasing awareness and changing attitudes and opinions, not creating sales. Advertising's contribution to sales is difficult to isolate because many factors influence sales. The contribution advertising makes to sales are best viewed over the long run.

The exception to this thinking is within the Internet arena. While banner ads, pop-ups, and interstitials should still be viewed as brand promoting and not necessarily sales drivers, technology provides the ability to track how many of a Web site's visitors click the banner, investigate a product, request more information, and ultimately make a purchase.

Through the use of symbols and images, advertising can help differentiate products and services that are otherwise similar. Advertising also helps create and maintain brand equity. Brand equity is an intangible asset that results from a favorable image, impressions of differentiation, or consumer attachment to the company, brand, or trademark. This equity translates into greater sales volume, and/or higher margins, thus greater competitive advantage. Brand equity is established and maintained through advertising that focuses on image, product attributes, service, or other features of the company and its products or services.

Cost is the greatest disadvantage of advertising. The average cost for a 30-second spot on network television increased fivefold between 1980 and 2005. Plus, the average cost of producing a thirty-second ad for network television is quite expensive. It is not uncommon for a national advertiser to spend in the millions of dollars for one thirty-second commercial to be produced. Add more millions on top of that if celebrity talent is utilized.

Credibility and clutter are other disadvantages. Consumers have become increasingly skeptical about advertising messages and tend to resent advertisers' attempt to persuade. Advertising is everywhere, from network television, to daily newspapers, to roadside billboards, to golf course signs, to stickers on fruit in grocery stores. Clutter encourages consumers to ignore many advertising messages. Further, technologies such as DVRs (digital video recorders) allow consumers to record programs and then skip commercials, and satellite radio provides a majority of its channels advertising free.

PUBLIC RELATIONS

Public relations is defined as a management function which identifies, establishes, and maintains mutually beneficial

relationships between an organization and the public upon which its success or failure depends. Whereas advertising is a one-way communication from sender (the marketer) to the receiver (the consumer or the retail trade), public relations considers multiple audiences (consumers, employees, suppliers, vendors, etc.) and uses two-way communication to monitor feedback and adjust both its message and the organization's actions for maximum benefit. A primary tool used by public relations practitioners is publicity. Publicity capitalizes on the news value of a product, service, idea, person, or event so that the information can be disseminated through the news media. This third party "endorsement" by the news media provides a vital boost to the marketing communication message: credibility. Articles in the media are perceived as being more objective than advertisements, and their messages are more likely to be absorbed and believed. For example, after the CBS newsmagazine *60 Minutes* reported in the early 1990s that drinking moderate amounts of red wine could prevent heart attacks by lowering cholesterol, red wine sales in the United States increased 50 percent. Another benefit publicity offers is that it is free, not considering the great amount of effort it can require to get out-bound publicity noticed and picked up by media sources.

Public relations' role in the promotional mix is becoming more important because of what Philip Kotler describes as an "over communicated society." Consumers develop "communication-avoidance routines" where they are likely to tune out commercial messages. As advertising loses some of its cost-effectiveness, marketers are turning to news coverage, events, and community programs to help disseminate their product and company messages. Some consumers may also base their purchase decisions on the image of the company, for example, how environmentally responsible the company is. In this regard, public relations plays an important role in presenting, through news reports, sponsorships, "advertorials" (a form of advertising that instead of selling a product or service promotes the company's views regarding current issues), and other forms of communication, what the company stands for.

DIRECT MARKETING AND DATABASE MARKETING

Direct marketing, the oldest form of marketing, is the process of communicating directly with target customers to encourage response by telephone, mail, electronic means, or personal visit. Users of direct marketing include retailers, wholesalers, manufacturers, and service providers, and they use a variety of methods including direct mail, telemarketing, direct-response advertising, online computer shopping services, cable shopping networks, and infomercials. Traditionally not viewed as an element in the promotional mix, direct marketing represents one of the most profound changes in marketing and promotion in the last twenty-five years. Aspects of direct marketing, which includes direct response advertising and direct mail advertising as well as the various research and support activities necessary for their implementation, have been adopted by virtually all companies engaged in marketing products, services, ideas, or persons.

Direct marketing has become an important part of many marketing communication programs for three reasons. First, the number of two-income households has increased dramatically. About six in every ten women in the United States work outside the home. This has reduced the amount of time families have for shopping trips. Secondly, more shoppers than ever before rely on credit cards for payment of goods and services. These cashless transactions make products easier and faster to purchase. Finally, technological advances in telecommunications and computers allow consumers to make purchases from their homes via telephone, television, or computer with ease and safety. These three factors have dramatically altered the purchasing habits of American consumers and made direct marketing a growing field worldwide.

Direct marketing allows a company to target more precisely a segment of customers and prospects with a sales message tailored to their specific needs and characteristics. Unlike advertising and public relations, whose connections to actual sales are tenuous or nebulous at best, direct marketing offers accountability by providing tangible results. The economics of direct marketing have also improved over the years as more information is gathered about customers and prospects. By identifying those consumers they can serve more effectively and profitably, companies may be more efficient in their marketing efforts. Whereas network television in the past offered opportunities to reach huge groups of consumers at a low cost per thousand, direct marketing can reach individual consumers and develop a relationship with each of them.

Research indicates that brands with strong brand equity are more successful in direct marketing efforts than little-known brands. Direct marketing, then, works best when other marketing communication such as traditional media advertising supports the direct marketing effort.

Direct marketing has its drawbacks also. Just as consumers built resistance to the persuasive nature of advertising, so have they with direct marketing efforts. Direct marketers have responded by being less sales oriented and more relationship oriented. Also, just as consumers grew weary of advertising clutter, so have they with the direct marketing efforts. Consumers are bombarded with mail, infomercials, and telemarketing pitches daily. Some direct marketers have responded by regarding privacy as a customer service benefit. Direct marketers must also overcome consumer mistrust of direct marketing efforts due to

incidents of illegal behavior by companies and individuals using direct marketing. The U.S. Postal Service, the Federal Trade Commission, and other federal and state agencies may prosecute criminal acts. The industry then risks legislation regulating the behavior of direct marketers if it is not successful in self-regulation. The Direct Marketing Association, the leading trade organization for direct marketing, works with companies and government agencies to initiate self-regulation. In March of 2003 the National Do Not Call Registry went into affect whereby consumers added their names to a list that telemarketers had to eliminate from their out-bound call database.

Database Marketing. Database marketing is a form of direct marketing that attempts to gain and reinforce sales transactions while at the same time being customer driven. Successful database marketing continually updates lists of prospects and customers by identifying who they are, what they are like, and what they are purchasing now or may be purchasing in the future. By using database marketing, marketers can develop products and/or product packages to meet their customers' needs or develop creative and media strategies that match their tastes, values, and lifestyles. Like IMC, database marketing is viewed by many marketers as supplanting traditional marketing strategies and is a major component of most IMC programs.

At the core of database marketing is the idea that market segments are constantly shifting and changing. People who may be considered current customers, potential customers, and former customers and people who are likely never to be customers are constantly changing. By identifying these various segments and developing a working knowledge of their wants, needs, and characteristics, marketers can reduce the cost of reaching non-prospects and build customer loyalty. Perhaps the most important role of database marketing is its ability to retain customers. The cumulative profit for a five-year loyal customer is between seven and eight times the first-year profit.

Since database marketing is expensive to develop and complex to implement effectively, companies considering database marketing should consider three important questions. First, do relatively frequent purchasers or high dollar volume purchasers for the brand exist? Secondly, is the market diverse enough so that segmenting into subgroups would be beneficial? Finally, are there customers that represent opportunities for higher volume purchases?

SALES PROMOTION/ SPONSORSHIPS/EXHIBITIONS

Sales promotions are direct inducements that offer extra incentives to enhance or accelerate the product's movement from producer to consumer. Sales promotions may be directed at the consumer or the trade. Consumer promo-

tions such as coupons, sampling, premiums, sweepstakes, price packs (packs that offer greater quantity or lower cost than normal), low-cost financing deals, and rebates are purchase incentives in that they induce product trial and encourage repurchase. Consumer promotions may also include incentives to visit a retail establishment or request additional information. Trade promotions include slotting allowances ("buying" shelf space in retail stores), allowances for featuring the brand in retail advertising, display and merchandising allowances, buying allowances (volume discounts and other volume-oriented incentives), bill back allowances (pay-for-performance incentives), incentives to salespeople, and other tactics to encourage retailers to carry the item and to push the brand.

Two perspectives may be found among marketers regarding sales promotion. First, sales promotion is supplemental to advertising in that it binds the role of advertising with personal selling. This view regards sales promotion as a minor player in the marketing communication program. A second view regards sales promotion and advertising as distinct functions with objectives and strategies very different from each other. Sales promotion in this sense is equal to or even more important than advertising. Some companies allocate as much as 75 percent of their advertising/promotion dollars to sales promotion and just 25 percent to advertising. Finding the right balance is often a difficult task. The main purpose of sales promotion is to spur action. Advertising sets up the deal by developing a brand reputation and building market value. Sales promotion helps close the deal by providing incentives that build market volume.

Sales promotions can motivate customers to select a particular brand, especially when brands appear to be equal, and they can produce more immediate and measurable results than advertising. However, too heavy a reliance on sales promotions results in "deal-prone" consumers with little brand loyalty and too much price sensitivity. Sales promotions can also force competitors to offer similar inducements, with sales and profits suffering for everyone.

Sponsorships. Sponsorships, or event marketing, combine advertising and sales promotions with public relations. Sponsorships increase awareness of a company or product, build loyalty with a specific target audience, help differentiate a product from its competitors, provide merchandising opportunities, demonstrate commitment to a community or ethnic group, or impact the bottom line. Like advertising, sponsorships are initiated to build long-term associations. Organizations sometimes compare sponsorships with advertising by using gross impressions or cost-per-thousand measurements. However, the value of sponsorships can be very difficult to measure. Companies considering sponsorships should consider the short-term public relations

value of sponsorships and the long-term goals of the organization. Sports sponsorships make up about two-thirds of all sponsorships.

Exhibits. Exhibits, or trade shows, are hybrid forms of promotion between business-to-business advertising and personal selling. Trade shows provide opportunities for face-to-face contact with prospects, enable new companies to create a viable customer base in a short period of time, and allow small and midsize companies that may not be visited on a regular basis by salespeople to become familiar with suppliers and vendors. Because many trade shows generate media attention, they have also become popular venues for introducing new products and providing a stage for executives to gain visibility.

PERSONAL SELLING

Personal selling includes all person-to-person contact with customers with the purpose of introducing the product to the customer, convincing him or her of the product's value, and closing the sale. The role of personal selling varies from organization to organization, depending on the nature and size of the company, the industry, and the products or services it is marketing. Many marketing executives realize that both sales and non-sales employees act as salespeople for their organization in one way or another. One study that perhaps supports this contention found that marketing executives predicted greater emphasis being placed on sales management and personal selling in their organization than on any other promotional mix element. These organizations have launched training sessions that show employees how they act as salespeople for the organization and how they can improve their interpersonal skills with clients, customers, and prospects. Employee reward programs now reward employees for their efforts in this regard.

Personal selling is the most effective way to make a sale because of the interpersonal communication between the salesperson and the prospect. Messages can be tailored to particular situations, immediate feedback can be processed, and message strategies can be changed to accommodate the feedback. However, personal selling is typically also the most expensive way to make a sale.

Sales and marketing management classifies salespersons into one of three groups: creative selling, order taking, and missionary sales reps. Creative selling jobs require the most skills and preparation. They are the "point person" for the sales function. They prospect for customers, analyze situations, determine how their company can satisfy wants and needs of prospects, and, most importantly, get an order. Order takers take over after the initial order is received. They handle repeat purchases (straight rebuys) and modified rebuys. Missionary sales

reps service accounts by introducing new products, promotions, and other programs. Orders are taken by order takers or by distributors.

INTERNET MARKETING

Just as direct marketing has become a prominent player in the promotional mix, so too has the Internet. Virtually unheard of in the 1980s, the 1990s saw this new medium explode onto the scene, being adopted by families, businesses and other organizations. Web sites provide a new way of transmitting information, entertainment, and advertising, and have generated a new dimension in marketing: electronic commerce. E-commerce is the term used to describe the act of selling goods and services over the Internet. In other words, the Internet has become more than a communication channel; it is a marketing channel itself with companies such as Amazon.com, eBay, and others selling goods via the Internet to individuals around the globe.

Public relations practitioners soon realized the value that Web sites offer in establishing and maintaining relationships with important publics. For example, company and product information can be posted on the company's site for news reporters researching stories and for current and potential customers seeking information. Political candidates have Web sites that provide information about their background and their political experience.

The interactivity of the Internet is perhaps its greatest asset. By communicating with customers, prospects, and others one-on-one, firms can build databases that help them meet specific needs of individuals, thus building a loyal customer base. Because the cost of entry is negligible, the Internet is cluttered with Web sites. However, this clutter does not present the same kind of problem that advertising clutter does. Advertising and most other forms of promotion assume a passive audience that will be exposed to marketing communication messages via the mass media or mail regardless of their receptivity. Web sites require audiences who are active in the information-seeking process to purposely visit the site. Therefore, the quality and freshness of content is vital for the success of the Web site.

VIRAL MARKETING

The Internet has also given rise to completely new forms of marketing. Often, these techniques are not generated by a marketing department, but rather, are adaptations of communications that have emerged independently. Ultimately, the Internet allows for direct communication with potential customers as well as providing those customers with a greater degree of interactivity. For example, David Meerman Scott notes that the marketers of FutureNow have released numerous press releases directly to the Web, instead of targeting the press and other media outlets. The strategy

here was to "reach bloggers and consumers via search engines and RSS feeds through news release content."

In particular, *blogs* (short for "Web logs") have become a way of communicating with potential customers as well as a means to track public perception of a company. For instance, Meerman Scott points out the ability to comment on blogs provides a way for marketers to target and tailor communication while also making this communication seem more like a dialogue.

Because of the interactive nature of the Internet, it lends itself to what is known as "viral marketing." Here, the public send and link content containing some marketing communication to people they know. This also lends a degree of authenticity to the message. With viral marketing, the goal is to generate "buzz."

However, companies must be careful when using these forms of marketing communication. For example, in 2006 it became known that a public relations firm was operating two blogs on behalf of Wal-Mart. However, the blogs themselves were presented in such a way as to appear that they were authored by independent individuals. Ultimately, the public relations firm apologized for the tactic. Perceived disingenuousness can change a company's fortunes, and the technologies that make viral marketing a powerful tool can also be used to quickly spread bad publicity.

COMPLICATIONS FROM GLOBALIZATION

The task of marketing communication has also become more difficult in a globalized age. A 2006 story in *Business Strategy* noted that a nation's standing in the world can affect consumers' purchasing decisions. The article points out that U.S. brands may have suffered in foreign countries because of citizens' disagreement with U.S. foreign policy. This is, of course, a matter that is mainly out of a company's hands. However, some argue that multinational corporations must become involved in "public diplomacy."

CONSUMER SAVVINESS

Though many feel that the information explosion of the late twentieth and early twenty-first centuries has provided companies with more marketing communications opportunities, the media environment has also resulted in a public that is increasingly savvy and sophisticated in terms of reading and interpreting marketing communications. In 2007, consultants Joseph Pine II and James Gilmore began to argue that consumers value "authenticity" in both products and marketing messages. They note that the patina of authenticity is crucial and that a lack of this (or a notable degree of insincerity) could mean the loss of a sale. Pine and Gilmore argue that "authenticity" can only be achieved through a combined marketing communications effort. Advertising, public relations, and other forms of communication must all be unified in message. This sense of authenticity can be derailed by aberrant messages.

An incomplete or superficial marketing communication effort can also result in cynicism. In 2008, with environmental concerns growing, the publication *Marketing* ran a story about "greenwashing," an attempt to appear environmentally friendly. However, the article points out that a brand can be damaged if this effort is seen as disingenuous. The lesson here is that a company's marketing communication cannot be out of step with a company's core business and practices.

THE FUTURE OF MARKETING COMMUNICATION

Marketing communication has become an integral part of the social and economic system in the United States. Consumers rely on the information from marketing communication to make wise purchase decisions. Businesses, ranging from multinational corporations to small retailers, depend on marketing communication to sell their goods and services. Marketing communication has also become an important player in the life of a business. Marketing communication helps move products, services, and ideas from manufacturers to end users and builds and maintains relationships with customers, prospects, and other important stakeholders in the company. Advertising and sales promotion will continue to play important roles in marketing communication mix. However, marketing strategies that stress relationship building in addition to producing sales will force marketers to consider all the elements in the marketing communication mix. In the future new information gathering techniques will help marketers target more precisely customers and prospects using direct marketing strategies. New media technologies will provide businesses and consumers new ways to establish and reinforce relationships that are important for the success of the firm and important for consumers as they make purchase decisions. The Internet will become a major force in how organizations communicate with a variety of constituents, customers, clients, and other interested parties.

MARKETING CONCEPT AND PHILOSOPHY

The marketing concept and philosophy is one of the simplest ideas in marketing, and at the same time, it is also one of the most important marketing philosophies. At its very core are the customer and his or her satisfaction. The marketing concept and philosophy states that the organization should strive to satisfy its customers' wants and needs while meeting the organization's goals. In simple terms, "the customer is king."

The implication of the marketing concept is very important for management. It is not something that the marketing department administers, nor is it the sole domain of the marketing department. Rather, it is adopted by the entire organization. From top management to the lowest levels and across all departments of the organization, it is a philosophy or way of doing business. The customers' needs, wants, and satisfaction should always be foremost in every manager and employees' mind. Wal-Mart's motto of "satisfaction guaranteed" is an example of the marketing concept. Whether the Wal-Mart employee is an accountant or a cashier, the customer is always first.

As simple as the philosophy sounds, the concept is not very old in the evolution of marketing thought. However, it is at the end of a succession of business philosophies that cover centuries.

EVOLUTION OF THE MARKETING CONCEPT AND PHILOSOPHY

The marketing concept and philosophy evolved as the last of three major philosophies of marketing. These three philosophies are the product, selling, and marketing philosophies. Even though each philosophy has a particular time when it was dominant, a philosophy did not die with the end of its era of dominance. In fact, all three philosophies are being used today.

Product Philosophy. The product philosophy was the dominant marketing philosophy prior to the Industrial Revolution and continued into the 1920s. The product philosophy holds that the organization knows its product better than anyone or any organization. The company knows what will work in designing and producing the product and what will not work. For example, the company may decide to emphasize the low cost or high quality of its products. This confidence in the company's ability is not a radical concept, but the confidence leads to the consumer being overlooked. Since the organization has the great knowledge and skill in making the product, the organization also assumes it knows what is best for the consumer.

This philosophy of only relying on the organization's skill and desires for the product did not lead to poor sales. In much of the product philosophy era, organizations were able to sell all of the products that they made. The success of the product philosophy era is due mostly to the time and level of technology in which it was dominant. The product era spanned both the pre-Industrial Revolution era and much of the time after the Industrial Revolution.

The period before the Industrial Revolution was the time when most goods were made by hand. The production was very slow and few goods could be produced. However, there was also a demand for those goods, and the slow production could not fill the demand in many cases. The importance for management of this shortage was that very little marketing was needed.

An example illustrates the effects of the shortages. Today, the gunsmith shop in Williamsburg, Virginia, still operates using the product philosophy. The gunsmiths produce single-shot rifles using the technology available during the eighteenth century. They are only able to produce about four or five rifles every year, and they charge from $15,000 to $20,000 for each rifle. However, the high price does not deter the demand for the guns; their uniqueness commands a waiting list of three to four years. Today's Williamsburg Gunsmith Shop situation was typical for organizations operating before the Industrial Revolution. Most goods were in such short supply that companies could sell all that they made. Consequently, organizations did not need to consult with consumers about designing and producing their products.

When mass production techniques created the Industrial Revolution, the volume of output was greatly increased. Yet the increased production of goods did not immediately eliminate the shortages from the pre-industrial era. The new mass production techniques provided economies of scale allowing for lower costs of production and corresponding lower prices for goods. Lower prices greatly expanded the market for the goods, and the new production techniques were struggling to keep up with the demand. This situation meant that the product philosophy would work just as well in the new industrial environment. Consumers still did not need to be consulted for the organization to sell its products.

One of the many stories about Henry Ford illustrates the classic example of the product philosophy in use after the Industrial Revolution. Henry Ford pioneered mass production techniques in the automobile industry. With the techniques, he offered cars at affordable prices to the general public. Before this time, cars were hand made, and only the very wealthy could afford them. The public enthusiastically purchased all the Model T Fords that the company could produce. The evidence that the product philosophy was alive and well in Ford Motor Company came in Henry Ford's famous reaction to consumer requests for more color options. He was said to have responded that "you can have any color car you want as long as it is black." Realizing that different colors would increase the cost of production and price of the Model T's, Henry Ford, using the product philosophy, decided that lower prices were best for the public.

Selling Philosophy. The selling philosophy era has the shortest period of dominance of the three philosophies. It began to be dominant around 1930 and stayed in widespread use until about 1950. The selling philosophy holds that an organization can sell any product it produces with the use of marketing techniques, such as advertising and personal selling. Organizations could create marketing departments that would be concerned with selling the goods, and the rest of the organization could be left to concentrate on producing the goods.

The reason for the emergence of the selling philosophy was the ever-rising number of goods available after the Industrial Revolution. Organizations became progressively more efficient in production, which increased the volume of goods. With the increased supply, competition also entered production. These two events eventually led to the end of product shortages and the creation of surpluses. It was because of the surpluses that organizations turned to the use of advertising and personal selling to reduce their inventories and sell their goods. The selling philosophy also enabled part of the organization to keep focusing on the product, via the product philosophy. In addition, the selling philosophy held that a sales or marketing department could sell whatever the company produced.

The Ford Motor Company is also a good example of the selling philosophy and why this philosophy does not work in many instances. Ford produced and sold the Model T for many years. During its production, the automobile market attracted more competition. Not only did the competition begin to offer cars in other colors, the styling of the competition was viewed as modern, and the Model T became considered as old-fashioned. Henry Ford's sons were aware of the changes in the automobile market and tried to convince their father to adapt. However, Henry Ford was sure that his standardized low-price automobile was what the public needed. Consequently, Ford turned to marketing techniques to sell the Model T. It continued to sell, but its market share began to drop. Eventually, even Henry Ford had to recognize consumer desires and introduce a new model.

The selling philosophy assumes that a well-trained and motivated sales force can sell any product. However, more companies began to realize that it is easier to sell a product that the customer wants, than to sell a product the customer does not want. When many companies began to realize this fact, the selling era gave way to the marketing era of the marketing concept and philosophy.

Marketing Philosophy. The marketing era started to dominate around 1950, and it continues to the present. The marketing concept recognizes that the company's knowledge and skill in designing products may not always be meeting the needs of customers. It also recognizes that even a good sales department cannot sell every product that does not meet consumers' needs. When customers have many choices, they will choose the one that best meets their needs.

MARKET CONCEPT AND PHILOSOPHY

The marketing concept and philosophy states that the organization should strive to satisfy its customers' wants and needs while meeting the organization's goals. The best way to meet the organization's goals is also by meeting customer needs and wants. The marketing concept's emphasis is to understand the customers before designing and producing a product for them. With the customer's wants and needs incorporated into the design and manufacture of the product, sales and profit goals are far more likely to be met.

With the customer's satisfaction the key to the organization, the need to understand the customer is critical. Marketing research techniques have been developed just for that purpose. Smaller organizations may keep close to their customers by simply talking with them. Larger corporations have established methods in place to keep in touch with their customers, such as consumer panels, focus groups, or third-party research studies. Whatever

the method, the desire is to know the customers so the organization can better serve them and not lose sight of their needs and wants.

The idea of keeping close to the organization's customers seems simple. In reality, it is very easy to forget the customer's needs and wants. Sometimes the management is so involved with the product that their own desires and wants begin to take dominance, even though they have adopted the marketing concept.

However, it is easy for managers to forget the marketing concept and philosophy. For example, many years ago—before there was a Subway restaurant on every corner—a college student opened a small submarine sandwich shop near his university's campus. The sub shop was an immediate success. By using the marketing concept, the young entrepreneur had recognized an unmet need in the student population and opened a business that met that need.

The sub shop was so successful that it began to outgrow its original location after about three years. The shop moved to a larger location with more parking spaces, also near the university. At the new sub shop, waiters in tuxedos met the students and seated them at tables with tablecloths. Besides the traditional subs, the shop now served full meals and had a bar. Within a few months the sub shop was out of business. The owner of the shop had become so involved with his business vision that he forgot the customers' needs and wants. They did not want an upscale restaurant—there were other restaurants in the area that met that need, they just wanted a quick sub sandwich. By losing sight of the customers' wants and needs, the owner of the sub shop lost his successful business.

MEETING CUSTOMER NEEDS WHILE MEETING ORGANIZATIONAL GOALS

Sometimes in the zeal to satisfy a customer's wants and needs, the marketing concept is construed to mean that the customer is always right. However, the marketing concept also states that it is important to meet organizational goals as well as satisfy customer wants and needs. Satisfying both customer wants and needs as well a meeting organizational goals may involve conflicts that sometimes cannot be resolved. The organization that adopts the marketing concept will do everything in its power to meet the needs of its customers, but it must also make a profit, which may involve disregarding some of the wants of customers.

Customers today often want both low price and environmental responsibility, two wants that cannot always be met simultaneously while also ensuring a profit for the organization. Consequently, the organization must hope for a compromise between what the consumer wants and what is practical for the business to provide. At the same time, unmet customer wants and needs can spur

further innovation so that the organization can hope to avoid these compromises and the consequent loss of sales.

In theory at least, no set of consumer wants and needs can go unmet with the application of innovation and technological advancement. In the twenty-first century, many organizations are finding ways to go "green" while continuing to offer low prices and high-quality goods and services. Wal-Mart, for example, announced in 2007 that it was pushing compact fluorescent light bulbs in an effort to improve its appeal to affluent consumers who typically favor environmental-friendly corporate practices.

Companies are also using cutting-edge information technologies to ascertain and track customers' wants and needs; these same technologies are also being used to organize production and distribution to enable efficient servicing of these wants and needs. As the authors of *Marketing Principle and Practices* note, "'Listening to the users,' involves the utilization of information technology in tracking customers' wants, thus, organizing network to create value for customers at a profit."

CRITICISM OF THE MARKETING CONCEPT

Interpreted literally, the marketing concept only advocates discovering consumers' wants and needs and satisfying them. Critics assert that consumers may not be aware of all of their wants and needs. For instance, in the 1950s, consumers were not aware of the ability to cook food by microwave. In the 1960s, consumers were not aware of the possibility of having personal computers in their homes. Critics argue that the marketing concept's concentration on consumers' wants and needs stifle innovation. Organizations will no longer concentrate on research and development in hopes that one product in ten might meet with consumer acceptance, and will less likely come up with innovative products such as microwaves and personal computers.

Supporters of the marketing concept have contended that it does not stifle innovation and that it does recognize that consumers cannot conceive of every product that they may want or need. However, need is defined in a very broad sense. In the microwave and personal computer examples, the need was not for the specific product, but there was a need to cook food faster and a need for writing and calculating. The microwave and personal computer satisfied those needs though the consumer never imagined these products. The marketing concept does not stifle creativity and innovation. It seeks to encourage creativity to satisfy customer needs.

The marketing concept is a relative newcomer as a philosophy of doing business. However, its evolution started before the Industrial Revolution. As time progressed,

customer and business needs also evolved. The product and selling philosophies eventually evolved into the marketing concept and philosophy. Today, the marketing concept and philosophy stands as a formula for doing business and many believe it is a prescription for success. It aims to satisfy customers by guiding the organization to meet the customers' needs and wants while meeting the organization's goals.

MARKETING RESEARCH

Marketing research is the function that links the consumer, customer, and public to the marketer through information. This information is used to identify and define marketing opportunities and problems; to generate, refine, and evaluate marketing actions; to monitor marketing performance; and to improve understanding of the marketing process. Marketing research specifies the information, manages and implements the data-collection process, analyzes the results, and communicates the findings and their implications. Marketing research is concerned with the application of theories, problem-solving methods, and techniques to identify and solve problems in marketing. In order to offset unpredictable consumer behavior, companies invest in market research.

Increased customer focus, demands for resource productivity, and increased domestic and international competition have prompted an increased emphasis on marketing research. Managers cannot always wait for information to arrive in bits and pieces from marketing departments. They often require formal studies of specific situations. For example, Dell Computer might want to know a demographic breakdown of how many and what kinds of people or companies will purchase a new model in its personal computer line. In such situations, the marketing department may not be able to provide the detailed information needed from existing knowledge, and managers normally do not have the skill or time to obtain the information on their own. This formal study, whether performed internally or externally, is called marketing research.

The marketing research process consists of four steps: defining the problem and research objectives, developing the research plan, implementing the research plan, and interpreting and reporting the findings.

DEFINING THE OBJECTIVES

The marketing manager and the researcher must work closely together to define the problem carefully and agree on the research objectives. The manager best understands the decision for which information is needed; the researcher best understands marketing research and how to obtain the information.

Managers must know enough about marketing research to help in the planning and to interpret research results. Managers who know little about the importance of research may obtain irrelevant information or accept inaccurate conclusions. Experienced marketing researchers who understand the manager's problem should also be involved at this stage. The researcher must be able to help the manager define the problem and suggest ways that research can help the manager make better decisions.

Defining the problem and research objectives is often the hardest step in the research process. The manager may know that something is wrong without knowing the specific causes. For example, managers of a retail clothing store chain decided that falling sales were caused by poor floor set-up and incorrect product positioning. However, research concluded that neither problem was the cause. It turned out that the store had hired sales persons who were not properly trained in providing good customer service. Careful problem definition would have avoided the cost and delay of research and would have suggested research on the real problem.

When the problem has been defined, the manager and researcher must set the research objectives. A marketing research project might have one of three types of objectives. Sometimes the objective is exploratory—to gather preliminary information that will help define the problem and suggest hypotheses. Sometimes the objective is descriptive—to describe things such as the market potential for a product or the demographics and attitudes of consumers who buy the product. Sometimes the objective is causal—to test hypotheses about cause-and-effect relationships.

DEVELOPING THE RESEARCH PLAN

The second step of the marketing research process calls for determining the information needed, developing a plan for gathering it efficiently, and presenting the plan to marketing management. The plan outlines sources of secondary data and spells out the specific research approaches, contact methods, sampling plans, and instruments that researchers will use to gather primary data.

A marketing researcher can gather secondary data, primary data, or both. Primary data consists of information collected for the specific purpose at hand. Secondary data consists of information that already exists somewhere, having been collected for another purpose. Sources of secondary data include internal sources such as profit and loss statements, balance sheets, sales figures, and inventory records; and external sources such as government publications, periodicals, books, and commercial data. Primary data collection requires more extensive research, more time, and more money. Secondary sources can sometimes provide information that is not directly available or would be too expensive to collect.

Secondary data also present problems. The needed information may not exist. Researchers can rarely obtain all the data they need from secondary sources. The researcher must evaluate secondary information carefully to make certain of its relevance (fits research project needs), accuracy (reliably collected and reported), currency (up to date enough for current decisions), and impartiality (objectively collected and reported). Researchers must also understand how secondary sources define basic terms and concepts, as different sources often use the same terms but mean slightly different things, or they attempt to measure the same thing but go about it in different ways. Either way, the result can be that statistics found in secondary sources may not be as accurate or as relevant as they appear on the surface.

RESEARCH APPROACHES

Observational research is the gathering of primary data by observing relevant people, actions, and situations. Observational research can be used to obtain information that people are unwilling or unable to provide. In some cases, observation may be the only way to obtain the needed information.

Survey research is the approach best suited for gathering descriptive information. A company that wants to know about people's knowledge, attitudes, preferences, or buying behavior can often find out by asking them directly. Survey research is the most widely used method for primary data collection, and it is often the only method used in a research study. The major advantage of survey research is its flexibility. It can be used to obtain many different kinds of information in many different marketing situations. A classic example of survey research comes from the 1980s, when cola companies began to run taste tests against their competitors. Participants were allowed to taste different cola brands without knowing which was which. The participant then decided which brand was preferred, providing the tester with impartial information about consumer tastes. (It should be noted that these tests were also used for advertising purposes,

which differed from the research purposes.) Today, online surveys are a common feature on a wide variety of Web sites, providing marketing researchers with an important source of survey data.

Whereas observation is best suited for exploratory research and surveys for descriptive research, experimental research is best suited for gathering causal information. Experiments involve selecting matched groups of subjects, giving them different treatments, controlling unrelated factors, and checking for differences in group responses. Thus, experimental research tries to explain cause-and-effect relationships.

RESEARCH CONTACT METHODS

Research may be collected by mail, telephone, e-mail, fax, or personal contact. Mail questionnaires can be used to collect large amounts of information at a low cost per respondent rate. Respondents may give more honest answers to more personal questions on a mail questionnaire than to an unknown interviewer in person or over the phone. However, mail questionnaires lack flexibility in that they require simply worded questions. They can also take a long time to complete, and the response rate—the number of people returning completed questionnaires—is often very low.

Telephone interviewing is the best method for gathering information quickly, and it provides greater flexibility than mail questionnaires. Interviewers can explain questions that are not understood. Telephone interviewing also allows greater sample control. Response rates tend to be higher than with mail questionnaires. But telephone interviewing also has its drawbacks. The cost per respondent is higher than with mail questionnaires, people may regard a phone call as more of an inconvenience or an intrusion, and they may not want to discuss personal questions with an interviewer.

Recent laws have created further difficulty with telephone interviewing. In 2003, the National Do-Not-Call Registry was created in the United States, blocking commercial telemarketers from calling numbers on the no-call list. By early 2008, over 157 million phone numbers in the United States were on the list. A similar list was created in Great Britain in 1999 and in Canada in 2004. The creation of these lists and their widespread use by telephone customers has significantly limited the use of telephone interviewing for marketing research purposes.

Personal interviewing consists of inviting several people to talk with a trained interviewer about a company's products or services. The interviewer needs objectivity, knowledge of the subject and industry, and some understanding of group and consumer behavior. Personal interviewing is quite flexible and can be used to collect large amounts of information. Trained interviewers can hold a respondent's

attention for a long time and can explain difficult questions. They can guide interviews, explore issues, and probe as the situation requires. The main drawbacks of personal interviewing are costs and sampling problems. Personal interviews may cost three to four times as much as telephone interviews.

SAMPLING PLAN

Marketing researchers usually draw conclusions about large groups of consumers by studying a relatively small sample of the total consumer population. A sample is a segment of the population selected to represent the population as a whole. Ideally, the sample should be representative so that the researcher can make accurate estimates of the thoughts and behaviors of the larger population. If the sample is not representative, it may lead the company to draw the wrong conclusions and misuse its resources.

The marketing researcher must design a sampling plan, which calls for three decisions:

1. Sampling unit—determining who is to be surveyed. The marketing researcher must define the target population that will be sampled. If a company wants feedback on a new basketball shoe, it would be wise to target active players and even professional players.

2. Sample size—determining the number of people to be surveyed. Large samples give more reliable results than small samples. Samples of less than 1 percent of a population can often provide good reliability, given a credible sampling procedure. Most commercial samples consist of between several hundred and several thousand respondents.

3. Sampling procedure—determining how the respondents should be chosen. To obtain a representative sample, a probability (random) sampling of the population should be drawn. This is a means of determining who is reached by the survey to ensure they are indeed a valid cross-section of the sampling unit. Choosing passersby on a street corner, for example, would not produce a random sample, whereas allowing a computer to pick names randomly from a relevant calling list probably would (depending on how the list was compiled). Probability sampling allows the calculation of confidence limits for sampling error.

RESEARCH INSTRUMENTS

In collecting primary data, marketing researchers have a choice of two main research instruments—the questionnaire and mechanical devices. The questionnaire is by far the most common instrument. A questionnaire consists of a set of questions presented to a respondent for his or her answers. In preparing a questionnaire, the marketing researcher must decide what questions to ask, the form of the questions, the wording of the questions, and the ordering of the questions. Each question should be checked to see that it contributes to the research objectives.

Although questionnaires are the most common research instrument, mechanical instruments are also used. Two examples of mechanical instruments are people meters and barcode scanners. People meters are not widely used because they tend to be expensive, require unrealistic advertising exposure conditions, and are hard to interpret. The use of data automatically collected by barcode scanners has become more common with the advent of powerful computers and sophisticated database and data-mining software. Data collected by scanners provide marketing researchers with valuable information drawn from a large data pool.

COLLECTING THE INFORMATION

The researcher must now collect the data. This phase is generally the most expensive and the most prone to error. In the case of surveys, four major problems arise. Some respondents will not be at home and will have to be replaced. Other respondents will refuse to cooperate. Still others will give biased or dishonest answers. Finally, some interviewers will occasionally be biased or dishonest.

CHARACTERISTICS OF GOOD MARKETING RESEARCH

Following are the characteristics of good marketing research:

1. Scientific method. Effective marketing research uses the principles of the scientific method: careful observation, formulation of hypotheses, prediction, and testing.

2. Research creativity. At its best, marketing research develops innovative ways to solve a problem.

3. Multiple methods. Competent marketing researchers shy away from over-reliance on any one method, preferring to adapt the method to the problem rather than the other way around. They also recognize the desirability of gathering information from multiple sources to give greater confidence.

4. Interdependence of models and data. Competent marketing researchers recognize that the facts derive their meaning from models of the problem. These models guide the type of information sought and therefore should be made as explicit as possible.

5. Value and cost of information. Competent marketing researchers show concern for estimating the value of

information against its cost. Value/cost evaluation helps the marketing research department determine which research projects to conduct, which research designs to use, and whether to gather more information after the initial results are in. Research costs are typically easy to quantify, while the value is harder to anticipate. The value depends on the reliability and validity of the research findings and management's willingness to accept and act on its findings. In general, the most valuable information tends to cost the most because it requires more intensive methods, although it is easy to spend a great deal of money on poorly conceived research.

6. Healthy skepticism. Competent marketing researchers will show a healthy skepticism toward assumptions made by managers about how the market works.

7. Ethical marketing. Most marketing research benefits both the sponsoring company and its consumers. Through marketing research, companies learn more about consumers' needs, and are able to supply more satisfying products and services. However, the misuse of marketing research can also harm or annoy consumers. There are professional ethical standards guiding the proper conduct of research.

PRESENTING THE RESEARCH PLAN

The last step in market research is the presentation of a formal plan. At this stage, the marketing researcher should summarize the plan in a written proposal to management. A written proposal is especially important when the research project will be large and complex or when an outside firm carries it out. The proposal should cover the management problems addressed and the research objectives, the information to be obtained, the sources of secondary information or methods for collecting primary data, and the way the results will help management decision making. A written research plan or proposal makes sure that the marketing manager and researchers have considered all the important aspect of the research and that they agree on why and how the research will be done.

MANAGEMENT'S USE OF MARKETING RESEARCH

In spite of the rapid growth of marketing research, many companies still fail to use it sufficiently or correctly. Several factors can stand in the way of its greater utilization.

1. A narrow conception of marketing research. Many managers see marketing research as only a fact-finding operation. The marketing researcher is supposed to design a questionnaire, choose a sample, conduct interviews, and report results, often without being given a careful definition of the problem or of the decision alternatives facing management. As a result, some fact-finding fails to be useful. This reinforces management's idea of the limited usefulness of some marketing research.

2. Uneven caliber of marketing researchers. Some managers view marketing research as little better than a clerical activity and reward it as such. Poorly qualified marketing researchers are hired, and their weak training and deficient creativity lead to unimpressive results. The disappointing results reinforce management's prejudice against expecting too much from marketing research. Management continues to pay low salaries, perpetuating the basic difficulty.

3. Late and occasional erroneous findings by marketing research. Managers want quick results that are accurate and conclusive. However, good marketing research takes time and money. If they cannot perceive the difference between quality and shoddy research, managers become disappointed, and they lower their opinion of the value of marketing research. This is especially a problem in conducting marketing research in foreign countries.

4. Intellectual differences. Intellectual divergences between the mental styles of line managers and marketing researchers often get in the way of productive relationships. The marketing researcher's report may seem abstract, complicated, and tentative, while the line manager wants concreteness, simplicity, and certainty. Yet in the more progressive companies, marketing researchers are increasingly being included as members of the product management team, and their influence on marketing strategy in growing.

MECHANISTIC ORGANIZATIONS

In their 1961 book *The Management of Innovation*, Burns and Stalker noted that mechanistic organizations are often appropriate in stable environments and for routine tasks and technologies. In some ways similar to bureaucratic structures, mechanistic organizations have clear, well-defined, centralized, vertical hierarchies of command, authority, and control. Efficiency and predictability are emphasized through specialization, standardization, and formalization. This results in rigidly defined jobs, technologies, and processes. The term mechanistic suggests that organizational structures, processes, and roles are like a machine in which each part of the organization does what it is designed to do, but little else.

It is easy to confuse mechanistic organizations with bureaucracies due to the considerable overlap between the two concepts. Yet despite the overlaps, a primary difference between mechanistic organizations and bureaucracy is the rationale for utilizing each of these. A goal of bureaucratic structures is to protect lower-level administrative positions from arbitrary actions of owners and higher-level managers. For example, an individual holding the job title of vice-president of production would, in a bureaucracy, be protected from indiscriminate changes in work hours, wages, and responsibilities through formal rules, regulations, and grievance procedures. The goal of the bureaucracy is protection of positions within the organization.

Mechanistic organizations, on the other hand, are utilized to increase efficiency when tasks and technologies are relatively stable. The vice-president of production in a mechanistic organization would employ production processes and techniques that minimize waste and maximize outputs for a given quantity of inputs. The goal of mechanistic structures is efficiency. Thus, the rationale for bureaucracy is protection while the rationale for mechanistic organizations is efficiency. Clearly, the two are not mutually exclusive; an organization could be structured as a bureaucracy and also be mechanistic. On the other hand, many examples of inefficient bureaucracies can quickly come to mind, suggesting that while there is overlap between the concepts, there are distinctions as well.

Burns and Stalker focused on the difference between mechanistic structures and organic structures, which they defined as being more fluid and interactive. Recently, focus has shifted to place more emphasis on organic systems, which are lauded for being more adaptable and friendly. In his 2008 article "Cultivate an Organic Organization," Dr. Ben Carlsen notes that "Whether in the boardroom or the supermarket, organic is healthier… having the characteristics of a living organism, the organic organization seeks the best and most synergistic 'match'"

Mechanistic structures, on the other hand, are highly formalized, which means that nearly all processes and procedures have been administratively authorized. The organization considers processes and procedures outside these established protocols as variances that must be brought under control. Such formalization is driven by efficiency; reduction in variance increases predictability, and increases in predictability allow for improvements in efficiency. Examples pertinent to product or service distribution include the processes a store clerk uses when presented with a customer's credit card or how returns of products by customers are to be handled. Examples pertinent to product or service production and assembly include how a book publisher manages the workflow from completed manuscripts to final bookbinding, and how Dell Computer manages assembly of made-to-order personal computers. Decision making is largely concerned with application of the appropriate predetermined rule, policy, procedure, or criteria.

When a mechanistic organization accepts innovation and implementation of new practices, it does so through its formalized channels. As Chapman's 2007 *Handbook of Management Accounting Research* details, the mechanistic structure allows business to implement new policy quickly and effectively. Innovations are transferred throughout the business with ease, and plans are followed through to the letter. While this encourages implementation of processes, it also makes it difficult for the mechanistic organization to change direction partway through innovation, or to scrap one idea for the sake of another in the midst of transition.

Mechanistic organizations also possess the environmental and technological stability to allow work to be clearly defined and differentiated. The work of the organization is divided into specific, precise tasks. Created from one or more such specific tasks, specialized job positions rigidly define skills needed, task methodology and procedures to be used, and specific responsibilities and authority. In effect, lower-level managers and other employees simply follow procedures, and while this may have the side effect of stifling creativity, it also increases efficiency of established processes. In stable environments, however, stifling creativity may be worth the improvements in efficiency. Few customers, for instance, would want a McDonald's employee to use creativity in preparing their hamburger. Instead, the repetitiveness and stability of the procedures needed to cook a hamburger are more efficient when the employee follows established procedures and customers can trust that each hamburger they purchase will taste the same.

However, specialized tasks are repetitive and can sometimes be boring. For example, at a Sam's Club store, one person stands at the door to perform the single task of

marking customer receipts. Because employees often work separately with little interaction, it is often hard for them to see how one small, specialized task relates to overall organizational objectives.

In addition, the work of mechanistic organizations tends to be impersonal. Jobs are designed around the task rather than the individual. Personnel selection, assignment, and promotion are based on the possession of skills required for specific tasks. Other people, like interchangeable parts of a machine, can replace people in a position.

Specialization carries throughout the organization. Positions are grouped together into specialized work units and, ultimately, into specialized functional departments such as production, marketing, or finance. Each organizational unit has clear and specific responsibilities and objectives. Communication is primarily vertical, with more emphasis on downward directives than on upward communication. Thus, such matters as goals, strategies, policies, and procedures are determined by top-level management and communicated downward as instructions and decisions to be implemented.

Upward communication usually involves transmittal of reports and other information for management to consider, usually at the request of management. Coordination is maintained through the chain of command. For example, top-level management is responsible for coordination across functional departments such as integrating marketing sales forecasts with production schedules. Within a department, the department manager is responsible for coordination across department subunits; production managers, for example, coordinate raw inventory requirements with work-in-process inventory.

At least two criticisms are generally made about mechanistic organizations. First, while focusing on task concerns such as efficiency and standardization, mechanistic organizations tend to ignore human needs and dynamics. Second, creativity, and thus innovation, are restricted by the rigidity of standardized and formalization. Thus, the appropriate environment for mechanistic organizations is a stable environment, while rapidly changing environments require more flexibility. For such environments, Burns and Stalker recommend the organic model of organization. Highly mechanized organizations operating in rapidly changing environments run the risk of becoming obsolete as competitors sacrifice maximum efficiency in exchange for flexibility to tackle new environmental conditions.

However, it has been argued by such authors as Robert Waldersee and Andrew Griffiths that certain developments in the business world are creating an increasingly strong environment for mechanistic organization. Waldersee and Griffith theorize that the increase in globalization will benefit mechanistic organizations, which can identify problems and respond to them more effectively than the less streamlined organic models. In agreement, such authors as Brad Moore and Alan Brown have suggested that the newer business models designed with organic organizations in mind are being established in mechanistic companies equally well. In their 2006 piece on TQM (Total Quality Management), they propose that mechanistic organizations have no trouble implementing such practices as TQM, which are thought to require a more fluid approach. This suggests mechanistic organizations are beginning to incorporate adaptability into their formalized structure.

MENTORING

Mentors are individuals with advanced experience and knowledge who take a personal interest in helping the careers and advancement of their protégés. Mentors may or may not be in their protégés' chain of command, be employed in the same organization as their protégés, or even be in the same field as their protégés. Mentoring relationships may range from focusing exclusively on the protégé's job functions to being a close friendship that

Table 1
Kram's Mentoring Roles

1. Career Development Roles
   • Coaching
   • Sponsoring advancement
   • Providing challenging assignments
   • Protecting protégé from adverse forces
   • Fostering positive visibility
2. Psychosocial Roles
   • Personal support
   • Friendship
   • Counseling
   • Acceptance
   • Role modeling

becomes one of the most important relationships in the protégé's life.

Most mentoring relationships are informal, and develop on the basis of mutual identification and the fulfillment of career needs. The mentor may see the protégé as a "diamond in the rough" or a younger version of himself or herself, while the protégé may view the mentor as a competent role model with valued knowledge, skills, and abilities. Members of mentoring relationships often report a mutual attraction or chemistry that sparks the development of the relationship.

According to Kathy Kram, mentors provide two primary types of behaviors or roles. First, they provide career development roles, which involve coaching, sponsoring advancement, providing challenging assignments, protecting protégés from adverse forces, and fostering positive visibility. Second, mentors provide psychosocial roles, which involve personal support, friendship, counseling, acceptance, and role modeling. A given mentor may engage in some or all of these roles and these roles may not only vary from relationship to relationship, but may also vary over time in a given relationship.

Kram observes that mentoring relationships pass through four phases: initiation, cultivation, separation, and redefinition. The relationship develops during the initiation and cultivation stages. In initiation, the mentor and protégé meet and first begin to know a little about each other. The real learning occurs in the cultivation stage, where the mentor helps the protégé to grow and develop. The separation stage is typically reached after two to five years, and the relationship may terminate because of physical separation or because the members no longer need one another. Research indicates that the majority of mentoring relationships end because of physical separation. After separation, the members of the relationship may redefine their relationship as a peer relationship, or may terminate their relationship entirely.

POSITIVE OUTCOMES OF MENTORING RELATIONSHIPS

Mentoring relationships are related to a variety of positive organizational and career outcomes. A number of different research studies indicate that mentored individuals have higher levels of mobility on the job, recognition, promotion, and compensation. Also, employees with mentors report higher levels of learning on the job than those without mentors. Additionally, research indicates that employees with positive mentoring experiences typically feel higher levels of pay satisfaction, career satisfaction, and organizational commitment. Finally, research indicates that the lower levels of turnover that occur with mentored individuals are due, in part, to their higher levels of organizational commitment that may be brought about by the mentoring relationship.

A meta-analysis (a statistical technique that combines results from numerous studies to give an "average" finding) conducted by Allen, Eby, Poteet, Lentz, and Lima in 2004 supports these findings. In their analysis of forty-three individual studies, they found that individuals who had been mentored had better career outcomes from both career-related and psychosocial mentoring; they were more satisfied with their careers, believed strongly that they would advance in their careers, and were committed to their careers. The meta-analysis indicated that mentored individuals also had better compensation and more promotions that those employees without mentors.

Mentoring relationships may also be beneficial for the mentor. Mentors have reported more benefits than costs to being a mentor. Research indicates that key benefits to mentors included a sense of satisfaction and fulfillment, recognition from others, career and job renewal, and support from their protégés. The business historian Pamela Laird has even suggested that mentors have gained status through their placing of protégés, since it could serve as a marker for the "ability to judge talent and character in a visible and competitive arena."

Finally, mentoring relationships may be beneficial for the organization. Mentoring relationships are a powerful tool for socializing new employees, for increasing organizational commitment, and for reducing unwanted turnover. Mentoring relationships can foster innovation and revitalize mentors who have reached career plateaus. Because members of the relationship may share different insights and perspectives regarding organizational and societal cultures, mentoring relationships may also be useful in mergers and in international organizations.

SOCIAL CAPITAL

Generally speaking, mentoring relationships are a type of "social capital." According to Wayne Baker, social capital refers to one's access to various networks, both in one's

personal and professional life. Pamela Laird has also shown that an individual moves through a series of networks in his or her career.

In her book, *Pull*, Laird notes that social capital is distributed unevenly and can have enormous impact in terms of "pull" discrimination, where certain members are granted access and others are not. Perception of potential is critical, but Laird points out that the criteria for "potential" often reflects the values and background of the "gatekeeper." Because of this, certain inequalities in the workplace can be perpetuated. The mentor/protégé is one example where "pull" can operate in this manner, often to the detriment of women and minorities throughout much of the twentieth century.

Baker notes that social capital is crucial to career success, specifically arguing against the American value of the "self-made man." He even suggests that businesses must learn to build social capital into their structures by such measures as rotating members through an organization.

GENDER, DIVERSITY, AND MENTORING

Although mentoring relationships are important for all organizational members, they are essential for women and employees of color. Mentors can help these individuals overcome barriers to advancement in organizations and break through the "glass ceiling," the invisible barrier to advancement based on gender biases. Research indicates that a full 91 percent of the female executives surveyed in a Catalyst study reported having a mentor, and the majority of respondents identified mentoring as a key strategy used to break through the glass ceiling.

A mentor can buffer women and people of color from both overt and covert forms of discrimination, and help them navigate the obstacle course to the executive suite. By conferring legitimacy on their female and minority protégés, mentors can alter stereotypic perceptions and send the message that the protégé has the mentor's powerful support and backing. Research indicates that mentors provide "reflected power" to their protégés, and use their influence to build their protégé's power in the organization. Mentors can train their female and minority protégés in the "ins and outs" of corporate politics and provide valuable information on job openings and changes in the organization—information that is typically provided in the "old boys' network."

Although most research indicates that women and people of color are as likely as their majority counterparts to have mentors, women reported greater barriers to getting a mentor than men. Research showed that women were more likely than men to report that mentors were unwilling to mentor them, that supervisors and coworkers would disapprove of the relationship, that they had less access to mentors, and that they were hesitant to initiate the rela-

tionship for fear that their efforts would be misconstrued as being sexual by either the mentor or others in the organization. In spite of these reported barriers, women were as likely as men actually to have a mentor, suggesting that women overcame these barriers in order to develop these important relationships. Laird notes that by the 1970s, mentoring had become a prominent concern for businesswomen. Similarly, other mentoring research indicates that African American protégés were more likely than Caucasian protégés to go outside their departments and formal lines of authority to develop mentoring relationships with higher ranking mentors of the same race. These studies indicate that women and minorities recognize the importance of mentors and are willing to overcome barriers to gaining this critical developmental relationship. Laird points out that African Americans and other ethnic minority groups have formed associations that serve in part of facilitate mentoring relationships for their members.

Another obstacle faced by female and minority protégés is that they are more likely than their majority counterparts to be in a "diversified mentoring relationship." Diversified mentoring relationships are composed of mentors and protégés who differ on one or more group memberships associated with power. Because of the scarcity of female and minority mentors at higher organizational ranks, female and minority protégés are more likely than their majority counterparts to be in cross-gender or cross-race relationships. These relationships provide limited role modeling functions, functions that are particularly important for women and employees of color. In addition, individuals in cross-gender relationships are less likely to engage in close friendship and social roles that involve after-work networking activities because of the threat or appearance of romantic involvement.

Female and minority protégés face a certain catch 22: even if they find a female or minority mentor who can provide role modeling functions, these mentors may be restricted in helping them advance since women and people of color have less power in organizations than their majority counterparts. In sum, majority protégés obtain mentors who can provide more functions than minority or female protégés, and these functions in turn lead to increased power and more promotions, thus perpetuating the cycle.

One area of diversity that has received research attention is the role of age in mentoring relationships. Age has become a more important workplace issue as the large group of American baby boomers ages. Experts suggest that mentors be eight to fifteen years (a half generation) older than their protégés, so that the age difference is not as large as that of parent and child, and not so small that the mentor and protégé act more as peers. However, not all mentoring relationships have this age span. Research indicates that the mentoring experience differs

for protégés based on their age, with younger protégés receiving more career-related mentoring than older protégés.

FORMAL MENTORING RELATIONSHIPS

In recognition of the benefits of mentoring relationships, many organizations attempt to replicate informal mentoring relationships by creating formal mentoring programs. One key difference between formal and informal mentoring relationships is that informal relationships develop spontaneously, whereas formal mentoring relationships develop with organizational assistance or intervention—usually in the form of voluntary assignment or matching of mentors and protégés. A second distinction is that formal relationships are usually of much shorter duration than informal relationships; formal relationships are usually contracted to last less than a year.

Although many organizations assume that formal relationships are as effective as informal relationships, existing research indicates that this is not the case. Georgia Chao and her associates found that protégés with formal mentoring relationships received less compensation than protégés with informal relationships. Other studies suggest that formal protégés not only received less compensation than informal protégés, but they also reported less psychosocial and career development functions and less satisfaction with their mentors than informal protégés. In fact, individuals with formal mentors did not receive more compensation or promotions than individuals who were not mentored. These researchers also found that women received fewer benefits from formal mentors than men did, indicating that female protégés may have the least to gain from entering a formal mentoring relationship. This research indicates that formal mentors are not a substitute for informal mentoring relationships.

In conclusion, organizations can create an environment that fosters mentoring relationships by structuring diverse work teams that span departmental and hierarchical lines and by increasing informal opportunities for networking and interaction. Organizations can increase the pool of diverse mentors by structurally integrating women and minorities into powerful positions across ranks and departments, and by rewarding these relationships in performance appraisals and salary decisions.

NEGATIVE MENTORING EXPERIENCES

Although there are numerous potential benefits for both the mentor and protégé from the mentoring relationship, it is not always a positive experience. Researchers have identified dysfunctional mentoring relationships in which the needs of either the mentor or protégé are not being met, or the relationship is causing some distress to either of the parties. Negative experiences that have been identified include the following:

- The mentor delegates too much work to the protégé.
- The mentor abuses his/her power over the protégé.
- Mentor inappropriately takes credit for the protégé's work.
- The mentor attempts to sabotage the protégé.
- The mentor intentionally deceives the protégé.
- The mentor intentionally is unavailable to or excludes the protégé.
- The mentor neglects the protégé's career, or does not provide support.
- The mentor is too preoccupied with his/her own career progress.
- The mentor lacks technical competence and cannot guide the protégé.
- The mentor lacks interpersonal competence and cannot interact with the protégé.
- There's a poor fit in personality between the mentor and protégé.
- There's a poor fit in work styles between the mentor and protégé.
- The mentor has a bad attitude about the organization or job.
- The mentor cannot mentor effectively due to problems in his/her personal life.
- The mentor sexually harasses protégé.

MENTORING SUCCESSES AND FAILURES

Though mentoring is now a widespread business practice, its results can vary. At its worst, mentoring can place incompetent or unscrupulous people in positions of power. Enron represents perhaps the most glaring example. Some have interpreted Jeff Skilling's relationship with Andy Fastow as a mentor/protégé relationship. Some press coverage of Enron indicated that Fastow would not have been named the company's chief financial officer without this relationship. Once in this position of power, Fastow was able to do enormous damage to the company and investors. Andy Fastow also cultivated his own protégé, Michael Kopper, who then became a partner in Fastow's more blatant fraudulent and criminal activity.

Enron's internal "Performance Review Committee," a process that was introduced by Jeff Skilling, was intended to make employee evaluation at the company more objective. However, managers often promoted their

own favorite employees. Some argue that this subverted the original goal of creating a meritocracy. This is one example where a mentoring relationship may have been harmful to an organization.

Despite these examples, many giants of the business world were once protégés. Warren Buffett, who is sometimes known as the "Sage" of Omaha, was mentored by the investor Benjamin Graham. Some have noted that Buffett's own successful investment strategies are derived from his time as Graham's protégé.

MERGERS AND ACQUISITIONS

A merger takes place when two companies decide to combine into a single entity. When the merger is forced through buyouts or financial leverage, it is referred to as an acquisition (also called a *takeover*). While the motivations may differ, the essential feature of both mergers and acquisitions involves one firm emerging where once there existed two firms.

Essentially, the difference rests in the attitude of the incumbent management of firms that are targeted. A so-called friendly takeover is often a euphemism for a merger. A hostile takeover refers to unwanted advances by outsiders. Thus, the reaction of management to the overtures from another firm tends to be the main influence on whether the resulting activities are labeled friendly or hostile.

Many kinds of mergers increase the emerging company's Herfindahl-Hirschman Index (HHI), the concentration rating of their industry. If the merger raises the HHI by 100 points or more (especially in industries rated 1800 or higher), the Justice Department may take steps to prevent the merger. This is done primarily to discourage monopolistic practices, as the combining firms often lessen competition. Although the HHI Index is used primarily by the United States, it has applications internationally in providing checks and balances for merger activity. For instance, in 2007 Ireland adopted the HHI Index as a guide in restraining monopolistic mergers in its private health insurance industry.

MOTIVATIONS FOR MERGERS AND ACQUISITIONS

There are a number of possible motivations that may result in a merger or acquisition. One of the most oft-cited reasons is to achieve economies of scale. Economies of scale may be defined as a lowering of the average cost to produce one unit due to an increase in the total amount of production. The idea is that the larger firm resulting from the merger can produce more cheaply than the previously separate firms. Efficiency is the key to achieving economies of scale, through the sharing of resources and technology and the elimination of needless duplication and waste. Economies of scale sounds good as a

rationale for merger, but there are many examples to show that combining separate entities into a single, more efficient operation is not easy to accomplish in practice.

A similar motivation is economies of scope, often found when the merger involves *vertical integration*. This involves acquiring firms through which the parent firm currently conducts normal business operations, such as suppliers and distributors.

By combining different elements involved in the production and delivery of the product to the market, acquiring firms gain control over raw materials and distribution outlets. This may result in centralized decisions and better communications and coordination among the various business units. It may also result in competitive advantages over rival firms that must negotiate with and rely on outside firms for inputs and sales of the product.

Horizontal integration is a merger or acquisition to achieve greater market presence or market share. The combined, larger entity may have competitive advantages such as the ability to buy bulk quantities at discounts, store and inventory needed production inputs, and achieve mass distribution through sheer negotiating power. Greater market share also may result in advantageous pricing, since larger firms are able to compete effectively through volume sales with thinner profit margins. This type of merger or acquisition often results in the combining of complementary resources, such as a firm that is very good at distribution and marketing merging with a very efficient producer. The shared talents of the combined firm may mean competitive advantages versus other, smaller competition.

The ideas above refer to reasons for mergers or acquisitions among firms in similar industries. When two unrelated firms join without an industrial relationship, it is referred to as a conglomerate merger. Since conglomerate mergers do not involve noticeable vertical or horizontal integration, they are more rare than other types of mergers.

Conglomerate mergers were especially popular in the 1960s wave of merger activity, when companies believed that combining certain departments—such as accounting or human resources—would streamline even unrelated businesses. Yet conglomerate mergers developed a history of being unsuccessful, and their use has faded. There are very few restrictions against conglomerate mergers today, since the combination of unrelated companies does not radically interfere in many industries. However, in Europe, legislation passed in 2007 which restricted even conglomerate mergers if (upon examination) they threatened to create monopolies.

There are several additional motivations for firms that may not necessarily be in similar lines of business. One of the often-cited motivations for acquisitions involves excess cash balances. Suppose a firm is in a mature industry, and has little opportunities for future investment beyond the existing business lines. If profitable, the firm may acquire large cash balances as managers seek to find outlets for new investment opportunities. One obvious outlet is to acquire other firms. The ostensible reason for using excess cash to acquire firms in different product markets is diversification of business risk.

Management may claim that by acquiring firms in unrelated businesses the total risk associated with the firm's operations declines. However, it is not always clear for whom the primary benefits of such activities accrue. A shareholder in a publicly traded firm who wishes to diversify business risk can always do so by investing in other companies' shares. The investor does not have to rely on incumbent management to achieve the diversification goal. On the other hand, a less risky business strategy is likely to result in less uncertainty in future business performance, and stability makes management look good. The agency problem resulting from incongruent incentives on the part of management and shareholders is always an issue in public corporations. However, regardless of the motivation, excess cash is a primary motivation for corporate acquisition activity.

To reverse the perspective, an excess of cash is also one of the main reasons why firms become the targets of takeover attempts. Large cash balances make for attractive potential assets; indeed, it is often implied that a firm with a very large amount of cash is not being efficiently managed. While that conclusion is situation specific, it is clear that cash is attractive, and the greater the amount of cash the greater the potential to attract attention. Thus, the presence of excess cash balances in either acquiring or target firms is often a primary motivating influence in subsequent merger or takeover activity.

Another feature that makes firms attractive as potential merger partners is the presence of unused tax shields. The corporate tax code allows for loss carry-forwards; if a firm loses money in one year, the loss can be carried forward to offset earned income in subsequent years. A firm that continues to lose money, however, has no use for the loss carry-forwards. However, if the firm is acquired by another firm that is profitable, the tax shields from the acquired firm may be used to shelter income generated by the acquiring firm. Thus the presence of unused tax shields may enhance the attractiveness of a firm as a potential acquisition target.

A similar idea is the notion that the combined firm from a merger will have lower absolute financing costs. For example, two firms, X and Y, have each issued bonds as a normal part of the financing activities. If the two firms combine, the cash flows from the activities of X can be used to service the debt of Y, and vice versa. Therefore,

with less default risk the cost of new debt financing for the combined firm should be lower. It may be argued that there is no net gain to the combined firm; since shareholders have to guarantee debt service on the combined debt, the savings on the cost of debt financing may be offset by the increased return demanded by equity holders. Nevertheless, lower financing costs are often cited as rationale for merger activity.

During the U.S. merger wave in the 1960s, many firms attempted to acquire other companies to artificially boost their earnings per share. Consider two firms, A and B. Firm A has earnings of $1,000, 100 shares outstanding, and thus $10 earnings per share. With a price-earnings ratio of 20, its shares are worth $200. Firm B also has earnings of $1,000, 100 shares outstanding, but due to poorer growth opportunities its shares trade at 10 times earnings, or $100. If A acquires B, it will only take one-half share of A for each share of B purchased, so the combined firm will have 150 total shares outstanding. Combined earnings will be $2,000, so the new earnings per share of the combined firm are $13.33 per share. It appears that the merger has enhanced earnings per share, when in fact the result is due to inconsistency in the rate of increase of earnings and shares outstanding. Such manipulations were common in the 1960s, but investors have learned to be more wary of mergers instigated mainly to manipulate per share earnings. It is questionable whether such activity will continue to fool a majority of investors. The use of this ploy has faded since the 1980s.

Finally, there is the ever-present hubris hypothesis concerning corporate takeover activity. The main idea is that the target firm is being run inefficiently, and the management of the acquiring firm is likely to do a better job of utilizing the target's assets and strategic business opportunities. In addition, there is additional prestige in managing a larger firm, which may include additional perquisites such as club memberships or access to amenities such as corporate jets or travel to distant business locales. These factors cannot be ignored in detailing the set of factors motivating merger and acquisition activity.

TYPES OF TAKEOVER DEFENSES

As the previous section suggests, some merger activity is unsolicited and not desired on the part of the target firm. Often, the management of the target firm will be replaced or let go as the acquiring firm's management steps in to make their own mark and implement their plans for the new, combined entity. In reaction to hostile takeover attempts, a number of defense mechanisms have been devised and used to try and thwart unwanted advances.

To any offer for the firm's shares, several actions may be taken which make it difficult or unattractive to subsequently pursue a takeover attempt. One such action is the creation of a staggered board of directors. If an outside firm can gain a controlling interest on the board of directors of the target, it will be able to influence the decisions of the board. Control of the board often results in de facto control of the company. To avoid an outside firm attempting to put forward an entire slate of their own people for election to the target firm's board, some firms have staggered the terms of the directors. The result is that only a portion of the seats is open annually, preventing an immediate takeover attempt. If a rival does get one of its own elected, they will be in a minority and the target firm's management has the time to decide how to proceed and react to the takeover threat.

Another defense mechanism is to have the board pass an amendment requiring a certain number of shares needed to vote to approve any merger proposal. This is referred to as a supermajority, since the requirement is usually set much higher than a simple majority vote total. A supermajority amendment puts in place a high hurdle for potential acquirers to clear if they wish to pursue the acquisition. This is sometimes referred to as a fair price amendment.

Finally, another preemptive strike on the part of existing management is a poison pill provision. A poison pill gives existing shareholders rights that may be used to purchase outstanding shares of the firms stock in the event of a takeover attempt. The purchase price using the poison pill is a significant discount from fair market value, giving shareholders strong incentives to gobble up outstanding shares, and thus preventing an outside firm from purchasing enough stock on the open market to obtain a controlling interest in the target. Such strategies as staggering director terms, fair price amendments, and poison pills are sometimes referred to as "shark repellents."

Once a takeover attempt has been identified as underway, incumbent management can initiate measures designed to thwart the acquirer. One such measure is a dual-class recapitalization; whereby a new class of equity securities is issued which contains superior voting rights to previously outstanding shares. The superior voting rights allow the target firm's management to effectively have voting control, even without a majority of actual shares in hand. With voting control, they can effectively decline unsolicited attempts by outsiders to acquire the firm.

Another reaction to undesired advances is an asset restructuring. Here, the target firm initiates the sale or disposal of the assets that are of primary interest to the acquiring firm, usually called the "crown jewel." The divestiture of the crown jewel results in an end to the acquisition activity. On the other side of the balance sheet, the firm can solicit help from a third party, friendly firm. Such a firm is commonly referred to as a "white knight," the implication being that the knight comes to

the rescue of the targeted firm, or "maiden." A white knight may be issued a new set of equity securities such as preferred stock with voting rights, or may instead agree to purchase a set number of existing common shares at a premium price. This is called the lockup defense. The white knight is supportive of incumbent management; by purchasing a controlling interest in the firm unwanted takeovers are effectively avoided.

There are other drastic measures that targeted firms can take. Professor Michael Baye, in his 2008 book *Managerial Economics and Business Strategy*, names several other options. One is the golden parachute strategy, in which leading managers retaliate against the takeover by creating contracts for themselves with provisions for significant severance pay or compensation in case they lose their jobs through an acquisition. If the takeover is successful, the golden parachute will grant top managers enormous gains upon their release from the new firm.

The targeted firm may also use the strategy called greenmail, in which it buys back the shares the hostile firm owns. If this practice is successful, the raider will sell its stock in the firm, usually at a very inflated price, to gain a significant profit. This leaves the targeted firm safe with its own shares, if also in debt.

Lastly, a maiden firm may use the going private defense as a last resort. They find a buyer (less agreeable than a white knight) to buy the public stock in the firm and delist it as a public firm. Stock trading is then no longer possible, and the firm, though privately owned, is safe from the raider.

Baye also lists several practices used by a hostile firm upon attempting a takeover. These include stripping, which is the practice of selling off the assets of the targeted company to create extra cash when the takeover is complete, and the less aggressive standstill agreement, which is a last-minute contract in which the hostile company ceases the acquisition process and ends the takeover, keeping only its current holdings in the company.

One of the most prominent takeover activities associated with liability restructuring involves the issuance of junk bonds. "Junk" is used to describe debt with high default risk, and thus junk bonds carry very high coupon yields to compensate investors for the high risk involved. During the 1980s, the investment-banking firm Drexel Burnham Lambert (led by Michael Milken) pioneered the development of the junk-bond market as a vehicle for financing corporate takeover activity. Acquisition groups, which often included the incumbent management group, issued junk bonds backed by the firm's assets to raise the capital needed to acquire a controlling interest in the firm's equity shares. In effect, the firm's balance sheet was restructured with debt replacing equity financing. In several instances, once the acquisition was successfully completed the acquiring management subsequently sold off portions of the firm's assets or business divisions at large premiums, using the proceeds to retire some or all of the junk bonds. The takeover of RJR Nabisco by the firm Kohlberg Kravis Roberts & Co. in the late 1980s was one of the most celebrated takeovers involving the use of junk-bond financing.

VALUING A POTENTIAL MERGER

There are several alternative methods that may be used to value a firm targeted for merger or acquisition. One method involves discounted cash flow analysis. First, the present value of the equity of the target firm must be established. Next, the present value of the expected synergies from the merger, in the form of cost savings or increased after-tax earnings, should be evaluated. Finally, summing the present value of the existing equity with the present value of the future synergies results in a present valuation of the target firm.

Another method involves valuation as an expected earnings multiple. First, the expected earnings in the first year of operations for the combined or merged firm should be estimated. Next, an appropriate price-earnings multiple must be determined. This figure will likely come from industry standards or from competitors in similar business lines. Now, the PE ratio can be multiplied by the expected combined earnings per share to estimate an expected price per share of the merged firm's common stock. Multiplying the expected share price by the number of shares outstanding gives a valuation of the expected firm value. Actual acquisition price can then be negotiated based on this expected firm valuation.

Another technique that is sometimes employed is valuation in relation to book value, which is the difference between the net assets and the outstanding liabilities of the firm. A related idea is valuation as a function of liquidation, or breakup, value. Breakup value can be defined as the difference between the market value of the firm's assets and the cost to retire all outstanding liabilities. The difference between book value and liquidation value is that the book value of assets, taken from the firm's balance sheet, are carried at historical cost. Liquidation value involves the current, or market, value of the firm's assets.

Some valuations, particularly for individual business units or divisions, are based on replacement cost. This is the estimated cost of duplicating or purchasing the assets of the division at current market prices. Some premium is usually applied to account for the value of having existing and established business in place.

Finally, in the instances where firms that have publicly traded common stock are targeted, the market value of the stock is used as a starting point in acquisition

negotiations. Earlier, a number of takeover defense activities were outlined that incumbent management may employ to restrict or reject unsolicited takeover bids. These types of defenses are not always in the best interests of existing shareholders. If the firm's existing managers take seriously the corporate goal of maximizing shareholder wealth, then a bidding war for the firm's stock often results in huge premiums for existing shareholders. It is not always clear that the shareholders interests are primary, since many of the takeover defenses prevent the use of the market value of the firm's common stock as a starting point for takeover negotiations. It is difficult to imagine the shareholder who is not happy about being offered a premium of 20 percent or more over the current market value of the outstanding shares.

METADATA OR META-ANALYSIS

In today's world of data management, it has become increasingly important to master methods of accumulating, controlling, and accessing information electronically. The key to this process is metadata, or data concerning data. Businesses use metadata every day when filing electronically, searching for documents on their intranets, and collecting customer data for analysis. E-retailers and businesses that interact online depend on metadata to run their companies. According to Nigel Ford's 2008 *Web-Based Learning Through Educational Informatics*, some common types of metadata found today are:

- General: Information pertaining to the data as a whole set, including its title, what language it is in, and its tag or description.

- Lifecycle: Who has accessed the data, added to or taken from it, and when.

- Technical: Refers to what format the data is in, how long it will last, and other IT information.

- Rights: Who owns the data, who has written it, and who owns the rights to publish or distribute it?

- Relation: Any information that connects one set of data to another, such as a chapter of a book, a summary of a report, or an addendum to a file.

- Annotation: Any added information concerning the usefulness of the data to particular operations.

- Classification: Where the data belongs within an organization's framework, pertaining to sources and applications—labeling data by names such as a human resources (HR) document, a financial report, or a customer service analysis.

GROUPINGS

Metadata is most often divided into three categories of use. The first is business metadata, or data that conforms to specific business regulations and is tailored for business use. This is a more common, linguistic type of metadata, based on intuitive relations and organized so that users can search for particular sets of data more easily.

The second type of metadata is database metadata, the labels referring to the database itself and how information is organized within it. IT practices, such as source-system mapping and defining objects for spreadsheets, use this type of metadata. Database metadata is also used for security purposes, such as keeping track of when the users last accessed the data and possibly even for what reason.

The third type of metadata is application metadata, an elaborate type of data that explains what other metadata means. For instance, an example of application metadata is a description/explanation of what the monthly customer service report is, and who has access to it.

ANALYSIS AND ACCOUNTING

Beyond helping users to understand data systems and search for specific information, metadata also plays an important role in analysis. Most analysis programs use metadata to collect the required information, organize it into sets, and conduct tests. Thanks to business metadata, data-mining parameters can be set (such as all data collected on the corporate Web sites from the past three months). This information can also be analyzed using metadata, which can include the number of online users who clicked on Web ads, or where the company made most of its revenue within a given time period. The most common barrier businesses find between themselves and this sort of in-depth information analysis is semantics—the need to apply simple language to the purely mathematical or technical metadata.

Other companies find metadata to be especially helpful in accountability practices. Since information concerning who created the data, who has accessed it, and what has been added or taken away from it, is all included in

metadata, mining such information can easily clear up electronic accountability issues. Most metadata made for business transactions includes every part of the process, a record of each step and when it was completed, which can help clear up misunderstandings. Metadata can also be helpful in analysis accountability; it defines data sets, separating them into proper fields and allowing creators to limit what the data can be used for so that none is mistakenly included in a data mining or analysis process.

To develop efficient metadata systems, companies should first accept a clear data scheme including accepted titles and parameters for what types of metadata should be included. Periodic updates using metadata can then be included in reports, giving managers and employees instant access to beneficial information concerning the company's data.

MILES AND SNOW TYPOLOGY

In their 1978 book *Organization Strategy, Structure, and Process,* Raymond E. Miles and Charles C. Snow argued that different company strategies arise from the way companies decide to address three fundamental problems: entrepreneurial, engineering (or operational), and administrative problems.

The entrepreneurial problem is how a company should manage its market share. The engineering problem involves how a company should implement its solution to the entrepreneurial problem. The administrative problem considers how a company should structure itself to manage the implementation of the solutions to the first two problems. Although businesses choose different solutions to these problems, Miles and Snow suggested that many companies develop similar solutions. As a result, they postulated that there are four general strategic types of organizations: prospector, defender, analyzer, and reactor organizations.

ORGANIZATION TYPES

Prospector Organizations. Prospector organizations face the entrepreneurial problem of locating and exploiting new product and market opportunities. These organizations thrive in changing business environments that have an element of unpredictability, and succeed by constantly examining the market in a quest for new opportunities. Moreover, prospector organizations have broad product or service lines and often promote creativity over efficiency.

Prospector organizations face the operational problem of not being dependent on any one technology. Consequently, prospector companies prioritize new product and service development and innovation to meet new and changing customer needs and demands and to create new demands. The administrative problem of these companies is how to coordinate diverse business activities and promote innovation. Prospector organizations solve this problem by being decentralized, employing generalists (not specialists), having few levels of management, and encouraging collaboration among different departments and units.

Defender Organizations. Defender organizations face the entrepreneurial problem of how to maintain a stable share of the market, and hence they function best in stable environments. A common solution to this problem is cost leadership, and so these organizations achieve success by specializing in particular areas and using established and standardized technical processes to maintain low costs. In addition, defender organizations tend to be vertically integrated in order to achieve cost efficiency.

Defender organizations face the administrative problem of having to ensure efficiency, and thus they require centralization, formal procedures, and discrete functions. In their 2006 guide *Designing and Executing Strategy in Aviation Management*, authors Flouris and Oswald remind readers that the danger in creating a defender organization lies in maintaining stability. Such companies require an industry where change occurs slowly and long-term planning can be conducted. In today's world of business, there are very few sectors of business that maintain such a stasis, and this poses a threat to those with a purely defender typology.

Analyzer Organizations. Analyzer organizations share characteristics with prospector and defender organizations; thus, they face the entrepreneurial problem of how to maintain their shares in existing markets and how to find and exploit new markets and product opportunities.

These organizations have the operational problem of maintaining the efficiency of established products or services, while remaining flexible enough to pursue new business activities. Consequently, they seek technical efficiency to maintain low costs, but they also emphasize new product

and service development to remain competitive when the market changes. The administrative problem is how to manage both of these aspects.

Like prospector organizations, analyzer organizations cultivate collaboration among different departments and units. Analyzer organizations are characterized by balance—a balance between defender and prospector organizations. Indeed, according to Flouris and Oswald, analyzer organizations are the natural progression of prospector organizations, since they take the innovation and inventions the prospectors create and market them with reliable business procedures.

Reactor Organizations. Reactor organizations, as the name suggests, do not have a systematic strategy, design, or structure. They are not prepared for changes they face in their business environments. If a reactor organization has a defined strategy and structure, it is no longer appropriate for the organization's environment. A reactor organization's new product or service development fluctuates in response to the way the managers perceive their environment. Reactor organizations do not make long-term plans, because they see the environment as changing too quickly for them to be of any use, and they possess unclear chains of command.

ADVANTAGES OF DIFFERENT STRATEGIES.

Miles and Snow argued that companies develop their adaptive strategies based on their perception of their environments. Hence, as seen above, the different organization types view their environments in different ways, causing them to adopt different strategies. These adaptive strategies allow some organizations to be more adaptive or more sensitive to their environments than others, and the different organization types represent a range of adaptive companies. Because of their adaptive strategies, prospector organizations are the most adaptive type of company. In contrast, reactor organizations are the least adaptive type. The other two types fall in between these extremes: analyzers are the second most adaptive organizations, followed by defenders.

Since business environments vary from organization to organization, having a less adaptive strategy may be beneficial in some environments, such as highly regulated industries. For example, a study of the airline industry in the 1960s and 1970s indicated that the defender airlines were more successful than the prospector airlines in that the business environment changed slowly during this period because of the heavy regulation. Hence, the emphasis on efficiency by the defender airlines worked to their advantage.

On the other hand, prospector organizations clearly have an advantage over the other types of organizations in

business environments with a fair amount of flux. Companies operating in mature markets in particular benefit from introducing new products or services and innovations to continue expanding. As Miles and Snow note, no single strategic orientation is the best. Each one—with the exception of the reactor organization—can position a company so that it can respond and adapt to its environment. What Miles and Snow argue determines the success of a company ultimately is not a particular strategic orientation, but simply establishing and maintaining a systematic strategy that takes into account a company's environment, technology, and structure.

FURTHER STUDIES

Scholars have attempted to verify the reliability and validity of the Miles and Snow typology. A study by Shortell and Zajac, conducted in 1990, indicated that this typology of strategic orientations and its predictions was generally accurate. They found that prospectors are likely to be the first organizations to adopt new products and services, analyzers are likely to be the first organizations to adopt new managerial procedures and systems, and defenders are usually the first organizations to adopt new production-related technology. Moore carried Miles and Snow's framework to the retail environment and concluded that the typology is generally applicable to retail contexts.

Some have suggested that Miles and Snow typology is important not as a study of static conditions, but as a dynamic cycle that businesses go through. *Methodological Issues in Accounting Research*, written by Zahirul Hoque in 2006, suggests that the Miles and Snow typology has remained viable because it shows how organizations respond to various business conditions. When confronted with a certain change, a department or section of an organization will usually react with one of the Miles and Snow typologies. In this view, the typologies are not so much classes of organizations as they are processes that businesses go through based on their environment.

Other researchers further broadened the scope and applicability of Miles and Snow's typology, relating the strategic approaches strategic decision processes, international strategies, and functional areas within organizations. In their 1993 article "An Empirical Examination of the Relationship Between Strategy and Scanning," Subramanian, Fernandes, and Harper found that strategic types differed in terms of how managers perform environmental scanning. Prospectors tended to be more proactive in their scanning, followed by analyzers; defenders tended to be less proactive or "ad hoc."

As an example of the effects of functional expertise in an international context, Professor David Naranjo-Gil explored the impact of sophisticated accounting information systems on strategic performance among hospitals in

Spain. Findings indicated that performance was enhanced primarily through sophisticated accounting information systems' role in implementing the prospector strategy.

Clearly, the Miles and Snow typology has contributed to the understanding of organizational behavior in a variety of settings. As demonstration for its further applicability, Peng, Tan, and Tong studied firms in the emerging Chinese economy. In their 2004 article "Ownership Types and Strategic Groups in an Emerging Economy," these authors concluded that the type of firm ownership can help predict strategic group membership. Specifically, state-owned enterprises tended to adopt defender strategies, and privately-owned enterprises tended to adopt prospector strategies. The analyzer orientation was also represented, most commonly under collective and foreign ownership. Future research efforts aimed at the extension of Miles and Snow's typology to international settings appears warranted.

MISSION AND VISION STATEMENTS

An organizational mission is an organization's reason for existence. It often reflects the values and beliefs of top managers in an organization. A mission statement is the broad definition of the organizational mission. It is sometimes referred to as a creed, purpose, or statement of corporate philosophy and values.

A good mission statement inspires employees and provides a focus and direction for setting lower level objectives. It should guide employees in making decisions and establish what the organization does. Mission statements are crucial for organizations to prosper and grow. While studies suggest that they have a positive impact on profitability and can increase shareholder equity, they also support that almost 40 percent of employees do not know or understand their company's mission.

Large as well as small corporations benefit from creating mission statements. Entrepreneurial businesses are driven by vision and high aspirations. Developing a mission statement helps the small business realize their vision. Its primary purpose is to guide the entrepreneur and assist in refining the planning process. By developing a strategic plan that incorporates the mission statement, entrepreneurs are more likely to be successful and stay focused on what is important. The mission statement encourages managers and small business owners alike to consider the nature and scope of the business. *Business Week* attributes 30 percent higher return on several key financial measures for companies with well-crafted mission statements.

COMMON ELEMENTS

While mission statements vary from organization to organization and represent the distinctness of each one, they all share similar components. Most statements include descriptions of the organization's target market; the geographic domain; their concern for survival, growth, and profitability; the company philosophy; and the organization's desired public image. The following is an example of a mission statement for a family dining restaurant chain:

> Our mission is to become the favorite family dining restaurant in every neighborhood in which we operate. This will be accomplished by serving a variety of delicious tasting and generously portioned foods at moderate prices. Our restaurants will be clean, fun, and casual. Our guests will be served by friendly, knowledgeable people who are dedicated to providing excellent customer service.

This mission statement describes the target market, which are families and the geographic domain of neighborhoods. It clearly states how it expects to be profitable by offering excellent customer service by friendly, knowledgeable people. When defining the mission statement it is important to take into account external influences such as the competition, labor conditions, economic conditions, and possible government regulation. It is important to remember, however, that mission statements should not attempt to be too broad.

Companies should have mission statements that clearly define expected shareholder returns and they should regularly measure performance in terms of those expected returns. If the major reason for a business's existence is to make a profit, then it stands to reason that expectations of profit should be included in the organization's mission. This means that management should reach a consensus about which aspects of the company's profit performance should be measured. These might include margin growth, product quality, market share changes, competitive cost position, and capital structure efficiency.

A mission statement sets the boundaries for how resources should be allocated and what strategic and operational goals should be set. It should acknowledge the company's strengths and then inform employees where to direct their efforts in order to take advantage of those strengths.

Before writing a mission statement organizations should take a look at how they are different from the competition, whether it is in technology, image and name brand, or employees. It can often be thought of as a recipe for success because it not only defines the organization's accomplishments but it also provides employees with directions to help them develop plans and look for opportunities for improvement.

The organization defines what is acceptable behavior through the mission statement. Values and beliefs are the core of a strong mission statement. For example:

> Quality and values will secure our success. We will live by our values, have fun, and take pride in what we do. Our values are to maintain a work environment where people enjoy coming to work, to serve our guests and exceed their expectations, and to be profitable and result oriented.

This mission statement is simple and straightforward. It does not, however, specify the products or target market. The mission statement also provides meaning to the organization by stating not only what goals the company wants to achieve but also why it wants to achieve these goals. It is not effective unless it is challenging and forces workers to establish goals and means

to measure the achievement of those goals. A mission statement should inspire employees and get them involved in the organization. It has been called the glue that holds the organization together through shared values and standards of behavior. A mission statement should be relevant to the history, culture, and values of the company.

Many statements refer to the social responsibility of the organization. For example, a company can show their concern for the community in the following:

> To be involved as good corporate citizens wherever we are around the world. We will treat customers and distributors with honesty, courtesy, and respect. We will respect and preserve the environment. Through all of this we will prove to be the worldwide leader in industry trade.

One important issue in organizations today is the concern with diversity. While it is not a traditional point included in mission statements, more and more companies are including it because of the globalization of the economy and the increased diversity of the workforce.

Before writing a mission statement, leaders in the organization must have an idea of what is in store for the future. This vision is the foundation for the mission statement. The vision provides a strategic direction, which is the springboard for the mission and its related goals. A vision statement differs from a mission statement. Vision statements are a view of what an organization is striving to become. For example:

> To bring back to neighborhoods all over America the importance of family unity. We will view ourselves as a family so these attributes will be carried over into our service.

Vision statements guide an organization into the future while mission statements are a reflection of the present. Because vision statements are a glimpse into the future, they are often not realized for several years. Organizations go through many changes and can face times of confusion and uncertainty. Changes are not always expected or easy, so a well thought out vision statement will help everyone stay focused and meet the organization's goals.

The following are two examples of well-known companies' mission statements:

- Wal-Mart: "To give ordinary folk the chance to buy the same thing as rich people."

- 3M: "To solve unsolved problems innovatively."

Historically, these may have seemed arrogant. But consider the outcome of the following mission statements from each company's early days:

- Ford Motor Company: "Ford will democratize the automobile."

- Sony: "Become the company most known for changing the world-wide poor-quality image of Japanese products."

- Wal-Mart: "Become a $125 billion company by the year 2000."

WRITING A MISSION STATEMENT

When creating a mission statement there are a few simple guidelines that can be followed. It is important to remember the basics so the mission statement stays simple and straight to the point. Some researchers, such as C.K. Bart, advise that it should be kept to between thirty and sixty words, while others believe it does not necessarily have to be that brief. Some organizations have mission statements that are only one sentence, while others are a paragraph.

An example of a mission statement that is limited to one sentence is "Our business is selling houses and our mission is total customer satisfaction." At a minimum, each mission statement should answer the following three questions: (1) What are the opportunities or needs the organization addresses? (2) What does the organization do to address those needs? and (3) What principles and values guide the organization? In other words, the statement should define the organization's purpose, business, and values.

Avoiding jargon and buzzwords will keep the mission statement clear and easy to understand. It should be universal and simple to comprehend for all employees in the organization, and should also be unique and identify the organization. A mission statement is often what sets one company apart from the competition. It should outline the organization's competitive advantages and differentiate it from everyone else. Specific products/services offered as well as markets or customers should be included. Also a general business definition, behavioral standards, and desired competitive position can be added to a strong mission statement.

Jim Collins revolutionized the idea of the mission concept in his 2001 book *Good to Great*, where he introduced the hedgehog concept. The hedgehog concept is, according to Collins, "a simple, crystalline concept that flows from deep understanding." The concept is formed from the combination of three definitions—what you can be best in the world at, what drives your economic engine, and what you are deeply passionate about. Collins proposes that businesses often fail because they do not ask the right questions, prompted by this three-in-one concept, and because they build their mission "more from bravado than from understanding." The hedgehog concept and its three components form an alternative method for creating a focused mission statement.

There are also several software programs designed to help start-up companies create their mission statements and build goals. Once such program is *Business Plan Pro*, although there are many to choose from.

Nonprofit businesses must take special care in composing their mission statements. Peri Pakroo, in *Starting and Building a Nonprofit*, advises that nonprofit organizations create very well-defined mission statements at the outset so that their activities and programs have clear goals. Since nonprofit organizations are usually centered around a clear goal, humanitarian project, or particular meaning, it is vital that they have a mission statement supporting their company.

EMPLOYEE INVOLVEMENT

It is often helpful to allow company-wide input when creating a mission statement. This "bottom up" approach results in greater commitment to the organization, and a better understanding of the organization. Employees from throughout the organization can help identify the core values of the company.

In order to encourage employee participation, many companies have created competitions inviting employees to submit suggestions. Cash prizes are sometimes provided as an incentive for creative and inspirational statements. Some companies find it useful to invite customers to assist in writing a mission statement because they can provide an honest perspective. Mission statements from other companies may also be reviewed to provide ideas.

It is important to keep in mind that there will be a draft process involved in creating the mission statement. Employees can often provide invaluable insight on how to improve on each draft. In the end, the mission statement should reflect the personality of the organization. Thus, each company should be creative and unique in developing its own statement.

Creating a mission committee that consists of members of management, frontline employees, and customers is another way to begin writing a mission statement. The major benefit of this strategy is the inclusion of all areas of the organization to ensure that everyone is represented. Another benefit is that employees will be more willing to work toward accomplishing the mission if they know they had a voice in its creation.

Jim Collins noted the effectiveness of creating what he termed "the Council." The Council is a circle of employees usually found in successful companies who focus on the three questions of the hedgehog concept— what can they be best at, what are they passionate about, and what can drive their economic engine—and use their understanding to form mission statements, goals, and vision statements for the future. The Council is often an informal body, five to twelve members, and can be

composed from nearly any position in the company. Collins notes the organic qualities of such bodies and recommends them for important decision making.

A "top down" approach can be effective in smaller organizations or even sole proprietorships. There is less time involved in creating a mission statement when it comes from the top. Also, many times frontline employees and lower level managers lack the insight necessary to see the big picture. They may not be able to conceptualize the entire organization and therefore miss important aspects of the business.

Participation may not always be a good option for small businesses. In small businesses that are started by entrepreneurs the mission statement is generally a vision of an individual and therefore may not be negotiable. When the mission statement comes from upper management, employees are more assured of the organization's commitment to the statement.

A word of caution should be noted when deciding whether to adopt a top down or a bottom up approach. If the mission statement is to be created with a wide variety of input from both employees and customers then it will take longer than a top down approach. There must be a sharing of views and ideas with compromises made.

A consensus should be developed without the problems associated with groupthink. There is always the possibility that too much compromise will distort the mission statement and the end result is something different from the original intent. The top down approach is not always effective because it rarely consults employees when making important decisions. Therefore, although it is the fastest route to take it is not always the most effective.

While the mission statement should be able to change with the times it is also understood to have a certain degree of permanence. As new businesses begin to grow and hire more employees the mission statement should provide a strong sense of stability and a clear definition of the culture.

A mission statement is worthless unless it has the support of the employees in the organization. It will only be successful if each employee commits to its success and internalizes it.

Once the statement is completed it is extremely important that the organization not put it on the shelf to collect dust. It should be shared with the entire company. The introduction of the mission statement should come directly from top management in order to set the example.

Organizations should be creative in making employees aware of the mission statement. Placing it strategically in locations where employees gather will increase awareness and remind them of the goals of the organization. Videos outlining the details of the new mission statement are often useful; however, it is critical that employees have the opportunity to discuss the statement with members of management.

Setting up meetings with members of management and frontline employees can often help uncover areas where the company does not meet the standards set by the mission statement. Communicating the mission statement to customers will make them feel valued and important. The mission statement can be sent to customers in a mass mailing or posted on signs in areas those customers frequent. It sets forth the goals of the organization so customers know what to expect when doing business with the company.

In his 2007 book *101 Mission Statements*, Jeffrey Abrahams suggests that companies can go even further and address themselves to specific groups within the mission statement. They can refer to these target audiences as headings. Some of the examples Abrahams gives include: "To our staff . . ." "To our employees . . ." "To our customers . . ." and "To our colleagues . . ." For the mechanics of the statement, various analyses can be used, such as the SWOT analysis, discussed next.

SWOT ANALYSIS

SWOT is an acronym for strengths, weaknesses, opportunities, and threats. SWOT analysis is a strategic planning tool that helps an organization match its internal strengths and weaknesses with external opportunities and threats. SWOT analysis is important and useful in creating and executing the organization's mission statement. Often the best strategies for accomplishing the organization's mission are revealed through the SWOT analysis. The best strategies are those that take advantage of strengths and opportunities, offset threats, and improve weaknesses.

Organizations should first begin by reviewing internal strengths and weaknesses. When analyzing an organization's strengths it is important to identify distinctive competencies or strengths possessed by only a few competing firms. These distinctive competencies often become the competitive advantages that are included in the mission statement. Distinctive competencies can be found in financial resources, quality products and services, proprietary technology, or cost advantages. Organizational weaknesses are skills and capabilities that prevent an organization from implementing strategies that achieve its mission. They can be problems with facilities, lack of a clear strategic direction, internal operating problems, too narrow a product line, weak market image, or the inability to finance changes.

The next step is to identify external opportunities and threats. Organizational opportunities are circumstances in an organization's environment that if capitalized on will result in above normal increases in economic performance. Examples of opportunities are related to the possibility of adding a new product line, increasing market growth, or

Figure 1

Organizational Mission Statement

Strategic Goals

| Tactical Goals & Objectives Operations | Tactical Goals & Objectives Sales | Tactical Goals & Objectives Finance |

| Operational Goals & Objectives Customer Service, Inventory, Billing | Operational Goals & Objectives Northern, Eastern, Central & Western Region | Operational Goals & Objectives Accounting, Accounts Payable, Accounts Receivable |

diversifying into related products. Threats are viewed as circumstances that give rise to normal or below normal economic performance. They can be found in the ease of entry of competitors, increased sales of substituted products, demographic changes, slowed market growth, or increased competition.

EVALUATION

Evaluation of the mission statement is necessary to ensure the organization is meeting its goals. If needed, new goals may have to be created in order to accommodate changes in the organization. It may be time to reevaluate what the organization is doing or where it is headed. This is a good time to think about entering into new areas or to begin doing things differently by rewriting part or all of the mission and vision statements.

It should be noted, however, that the stronger a mission statement is, the less it will need to be changed as the company progresses with time and technology. In a 2008 article, *Inc. Magazine* writer Professor Jay Ebben suggests that one of the questions mission statement creators should ask is, "What do we do?" This question, according to Ebben, should be answered in a psychological way in terms of meeting intrinsic customer needs so that the company and its products or services can evolve with time.

In evaluating an organization's performance, management must look at several different aspects of the organization. First, managers need to determine if the organization's

plans are clearly linked to its mission statement and related goals. Plans should be developed for both the short run and long run. Secondly, assigning jobs that are directly related to the achievement of organizational goals will help ensure they are attained. The goals should be communicated clearly so employees understand what tasks need to be carried out and what the rewards will be. Finally, when evaluating individual performance, the information gathered should be recent and compared to established standards.

Mission statements are often difficult to evaluate because of their abstract form. Poor mission statements are not directly measurable and are vaguely worded. Figure 1 presents an example of how mission statements can be measured from the top of the organization to the bottom. Strategic goals are directly tied to the organization's mission statement and apply to the organization as a whole. Tactical goals are departmental goals that support the strategic goals. Finally, operational goals are written at the individual level. Each one of these makes it possible to measure the organization's mission statements. An organization's likelihood of accomplishing its mission is increased as it creates strong and measurable goals at each level.

It is not necessary that the mission statement be measured in quantifiable terms. It may also be measured qualitatively. For example, "We will answer all of our customers' questions and if we do not know the answer, we will find out." While this is not a quantitative statement it can be measured by monitoring customer service

calls and setting operational goals for employees that revolve around follow up and thoroughness.

Mission and vision statements give organizations a focus and a strategy for the future. According to Bart and Tabone, they have become the cornerstones of organizations. They contribute to an organizations' success and can lead to increases in productivity and performance. They do not have to be reserved for the entire organization—each department or division can benefit from developing a mission statement, as long as they are not in contradiction to the company's overall mission. Preferably, an individual department's mission links it to the fulfillment of the overall company mission. Mission statements for functional departments provide the same benefits as they do for the entire organization.

In conclusion, mission statements provide a sense of direction and purpose. In times of change and growth they can be an anchor and a guide in decision making. The benefits far outweigh the disadvantages and challenges when looking at the potential for increases in profitability and returns. Defining an organization by what it produces and who it satisfies are major steps towards creating a sound and stable mission statement. Setting a company apart from the competition is probably one of the biggest advantages.

MOBILE COMMERCE

The use of portable wireless electronic devices to conduct transactions through the Internet is commonly referred to as mobile commerce (m-commerce). Advanced wireless electronic gadgets such as mobile phones, personal digital assistants (PDAs), laptops, and smartphones are increasingly being used to access and execute electronic transactions through the Internet. M-commerce gadgets facilitate Internet access to customized news services, local maps, stock reports, and financial updates without the need for fixed plug-in accessories to Web servers.

Although m-commerce can easily be confused with e-commerce, the two electronic modes of transacting business are quite different; whereas m-commerce transactions can be accessed through wireless mobile electronic gadgets at anytime from any location, e-commerce transactions are limited to stationary computer networks. In a 2006 Internet article titled "Mobile Banking Stages a Remarkable Comeback," Rajnish Tiwari and Stephan Buse note that m-commerce applications draw usability convenience from the following characteristics:

- Real-time access to information and data
- Authenticity
- Ubiquitous features
- Customized contents
- Multiple communication functionalities
- Round-the-clock access

M-commerce devices come with many advantages that enhance the convenience of conducting business through the Internet without having access to fixed power portals and Internet connections. In addition to providing users with the advantage of instant access to the Internet even when out of their work stations or homes, the ubiquitous nature of m-commerce devices also enables users to access personalized or customized content services. Moreover, the unique user identification code of each m-commerce devices can provide users with security advantage through authenticating information and tailoring content to desired degrees of privacy.

ACCESS TO THE WEB

Internet access via wireless mobile technologies is not an entirely new phenomenon in the communications market because modem-connected laptops with access to the Internet have been used ever since the Global System for Mobile Communications (GSM) network was unveiled in the early 1990s. The ability of GSM to support wireless application protocol (WAP) connections prompted handset manufacturers to introduce new generation WAP-enabled mobile devices with instant access to the Internet. Mobile Internet access was later boosted by the arrival of high-speed Internet infrastructures such as the High Speed Circuit Switched Data (HSCD) in 2000, General Packet Service Radio (GPRS) in 2001, and Enhanced Data Rates for Global Evolution (EDGE) in 2002.

Each preceding network infrastructure is characterized by advanced technological features and enhanced speed for displaying and relaying text-based data, in addition to instant access capabilities that are charged according to megabytes per second (Mbps) usage. The 2003 arrival of 3G, a third-generation broadband mobile network service which is supported by the Universal Mobile Telecommunications System (UMTS) has introduced much convenience in the m-commerce industry. The 3G broadband network facilitates the use of mobile devices to transmit high-speed video downloads and chat services in addition to relaying text-based data and instant Internet.

The concept of m-commerce is mainly based on the WAP technology. Mobile phones, PDAs, smartphones, and dashboard phones are equipped with standardized features tailored to accommodate small-screen data displays. The use of mobile devices to execute commercial transactions can be used in combination with other wireless technology applications such as the wireless-fidelity (Wi-Fi) mobile access, Bluetooth technology, and radio frequency identification devices (RFID), which transmit data between mobile electronic gadgets and service terminals without the need to swap card readers.

Wi-Fi technology enables Internet access through mobile devices in specially selected areas commonly referred to as "hotspots". Hotspots are usually high traffic areas such as cities, airports, rail stations, and hotels. Internet access via Wi-Fi can be facilitated by equipping laptops with mobile chips which act as routers from hotspots. In the book titled *E-Business and E-Commerce Management*, Dave Chaffey confirms that Wi-Fi networks use the 802.11 a, b, or g standard protocol which provides an average speed of 11 Mbps, subject to the strength of the signal from service providers.

American Airlines is one example of a company that has taken the lead in the use of Wi-Fi technology to access the Internet via wireless devices. According to the American Airlines Web site, the airline launched its first ever in-flight Internet access via Wi-Fi technology in August 2008 in a bid to gain competitive advantage over its competitors.

Bluetooth wireless technology is particularly applied over short-distance data exchange between electronic devices to transfer or convert information from mobile devices to storage devices. Bluetooth technology relies on the capacity to beam commands and data information between wireless devices such as a wireless mouse and a computer, a wireless keyboard and a computer, a PDA and a computer, or a laptop and a printer. The increase in the use of Bluetooth-enabled mobile phones to connect to the Internet has prompted leading handset manufactures to increase the production of WAP-enabled smartphones such as Blackberry, which among many other technical features, are equipped with fax, phone, and e-mail capabilities.

M-COMMERCE BUSINESS APPLICATIONS

Just like e-commerce, m-commerce has eliminated the need for processing transactions through paperwork. Wide-ranging business transactions such as ticketing, content purchasing, banking, advertising, electronic payments, and auctions can be carried out through m-commerce devices.

M-Ticketing. Mobile ticketing is an m-commerce business application that uses advanced electronic technologies to deliver tickets to mobile phones, thereby providing customers with immediate and convenient access to their tickets by simply presenting their mobile phones to service vendors. This mode of ticketing is mainly used by car hire companies, public transport companies, airlines, events organizers, night clubs, cinema houses, and train stations. Trinity and bCode are some of the companies in the United States that offer mobile ticketing services to other companies.

M-Purchasing and Delivering Content. The use of mobile devices to purchase and deliver content rank among the most successful m-commerce activities in the mass markets, because it involves convenient transfer of services and products such as mobile phone ring tones, games, and wallpapers that are always sought by mobile phone users. The unprecedented success of sales volumes that Apple's iPods registered as a result of the rush for Apple iTunes serves as a testimony of how the use of mobile devices to purchase and download content has penetrated the mass markets. The impending upgrade of speed capacities of 3G broadband network to fourth generation (4G) will facilitate the purchase of video content such as movies through mobile devices.

M-Shopping. Mobile phones are used to purchase products and services from e-commerce sites such as Amazon.com and eBay.com and other sites that offer online shopping services.

M-Banking. Mobile banking enables bank account holders to access and track the trends of activities in their accounts using mobile phones. Individuals can use mobile phones to check balances, remit money to and from online sources such as PayPal, make bank transfers, and fund stock purchases from different stock exchange markets around the world. However, m-banking is characterized by security concerns because of phishing, sniffing, and theft concerns. Sniffers can easily intercept wireless communications by using appropriate software to break security codes. In an Internet article titled *New E*Trade App Lets BlackBerry Users Wheel and Deal*, Keith Regan notes that companies are adopting sophisticated software to guard m-commerce applications against probable security risks. The author notes the example of *E*Trade Mobile Pro*, a customized mobile service which was launched by E*Trade in June 2008 to enhance security of wireless access to the E*Trade Web site by limiting access strictly to BlackBerry smart phones, which are equipped with advanced user interface and security features for banking and trading services.

M-Marketing and Advertising. Mobile phones are gaining increased acceptance as effective tools for marketing and advertising. Token items such as newsletters, business vouchers, and coupons can be distributed to mobile phones and other mobile devices, especially in instances where a firm seeks to benefit from the advantages of target marketing. In the United States, for example, businesses use the *vSnax* mobile service to advertise by providing free video access to different services, such as news, weather, and stock updates, and attaching matching advertisements on them.

INDUSTRY TRENDS AND PREDICTIONS

Unlike e-commerce, the emergence of m-commerce did not register much enthusiasm and acceptance among the masses, a situation that led to low purchases and minimal use of WAP-enabled mobile phones for Internet content access during the introductory phase. This caused the collapse of many early m-commerce service providers in Europe, such as Sweden's M-box.

However, these trends are set to reverse with the rapid commercialization and widespread availability of the 3G broadband network as well as the introduction of upgraded network applications such as fourth generation (4G). This is because 3G broadband networks do wonders with suitable mobile access devices such as BlackBerry smartphones that facilitate the fast transmission of colored content and graphical images.

IDC statistics predict that the twenty-first century will experience an unprecedented surge in the use of mobile devices and applications in commercial activities to levels that will exceed the use of fixed Internet and PCs. This will result from the increased coverage of the 3G network and unveiling of the 4G broadband network. Designed to transmit wireless broadband services at a speed ten to twenty times higher than previous broadband wireless applications, 4G broadband will run on the Worldwide Interoperability for Microwave Access (WiMAX) network infrastructure. As such, the arrival of the 4G broadband network is expected to introduce new dimensions in visual entertainment applications by enabling users to download video images and movies using mobile phones.

A good example of how network structures with enhanced transmission capabilities for m-commerce devices can attract unprecedented levels of purchases is the enthusiasm with which i-Mode (a mobile accessory gadget that provides the platform for content subscription services and graphical display of colors) was received in the Japanese market immediately after it was unveiled. i-Mode registered unprecedented success through music and ring tone purchases as well as subscription services in the Japanese market.

Apple's iPhone, a phone that also doubles as a mini-computer, has registered tremendous success in penetrating the mobile phone markets because of its unique performance features and advanced user interface. For example, iPhone enables users to access advertised products in the market by simply pressing on the appropriate icons on the phone's screen to be directed to dealers.

Therefore, companies can achieve increased sales volumes of products and services by focusing on appropriate m-commerce strategies and technologies that enhance access to mass markets. The youth segment of the market is particularly known for having strong preferences for new mobile technologies and premier mobile content such as mobile phone games, ring tones, wall papers, and visual graphics. The fact that youths exhibit low sensitivity to prices allows vendors, distributors, and marketers of m-commerce devices to use the youth mind-set as a market penetration strategy for accessing the mass markets.

MODELS AND MODELING

A model is an abstraction of reality or a representation of a real object or situation. In other words, a model presents a simplified version of something. It may be as simple as a drawing of house plans, or as complicated as a miniature but functional representation of a complex piece of machinery. A model airplane may be assembled and glued together from a kit by a child, or it actually may contain an engine and a rotating propeller that allows it to fly like a real airplane.

A more useable concept of a model is that of an abstraction, from the real problem, of key variables and relationships. These are abstracted in order to simplify the problem itself. Modeling allows the user to better understand the problem and presents a means for manipulating the situation in order to analyze the results of various inputs ("what if" analysis) by subjecting it to a changing set of assumptions.

In the business world, models can be used for many different types of analysis, and created models are considered to be intellectual property under U.S. law.

MODEL CLASSIFICATIONS

Some models are replicas of the physical properties (relative shape, form, and weight) of the object they represent. Others are physical models but do not have the same physical appearance as the object of their representation. A third type of model deals with symbols and numerical relationships and expressions. Each of these fits within an overall classification of four main categories: physical models, schematic models, verbal models, and mathematical models.

Physical Models. Physical models look like the finished object they represent. Iconic models are exact or extremely similar replicas of the object being modeled. Model airplanes, cars, ships, and even models of comic book superheroes look exactly like their counterpart but in a much smaller scale. Scale models of municipal buildings, shopping centers, and property developments such as subdivisions, homes, and office complexes all hopefully look exactly as the "real thing" will look when it is built. The advantage is the models' correspondence with the reality of appearance. In other words, the model user can tell exactly what the proposed object will look like, in three dimensions, before making a major investment.

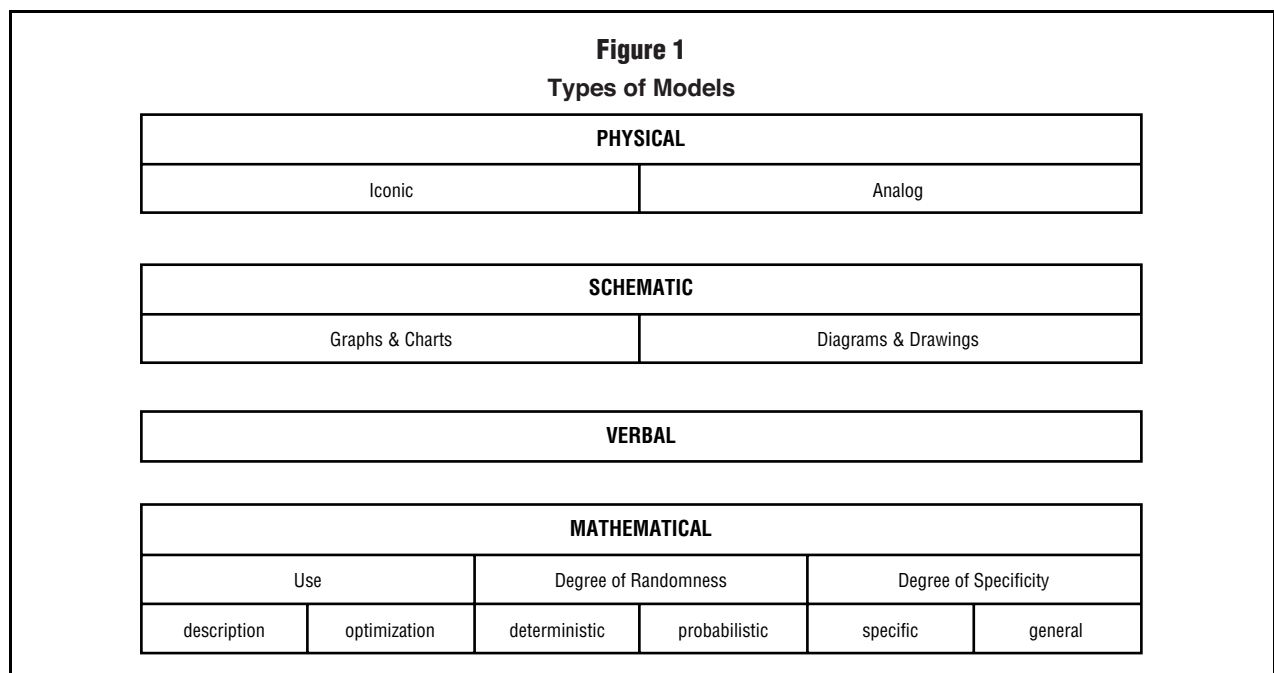
Figure 1

Types of Models

PHYSICAL		
Iconic		Analog

SCHEMATIC		
Graphs & Charts		Diagrams & Drawings

VERBAL

MATHEMATICAL					
Use		Degree of Randomness		Degree of Specificity	
description	optimization	deterministic	probabilistic	specific	general


In addition to looking like the object they represent, some models perform as their counterparts would. This allows experiments to be conducted on the model to see how it might perform under actual operating conditions. Scale models of airplanes can be tested in wind tunnels to determine aerodynamic properties and the effects of air turbulence on their outer surfaces. Model automobiles can be exposed to similar tests to evaluate how wind resistance affects such variables as handling and gas mileage. Models of bridges and dams can be subjected to multiple levels of stress from wind, heat, cold, and other sources in order to test such variables as endurance and safety.

A scale model that behaves in a manner that is similar to the "real thing" is far less expensive to create and test than its actual counterpart. These types of models often are referred to as prototypes.

Additionally, some physical models may not look exactly like their object of representation but are close enough to provide some utility. Many modern art statues represent some object of reality, but are so different that many people cannot clearly distinguish the object they represent. These are known as analog models. An example is the use of cardboard cutouts to represent the machinery being utilized within a manufacturing facility. This allows planners to move the shapes around enough to determine an optimal plant layout.

Schematic Models. Schematic models are more abstract than physical models. While they do have some visual correspondence with reality, they look much less like the physical reality they represent. Graphs and charts are schematic models that provide pictorial representations of mathematical relationships. Plotting a line on a graph indicates a mathematical linear relationship between two variables. Two such lines can meet at one exact location on a graph to indicate the break-even point, for instance. Pie charts, bar charts, and histograms can all model some real situation, but really bear no physical resemblance to anything.

Diagrams, drawings, and blueprints also are versions of schematic models. These are pictorial representations of conceptual relationships. This means that the model depicts a concept such as chronology or sequence. A flow chart describing a computer program is a good example. The precedence diagrams used in project management or in assembly-line balancing show the sequence of activities that must be maintained in order to achieve a desired result.

Verbal Models. Verbal models use words to represent some object or situation that exists, or could exist, in reality. Verbal models may range from a simple word presentation of scenery described in a book to a complex business decision problem (described in words and numbers). A firm's mission statement is a model of its beliefs

about what business it is in and sets the stage for the firm's determination of goals and objectives.

Verbal models frequently provide the scenario necessary to indicate that a problem is present and provide all the relevant and necessary information to solve the problem, make recommendations, or at least determine feasible alternatives. Even the cases presented in management textbooks are generally verbal models that represent the workings of a business without having to take the student to the firm's actual premises.

Oftentimes, these verbal models provide enough information to later depict this problem in mathematical form. In other words, verbal models frequently are converted into mathematical models so that an optimal, or at least functional, solution may be found utilizing some mathematical technique. A look in any mathematics book, operations management book, or management science text generally provides some problems that appear in word form. The job of the student is to convert the word problem into a mathematical problem and seek a solution.

Mathematical Models. Mathematical models are perhaps the most abstract of the four classifications. These models do not look like their real-life counterparts at all. Mathematical models are built using numbers and symbols that can be transformed into functions, equations, and formulas. They also can be used to build much more complex models such as matrices or linear programming models.

A common mathematical model used by businesses is the bell curve, which shows the statistical occurrence of data. The user can then solve the mathematical model (seek an optimal solution) by utilizing simple techniques such as multiplication and addition or more complex techniques such as matrix algebra or Gaussian elimination. Since mathematical models frequently are easy to manipulate, they are appropriate for use with calculators and computer programs.

Mathematical models can be classified according to use (description or optimization), degree of randomness (deterministic and stochastic), and degree of specificity (specific or general). Following is a more detailed discussion of mathematical model types.

TYPES OF MATHEMATICAL MODELS

Descriptive Models. Descriptive models are used to merely describe something mathematically. Common statistical models in this category include the mean, median, mode, range, and standard deviation. Consequently, these phrases are called "descriptive statistics." Balance sheets, income statements, and financial ratios also are descriptive in nature.

Table 1

	Type 1	Type 2
Profit per unit	$60	$50
Assembly time per unit	4 hours	10 hours
Inspection time per unit	2 hours	1 hour
Storage space per unit	3 cm^3	3 cm^3
Resource	**Amount available**	
Assembly time	100 hours	
Inspection time	22 hours	
Storage space	39 cm^3	

Optimization Models. Optimization models are used to find an optimal solution. The linear programming models are mathematical representations of constrained optimization problems. These models share certain common characteristics. Knowledge of these characteristics enables the user to recognize problems that can be solved using linear programming.

For example, a firm that assembles computers and computer equipment is about to start production of two new types of computers. Each type will require assembly time, inspection time, and storage space. The amounts of each of these resources that can be devoted to the production of the computers is limited. The manager of the firm would like to determine the quantity of each computer to produce in order to maximize the profit generated by their sale. In order to develop a suitable model, the manager has obtained the information in Table 1.

In this problem, the total impact of each type of computer on the profit and each constraint is a linear function of the quantity of that variable. By completing the model with the relevant constraints, the user has a suitable model for determining the quantity of each computer to produce in order to maximize (the optimum) the firm's profit. Optimization also can mean minimization when referring to financial losses, scrap, rework, time, or distance. Again, optimization models may be used in this sense.

Deterministic Models. Deterministic models are those for which the value of their variables is known with certainty. In the previous example, the manager knew profit margins

Table 2

	High demand (70%)	Low demand (30%)
Large facility	$5,000.00	(-$2,000.00)
Small facility	$3,000.00	$3,000.00

and constraint values with certainty. This makes the linear programming model a deterministic optimization model.

Models that have values that are not known with certainty are said to be *stochastic or probabilistic models.* For example, a manufacturer that is having trouble deciding whether to build a large or small facility knows that the solution to this capacity problem depends upon the volume of demand that materializes. High demand would require a large facility while low demand would require a small facility. While the manufacturer has no way of knowing with certainty what demand will be, it can at least determine the probability of the occurrence of each. For example, if the manufacturer estimates that the probability of the occurrence of high demand is 70 percent and the occurrence of low demand is 30 percent, it can use this information along with the monetary value (expected payoff) of each situation to construct mathematical models such as payoff matrices or decision trees to find an optimal decision (see Table 2).

This type of model can be said to be a stochastic optimization model. Some models can be very similar with the degree of randomness being the key differentiator. For example, in project management techniques, program evaluation and review technique (PERT) and the critical path method (CPM) are very similar except that CPM is used whenever the required time to complete the activities is known and PERT is used whenever the required activity times are not known but can be estimated. CPM is considered to be deterministic while PERT generally is said to be probabilistic. Once the activity times are established, the two techniques are virtually the same throughout the remainder of the problem's completion.

Specific Models. Specific models apply to only one situation or model one unique reality. The previous examples of profit function (descriptive), objective function (optimization), and payoff matrix (probabilistic), are all specific models. In other words, the values established in the model are relevant for that one unique situation. Linear programming models can be said to be deterministic specific, while decision trees can be called probabilistic specific models.

General Models. General models can be utilized in more than one situation. For example, the question of how much to order is determined by using an economic order quantity (EOQ) model. EOQ models identify the optimal order quantity by minimizing the sum of certain annual costs that vary with order size. On the other hand, the question of how much should be ordered for the next (fixed) interval is determined by the fixed order interval (FOI) model, which is used when orders must be placed at fixed time intervals (weekly, twice, etc.).

USING THE CLASSIFICATIONS

Knowing the type of model that is required provides the user with some advantage when converting a verbal model to a mathematical model. For example, if the decision maker reads the verbal model and determines that the situation is probabilistic and uses situation-specific variables, he or she might seek to convert the verbal model to a payoff matrix or a decision tree (both examples of stochastic/probabilistic specific models).

BENEFITS OF MODEL USE

The goal of modeling use is to adequately portray realistic phenomenon. Once developed properly, a great deal can be learned about the real-life counterpart by manipulating a model's variables and observing the results.

Real-world decisions involve an overwhelming amount of detail, much of which may be irrelevant for a particular problem or decision. Models allow the user to eliminate the unimportant details so that the user can concentrate on the relevant decision variables that are present in a situation. This increases the opportunity to fully understand the problem and its solution.

In his book, *Operations Management,* William J. Stevenson lists nine benefits of models:

1. Models generally are easy to use and less expensive than dealing with the actual situation.

2. Models require users to organize and sometimes quantify information and, in the process, often indicate areas where additional information is needed.

3. Models provide a systematic approach to problem solving.

4. Models increase understanding of the problem.

5. Models enable managers to analyze "what if" questions.

6. Models require users to be very specific about objectives.

7. Models serve as a consistent tool for evaluation.

8. Models enable users to bring the power of mathematics to bear on a problem.

9. Models provide a standardized format for analyzing a problem.

With the advent of Internet business, web business models were born, and these are considered especially helpful in allowing companies to view complex relationships that exist only in cyberspace. According to Michael Rappa's 2008 article "Business Models on the Web," basic business models such as the advertising model or the infomediary model can now be applied to Internet companies, replacing physical departments and processes with virtual components.

MODEL CONSTRUCTION

The accuracy of the results of the model analysis is dependent upon how well the model represents reality. The closer the model is to its actual counterpart, the more accurate the conclusions drawn and the predictions made about the object of attention. Hence, the model user must strive for the most accurate representation possible.

Model users also must be careful to identify the decision variable values that provide the best output for the model. This is referred to as the model's optimal solution. However, irrelevant variables may cloud the picture and cause inaccurate conclusions or sluggish analysis.

In their book *Operations Management: Concepts, Methods, and Strategies,* Mark Vonderembse and Gregory White present a step-by-step process for successfully building a useful model:

1. Define the problem, decision, situation, or scenario and the factors that influence it.

2. Select criteria to guide the decision, and establish objectives. A perfect example of this is the use of heuristics in assembly-line balancing to guide the decision and the criteria of maximizing efficiency/minimizing idle time as an objective.

3. Formulate a model that helps management to understand the relationships between the influential factors and the objectives the firm is trying to achieve.

4. Collect relevant data while trying to avoid the incorporation of superfluous information into the model.

5. Identify and evaluate alternatives. Once again, the example of assembly-line balancing is appropriate. The user can manipulate the model by changing the heuristics and comparing the final results, ultimately finding an optimal solution through trial-and-error. However, the production of alternatives may not be necessary if the model in use initially finds an optimal solution.

6. Select the best alternative.

7. Implement the alternative or reevaluate.

If the user is not familiar with models and their use, he or she would be wise to study the variety of models that are available for use and seek to understand their purpose and how each is used to generate results. Additionally, the user would be well served to learn how the individual model's results are interpreted and used, and what assumptions and limitations apply to each.

ADVANTAGES AND DISADVANTAGES

Models provide the most effective means developed for predicting performance. It is hard to conceive a prediction system that is not finally a model. To construct a model of a real process or system, careful consideration of the

system elements that must be abstracted is required. This in itself usually is a profitable activity, for it develops insights into the problem.

Lack of information quickly appears when beginning to build a model. Companies may consider asking the following questions: What do we really know? Where are the gaps in available data? It is often impractical or impossible to manipulate the real world system in order to determine the effect of certain variables. The dangers in using predictive models lie in the possibility of oversimplifying problems to keep models in workable form. The decision maker may place too much faith in a seemingly rigorous and complete analysis.

It is important for the model user to realize that model development and model solution are not completely separable. While the most accurate representation possible may seem desirable, the user still must be able to find a solution to the modeled problem. Model users need to remember that they are attempting to simplify complex problems so that they may be analyzed easily, quickly, and inexpensively without actually having to perform the task. Also desirable is a model that allows the user to manipulate the variables so that "what if" questions can be answered.

Models come in many varieties and forms, ranging from the simple and crude to the elegant and exotic. Whatever category they are in, all models share the distinction of being simplifications of more complex realities that should, with proper use, result in a useful decision-making aid.

Models are important and widely used in management. Marketing managers utilize the product life cycle model to facilitate understanding of the phases of product life. Accounting managers use ratios, such as the current ratio and the quick ratio, to quickly grasp the ability of an organization to pay its bills in the short term. Information systems managers have flow diagrams to depict the logic needed to develop a computerized order-entry system. Financial managers use net present value and internal rate of return in analyzing investment alternatives. Operations managers have precedence diagrams, decision trees, lot sizing models, material requirements planning, assembly-line balancing, and a host of other models they can use to make better decisions. Organizational performance is a result of the decisions that management makes. Models make these decisions easier to understand and often can lead to an optimal choice.

MORALE

From a managerial perspective, morale embodies the collective spirit and motivation of a group of employees. Other terms used to designate this concept include *esprit* and *esprit de corps.* In fact, esprit de corps was one of the first management principles identified by Henri Fayol in the early twentieth century. Employee morale is how employees actually feel about themselves as workers, their work, their managers, their work environment, and their overall work life. It incorporates all the mental and emotional feelings, beliefs, and attitudes that individuals and groups hold regarding their job.

Consideration of employee morale and job satisfaction was a major emphasis of the behavioral school of management that started with the famous Hawthorne Experiments in the late 1930s. The behavioral school held that employee morale influences employee productivity. Theorists (such as Frederick Herzberg) conducted research in the 1950s and 1960s indicating that employees' satisfaction and motivation were influenced more by how employees felt about their work than the specific attributes of their job, including pay and workplace surroundings.

Since Herzberg's findings, different studies have found different links between employee morale and productivity. For example, according to a 2007 study conducted by research and consulting firm LLC, employee morale is connected to customer satisfaction, which directly relates to the bottom line. The study found that the most effective organizational strategy for boosting morale in the workplace is the use of cross-functional teams, which involves different departments—such as finance and marketing—collaborating on a single project.

Additionally, almost half of the companies in the survey responded that connecting with employees on a personal level is important for employee morale. The study also found that different organizational strategies are suited to larger and smaller companies. Large companies tend to manage morale using communication and rewards, where employees at smaller companies value flexibility and recognition.

Some organizations try to measure morale on a formal basis by conducting morale audits or attitude surveys that indicate the level of employee job satisfaction. Such

measures, however, are fraught with ambiguities; it is difficult, if not impossible, to determine the level of truthfulness of employees' answers or the complexity of the variables. For instance, employees may have a very different level of job satisfaction regarding their company, their pay, their benefits, their profession, and their specific department's policies. A true overall measure of what employees are feeling about their work is therefore difficult to obtain and to interpret. Since there are many variables at play, morale is not always directly linked to productivity, absenteeism, turnover, sales, etc. Nonetheless, morale is widely accepted as important to motivation and team building. The challenge for managers, then, is to negotiate these disparate factors in the manner that most contributes to the overall spirit of the employees.

In "Tips for Increasing Employee Morale and Reducing Absenteeism," Melissa Bushman lists the typical causes of low morale in the workplace and how they can most effectively be resolved. One of the most common causes of low morale is stress, which employees often experience as a result of problems with their manager. Bushman suggests that management training can be useful in this instance. Rumors, negativity, and gossip can also drag down morale in the workplace, which is why Bushman emphasizes the importance of teambuilding to encourage camaraderie and respect among employees. Finally, the author makes the case for incentive programs, which she claims can clearly communicate the goals of the organization, motivate employees to perform well, and give employees a sense of accomplishment.

The major determinant of morale is, in fact, the manager. Employees form their attitudes about work based primarily on their interactions with the supervisors and managers they work with every day. Since no two employees or companies are the same, it is not easy to construct a stable model of managerial techniques that will consistently contribute to high morale across the board. Nevertheless, most employees respond positively to certain managerial practices. Some suggested morale-boosters include:

- Practicing of fairness and consistency

- Bestowing praise in public while leveling criticism in private

- Encouraging humor and fun in the workplace

- Communication

- Listening and remaining receptive to new ideas

- Getting to know something about employees' personal lives and treating them as individuals

- Creating opportunities for employees to learn and grow

- Sharing decision making and offering employees choices

- Promoting from within

- Leading by example

Organizations have tried many techniques to increase morale. The National Alliance for Youth Sports believes creating an atmosphere of fun and camaraderie goes a long way toward maintaining a high level of morale. Every Friday morning the first 30 minutes of the workday is spent with the 35-member staff broken into five teams to compete in different types of games, including miniature golf and Frisbee football. Symbiosis Corporation, a producer of medical products, uses mentors to build morale of nonexempt hourly employees by supporting personal growth and promoting a sense of belonging. After the pilot project recorded improvements in attitudes, productivity, and morale, Symbiosis expanded the program.

In order to allow employees a sense of balance in their lives, some companies provide benefits that help employees run a household and put in a productive day at the office. Employees at Wilton Connor Packaging in Charlotte, North Carolina, can take their laundry to work and have it washed, dried, and folded for the cost of the soap; while at PepsiCo's headquarters employees are provided an on-site dry cleaning drop-off. Some companies offer concierge services that run errands and send someone to be at an employee's home for a delivery. Many companies also provide on-site child care, elder care, and fitness centers for their employees and their families.

To retain employees in an increasingly competitive marketplace, organizations must reinforce managerial techniques that foster a high degree of employee morale. Managers can make a difference by following common morale-boosting strategies, trying to provide their employees with supportive working environments, and incorporating creative techniques that make employees feel fulfilled personally and as part of a larger entity in which they feel integrated. The best managers take care of their employees so their employees can take care of business.

MOTIVATION AND MOTIVATION THEORY

The term *motivation* is derived from the Latin word *movere,* meaning "to move." Motivation can be broadly defined as the forces acting on or within a person that cause the arousal, direction, and persistence of goal-directed, voluntary effort. Motivation theory is thus concerned with the processes that explain why and how human behavior is activated.

The broad rubric of motivation and motivation theory is one of the most frequently studied and written-about topics in the organizational sciences, and it is considered one of the most important areas of study in the field of organizational behavior. Despite the magnitude of the effort that has been devoted to the study of motivation, there is no single theory of motivation that is universally accepted. The lack of a unified theory of motivation reflects both the complexity of the construct and the diverse backgrounds and aims of those who study it. To delineate these crucial points, it is illuminating to consider the development of motivation and motivation theory as the objects of scientific inquiry.

HISTORICAL DEVELOPMENT

Early explanations of motivation focused on instincts. Psychologists writing in the late nineteenth and early twentieth centuries suggested that human beings were basically programmed to behave in certain ways, depending upon the behavioral cues to which they were exposed. Sigmund Freud, for example, argued that the most powerful determinants of individual behavior were those of which the individual was not consciously aware.

According to Steers, Porter, and Bigley in *Motivation and Leadership at Work,* in the early twentieth century researchers began to examine other possible explanations for differences in individual motivation. Some researchers focused on internal drives as an explanation for motivated behavior. Others studied the effect of learning and how individuals base current behavior on the consequences of past behavior. Still others examined the influence of individuals' cognitive processes, such as the beliefs they have about future events. Over time, these major theoretical streams of research in motivation were classified into two major schools: the content theories of motivation and the process theories of motivation.

MAJOR CONTENT THEORIES

Content (or need) theories of motivation focus on factors internal to the individual that energize and direct behavior. In general, such theories regard motivation as the product of internal drives that compel an individual to act or move (hence, "motivate") toward the satisfaction of individual needs. The content theories of motivation are based in large part on early theories of motivation that traced the paths of action backward to their perceived origin in internal drives. Major content theories of motivation are Maslow's hierarchy of needs, Alderfer's ERG theory, Herzberg's motivator-hygiene theory, and McClelland's learned needs or three-needs theory.

Maslow's Hierarchy of Needs. Abraham Maslow developed the hierarchy of needs, which suggests that individual needs exist in a hierarchy consisting of physiological needs, security needs, belongingness needs, esteem needs, and self-actualization needs. Physiological needs are the most basic needs for food, water, and other factors necessary for survival. Security needs include needs for safety in one's physical environment, stability, and freedom from emotional distress. Belongingness needs relate to desires for friendship, love, and acceptance within a given community of individuals. Esteem needs are those associated with obtaining the respect of one's self and others. Finally, self-actualization needs are those corresponding to the achievement one's own potential, to the exercising and testing of one's creative capacities, and, in general, to becoming the best person one can possibly be. Unsatisfied needs motivate behavior; thus, lower-level needs such as the physiological and security needs must be met before upper-level needs such as belongingness, esteem, and self-actualization can be motivational.

Applications of the hierarchy of needs to management and the workplace are obvious. According to the implications of the hierarchy, individuals must have their lower level needs met by, for example, safe working conditions, adequate pay to take care of one's self and family, and job security before they will be motivated by increased job responsibilities, status, and challenging work assignments.

Alderfer's ERG Theory. The ERG theory is an extension of Maslow's hierarchy of needs. Alderfer suggested that needs could be classified into three categories, rather than five. These three types of needs are existence, relatedness, and growth. Existence needs are similar to Maslow's

physiological and safety need categories. Relatedness needs involve interpersonal relationships and are comparable to aspects of Maslow's belongingness and esteem needs. Growth needs are those related to the attainment of one's potential and are associated with Maslow's esteem and self-actualization needs.

The ERG theory differs from the hierarchy of needs in that it does not suggest that lower-level needs must be completely satisfied before upper-level needs become motivational. ERG theory also suggests that if an individual is continually unable to meet upper-level needs that the person will regress and lower-level needs become the major determinants of their motivation. ERG theory's implications for managers are similar to those for the needs hierarchy: managers should focus on meeting employees' existence, relatedness, and growth needs, though without necessarily applying the provision that job-safety concerns necessarily take precedence over challenging and fulfilling job requirements.

Motivator-Hygiene Theory. Frederick Herzberg developed the motivator-hygiene theory. This theory is closely related to Maslow's hierarchy of needs but relates more specifically to how individuals are motivated in the workplace. Based on his research, Herzberg argued that meeting the lower-level needs (hygiene factors) of individuals would not motivate them to exert effort, but would only prevent them from being dissatisfied. Only if higher-level needs (motivators) were met would individuals be motivated.

The implication for managers of the motivator-hygiene theory is that meeting employees lower-level needs by improving pay, benefits, safety, and other job-contextual factors will prevent employees from becoming actively dissatisfied but will not motivate them to exert additional effort toward better performance. To motivate workers, according to the theory, managers must focus on changing the intrinsic nature and content of jobs themselves by "enriching" them to increase employees' autonomy and their opportunities to take on additional responsibility, gain recognition, and develop their skills and careers.

McClelland's Learned Needs Theory. McClelland's theory suggests that individuals learn needs from their culture. Three of the primary needs in this theory are the need for affiliation (n Aff), the need for power (n Pow), and the need for achievement (n Ach). The need for affiliation is a desire to establish social relationships with others. The need for power reflects a desire to control one's environment and influence others. The need for achievement is a desire to take responsibility, set challenging goals, and obtain performance feedback.

The main point of the learned needs theory is that when one of these needs is strong in a person, it has the

potential to motivate behavior that leads to its satisfaction. Thus, managers should attempt to develop an understanding of whether and to what degree their employees have one or more of these needs, and the extent to which their jobs can be structured to satisfy them.

MAJOR PROCESS THEORIES

Process (or cognitive) theories of motivation focus on conscious human decision processes as an explanation of motivation. The process theories are concerned with determining how individual behavior is energized, directed, and maintained in the specifically willed and self-directed human cognitive processes. Process theories of motivation are based on early cognitive theories, which posit that behavior is the result of conscious decision-making processes. The major process theories of motivation are expectancy theory, equity theory, goal-setting theory, and reinforcement theory.

Expectancy Theory. In the early 1960s, Victor Vroom applied concepts of behavioral research conducted in the 1930s by Kurt Lewin and Edward Tolman directly to work motivation. Basically, Vroom suggested that individuals choose work behaviors that they believe lead to outcomes they value. In deciding how much effort to put into a work behavior, individuals are likely to consider:

- Their expectancy, meaning the degree to which they believe that putting forth effort will lead to a given level of performance

- Their instrumentality, or the degree to which they believe that a given level of performance will result in certain outcomes or rewards

- Their valence, which is the extent to which the expected outcomes are attractive or unattractive

All three of these factors are expected to influence motivation in a multiplicative fashion, so that for an individual to be highly motivated, all three of the components of the expectancy model must be high. And, if even one of these is zero (e.g., instrumentality and valence are high, but expectancy is completely absent), the person will have no motivation for the task. Thus, managers should attempt, to the extent possible, to ensure that their employees believe that increased effort will improve performance and that performance will lead to valued rewards.

In the late 1960s, Porter and Lawler published an extension of the Vroom expectancy model, which is known as the Porter-Lawler expectancy model or simply the Porter-Lawler model. Although the basic premise of the Porter-Lawler model is the same as for Vroom's model, the Porter-Lawler model is more complex in a number of ways. It suggests that increased effort does not automatically lead to improved performance because individuals may not

possess the necessary abilities needed to achieve high levels of performance, or because they may have an inadequate or vague perception of how to perform necessary tasks. Without an understanding of how to direct effort effectively, individuals may exert considerable effort without a corresponding increase in performance.

Equity Theory. Equity theory suggests that individuals engage in social comparison by comparing their efforts and rewards with those of relevant others. The perception of individuals about the fairness of their rewards relative to others influences their level of motivation. Equity exists when individuals perceive that the ratio of efforts to rewards is the same for them as it is for others to whom they compare themselves. Inequity exists when individuals perceive that the ratio of efforts to rewards is different (usually negatively so) for them than it is for others to whom they compare themselves.

There are two types of inequity—under-reward and over-reward. Under-reward occurs when a person believes that he or she either puts in more efforts than another, yet receives the same reward, or puts in the same effort as another for a lesser reward. For instance, if an employee works longer hours than her coworker, yet receives the same salary, the employee would perceive inequity in the form of under-reward. Conversely, with over-reward, a person will feel that his efforts-to-rewards ratio is higher than another person's, such that he is getting more for putting in the same effort, or getting the same reward even with less effort. While research suggests that under-reward motivates individuals to resolve the inequity, research also indicates that the same is not true for over-reward. Individuals who are over-rewarded often engage in cognitive dissonance, convincing themselves that their efforts and rewards are equal to another's.

According to the equity theory, individuals are motivated to reduce perceived inequity. Individuals may attempt to reduce inequity in various ways. A person may change his or her level of effort; an employee who feels under-rewarded is likely to work less hard. A person may also try to change his or her rewards, such as by asking for a raise. Another option is to change the behavior of the reference person, perhaps by encouraging that person to put forth more effort. Finally, a person experiencing inequity may change the reference person and compare him or herself to a different person to assess equity. For managers, equity theory emphasizes the importance of a reward system that is perceived as fair by employees.

Goal-Setting Theory. The goal-setting theory posits that goals are the most important factors affecting the motivation and behavior of employees. This motivation theory was developed primarily by Edwin Locke and Gary Latham. Goal-setting theory emphasizes the importance of specific and challenging goals in achieving motivated behavior. Specific goals often involve quantitative targets for improvement in a behavior of interest. Research indicates that specific performance goals are much more effective than those in which a person is simply told to do their best. Challenging goals are difficult but not impossible to attain. Empirical research supports the proposition that goals that are both specific and challenging are more motivational than vague goals or goals that are relatively easy to achieve.

Several factors may moderate the relationship between specific and challenging goals and high levels of motivation. The first of these factors is goal commitment, which means that the more dedicated the individual is to achieving the goal, the more they will be motivated to exert effort toward goal accomplishment. Research suggests that having employees participate in goal setting will increase their level of goal commitment. A second factor relevant to goal-setting theory is self-efficacy, which is the individual's belief that he or she can successfully complete a particular task. If individuals have a high degree of self-efficacy, they are likely to respond more positively to specific and challenging goals than if they have a low degree of self-efficacy.

Reinforcement Theory. This theory can be traced to the work of the pioneering behaviorist B.F. Skinner. It is considered a motivation theory as well as a learning theory. Reinforcement theory posits that motivated behavior occurs as a result of reinforcers, which are outcomes resulting from the behavior that makes it more likely the behavior will occur again. This theory suggests that it is not necessary to study needs or cognitive processes to understand motivation, but that it is only necessary to examine the consequences of behavior. Behavior that is reinforced is likely to continue, but behavior that is not rewarded or behavior that is punished is not likely to be repeated. Reinforcement theory suggests to managers that they can improve employees' performance by a process of behavior modification in which they reinforce desired behaviors and punish undesired behaviors.

MYERS-BRIGGS TYPE INDICATOR (MBTI)

The Myers-Briggs Type Indicator is a personality survey designed during WWII when women were entering the industrial workforce. The idea behind the questionnaire was to use women's personality preferences to place them in the positions where they would be most effective. In 2005, Steven Flannes and Ginger Levin came up with the idea that the MBTI could be used to determine what motivation strategies would be most effective on individual employees. The test analyzes four traits: the need for personal contact with others, the application of realism,

the ability to apply logic, and influences of judgment. According to this theory, this information enables managers to tailor their communication approach according to the personality preferences of each individual.

MULTIMEDIA

Multimedia is the term used to describe two or more types of media combined into a single package—usually denoting a combination of some or all of the following: video, sound, animation, text, and pictures. Multimedia gives the user the opportunity to influence the presentation of material. The selection and manipulation of various aspects of the presentation material is the interactive aspect of a multimedia presentation. Interactive features could range from a question-and-answer function to choosing from a menu of particular subjects or aspects of a presentation. One application of multimedia, for example, involves presenting the user with a "what if" scenario, in which the choices the user makes affect the outcome of the presentation. This affords the user a degree of control, not unlike directing a motion picture and having the opportunity to make changes to the plot at various junctures.

TYPES OF MEDIA

There are certain types of media used in multimedia presentations, from simple to complex visual and audio devices. Multimedia components are divided into:

- **Text.** This refers to written documents, the words seen in handouts, powerpoint presentations, Web sites, and reports. One of the most simple types of media, text is also used to communicate the most information and appears in conjunction with visual aids.

- **Audio.** This is the sounds that often accompany visual presentations. Sound by itself can be used in radio broadcasts or online audio files, but in multimedia presentations audio is used as a complementary media. Sound effects can help make a presentation more memorable, while hearing the main points of information spoken can help listeners focus.

- **Still images.** Photographs, taken either by digital or analog means, are an important part of multimedia productions. Well-placed visual aids can explain concepts with clarity.

- **Animation.** Animations are graphics that move, accompanied by audio effects.

- **Video.** Video media is used to spread interviews, create movies, and post personal updates to communicate business messages. Currently, businesses can use videos online or create CDs to spread for instructional use within their company.

- **Interactivity.** The newest form of multimedia, interactivity, is a computer-based tool which allows users to choose to learn different parts of information on their own terms. By highlighting or choosing links and sections, users can manipulate the information environment, examining whatever knowledge is important to them.

ANALOG AND DIGITAL MEDIA

Analog media saves sounds, pictures, and text in non-electronic forms. This can include more traditional types of media, such as cassette tapes, records, and videocassettes, which use waves to transmit information. Analog equipment is generally more specialized than digital. Analog devices rely on tape recorders, video cameras, and older playback equipment to edit their contents.

Digital media transmits the information recorded in the waves into a more flexible format, namely, digitized code that can be transferred across a variety of devices, such as computers, internet systems, digital cameras, and more. Scanners, sound cards, and video compression are all used to record these types of media. Businesses currently use digital media most often in their multimedia applications, such as:

- Accounting and employee records management
- CDs for catalogs, records, and presentations
- Interactive training sessions for employees
- Internet tools such as company Web sites
- Product refinement and development using various computer-assisted design programs
- Sales presentations, and other communication to a wide audience.
- Self-running media presentations that can be used for commercial purposes

THE MECHANICS OF DIGITAL MULTIMEDIA

The CD-ROM and its successor, the DVD-ROM, store data in the form of a binary code. The binary code is placed onto the discs by a stamping process that impresses lands (flat areas that represent the zero in binary code) and hollows (pits that represent the one in binary code) onto the surface of the disc. When the discs are placed into a player or computer drive, the playing mechanism spins the disc and flashes a laser beam over the surface of the disc. The reflected light patterns caused by the embossed data contained on the surface of the disc are then decoded by the reader/player and translated back into audio and video. The storage capacity of a CD-ROM disc is 635 megabytes, while the storage capacity of a DVD-ROM disc can be as great as 5.2 gigabytes. Since sound, graphics, and other visuals take up considerably more data space than text alone, the increased storage capacities of the CD-ROM and DVD-ROM discs have played an integral part in making the use of multimedia more commonplace. The durability, portability, and relatively low manufacturing cost of the discs also play a critical role in their proliferation. While the Read Only Memory (ROM) format is still the most common

for both CDs and DVDs, today recordable disc drives are widely available to enable users to "burn" data (write, erase, and/or rewrite data) to a disc on their own.

RICH MEDIA

Rich media is a term referring to digital, interactive multimedia programs, the newest type of multimedia, most often found online via company Web sites or social networks. Rich media involves a combination of sound, pictures, animations, and video with integrated interactivity so that users, by pointing and clicking, can access online information as they desire. Rich media, because of its use of video and animation, can be built in two different formats. The first type is downloadable, which means Internet users can download the presentation and view it with a media player of their own, such as Apple's Quick-Time, Microsoft's Media Player, or Real Network's Real-Player. The second type of rich media is embedded into a Web site, meaning that it does not need to be downloaded, only accessed by the online user. This involves more cost on the producer's part, but makes it easier for users to have a seamless, interactive experience.

As the use of rich media increases, so do the benefits and complications. More and more companies are making use of rich media as marketing tools and training programs. However, downloadable media is dependent on its format, and problems can arise when transmitting rich media from one player to another. Animations and audio files may play differently from one media player to another. A successful rich media presentation will be interesting, informative, and easily accessed by any user.

HYPERMEDIA

Hypermedia, used in online multimedia presentations such as rich media, refers to the hyperlinks embedded in visual media. When a customer or employee clicks on a Web site link to learn more about a subject or choose a certain option, this is an example of hypermedia. It is ideal as a tool for allocating information on appropriate levels, giving users knowledge in pertinent pieces.

These types of nonlinear interaction are becoming increasingly common in the business world. As more people internationally gain access to hypermedia, companies are beginning to develop multimedia presentations to communicate their visions, opportunities, outsource training, and updates.

USES OF MULTIMEDIA

Multimedia devices have an almost innumerable variety of applications. They are used in home-entertainment systems and can be extremely powerful educational tools. Educators, for example, have been exceptionally creative in combining some of the exciting elements of video-game

applications with select features of educational material. By doing this, the concept of "edutainment" was created. The goal of using the multimedia edutainment approach is to entertain the user so effectively that the user remains unaware that he or she is actually learning in the process.

Multimedia can also offer critical services in the business world. While information can certainly be conveyed adequately by the singular use of still pictures, video, film, audio, or text, multimedia potentially multiplies the degree of effectiveness, in no small part due to the added entertainment value and the extent to which the viewers feel a part of the action. Such benefits can't easily be matched by the application of a singular medium. The effectiveness of teaching, selling, informing, entertaining, promoting, and presenting are all dependent upon one factor: the ability of the presented material to hold the attention of the desired audience. A dynamic multimedia presentation can usually be more effective than earlier methods at accomplishing this task with an audience that was raised on television and motion pictures. The computerized multimedia presentation offers the added benefit of cost-effective flexibility, allowing easy editing of the basic materials in order to tailor them to specific target audiences.

Training, informational and promotional materials, sales presentations, and point-of-sale displays that allow for customer interaction and communication both within and outside the organization are all common applications of multimedia in the business world. Multimedia presentations for many such applications can be highly portable, particularly in the cases of the CD-ROM, DVD-ROM, and videotape. The equipment required to produce these presentations is relatively commonplace or otherwise easy to access.

Perhaps the vanguard application of multimedia is virtual reality, a combination of video, stereo, and computer graphics that attempts to create an interactive three-dimensional environment that immerses the user within the simulation. Virtual reality has been employed in a wide range of practical applications: to train military troops, to streamline manufacturing and architectural design processes, to create simulated test environments for industry, and as a form of public entertainment.

One should still keep in mind, however, that even if rendered in a highly advanced multimedia format, an ineffectual presentation is still an ineffectual presentation. One should remain focused on the message being conveyed while shaping the choice and use of materials in accordance with that message.

MULTINATIONAL CORPORATIONS

Multinational corporations have existed since the beginning of overseas trade. They have remained a part of the business scene throughout history, entering their modern form in the seventeenth and eighteenth centuries with the creation of large, European-based monopolistic concerns such as the British East India Company during the age of colonization. Multinational concerns were viewed at that time as agents of civilization and played a pivotal role in the commercial and industrial development of Asia, South America, and Africa.

By the end of the nineteenth century, advances in communications had more closely linked world markets, and multinational corporations retained their favorable image as instruments of improved global relations through commercial ties. The existence of close international trading relations did not prevent the outbreak of two world wars in the first half of the twentieth century, but an even more closely bound world economy emerged in the aftermath of the period of conflict.

In particular, the period after World War Two is described as the "American era" by business historians Louis Galambos and Joe Pratt. During this era (which lasted until the late 1960s), many U.S. companies began or increased international expansion. Firms also expanded operations and businesses, resulting in large conglomerates that spanned different countries. Though this era came to a close with the economic turmoil of the early 1970s, multinational corporations have remained. Since the late 1990s and early 2000s, the term "globalization" has been closely linked with multinational corporations. Some see multinationals as the driving force behind this phenomenon.

While multinational corporations have grown in power and visibility, they have also come to be viewed more ambivalently by both governments and consumers

worldwide. Indeed, multinationals today are viewed with increased suspicion given their perceived lack of concern for the economic well-being of particular geographic regions and the public impression that multinationals are gaining power in relation to national government agencies; international trade federations and organizations; and local, national, and international labor organizations.

Despite such concerns, multinational corporations appear poised to expand their power and influence as barriers to international trade continue to be removed. Furthermore, the actual nature and methods of multinationals are in large measure misunderstood by the public, and their long-term influence is likely to be less sinister than imagined. Multinational corporations share many common traits, including the methods they use to penetrate new markets, the manner in which their overseas subsidiaries are tied to their headquarters operations, and their interaction with national governmental agencies and national and international labor organizations.

WHAT IS A MULTINATIONAL CORPORATION?

As the name implies, a multinational corporation is a business concern with operations in more than one country. These operations outside the company's home country may be linked to the parent by merger, operated as subsidiaries, or have considerable autonomy. Multinational corporations are sometimes perceived as large, utilitarian enterprises with little or no regard for the social and economic well-being of the countries in which they operate, but the reality of their situation is more complicated.

There are tens of thousands of multinational corporations currently operating in the global economy, in addition to hundreds of thousands of overseas affiliates running cross-continental businesses. The top multinational corporations are headquartered in the United States, Western Europe, and Japan; they have the capacity to shape global trade, production, and financial transactions. Multinational corporations are viewed by many as favoring their home operations when making difficult economic decisions, but this tendency is declining as companies are forced to respond to increasing global competition.

The World Trade Organization (WTO), the International Monetary Fund (IMF), and the World Bank are the three institutions that underwrite the basic rules and regulations of economic, monetary, and trade relations between countries. Many developing nations have loosened trade rules under pressure from the IMF and the World Bank. The domestic financial markets in these countries have not been developed and do not have appropriate laws in place to enable domestic financial institutions to stand up to foreign competition. The administrative setup, judicial systems, and law-enforcing agencies generally cannot guaran-

tee the social discipline and political stability that are necessary in order to support a growth-friendly atmosphere. As a result, many multinational corporations invest only in geographic locations that they believe are politically stable (such as Latin America).

Multinational corporations are often viewed as being exploitative of both their workers and the local environment, given their relative lack of association with any given locality. This criticism of multinationals is valid to a point, but it must be remembered that no corporation can successfully operate without regard to local social, labor, and environmental standards, and that multinationals in large measure do conform to local standards in these regards.

Multinational corporations are also seen as acquiring too much political and economic power in the modern business environment. Indeed, corporations are able to influence public policy to some degree by threatening to move jobs overseas, but companies are often prevented from employing this tactic given the need for highly trained workers to produce many products. Such workers can seldom be found in low-wage countries. Furthermore, once they enter a market, multinationals are bound by the same constraints as domestically owned concerns, and find it difficult to abandon the infrastructure they produced to enter the market in the first place.

Because so many early multinational corporations were originally based in the United States, some of these corporations—especially consumer businesses with well known brands—came to be seen as symbols of "Americanization." However, the modern multinational corporation is not necessarily headquartered in a wealthy nation. Many countries that were recently classified as part of the developing world, including Brazil, Taiwan, Kuwait, and Venezuela, are now home to large multinational concerns. The days of corporate colonization seem to be nearing an end. At the most extreme end, in 2008 *Business Week* featured a story on Lenovo, a multinational that does not have a headquarters, effectively denying the company's ties to a single nation as its home.

ENTRY OF MULTINATIONAL CORPORATIONS INTO NEW MARKETS

Multinational corporations follow three general procedures when seeking to access new markets: merger with or direct acquisition of existing concerns; sequential market entry; and joint ventures.

Merger or direct acquisition of existing companies in a new market is the most straightforward method of new market penetration employed by multinational corporations. Such an entry, known as foreign direct investment, allows multinationals, especially the larger ones, to take full advantage of their size and the economies of scale that this provides. The rash of mergers within the global automotive

industries during the late 1990s are illustrative of this method of gaining access to new markets and, significantly, were made in response to increased global competition.

Multinational corporations also make use of a procedure known as sequential market entry when seeking to penetrate a new market. Sequential market entry often also includes foreign direct investment, and involves the establishment or acquisition of concerns operating in niche markets related to the parent company's product lines in the new country of operation. Japan's Sony Corporation made use of sequential market entry in the United States, beginning with the establishment of a small television assembly plant in San Diego, California, in 1972. For the next two years, Sony's U.S. operations remained confined to the manufacture of televisions, the parent company's leading product line. Sony branched out in 1974 with the creation of a magnetic tape plant in Dothan, Alabama, and expanded further by opening an audio equipment plant in Delano, Pennsylvania, in 1977.

After a period of consolidation brought on by an unfavorable exchange rate between the yen and dollar, Sony continued to expand and diversify its U.S. operations, adding facilities for the production of computer displays and data storage systems during the 1980s. In the 1990s, Sony further diversified it U.S. facilities and now also produces semiconductors and personal telecommunications products in the United States. Sony's example is a classic case of a multinational using its core product line to defeat indigenous competition and lay the foundation for the sequential expansion of corporate activities into related areas.

Finally, multinational corporations often access new markets by creating joint ventures with firms already operating in these markets. This has particularly been the case in countries formerly or presently under communist rule, including those of the former Soviet Union, Eastern Europe, and the People's Republic of China. In such joint ventures, the venture partner in the market to be entered retains considerable or even complete autonomy, while realizing the advantages of technology transfer and management and production expertise from the parent concern. The establishment of joint ventures has often proved awkward in the long run for multinational corporations, which are likely to find their venture partners are formidable competitors when a more direct penetration of the new market is attempted.

Multinational corporations are thus able to penetrate new markets in a variety of ways, which allows existing concerns in the market to be accessed with a varying degree of autonomy and control over operations.

CONCERNS ABOUT MULTINATIONAL CORPORATIONS

While no one doubts the economic success and pervasiveness of multinational corporations, their motives and actions have been called into question by social welfare, environmental protection, and labor organizations and government agencies worldwide.

National and international labor unions have expressed concern that multinational corporations in economically developed countries can avoid labor negotiations by simply moving their jobs to developing countries where labor costs are markedly less. Labor organizations in developing countries face the converse of the same problem, as they are usually obliged to negotiate with the national subsidiary of the multinational corporation in their country, which is usually willing to negotiate contract terms only on the basis of domestic wage standards, which may be well below those in the parent company's country.

Offshore outsourcing, or offshoring, is a term used to describe the practice of using cheap foreign labor to manufacture goods or provide services only to sell them back into the domestic marketplace. Today, many Americans are concerned about the issue of whether American multinational companies will continue to export jobs to cheap overseas labor markets. In the fall of 2003, the University of California-Berkeley showed that as many as 14 million American jobs were potentially at risk over the next decade. Opponents of offshoring claim that it takes jobs away from Americans, while also increasing the imbalance of trade.

When foreign companies set up operations in America, they usually sell the products manufactured in the United States to American consumers. However, when U.S. companies outsource jobs to cheap overseas labor markets, they usually sell the goods they produce to Americans, rather than to the consumers in the country in which they are made. In 2004, the states of Illinois and Tennessee passed legislation aimed at limiting offshoring; in 2005, another sixteen states considered bills that would limit state aid and tax breaks to firms that outsource abroad.

However, foreign multinationals may also outsource their operations to the United States. For example, many non-U.S. auto manufacturers have built plants in the United States, thus ensuring access to American consumers. For example, Toyota now makes approximately one-third of its profits from U.S.-built car sales.

Social welfare organizations are similarly concerned about the actions of multinationals, which are presumably less interested in social matters in countries in which they maintain subsidiary operations. Environmental protection agencies are equally concerned about the activities of multinationals, which often maintain environmentally hazardous operations in countries with minimal environmental protection statutes.

Business and social developments can also produce new criticisms of multinational corporations. In 2007, widely publicized recalls of toys containing lead paint that

were manufactured in China for multinational corporations illuminated other issues with outsourcing. As multinationals outsource operations, they lose accountability and control over manufacturing, environmental, and safety standards. Even if a multinational requires certain standards, the ability to ensure that they are followed is diminished. This can be exacerbated by even further subcontracting of already-outsourced tasks.

Finally, government agencies fear the growing power of multinationals, which once again can use the threat of removing their operations from a country to secure favorable regulation and legislation. In effect, a multinational corporation has the ability to shift capital, resources, and operations around the world as it sees fit. The mobility inherent in capital investment also means that some locations and local governments might compete with one another in attracting a multinational corporation by creating favorable business conditions. Scholars and others have debated whether or not this development is positive or negative. For example, Thomas Friedman has developed what he calls the "McDonald's Theory of Conflict Prevention," which states that any two countries that have the same economic standing (represented by McDonald's) will not go to war. In effect, Friedman sees multinationals as a stabilizing force in that it links different nations together in a world economy. On the other hand, others see multinationals as thriving through exploiting economic differences across the globe, what some geographers term "uneven development." Some point out that different parts of the production process happen in different parts of the world. Because of this, multinational corporations actually contribute to spatial, economic, and power inequalities.

All of these concerns are valid, and abuses have undoubtedly occurred, but many forces are also at work to keep multinational corporations from wielding unlimited power over even their own operations. Increased consumer awareness of environmental and social issues and the impact of commercial activity on social welfare and environmental quality have greatly influenced the actions of all corporations in recent years, and this trend shows every sign of continuing. Multinational corporations are constrained from moving their operations into areas with excessively low labor costs given the relative lack of skilled laborers available for work in such areas. Furthermore, the sensitivity of the modern consumer to the plight of individuals in countries with repressive governments mitigates the removal of multinational business operations to areas where legal protection of workers is minimal. Examples of consumer reaction to unpopular action by multinationals are plentiful, and include the outcry against the use of sweatshop labor by Nike and activism against operations by the Shell Oil Company in Nigeria and PepsiCo in Myanmar (formerly Burma) due to the repressive nature of the governments in those countries.

Multinational corporations are also constrained by consumer attitudes in environmental matters. Environmental disasters such as those which occurred in Bhopal, India (the explosion of an unsafe chemical plant operated by Union Carbide, resulting in great loss of life in surrounding areas) and Prince William Sound, Alaska (the rupture of a single-hulled tanker, the Exxon Valdez, causing an environmental catastrophe) led to ceaseless bad publicity for the corporations involved and continue to serve as a reminder of the long-term cost in consumer approval of ignoring environmental, labor, and safety concerns.

Similarly, consumer awareness of global issues lessens the power of multinational corporations in their dealings with government agencies. International conventions of governments are also able to regulate the activities of multinational corporations without fear of economic reprisal, with examples including the 1987 Montreal Protocol limiting global production and use of chlorofluorocarbons and the 1989 Basel Convention regulating the treatment of and trade in chemical wastes.

In fact, despite worries over the impact of multinational corporations in environmentally sensitive and economically developing areas, the corporate social performance of multinationals has been surprisingly favorable to date. The activities of multinational corporations encourage technology transfer from the developed to the developing world, and the wages paid to multinational employees in developing countries are generally above the national average. When the actions of multinationals do cause a loss of jobs in a given country, it is often the case that another multinational will move into the resulting vacuum, with little net loss of jobs in the long run. Subsidiaries of multinationals are also likely to adhere to the corporate standard of environmental protection even if this is more stringent than the regulations in place in their country of operation, and so in most cases create less pollution than similar indigenous industries.

THE FUTURE FOR MULTINATIONAL CORPORATIONS

Current trends in the international marketplace favor the continued development of multinational corporations. Countries worldwide are privatizing government-run industries, and the development of regional trading partnerships such as the North American Free Trade Agreement (a 1993 agreement between Canada, Mexico, and United States) and the European Union have the overall effect of removing barriers to international trade. Privatization efforts result in the availability of existing infrastructure for use by multinationals seeking to enter a new market, while removal of international trade barriers is obviously a boon to multinational operations.

Perhaps the greatest potential threat posed by multinational corporations would be their continued success in a still underdeveloped world market. As the productive capacity of multinationals increases, the buying power of people in much of the world remains relatively unchanged. This could lead to the production of a worldwide glut of goods and services. Such a glut, which has occurred periodically throughout the history of industrialized economies, can in turn lead to wage and price deflation, contraction of corporate activities, and a rapid slowdown in all phases of economic life. Such a possibility is purely hypothetical, however, and for the foreseeable future the operations of multinational corporations worldwide are likely to continue to expand.

MULTIPLE-CRITERIA DECISION MAKING

Real-world decision-making problems are usually too complex and ill-structured to be considered through the examination of a single criterion, attribute, or point of view that will lead to the optimum decision. In fact, such a unidimensional approach is merely an oversimplification of the actual nature of the problem at hand, and it can lead to unrealistic decisions. A more appealing approach would be the simultaneous consideration of all pertinent factors that are related to the problem. However, through this approach some very essential issues/questions emerge: how can several and often conflicting factors be aggregated into a single evaluation model? Is this evaluation model a unique and optimal one?

Researchers from a variety of disciplines have tried to address the former question using statistical approaches, artificial intelligence techniques, and operations research methodologies. The success and usefulness of these attempts should be examined with regard to the second question. Obviously, a decision problem is not addressed in the same way by all decision makers. Each decision maker has his or her own preferences, experiences, and decision-making policy; thus one person's judgment is expected to differ from another's. This is a significant issue that should be considered during the development of decision-making models.

Addressing such issues constitutes the focal point of interest in multiple-criteria decision making (MCDM). MCDM constitutes an advanced field of operations research that is devoted to the development and implementation of decision support tools and methodologies to confront complex decision problems involving multiple criteria, goals, or objectives of conflicting nature.

The tools and methodologies provided by MCDM are mathematical models aggregating criteria, points of view, or attributes, and they are decision-support oriented as well. Actually, support is a key concept in MCDM, implying that the models are not developed through a straightforward sequential process where the decision maker's role is passive. Instead, an iterative process is employed to analyze the preferences of the decision maker and represent them as consistently as possible in an appropriate decision model. This iterative and interactive preference modeling procedure constitutes the underlying basis of the decision-support orientation of MCDM, and it is one of the basic distinguishing features of the MCDM as opposed to statistical and optimization decision-making approaches.

However, the use of one decision-maker's set of preferences to formulate a model for assisting decision making means that the final decision is subject to the priorities of one person. Thus the multi-objective model cannot yield a single best solution because the decision varies according to the decision-maker's value system. In "Multi-Criteria Analysis in Environmental Decision-Making" (2007), Mohan Munasinghe suggests "MCA used in conjunction with a variety of models, and effective stakeholder consultations, could help to reconcile the differences between individual versus social, and selfish versus altruistic preferences."

HISTORICAL OVERVIEW

From the beginning of mankind, decision making always involved multiple criteria that have been treated either implicitly or explicitly, although no specific mathematical framework existed for this purpose. Pareto was the first to study, in an axiomatic way, the aggregation of conflicting criteria into a single evaluation index. He was also the first to introduce the concept of efficiency, one of the key aspects of the modern MCDM theory.

Several decades later, Koopmans extended Pareto's work introducing the notion of efficient vector, or the non-dominated set of alternatives. During the same period (1940s to 1950s), von Neumann and Morgenstern introduced the expected utility theory, thus setting the foundations of another MCDM approach. In the 1960s the concepts and procedures described in these early works were extended by Charnes and Cooper and Fishburn. By the end of the 1960s significant research started

to be undertaken in this field by the European operational research community. Roy, the founder of the European stream of MCDM, developed a new theoretical approach based on the concept of outranking relations.

From the 1970s to the 1990s, MCDM evolved rapidly, scientific MCDM associations were formed, and numerous advances were published in the international literature, both on the theoretical aspects of MCDM as well as on its practical implementation. The field has benefited significantly from the widespread use of personal computers, which enabled the development of software packages employing MCDM methods. These software packages, known as multicriteria decision support systems, provide the means to implement the theoretical advances in MCDM in user-friendly systems that enable real-time decision making through interactive and iterative procedures that enhance the decision maker's perception of the problem and his or her judgment and decision-making policy.

THEORETICAL APPROACHES TO MCDM

Among the MCDM methods and tools, several approaches and theoretical disciplines can be defined, although their distinctions and boundaries are often difficult to determine. This discussion adopts the classification of MCDM approaches proposed by Pardalos et al. It distinguishes four categories: (1) multi-objective mathematical programming, (2) multi-attribute utility theory, (3) outranking relations approach, and (4) preference disaggregation approach.

Multi-Objective Mathematical Programming. Multi-objective mathematical programming (MMP) is an extension of the well-known single-objective mathematical programming framework. It involves the optimization of a set of objectives that are expressed in the form of linear or nonlinear functions of some decision variables. The optimization of these objectives is performed subject to constraints imposed either by the decision environment or by the decision maker.

The conflicting nature of the objectives in real-world decision problems makes their simultaneous optimization impossible. Thus, the decision maker cannot obtain an optimum solution, but has to consider finding a satisfying one. The determination of this satisfying solution depends on the decision maker's preferences, judgment, and decision policy.

The MMP techniques that have been developed aim to determine initially the set of efficient solutions (solutions that are not dominated by any other solution with respect to the specified objectives) and then to identify a specific solution that meets the decision maker's preferences, through an interactive and iterative procedure.

More details on this category of methods can be found in the books of Zeleny and Steuer.

Multi-Attribute Utility Theory. The multi-attribute utility theory (MAUT) is an extension of the classical utility theory. Its aim is to represent/model the decision maker's preferences through a utility function $u(g)$ aggregating all the evaluation criteria: $u(g) = u(g_1, g_2, \ldots, g_n)$, where g is the vector of the evaluation criteria $g_1, g_2, \ldots, g_n$. In general, it is possible to decompose a multicriteria utility function in real functions $u_1, u_2, \ldots, u_n$ concerning the independence of criteria. Thus, different utility function models are obtained. The most studied form of utility function, from a theoretical point of view, is the additive form: $u(g_1, g_2, \ldots, g_n) = u_1 g_1) + u_2(g_2) + \ldots + u_n(g_n)$, where $u_1, u_2, \ldots, u_n$ are the marginal utilities defined on the scales of criteria. On the basis of the utilities of the alternatives that are determined through the developed utility function, the decision maker can rank them from the best alternatives (alternatives with the higher utility) to the worst ones (alternatives with the lower utility), classify them into appropriate classes through the definition of appropriate utility thresholds, or select the alternative with the higher utility as the best one. The books of Zeleny and Keeney and Raiffa provide a comprehensive discussion of MAUT, its axiomatic foundations, and the forms of utility functions that are commonly employed in decision-making problems, both under certainty and uncertainty.

Outranking Relations Approach. The outranking relations approach was developed in Europe with the presentation of the ELECTRE methods (*ELimination Et Choix Traduisant la REalité*) by Roy. An outranking relation allows one to conclude that an alternative *a* outranks an alternative *b* if there are enough arguments to confirm that *a* is at least as good as *b*, while there is no essential reason to refuse this statement.

To develop the outranking relation, the decision maker, in collaboration with the decision analyst, must specify the weights of the evaluation criteria as well as some technical parameters (preference, indifference, and veto thresholds). The definition of these parameters enables the examination of whether there is a sufficient majority of criteria for which *a* is better than *b* (concordance) and if the unfavorable deviations for the rest of the criteria (discordance) are not too high. In this case it is possible to conclude that alternative *a* outranks alternative *b*.

Furthermore, through this modeling procedure it is possible to identify the cases where the performances of two alternatives on the evaluation criteria differ significantly, thus making impossible their comparison (incomparability). A detailed presentation of all outranking methods can be found in the works of Vincke and Roy and Bouyssou.

Preference Disaggregation Approach. The preference disaggregation approach refers to the analysis (disaggregation) of the global preferences (judgment policy) of the decision maker in order to identify the criteria aggregation model that underlies the preference result (ranking or classification/sorting). Similar to MAUT, preference disaggregation analysis uses common utility decomposition forms to model the decision maker's preferences. Nevertheless, instead of employing a direct procedure for estimating the global utility model (MAUT), preference disaggregation analysis uses regression-based techniques (indirect estimation procedure).

More specifically, in preference disaggregation analysis the parameters of the utility decomposition model are estimated through the analysis of the decision maker's overall preference on some reference alternatives, which may involve either examples of past decisions or a small subset of the alternatives under consideration. The decision-maker is asked to provide a ranking or a classification of the reference alternatives according to his or her decision policy (global preferences). Then, using regression-based techniques the global preference model is estimated so that the ranking or classification specified by the decision maker can be reproduced as consistently as possible through the developed decision model. A rather exhaustive bibliography of the methods of the disaggregation of preferences can be found in the works of Jacquet-Lagrèze and Siskos, and Pardalos, Siskos, and Zopounidis.

Differences in the Approaches. Except for the functional and methodological differences among the four aforementioned MCDM approaches, their differences with regard to the types of decision problems that they address should also be pointed out. Real-world decision problems can be categorized into two groups:

1. Problems where the decision maker must evaluate a finite set of alternatives in order to select the most appropriate one, to rank them from the best to the worst, to classify them into predefined homogeneous classes, or to describe them. Typical examples involve the selection among different investment projects, personnel evaluation (ranking problem), and financial distress prediction (classification problem; i.e., discrimination between healthy and financially distressed firms). These type of problems are referred to as discrete MCDM problems.

2. Problems where there is an infinite set of alternatives. Thus the decision maker must construct the most appropriate one according to his or her goals or objectives. Recourse allocation problems are a typical example of this kind. For instance, a portfolio manager faces the problem of constructing a portfolio of securities according to his specific investment policy

and objectives. Different combinations of securities can result in numerous portfolios. Thus, it is impossible to define an exhaustive set of portfolios for evaluation and selection of the most appropriate one. Instead, the portfolio manager must construct the most appropriate portfolio through the determination of the amount of capital that should be invested in each security. These type of problems are referred to as continuous MCDM problems.

Discrete MCDM problems are addressed through MAUT, the outranking relations approach, and preference disaggregation, while continuous MCDM problems are addressed through MMP.

MCDM APPLICATIONS

In the international literature on management science and operations research there is an increasing number of real-world applications of MCDM. The following list outlines some of the most significant areas to which MCDM has contributed:

1. Finance and economics

   - Business failure prediction
   - Credit risk assessment
   - Portfolio selection and management
   - Company mergers and acquisitions
   - Financial planning
   - Supply chain management
   - Country risk evaluation
   - Regional economic policy specification

2. Environmental management and energy planning

   - Forest management
   - Waste management
   - Power plant siting
   - Water resources planning
   - Nuclear power management
   - Energy intensity evaluation

3. Marketing

   - Customer satisfaction
   - Design of market penetration strategies
   - Retail evaluation

4. Transportation

   - Highway planning
   - Subway design

5. Human resources management

   - Job evaluation
   - Personnel selection

6. Education

7. Agriculture

Extensive information on these applications can be found in the books of Vincke, Pardalos et al., and Roy.

The complexity of real-world decisions and the plethora of factors and criteria that are often involved necessitate the implementation of a sound theoretical framework to structure and model the decision-making process. MCDM provides such a framework, as well as a wide variety of sophisticated methodological tools that are oriented towards the support of the decision makers in facing real-world decision problems.

This decision-support orientation of MCDM, in combination with the focus given by researchers in this field to develop advanced and realistic preference modeling techniques, is its main distinguishing feature as opposed to statistical analysis and optimization theory. The advances in the field continue rapidly. According to Fishburn and Lavalle, they involve foundation aspects of MCDM such as the interface between behavioral decision theory and prescriptive practice and the underlying assumptions of MCDM methods, methodological aspects involving the development of more effective methods, and implementation aspects through the development of multicriteria decision-support systems. Along with these advances, researchers are also exploring the application of MCDM to other fields, including artificial intelligence (neural networks, expert systems, genetic algorithms) and fuzzy sets. The integration of the diverse nature of these fields within the MCDM framework increases the potentials regarding the development of advanced decision-support tools to confront the complexity of real-world decisions.

NANOTECHNOLOGY

Applied to various materials across many industries, nanotechnology is the science of the very small. Originally, it dealt with the engineering of nanoparticles to build mechanisms on an atomic level, but this has become only one definition, now referred to as MNT, or molecular nanotechnology. The meaning of nanotechnology has evolved to now include all scientific endeavors below "micro technology," thereby encompassing any products and materials dealing with nanoscale operations. Due to the possibilities of nanotechnology in so many fields, the science has received increased attention from both businesses and media in recent years.

"Nano" refers to the infinitesimal nanometer, one billionth of a meter; at this level, the components of molecules, atoms, and their parts are large enough to be physically manipulated, arranged, and built into layers. At the technical level, nanotechnology is interested in using these molecular construction abilities to create machines and computers at this nanoscale. In theory, these tiny systems will be capable of incredible speed and atomic precision performance. On a more universal and practical level, nanotechnology can arrange molecules to help create every day, life-size products with new qualities such as weather resistance, conductivity, and enhanced efficiency.

The predicted uses for nanotechnology are myriad, covering nearly all industries from fashion to medical procedures, but in reality only a handful of marketable products are currently being created by nanotechnology methods. Certain cosmetics and sunscreens are amplified by nano-engineered substances derived from certain metals. Healthcare devices, such as testing tools and treatments, are being produced to carry entire laboratories on computer chip-sized areas. Coatings and fabrics are being created with nanotechnology protection. However, the large scale investment in nanotechnology still outpaces its current profits, if not its expectations.

THE HISTORY OF NANOTECHNOLOGY

Nanotechnology has had a long and colorful history, due to the large number of predictions made concerning its powers and world-changing abilities—abilities which have been neither disproved nor fully confirmed in the continuing study of nano mechanisms. In 1959, Richard Feynman gave a famed speech to the American Physical Society in which he explored the possibility of engineering molecules to contain information (specifically writing); from there, Feynman extrapolated to mention possible biological and computorial applications. This speech was the first notable exploration into nanotech science.

The term "nanotechnology" was not coined until 1974, when Japanese Professor Norio Taniguchi used it to describe production technology capable of working in the nanometer range, such as the thin film deposition and ion beam milling used in semiconductor creation processes. In 1977, engineer K. Eric Drexler (1955–) again used the word nanotechnology in his studies on molecular engineering and his influential books *Engines of Creation:*

The Coming Era of Nanotechnology and *Nanosystems Molecular Machinery Manufacturing and Computation.* Drexler was one of the first scientists to work with practical nanotechnology theory, creating such key concepts as the nano assembler, an atomic-scale machine that would be capable of replicating itself and creating other simple constructions. He also explored the biological and ethical implications in depending on nanotechnology.

In the 1980s and 1990s many processes vital to nano theory were formed. STM, or scanning tunneling microscopy, was invented in 1981 and allowed researchers to analyze and manipulate atoms. In 1985, spherical fullerenes were discovered and nicknamed "buckyballs"; these complex carbon molecules became the basis for the first practical nanoengineering. The late 1980s blossomed the science as the first books, journals, classes, and organizations of nanotechnology were created. Goals and research grants become much more common, and in 1993 the first Feynman Prize in Nanotechnology was awarded to Charles Musgrave. As the 1990s progressed, government interest and involvement in nanotechnology increased. The first nano company, Zyvex, was founded in 1997, the first possible designs of nanorobotics and nanobio ideas being developed around the same time.

Into the Twenty-First Century. The 2000s began several close inspections of the societal implications involved in the rising nanotechnology. Congressional hearings were conducted to investigate the dangers and necessary safety protocols, and the Nanotechnology R&D Act of 2003 required that all federally supported nanotechnology research consider the new societal and ethical implications of nanotechnology (SEIN). The year 2003 also saw the publication of the debate between scientists Eric Drexler and Rice University professor Richard Smalley (1943–2005) concerning the future of nanotechnology. Smalley, winner of a Nobel Prize in chemistry, argued against many of the entrenched ideas developed by Drexler, including the concept of molecular assemblers, which he thought badly conceptualized. To explain his argument, Smalley created the "sticky fingers" and "fat fingers" problems, which proposed that technicians could not be precise enough—given current nano theory—to create and maintain the sort of assemblers Drexler visualized. His counter-theories involved a much heavier emphasis on catalysts and chemical progression in nanotechnology. Smalley also disagreed with the rising speculation on the dangers of nanotechnology, especially the doomsday scenarios which he found to be impossible.

Mihail Roco of the U.S. National Nanotechnology Initiative has given a description of four stages in the evolutionary history of nanotechnology. The first stage, he suggested, was the passive stage, in which simple materials are made with passive nanotech abilities, such as coatings, fabrics, aerosols, and many construction elements. This is the stage which nanotechnology has currently reached. The second stage, active nanostructures, includes biological and computer-related nanosystems that can carry out specific operations. Biological nanostructures can consist of disease-targeting drugs, and computer structures can be mini-transistors and amplification systems. In the late 2000s, this is the stage nanotechnology is beginning to enter. The third stage, which the science is currently still experimenting with, sees nanotechnology expanding to include nano systems that can assemble and plot various three-dimensional operating structures (simple robotics). The fourth stage occurs when nanotechnology reaches the creation of molecular nanosystems which can produce complex computer devices at the nano level.

TYPES OF NANOMATERIALS

There are many different types of nano-produced substances, each with its own abilities and uses in multiple industries. Most involve simple structures, all with functional properties:

- **Nanocomposites**. Nanocomposites are materials that are infused into other objects so that products gain new properties or abilities. A silica-based nanocomposite is currently being used in experimental removal of toxic waste, creating a semiporous bundle of coated silica that can attach to some heavy metals and cleanse them from liquids such as water. Other more simple nanocomposites are being used in vehicle construction, especially plastic add-ons like bumpers, protectors, and steps. The composites are more resistant, stronger, less prone to damage, and more lightweight than the normal plastics they replace. Given these qualities, it is no surprise that many companies are beginning to use nanocomposites across different industries, such as the creation of sports equipment such as golf clubs and tennis rackets.

- **Nanocrystals**. The nanoparticles infused into other materials are often nanocrystals, or molecules created in multiple-layered crystals with special characteristics. For instance, metal aligned in these crystalline forms has proven to be much stronger and longer lasting than normal metal composition. Due to the arrangement of nanocrystals, a metal nanocrystal structure is able to support itself so thoroughly that it becomes 100 to 200 percent stronger than more commonly used metal compositions. Other crystals are able to absorb light and refract it in a different color, a property useful in microscopic inspections. Because of these light-

changing qualities, nanocrystals play an important role in solar-energy panels.

- **Nanoparticles**. Nanoparticles are single nanomaterials that are not joined together in specific structures the way composites and crystals are, but instead are strewn along and amidst the affected item to give it certain abilities. Many of the new stain-warding fabrics used in khakis, dress shirts, and ties are made with nanoparticles attached to fibers; this allows spills or stains to slide off the material. Types of paint also make use of polymer nanoparticles to repel water. Types of medicine can also be administered using nanoparticular technology, which transforms normal pills into highly soluble, bio-absorbable materials made completely of nanoparticles.

- **Nanopowders**. Nanopowder is part of a manufacturing process to create superior products. Often, nanopowders can be a beginning stage of materials that will be refined to become nanocomposites. An excellent example is the carbide nanopowder, the grains of which are 15 nanometers or less. This powder is used to make an alloy nearly as hard as diamond; this has multiple applications, from drill bits to bulletproof armor.

- **Nanoclays**. Nanoclay is made of volcanic minerals, or smectite, structured into plates so thin they are approximately only one nanometer thick but several hundred nanometers in width and length. These nanoclays are often put through a process (known as intercalation) to make them more integratable into organic polymers. Once intercalated, nanoclays and polymers are mixed to create many kinds of composite products. Such products have the inherent strength and protective abilities common in nano-created materials. These clay composites account for about one quarter of the nano market today.

- **Nanocomposite coatings**. These coatings are nanocomposite in form, made from synthetic nanocrystals or the carefully mixed nanoclays and polymers. However, instead of being fully integrated into the material, these coatings are preserved in liquid form and painted on the surface of items to instill nano qualities in them. Uses include the area of electronics, where a sprayed nanocomposite coating can protect the screens of phones and other handheld devices. The attractiveness of nano coatings in manufacturing is increased by their non-toxic nature and environmentally friendly composition, different from many of the chemicals used today.

- **Nanotubes**. Most often made of carbon, nanotubes are structured in a honeycomb pattern that doubles over itself to form a tube-like shape. These tubes can be combined in many layers to form a fiber that is intensely strong and also has unique electrical properties. The way a nanotube is formed, molecule by molecule, can make it into either a type of semiconductor (such as silicon) or a metal. The semiconductive properties of nanotubes means that they could be used to make more efficient electronic viewing screens than those currently in use today.

- **Nanocatalysts**. Nanocatalysts are used to begin chemical reactions that change the properties of materials. Many nanoparticles have exceptionally large surface areas relative to the total amount of material, and so they serve as a better catalyst, since a chemical catalyst depends on how much of one substance comes in contact with another. The incredibly small nanoparticles are able to affect catalysts very efficiently in processed reactions. Current experiments are using gel-based nanocatalysts to transform coal into oil products. The use of nanocatalysts as enzyme-like actors in chemical processes was a process supported by scientist Richard Smalley, and such reactions could be used in both biological manipulating and purification processes.

- **Nanofilters**. Nanofilters operate by forming nanofibers of incredible complexity that can allow only certain particles through, based on what the nanofiber is made of and how tightly it is structured. The better types of nanofilters can attract and trap amazingly small particles, such as those micron-sized and below. This allows nano-designed filters to trap nearly all possible contaminants, letting only water or other liquids through. They also act much more efficiently than other kinds of filters, which allows water to pass through them at much higher speeds. Nanofilters can be used to help sterilize serums and protect people against biological warfare.

BUSINESS APPLICATIONS

Thanks to the theory called the "precautionary principle," legislation has encouraged developing nanotechnology to progress very slowly, making sure that each experimental step is free of harmful possibilities. For this reason, many nanotech applications forecasted are being stalled as scientists work on removing flaws and perfecting processes. Many industries, such as pharmaceutical companies, are currently hesitant about embracing the promising technology when results are sure but still very slow. Also, due to the complexity of nanotechnology, the number of scientists working with it in companies is not increasing nearly as fast as the number of nano technicians—the people who actually put the technology into practice

and develop, coat, and fuse nanoparticles to the products. Technician positions, then, are the fastest-growing positions in the nanotechnology field, creating an entirely new workforce class with new training required. Despite certain setbacks, there are several key areas in which nanotechnology is directly affecting the business world.

There is a small number of fields in which business investment in nanotechnology has reaped profitable rewards, and these areas can be expected to continue embracing nanotechnology and growing in size and influence. One of these promising fields is in the development of silver nanoparticles, which are currently being used in a wide number of products, from clothing and toys to food and food utensils. Since many substances gain new properties when reduced to nano-sized pieces, common elements such as silver can be used in innovate processes—for example, as an antimicrobial treatment. Nanoparticle silver, it turns out, kills germs and is easily spread, so it has found a strong market in products meant for young children, many types of food production, and simple utensils such as forks and chopsticks.

The coatings, fibers, and compositions developed through nanotechnology have become successful fields in which better materials have been and are being developed. Nanomedicine is also a very important field, although its current success is limited to drug delivery. Thanks to nanoparticle creation, drugs are being marketed that have greater longevity, more effective cell penetration, and specific disease targeting. This has lead to the production of several helpful oral medications. There are also promising early results from some of the more entrepreneurial nanomedicine experiments.

There are also several nanotech applications that affect businesses directly through manufacturing and technology development. In manufacturing and production, nanotechnology allows for the creation of incredibly detailed and smooth machine parts, literally constructed to molecular plans. Production machines can then run more quickly, needing far less maintenance and wearing down much more slowly.

Many nanotech applications have occurred in the technology field, especially in computer devices that can be constructed on a microscopic level to perform more efficiently or carry tasks they could not from normal production methods. Tolfree and Jackson, in their 2007 *Commercializing Micro-technology Products*, give several examples of computer systems effectivly built by nano-construction. Called micro-electromechanical systems (MEMS), these devices have been produced mostly in Germany, Japan, and the United States, and they include:

- Ink-jet head markets, which are created through nanotechnology to be very precise. These ink-jet heads are being developed primarily by Hewlett-

Packard, which has designed a model that does not require complete replacement.

- Pressure sensors, which have some medical uses but are popular in the automotive industry. These MEMS can monitor tire pressure for automobiles, a technology that is growing more quickly than other sensor applications.

- Silicone microphones, a line of products that is growing rapidly.

- Accelerometers, which are used not only in vehicles but also a number of handheld applications, such as cell phones, global positioning systems, and simple pedometers. This is considered a strong market, but difficult to profit in because of price pressures and competition.

- Gyroscopes, which like accelerometers are used in automobiles and phones.

- Optical MEMS, pioneered by Texas Instruments, deal with imaging sensors and televideo communications.

- Microfluidics is a fairly small market that works with polymers to create chemical reactions or detection screens.

- Micro fuel cells are a new market that uses nanotechnology to form microscopic fuel cells that usually use hydrogen or methanol to create energy.

The twenty-first century has also seen the rise in nanotechnology patents, as more products and processes become open to nanotech possibilities, and more companies claim to be using nanotechnology to create their products and technology. Because of the myriad possible applications, it is difficult to be sure what companies are truly using nanotech abilities and what patents will prove successful.

Entrepreneurs have an exciting new field to invest in and explore with technology, but the new science also requires several important choices. Should entrepreneurs attempt to incorporate nanotechnology into existing business systems and manufacturing, or should they develop a new business structure to market purely nanotech products? How can performance and efficiency be improved by nano-designed properties? Amanda Kooser gives several guidelines for such entrepreneurial questions in her article, "Think Big with a Nanotechnology Business:"

1. Look to the labs. The pioneering of nanotechnology is being conducted in company and university labs where scientists are exploring the possibilities of different particles. To begin an effective entrepreneurial endeavor in nanotechnology, it is important to take

advantage of the newest discoveries, and these discoveries begin in the laboratory.

2. Find the business connection. Nanotechnology will not be profitable unless it helps an existing industry or creates a new market. Entrepreneurs need to connect a particular business need with a solution that nanotechnology can currently provide.

3. Leverage new discoveries. With all the hype concerning nanotechnology, many companies are curious to see what products and abilities will be developed next. Keeping an eye on new discoveries will lead to profitable solutions for business systems.

4. Uncover the compelling reasons. Why should a business use the entrepreneur's nanoproduct? Or, if the entrepreneur is incorporating nanotechnology into an existing system, what are the clear benefits?

5. Keep up on the latest and greatest. Subscribing to nanotechnology journals and attending nano conferences are great ways to keep up on the latest scientific events. For more simple research, there are many Web sites and several helpful books, too.

NANOTECHNOLOGY ETHICS AND RESPONSIBILITY

There are several concerns about nanotechnology, and most center on the fact that nanoparticles are recent creations, not fully understood, often with different properties than the same element in a normal size. The British Royal Society even petitioned, in 2004, for nanoparticles to be branded as new substances and so subject to stringent definition and testing. The common concern is that nanoparticles will have harmful, toxic effects on both humans and the environment. Many biological rules do not apply to nanoparticles—they can travel easily through tissue, they are often not affected by antibodies, and they can accumulate in organs such as the brain. Most nanoparticles can also be spread through the air and pass through filters that would keep larger particles out.

Because every new nanoparticle created has unknown, possible harmful biological consequences (especially in the long term), scientists apply what is now known as the "precautionary principle" to current nano research. Coined as a political and ethical standpoint, the precautionary principle states that any scientific endeavor that has any potential to cause harm to society or the environment should first be agreed upon as safe by a consensus of the applicable scientific community. In other words, if there is doubt, the research is out. However, despite ethic frameworks put into place to guide nanotech science, some argue that key issues have not yet been addressed.

A European team headed by scientist Stephen Hansen released a 2008 report that suggested several problems with current attitudes toward nanotechnology. In general, they said, scientists and governments have ignored early warning signs and stand to suffer from the same mistakes that have been made in the past with such science as atomic radiation. The call for more information can sometimes be used as an excuse for not taking action by involved governments. Hansen also pointed out that many governments that legislate rules for nanotechnology also openly support it, leading to accountability problems. The team also discovered that the critical ethical questions about nanotechnology do not seem to be answered by the current research.

The key to responsible discoveries in nanotechnology appears to be a mixture of applying the precautionary principle and being innovative in the uses of nanotechnology. Even with the enormous pressure placed on it by businesses and media, nanotechnology is a highly promising field that could provide an entire array of revolutionary products.

NEGOTIATION

SEE *Conflict Management and Negotiation*

NEPOTISM

Nepotism describes a variety of practices related to favoritism; it can mean simply hiring one's own family members, or it can mean hiring and advancing unqualified or under-qualified family members based simply on the familial relationship. The word *nepotism* stems from the Latin word for "nephew," especially the nephews of the prelates in medieval times. While attitudes toward nepotism vary according to cultural background, nepotism is a sensitive issue in American business. Many companies and individuals consider the practice to be unethical, largely due to its conflict with traditional American values of self-reliance and fairness.

However, nepotism may have played a role in the success stories of such self-made men as Andrew Carnegie. The business historian Pamela Laird has shown how various personal networks can contribute to career success. Laird has shown that kin networks can be an early and crucial aid in business success.

In Western societies nepotism raises legal concerns. Although U.S. laws do not specifically prohibit hiring one's relatives, studies show that between 10 and 40 percent of U.S. companies maintain formal policies prohibiting such a practice. Many of these anti-nepotism rules were instituted in the 1950s with the aim of preventing the hiring of incompetent male relatives of male employees. In the 1960s and 1970s the same rules applied but failed to reflect the change in the workforce as more women entered the job market; females were often the victims of these rules, however, and many were forced to quit.

Nepotism is also tied to discrimination issues and pragmatic concerns. There is substantial debate over whether employers with any form of biased preferences for hiring, including nepotism, can even survive in the business market, ethical issues notwithstanding. On the other hand, a 2006 report noted that approximately one-third of all Fortune 500 firms are family owned, and that family-owned businesses accounted for about half of the country's gross domestic product. In addition, these firms accounted for about three-fifths of all employment, and an even higher proportion of new job creation. The success of these businesses can be viewed as an implicit endorsement of nepotism.

Larry Singell and James Thornton identify four levels of anti-nepotism rules. They note that companies may institute policies that prohibit the employment of a current employee's relatives in any of the following situations:

- Anywhere in the organization
- At the same facility
- In the same department or work group
- In positions where one may immediately influence the compensation, promotion, or work situation of the other

Even if a company has a clearly stated policy, complications may follow in its enforcement. For example, the increase in dual-career marriages increased legal challenges to nepotism issues. Employees occasionally meet at work, socialize, fall in love, and eventually marry. In some cases, couples have had to decide which spouse has to quit, as company policy would not allow them to work for the same organization. Do practices such as hiring (or even not firing) family actually constitute discrimination?

Further, even if there is no complication between the two individuals as a result of marriage, there is sometimes pressure from in-laws and even close friends of in-laws for favoritism in hiring. There appear to be differences in nepotism practices between family-owned businesses and publicly owned businesses. Most family-owned businesses simply expect family to be involved in the future, as do the in-laws who join the family. However, there are usually more formal rules for publicly held companies; these companies must therefore be cautious, since they are open to outside scrutiny over their hiring and promotion practices.

ADVANTAGES

If practiced fairly (itself a contentious term in this regard), nepotism can be a true asset, Sharon Nelton suggests, citing the example of Thomas Publishing Company. In 1998 there were seven third- and fourth-generation family members working for the company. The third-generation president, Tom Knudson, encouraged nepotism among their independent sales contractors because he believed it resulted in high performance, stability, and long-term commitment.

Chad Kaydo also writes that nepotism may be viable. For example, a top salesperson's relative may have many of the same qualities that make the representative successful. Recruiting family members can therefore boost both performance as well as retention. For instance, one senior contractor began working for Thomas in 1940. By 1998

his wife and three of his adult children (two daughters and a son) all worked for the company. The son encountered a challenge when calling on a client at odds with the senior contractor. He easily and politely diffused the situation using the diplomacy techniques he had gleaned from his father, the very senior contractor the client disliked, and gained a larger-than-usual sale.

Wrigley is another successful company that has been run by a family for many years. One *Business Week* story noted that family-run businesses can have lower employee turnover rates as specific managerial values are passed down from generation to generation.

In the 2000s the tide in business seemed to be turning toward policies that encouraged hiring qualified relatives and spouses, with idea that good people tend to associate with good people. Jacquelyn Lynn noted that such policies can promote employee satisfaction by aiding individual efforts to balance professional and personal lives. Hiring family members can also provide benefits to companies, for example by reducing their health insurance costs. Nepotism can also extend to older family members. Bill Gates's father serves as the Gates Foundation's chairman.

Adam Bellow has coined the term "new nepotism" in his book, *In Praise of Nepotism*. Bellow and others have commented that nepotism can be a savvy business strategy, especially when a family is closely associated with a particular company or brand. In these cases, nepotism can work to bolster confidence in a firm.

DISADVANTAGES

There are, to be sure, nepotism disasters. Lines Brothers in Britain, once a highly successful maker of Triang toys, was rendered worthless in just a few years by its second generation of leadership. Yale Express, a U.S. delivery company, was bankrupt within five years of the second generation assuming the presidency. The Great Atlantic and Pacific Tea Company (A&P) was once the largest supermarket chain in the United States, but went bankrupt under its heir.

Linda Wong and Brian Kleiner suggest that trouble arises most often when family and business needs conflict. A family's purpose is to care for and nurture family members; a business must produce quality goods and/or services as efficiently and as profitably as possible. If a company hires or promotes an incompetent family member, other employees may see this is a gross injustice and many complications may result. More directly, the unqualified heir may simply instill policies that drive the company into the ground.

Nepotism can also publicize family disagreements and prejudices to those within the company. It may even cause a company to lose valued executives and make it very difficult to attract and retain high-quality newcomers. Family squab-

bles can also serve as bad publicity. For example, the CEO of Carlson Cos. fired her son, prompting a series of lawsuits between the two. Likewise, Viacom's Sumner Redstone has been embroiled in public disputes with his children who also worked in the business. On the other hand, some see the DuPont family's competition among members as having contributed to that company's success.

Adelphia Communications represents what is perhaps one of the most disastrous instances of corporate nepotism. In 2004, John Rigas and his two sons were disgraced in a highly publicized case of corporate fraud. This can be seen as a case where nepotism ruined a company not by placing incompetents in powerful positions, but rather by generating a corrupt culture at the company's top.

INTERNATIONAL ASPECTS

Abdalla Hayajenh, Ahmen Maghrabi, and Taher Al-Dabbagh note that nepotism has maintained a particularly strong footing in the Arab world. They indicate that there are several major factors behind nepotism in Arab business:

- Socio-cultural structure (tribal and kinship relations)
- Economic structure (a tight labor market making it difficult to find a job in other ways)
- Educational structure (poor preparation of workers for economic development)
- Political structure (governments' assignation of educated tribal chiefs and their sons to key positions in return for loyalty)

In Asia the majority of entrepreneurs look to the family, rather than the broader populace, for the succession of the business. Studying Asian nepotism practices, Leon Richardson holds that nepotism works as well as any other management choice as long as one never tolerates incompetence. He notes that the Japanese successfully use nepotism, with senior men and women enjoying power and not hesitating to fire an incompetent "nephew."

In addition, many Latin American countries accept nepotism as the norm and are baffled by the often-negative U.S. attitude toward the practice. As one South American executive commented, "If I cannot hire and trust my own family, just who can I trust?"

However, attitudes towards nepotism in foreign countries can also change over time. In 2008, Italy's supreme court decided that nepotism was illegal. Still, one London newspaper reported that the vast majority of businesses in that country were family owned.

GUIDELINES

Craig Aronoff and John Ward argue that the key to the successful use of nepotism is clear communication of the

rules before they are needed and fair application of the rules as needed. They believe in holding relatives to at least three standards in hiring:

1. Appropriate education for the job

2. Three to five years of outside work experience

3. Entry into an already existing and vital position with determined pay and performance expectations

Many experts believe that outside experience is vital to the potential family-member hire. They feel the family member should establish his or her own competence and professional sense of worth before assuming work responsibilities within the family's firm. Testing and honing his or her skill set and abilities allows one to bring expertise to the enterprise.

In the first sixteen years of business, CAM Specialty Products practiced a strict policy of not hiring family members. However, in 1997 an opportunity to invest in Deckare appeared and co-owner Gordon Hammett hired his son as work crew chief to handle on-site fieldwork. Hammett interviewed his son like all other candidates and honestly felt his son was a perfect fit for the job; he was familiar with his son's work ethic and knew his son enjoyed the type of work. As a result, the decision met with great success. The key was to have clear criteria for the job and to apply it consistently for all candidates, neither favoring nor discriminating against family members.

Nepotism is not a new phenomenon in business, but it is of particular interest as the world of business shrinks due to rapid travel and convenient and fast technological communication. As business becomes increasingly globalized, it is crucial to understand how cultural attitudes toward nepotism vary between the different countries in which a business operates. Furthermore, as more families rely on multiple incomes for their standard of living, the ethical and pragmatic considerations regarding nepotism must be carefully negotiated to ensure the most effective overall business strategy. While certain guidelines have been known to effect a smooth incorporation of nepotism into a successful business, there are no definitive strategies. Clearly, however, nepotism can lead to success if applied appropriately, or to disaster if applied without careful consideration of all the variables involved.

NEW PRODUCT DEVELOPMENT

The dynamics of markets, technology, and competition have brought changes to virtually every market sector and have made new product development one of the most powerful business activities. The monumental changes that constantly impact commerce have forced companies to innovate with an increasing amount of speed, efficiency,

and quality. In turn, this has made new product development one of the most complex and difficult business functions. However, firms must innovate in order to survive. The power of innovation is revealed in numerous studies, which show that companies leading their industries attribute about half of their revenues to products developed in the most recent five years. By comparison, companies at the bottom of their industries achieve approximately one-tenth of their sales from new products.

In a larger sense, new product development can be seen as a facet of "creative destruction." Companies that fail to innovate will eventually be toppled by those that do.

A firm's new product development efforts are shaped by its size, as well as the nature of the industry in which it operates. New products may be defined as any product, service, or idea not currently made or marketed by a company, or which the consumer may perceive as new. Many types of new products exist, from never-seen-before products like Apple's personal communicator, to repositioned standards like Sears's shift to Sears Brand Central. Various studies suggest that between 50 and 80 percent of new products fail—the greater the rate of new product development, the higher the failure rate. *New Product News* predicts that more than 36,000 new products will be brought to market in 2005. Although there are numerous reasons why new products fail, faulty management and planning are at the core of most failures. Therefore, managing the new product development process is a key to a healthy organization.

HISTORY

Ford Motor Company provides the classic cautionary tale for new product development. After numerous attempts, Ford found success with its Model T in the early twentieth century. The Model T was reliable, and Ford nearly perfected the production process (so much so that "Fordism" became the model for production for much of the twentieth century). Through this production process, Ford was able to produce a reliable product as well as reduce production costs, allowing the company to offer the Model T at increasingly lower cost.

However, during this time the company did not offer any new products, focusing completely on the Model T. This left an opening for Ford's competitors; notably, General Motors was able to segment the automobile market in the United States by offering a range of makes and models. Furthermore, General Motors (under the leadership of Alfred P. Sloan) introduced annual model changes, in effect making new product development a large part of its overall strategy. As a result, Ford lost its vaunted position, and was forced to introduce newer products in the 1920s.

New product development became key following World War II. After experiencing wartime shortages of goods, Americans were eager to buy the many new products manufactured during the post-war era. Engineers, who were more product-oriented than consumer-oriented, designed new products that might or might not find places in consumers' hearts and minds. This was a product-oriented process in which the market was considered the receptacle for products that emerged from the firm's research and development efforts. This is known as the product-oriented or technology-pushed stage.

However, competition escalated and consumers became more skeptical and selective about the types of products they purchased. Marketers found it increasingly difficult to rely on persuasive sales techniques to move products. Retailers grew restless when these products did not move off shelves as quickly as planned. Companies had to know more about their target markets. What were the wants and needs of the people who were buying their products? How could their firm satisfy these wants and needs?

The second stage was marked by the emergence of the market as the driver of innovation. Instead of being technology-driven, new product development evolved into a market-led process in which new products emerged from well-researched customer needs. The new product development process was placed in the hands of marketers who knew consumers' wants and needs. Customer demand "pulled" the product through the development process.

Modern new product development is a blending of these two orientations into a "dual-drive" approach to innovation. Companies recognize that innovation is a complex process that requires sound investment in research and development, as well as significant marketing expertise that focuses on satisfying consumers' wants and needs.

The rapid pace of change that engulfed businesses toward the end of the twentieth century put an even greater burden on companies to build adaptive capabilities into their organizations. Global competition means there are more competitors capable of world-class performance. This has made competition more intense, rigorous, and aggressive than ever before. Fragmenting and more sophisticated markets mean that consumers demand more from products in terms of quality, differentiation, and "meaningfulness."

New technologies have had two important outcomes in regards to innovation. First, new technologies are responsible for this new market sophistication in which consumers have more choices and are thus more demanding. Secondly, new technology has increased manufacturers' capabilities for rapid response to shifting market needs.

Finally, product life cycles have become more compressed as the skills required for developing new products increase in complexity. For example, consider the development of a new type of computer software. The expertise needed to develop the software from conception to commercialization might take years. The product's life cycle in such a competitive and turbulent environment might last only a few months. Therefore, companies have embraced the view that new products are transient, whereas the skills and expertise needed to develop these products are a much more persistent requirement for success. Instead of the mono-approach, in which technology or markets drive innovation, new product development now requires a convergence of technology, marketing, product design, engineering, and manufacturing capabilities. Speed, efficiency, and quality in product development are the challenges that new product development faces in today's intense competitive environment.

TYPES AND SOURCES OF NEW PRODUCTS

There are five categories of new products. New-to-the-world products or services are new inventions like in-line skates and health maintenance organizations. New category entries, such as sport utility vehicles, are products or services that are new to a firm. Additions to product lines add products or services to a firm's current markets. For example, when a powder laundry detergent offers a liquid version, it is considered a line extension. Product improvements are another type of new product and are common to every product category. Repositionings target products to new markets or for new uses.

Firms also employ what is known as "planned obsolescence." Here, a firm plans a specific shelf-life for a product. The concept was described in 1959 by the author Vance Packard in *The Waste Makers*. In high-technology markets, this term can sometimes refer to the idea of updating and improving a product. While the product might not be functionally obsolete, like earlier instances of planned obsolescence, the updated product will constitute a dramatic improvement over the old one.

Firms can obtain new products internally or externally. External sourcing means the company acquires the product or service, or obtains the rights to market the product or service, from another organization. Internal development means the firm develops the new product itself. This is riskier than external development because the company bears all of the costs associated with new product development and implementation. Collaborations, which include strategic partnerships, strategic alliances, joint ventures, and licensing agreements, occur

when two or more firms work together on developing new products.

NEW PRODUCT DEVELOPMENT PROCESS

Historically, the new product development process has been conceived in discrete terms with a beginning and an end. Different companies and different industries may alter this seven-step process for different products, or the steps themselves may become blurred as companies become engaged in several stages at the same time.

The process begins with idea generation. For every successful new product, many new product ideas are conceived and discarded. Therefore, companies usually generate a large number of ideas from which successful new products emerge.

Idea screening, the second step, considers all new product ideas in the idea pool and eliminates ones that are perceived to be the least likely to succeed. Not only should the firm's manufacturing, technology, and marketing capabilities be evaluated at this stage, but also how the new idea fits with the company's vision and strategic objectives.

The third stage, concept development and testing, requires formal evaluations of the product concept by consumers, usually through some form of marketing research. New product ideas with low-concept test scores are discarded or revised. While the Internet is making it easier to gather consumer data, there are limitations. As people get deluged with an increasing number of surveys and solicitations, it is possible that they will grow tired of helping marketers.

The business analysis stage is next. At this point the new product idea is analyzed for its marketability and costs. After passing the first three stages an idea may be discarded once marketing and manufacturing costs are analyzed, due to limited potential for profitability or commercial success. Throughout these four stages, the new idea has remained on paper requiring relatively small investment.

The fifth stage, prototype development, is the first stage where new product costs begin to escalate. Because of this, many companies have placed greater emphasis on the first four stages and reduced the proportion of new products that reach the prototype stage from about 50 percent to around 20 percent. At this stage the concept is converted into an actual product. A customer value perspective during this phase means the product is designed to satisfy the needs expressed by consumers. Firms may use quality function deployment (QFD) as they develop the prototype. QFD links specific consumer requirements such as versatility, durability, and low maintenance with specific product characteristics (for example, adjustable

Figure 1

New Product Development Process, Factors and Strategies

Factors Influencing the New Product Development Process	New Product Development Process	Strategies for Improving Speed, Efficiency and Quality
Organizational Structure and Culture • Fast cycle capability • Autonomy • Planning and coordination	Idea generation	Product development maps
	Idea screening	
	Concept development and testing	Aggregate project plans
Leadership • Level of involvement • Clarity and vision • Project management • Tolerance for trial and error • Individual initiative	Business analysis

	Test marketing	
Team building • Reduced interdepart- mental conflict • Social cohesion • Frequency and direction- ality of communication	Commercialization	Purchasing expertise in process

shelves, a door-mounted ice and water dispenser, and touch controls for a refrigerator). The customer value perspective requires the new product to satisfy customer needs and meet desired quality levels at specified produc- tion costs.

Test marketing tests the prototype and marketing strategy in simulated or actual market situations. Because of the expense and risks associated with actual test mar- kets, marketers use them with caution. Products that test poorly are pulled back and reconceptualized or discarded.

Commercialization, the final stage, is when the prod- uct is introduced full scale to the marketplace. The level of investment and risk are highest at this stage. Consumer adoption rates, timing decisions for introduction, and coordinating efforts with production, distribution, and marketing should be considered.

FACTORS INFLUENCING NEW PRODUCT DEVELOPMENT

The seven-step process assumes a definite beginning and end. However, studies suggest that what goes on before and after new products are introduced is as important as the process itself. Organizational structure, leadership, and team building influence the speed and efficiency with which new products are introduced. Structure influences efficiency, autonomy, and coordination. New product innovation requires structure that optimizes direction and guidance. Structure that facilitates internal informa- tion exchange, decision-making, and material flow is essential. A "fast-cycle" structure allows more time for planning and implementing activities to gain competitive advantage. This type of structure also cuts costs because production materials and information collect less over- head and do not accumulate as work-in-process inventory.

Autonomy refers to the amount of decision-making allowed at lower levels of management. The coordination of the engineering, product design, manufacturing, and marketing is vital in the new product development process.

Leadership influences strategy, culture, and the firm's overall ability to undertake new product development. Top management can demonstrate involvement in the development process by providing career advancement for entrepreneurial skills and encouraging broad employee participation. Clarity and vision are crucial to ensuring that new product ideas are good strategic fits for the company. The degree to which leadership allows trial and error and promotes individual initiative positively influences the development of new products. This acceptance of risk and support for an entrepreneurial spirit within the organization are crucial in order for innovation to flourish. New products emerge in a variety of ways and their development does not always proceed in rational and consistent manners. It is necessary for leadership to view the process as iterative and dynamic, and to foster adaptation and flexibility. Management flexibility and responsiveness to change also are needed. This type of leadership is particularly important to the project manager who must coordinate and integrate the various parts of the new product development process so that a coherent system emerges that produces a product with compelling value. Initiative encourages creativity and problem-solving skills.

Teams provide mechanisms for breaking down functional biases created by a strict adherence to structure. The amount of interdepartmental conflict in the organization, the social cohesion among team members, and the frequency and directionality of interdepartmental communication influence team building. Through shared understanding of the objectives and purposes of the project, as well as the tasks required in the development process, teams can shape the project and influence how work gets done in the organization.

CONSUMERS AND NEW PRODUCT DEVELOPMENT

In many ways, consumers have played an active role in new product development. The business historian Regina Lee Blaszczyk has shown that as early as the eighteenth century, companies and manufacturers have had to learn what it is consumers wanted from a product. By simply rejecting or purchasing a product, consumers play a vital role in the production process. As the twentieth century progressed, companies developed ways to discover consumer tastes and used this information in product design.

The rise of software in the late twentieth century provided an even greater role for the consumer in new product development. Kevin Kelley has noted that releas-

ing beta versions and open source software for free can aid in product development. Savvy potential users will find and fix bugs in the product. GNU/Linux is a well-known example of software that has been developed using an open-source method.

Though open-source software has sometimes been seen as the province of hobbyists and computer programmers, open-source strategies can be used in other types of product development. Advanced Micro Devices (AMD) is one example. In 2007 AMD switched to an open-source graphics driver, a move that made its customers an essential part of the development process.

IMPROVING SPEED, EFFICIENCY, AND QUALITY

New products often fail because of unanticipated market shifts that result in missed opportunities and misused channels of distribution. Failures also occur because companies miscalculate their own technological strengths or the product's technological challenges. These potential problems often crop up in the latter stages and result in delays, redesigns, or poor quality products.

Companies are constantly seeking ways to avoid these pitfalls. One solution is new product development maps that chart the evolution of a company's product lines. This historical perspective helps the firm to identify and analyze functional capabilities in a systematic, repetitive fashion that allows for the development of linkages and the identification of resources for new endeavors. These maps can direct the firm to new market opportunities and point out technological challenges.

Aggregate plans for projects offer another solution. Rather than viewing each new product development project individually, they consider all of the new product development projects under consideration by the firm. This is particularly important in firms with hundreds of new product development projects going on at the same time. Projects are categorized according to resources required and contribution to the firm's bottom line. Aggregate project plans enable management to improve the handling of new product development by providing greater control over resource allocation and utilization. These plans help to point out where capabilities need to be improved, how sequencing projects may help, and how projects fit with the firm's development strategies.

Return maps graphically represent the contributions of all team members to product success in terms of time and money. Their focus is on the point at which product sales generate sufficient profit so that the firm's initial investment in development is returned. Return maps show team members the time and money needed to complete their tasks in the development process so that they may estimate and re-estimate their investment in the

process. In doing this return maps illustrate the impact of their actions on the project's overall success.

Another way to improve the speed and efficiency with which new products are introduced is to involve purchasing in the development process. When purchasing expertise is introduced into the development project team, quality may increase, time to market entry may decrease, investment in inventory may diminish, and costs may significantly decrease.

Technology continues to change and create new opportunities and threats. Customer requirements and expectations continue to shift and create new demands. Old channels of distribution are becoming obsolete and new channels are opening new opportunities. Some competitors are falling by the wayside while others are surging to the forefront by making new and unexpected moves to gain advantage. The very structure of industry is changing. A key to success in this tumultuous environment will continue to be the ability to sustain a competitive advantage through innovation. However, speed, efficiency, and quality in product development will be paramount. Building capabilities in all aspects of product creation and implementation, overcoming uncertainty and facilitating decision-making, ensuring these innovations are strategically linked to the firm's vision, and doing this on a continuous basis is the challenge of new product development in the next century.

NON-COMPETE AGREEMENTS

A non-compete agreement, or a covenant not to compete is a contract in which one party agrees not to compete with another party in exchange for payment of some consideration. Non-compete agreements are most commonly found in employment contracts, particularly with management or sales employees; in agreements among shareholders or partners of a business; in contracts for the sale of a business; and in agreements for the funding of a business. Non-compete agreements are difficult to enforce, and must be carefully drafted to conform to the regulations of the state in which the agreement is to be performed.

NON-COMPETE AGREEMENTS IN EMPLOYMENT CONTRACTS

In an employment setting, a non-compete agreement is a contract between an employer and an employee, which prevents the employee from working for a competing company and from divulging to third parties, including new employers, the confidential business and proprietary information, trade secrets, customer lists, and technical and manufacturing processes of the contracting employer. A non-compete agreement must seek to protect a company's legitimate business interests and property. Without such an agreement, employees can leave a company, and subject to state protection against misappropriating a company's trade secrets and federal intellectual property statutes, freely compete with their former employers.

With some exceptions, most states recognize non-compete agreements or restrictive covenants in employment contracts, either through specific provision in a state statute or through the state courts' application of a common law "rule of reason" analysis. The rule of reason analysis weighs the company's interest in protecting its

proprietary and confidential information in a geographic area for a period of time against the employee's need to have a way in which to earn a living. However, the specific provisions and types of non-compete agreements that the state will recognize varies among the states, and quite often a non-compete agreement which is found valid in one state is determined by the courts in another state to be unenforceable because, for example, it is too broad in scope or time.

Courts are generally not eager to broadly enforce such agreements because they may restrict an individual's ability to earn a living. Courts will also not enforce agreements that are merely broad-based attempts to prevent all competition. As a result, non-compete agreements must be drafted with care to conform with each state's requirements for a valid non-compete agreement.

Non-compete agreements in and of themselves do not change the nature of the employment relationship. If it is an at-will relationship, either party can terminate the relationship at any time, and the drafter of a non-compete agreement must be careful, in the attempt to restrict competition, that there is not instead a promise made that the employee will have a job with the employer for life.

One question regarding the at-will employment relationship when a non-compete agreement is in place is whether an employer can discharge an employee for refusing to sign a non-compete agreement, even if that agreement is deemed to be unreasonable. There is concern that such a discharge violates the public policy exception to employment-at-will; the non-compete agreement may have negative societal effects on the freedom of employees to seek or change jobs and limits to technological advancements. Whether a court will deem a discharge as a violation of public policy depends on the nature of that state's public policy exception and the nature of the state's laws regarding non-compete agreements.

Non-Compete Agreements and State Laws. The legality and enforceability of the non-compete agreement varies by state. Scott Westcott provides a rough guide to non-compete agreements in "The Legal Landscape." Non-compete agreements are the least enforceable in California, where (under section 16600 of the California Business & Professions Code) it states that, subject to statutory exceptions, any contract that restricts a person from engaging in gainful employment is void. Georgia and Wisconsin are less strict but if one item in an agreement is deemed unenforceable, the entire agreement is considered void. Non-compete agreements are rarely enforced in Colorado or Oregon. In fact, Oregon passed additional legislation to restrict non-compete agreements in January 2008.

The majority of states will enforce non-compete agreements if they are narrowly defined to protect intellectual property of customer relationships. Some states will revise a non-compete agreement by scratching out the terms that are not enforceable. Among the states that are reluctant to enforce non-compete agreements are New York, Massachusetts, and Illinois. Florida, Texas, Michigan, and New Jersey are more likely to enforce a non-compete agreement.

There are some common provisions in non-compete agreements that are required in all the states that have enforced such agreements. All contractual provisions that seek to restrict competition must be in writing. An oral contract between an employer and an employee, under which the employee promised to not work for a competing company, is not enforceable. As with any contract, there must be "valuable consideration" for the non-compete agreement. The definition of what is sufficient to constitute valuable consideration differs by locale, but generally if the non-compete provisions are part of the employment contract at the time of hire, being hired itself has been held to be sufficient consideration for a contract preventing competition if the employment relationship ends. If a non-compete agreement is presented to an employee after employment has commenced, there must be some payment, or at least the promise of a raise or promotion, to the employee in order for the agreement to be found to be based on sufficient consideration. While an employer could claim that continued employment itself was sufficient consideration and that the employee would have been fired if he or she had not signed the contract, such arguments are not favored by courts.

Most importantly, the provisions of the non-compete agreement regarding the geographic territory which the agreement covers, the areas of competition which the agreement protects, and the length of the time period of non-competition must be restricted. No court will enforce a contract that attempts to prevent an employee from ever working again. Accordingly, a non-compete agreement should include in very specific terms the interests which the employer wishes to protect from competition, such as technology, research and development efforts, customer lists, pricing information, suppliers, prospective customers and projects, the company's strategic planning efforts, and other confidential and proprietary business information. Companies commonly refer to these interests as "trade secrets."

Courts are most willing to set aside non-compete agreements, or at least modify them, on the issues of the length of the period of non-competition, and the geographic area which it covers. The basis for the time and geographic restrictions is that they must be "reasonable." This determination differs from state to state, and within

a state, from industry to industry. For instance, geographic restrictions tend to be broader on non-compete agreements regarding Internet commerce because web businesses often sell to customers worldwide. Anyone attempting to enforce a non-compete agreement must be aware that the agreement will not be looked upon with favor if the amount of time it extends or the geographic area it covers is too broad, based on the type of business, the location of the customer base, and the job duties of the employee restrained by the non-compete agreement. Recent court rulings indicate that the following time periods are likely to be upheld: up to five years for agreements regarding trade secrets, up to three years for agreements regarding sale of a business, and up to six months for other types of agreements (e.g., use of client lists).

NON-COMPETE PROVISIONS IN SHAREHOLDER/PARTNER, FUNDING, OR SALE OF A BUSINESS AGREEMENTS

Agreements among shareholders of or partners in privately held companies often contain non-compete provisions. These protect each of the parties to the agreement from competitive activities of another that would damage the business, since each of the shareholders or partners has access to the company's trade secrets and confidential and proprietary information. Similarly, in agreements to provide funds to a business, particularly where the funding is provided by a venture capital source, there regularly appear non-compete provisions. The funding source includes these provisions because it wants to ensure the likelihood of the business's success by preventing competition by the owners or key managers of the business.

In a sale of a business, the former owners are often restrained from setting up a new business within some geographic area that will compete with the business they just sold, for a specified period of time, again so that the business which was sold can have a chance to survive without competition from those who have information about the company's strengths and weaknesses. There is usually a separately negotiated payment for the non-compete provisions in a sale of a business agreement, and often the sold business will retain the former owners as consultants during the pendency of the non-compete period. Courts are more willing to enforce these types of non-compete agreements, as opposed to those in employment contracts, since the parties have received something of value—an ownership interest, proceeds of a sale, or funding—that is more than just continued employment.

NON-SOLICITATION AGREEMENTS

A non-solicitation contract, which is similar to an agreement not to compete, prevents one party to the contract from seeking business from clients of the other party to the contract. These kinds of contracts can also restrict one party from recruiting for hire people who work for the other party.

NONPROFIT ORGANIZATIONS

In the United States, nonprofit organizations (NPOs) are organizations that qualify for tax-exempt status under the U.S. Internal Revenue Code. About half are public charities, to which donors can deduct contributions from their taxes. Private foundations also are charitable organizations, but they are not public charities. They exist primarily to fund charities or individuals. Other types of tax-exempt organizations include social welfare, labor, or agricultural organizations, business leagues, and fraternal beneficiary societies. Nonprofit organizations are not prohibited from earning a profit or paying salaries and wages, but they must devote any surplus to the organization.

Nonprofit organizations also are known as not-for-profit organizations, or as the "independent sector," as opposed to business or government. Nonprofits constitute about 10 percent of U.S. employees. These organizations play a unique role in society, falling between the concepts of public and private entities. Public agencies provide goods and services that are considered to be universally desirable (such as national security or infrastructure). Private enterprises serve individual tastes and preferences

and depend on market-based competition to prosper. By contrast, nonprofit organizations supply services that are considered good for the community as a whole or for specific community members, but which do not elicit widespread taxpayer support for direct provision. The distinction may be characterized as the difference between "it is right" that these services should exist, and the idea that all members of society "have a right" to such services.

While the nonprofit organization exists in many countries, the focus here is on the American NPO. The primary factors unique to this American sector are volunteers, contributions, and tax-exempt status.

THE ROLE OF NONPROFITS IN THE AMERICAN ECONOMY

Nonprofit organizations play a large role in the American economy. It is difficult to get an accurate count of nonprofits, because only organizations with more than $5,000 in annual gross receipts must register with the IRS and only those with receipts in excess of $25,000 must file with the IRS. According to the National Center for Charitable Statistics (NCCS), in 2006 there were 1.47 million total nonprofit organizations in the United States. This figure includes those registered and filing with the IRS. Of these, 904,313 were registered public charities, and 109,852 were private foundations. According to *The United States Nonprofit Sector 2003,* human services organizations make up 34 percent of the charitable nonprofits; education is the second largest field with 18 percent, and healthcare/mental health is the third with 13 percent. The remaining nonprofit categories include community improvement and social benefit groups; arts, culture, and humanities groups; environmental and animal groups; religious institutions; and various research organizations, which make up only 1 percent of all nonprofit organizations.

Though nonprofit organizations can be very large, most are small. *The United States Nonprofit Sector 2003* notes that 44 percent of such organizations have less than $100,000 in assets. Only 5 percent have more than $10 million.

It is estimated that there are twice as many organizations not required to file with the IRS because they did not take in $5,000 annually. This would include such familiar organizations as PTAs and Little Leagues. No statistics are available regarding these organizations.

The NCCS collects and disseminates statistics on the U.S. nonprofit sector. This data is gathered from the IRS and other government agencies, private sector service organizations, and the scholarly community. The NCCS builds compatible national, state, and regional databases and develops uniform standards for reporting on the activities of charitable organizations. Excellent charts rep-

resenting this data are presented in *The United States Nonprofit Sector 2003,* which is available from The National Council of Nonprofit Associations.

In 2004 nonprofit organizations contributed about 5 percent of the gross domestic product. In 2006 more than 12.9 million people were employed by nonprofit organizations. This means that employment in the nonprofit sector is significant. According to the Council of Foundations, the average annual turnover rate for associations is 24 percent, but there appears to be wide variation among nonprofit subsectors. For example, employee turnover in child welfare agencies can show rates between 100 and 300 percent.

The nonprofit sector relies heavily on volunteers. This can be a problem for nonprofit managers who must provide creative incentives in "psychic income," such as recognition to volunteers who are motivated to support a particular cause despite the lack of pay and benefits. In addition, attendance may be sporadic, leading to variable levels of capacity at any given time. Some organizations in this sector exist primarily to supply employment to those who have traditionally been considered unemployable, with the goal of boosting both morale and self-sufficiency.

FINANCIAL INFORMATION

To generate revenue, NPOs rely on direct appeal to those individuals, corporations, and other entities that value the underlying cause represented by the organization. Fundraising events, including door-to-door appeals and mass mailings, are highly visible means of garnering funds. According to *The United States Nonprofit Sector 2003,* charitable nonprofits had about $945 billion in expenditures in 2003. This revenue came primarily from fees, government grants and contracts, as well as investments. About 14 percent came from private contributions, while 72 percent came from what is termed "Program Service Revenue." Competition for funds is more complex than in the corporate world, as there is no financial reward for the contributor. Each year, the American Association of Fundraising Counsel (AAFRC) publishes national giving estimates in its *Giving USA* report. For 2006, *Giving USA* reported the following national totals:

- Individuals: $222.89 billion (75%)
- Foundations: $36.5 billion (13%)
- Bequests: $22.91 billion (8%)
- Corporations: $12.72 billion (4%)

Some organizations rely heavily on competitive grants from governmental or philanthropic institutions. Nationally generated funds may be redistributed to local communities on the basis of need, as is done by the United Way and the Red Cross. Increasingly, nonprofits have

relied on participant dues, fees, or charges. Such charges can range from the minimal "suggested contribution" for a senior center lunch to the bill for costly medical procedures at a major hospital.

The United States Nonprofit Sector 2003 states that in 2003, hospitals had the greatest percentage of total sector assets (about 30 percent), followed by higher education with approximately 20 percent. Human services, healthcare (excluding hospitals), and lower education, each had about 10 percent. Interestingly, lobbying accounts for a sizeable portion of nonprofit expenditures. According to the report, large nonprofit organizations spend the most on lobbying.

The accuracy of financial information regarding this sector of the economy is limited. First, the ongoing initiative to collect and computerize data in standardized form began in the late 1980s to early 1990s. While the Bureau of Labor Statistics tabulates employment figures, the financial information lags due to attempts to standardize and code the data. Second, while all tax-exempt organizations must apply for such status, only those with

total annual revenues of at least $25,000 are required to file a Form 990 with the Internal Revenue Service. These non-filers represent about two-thirds of all registered nonprofit organizations. Third, churches are not required to file a Form 990, leaving this data estimation to private sources. Fourth, pass-through contributions (for example, revenues to both the United Way and the local charities it supports) may be double-counted. Therefore, financial figures are at best an estimate.

There is no single agency with oversight for nonprofit organizations. The IRS serves as one control, but some states have instituted more rigorous guidelines than those at the federal level. The Financial Accounting Standards Board, a private self-regulatory body for the accounting profession, developed Financial Accounting Standards 116 and 117 covering nonprofits, but these prescriptions allow a different form of generally accepted accounting practices (GAAP) from private organizations with similar functions.

The BBB Wise Giving Alliance collects and distributes information on national nonprofit organizations. It routinely asks such organizations for information about their programs, governance, fund-raising practices, and finances. Although The BBB Wise Giving Alliance does not recommend charities, it does select charities for evaluation based on the volume of donor inquiries about individual organizations. The BBB Wise Giving Alliance was formed in 2001 with the merger of the National Charities Information Bureau and the Council of Better Business Bureaus Foundation and its Philanthropic Advisory Service. The BBB Wise Giving Alliance is a nonprofit charitable organization, affiliated with the Council of Better Business Bureaus.

TAX-EXEMPT STATUS

In exchange for the supply of quasi-public goods and services, nonprofit organizations are exempt from federal taxation on the excess of revenues over costs within the

fiscal year. This practice was established in 1913 with the passage of the first federal income tax law. In addition, they also may be forgiven state and local property taxes, and may receive discount postal privileges. Thus, these organizations are publicly subsidized while not directly supported by all taxpayers.

To qualify for tax-exempt status, the nonprofit organization must satisfy a variety of prerequisites. Among these is the declaration of a primary purpose or cause that qualifies under the Internal Revenue Service code. There is no ownership of assets or income other than that of the organization itself. Externally, this implies that there is no income distribution in the form of dividends or other such payments. Internally, there is the further requirement that the organization does not exist for the benefit of individual employees or board members; the IRS scrutinizes payment to such individuals in the form of salary, rent, or contractual arrangement. However, the only available penalty is the withdrawal of tax-exempt status, a punishment that the IRS has historically rarely delivered.

Examples of nonprofit organizations include such well-known giants as the United Way, the Red Cross, and the Boy Scouts and Girl Scouts. At the other end of the spectrum are local volunteer fire departments, churches, crisis intervention centers, and civic centers.

Many hospitals and universities function as nonprofit institutions as well.

Figure 1 lists the full range of categories of American NPOs as defined by the National Taxonomy of Exempt Entities. This classification system offers a definitive classification system for nonprofit organizations recognized as tax-exempt under the Internal Revenue Code. Figure 2 lists the major categories by which summaries relating to this sector are frequently reported.

From 1940 to the early 1990s, human services and health accounted for approximately half of the NPOs in the United States. In some NPOs, benefits are limited to a select group, such as senior citizens (local agencies on aging) or those suffering from a specific disease (the American Cancer Society). Other groups have relatively open membership for those willing to pay the fee; an example is the YMCA, which provides recreational facilities.

CHALLENGES FOR NONPROFIT MANAGEMENT

Management must contend with the unique aspects of nonprofit organizations: volunteer labor, solicited contributions, and maintaining tax-exempt status. In addition, Herzlinger suggests that NPOs are highly antithetical to business in other important ways: they lack ownership,

competition, and the profit motive. Without these incentives it may be difficult to maintain effectiveness and efficiency. Even measurement of customer satisfaction may prove elusive, as customers may have no alternatives against which to compare the services received. Some controversy exists over several aspects of nonprofit organizations:

1. For example, some question the rationale of the tax-exempt status of open-membership facilities, such as the YMCA. For-profit providers of similar services submit that the subsidy of NPOs diminishes the for-profit organization's ability to compete. This situation has led to as yet unsuccessful legislative attempts to level the playing field.

2. Some people question how much nonprofits spend on programs. The BBB Wise Giving Alliance (a nonprofit organization itself) recommends that nonprofits spend at least 50 percent on program activity. Other organizations set this level as high as 80 percent. The remainder is to be spent on non-program expenses, such as administrative and fundraising costs. The amount spent on fundraising can vary widely based upon whether the nonprofit is new or established with many donors. However, no regulation exists to ensure that the majority of revenues are spent on the cause for which the funds were collected.

3. Others question how nonprofits are regulated and who regulates them. State agencies are increasingly requiring reports from active NPOs to monitor fundraising activity; the agency in turn responds to individual inquiries about the NPO's self-reported record. As in the corporate and governmental groups, administrative salaries occasionally make the news, encouraging contributors to reconsider how their contributions are being used.

Nonprofit organizations are a valuable part of the economy in America and many other countries, providing a broad range of services that might not otherwise be affordable or available without the subsidy of tax exemption. As NPOs grow in number and scope, there is increasing pressure to report on financial activity and performance fulfillment in this sector. The future of nonprofits may rely on disclosure and accountability.

NONVERBAL COMMUNICATION

People in the workplace can convey a great deal of information without even speaking; this is called nonverbal communication. Nonverbal communication can convey just as much as written and verbal communication, and human beings read and react to these nonverbal signals in the workplace.

Body language is nonverbal communication that involves body movement and gestures. The catalogue of these movements, together with attempts at defining their meaning, is called *kinesics*. Each culture is believed to possess a separate "language" of kinesics. This branch of study is used in matters of negotiation and interrogation, where reading nonverbal cues is of great importance. According to the 2008 Encyclopedia Britannica, *kinesics* is a primarily American attempt at movement-classification, designed to

create a vocabulary of gestures, "both amusing and potentially practical."

There are hundreds of thousands of possible signs that can be communicated through body movements and gestures. In addition to those movements and gestures, the nonverbal cues given through facial expressions and eye contact, personal space, and touch also influence individual interactions in the workplace. While this body language is generally well understood in each culture, there are major cultural differences in nonverbal communication.

EKMAN AND FRIESEN'S CATEGORIES

Albert Mehrabian, in his 2007 book *Nonverbal Communication*, focuses on the five categories of nonverbal communication developed by Ekman and Friesen in 1969 and widely used by sociologists since. These definitions are used to inspect and learn from movements in social interactions. A movement may belong to more than one of these categories.

The first category is *emblem*. These are movements so common that there are specific words used to designate them, such as the English "handshake" or "smile." Emblems often carry intrinsic meaning and are easy to understand to someone who has experience with them. Gestures, or movements of the head, hands, arms, and legs, can be used to convey specific messages that have linguistic translations. For example, a person might wave his or her hand rather than saying "hello," or nod his or her head in agreement, which means "yes" or "okay." These gestures can be very useful in the workplace because they are a quick way to convey thoughts and feelings without needing to speak or write. Additionally, many such gestures are generally widely understood, although they may carry different meanings in other cultures. For instance, although the "ok" sign that is made through the touch of the thumb and forefinger with the remaining fingers extended is seen as a positive gesture in the United States, in some other cultures, this is seen as a vulgar gesture.

The second category is *illustrator* movements. Illustrators accompany words in natural manners and are used to add meaning to verbal communication. An illustrator may be a particular nod to emphasize a phrase, or a wave of a hand to show an idea. In addition to the gestures that people use that have a particular meaning, people also use gestures that do not have specific, generally understood meanings. These gestures are the illustrators that add meaning to a verbal message. For instance, when giving a presentation, a person might use hand gestures to emphasize a point. Many people use gestures while speaking to others to accompany their words, and while these

body movements may not have a meaning that can be pinpointed, they serve to embellish a person's words.

The third Ekman and Friesen category is *affect display*, the category most important to Mehrabian. These are actions that are paired with emotions, such as the facial movements that indicate disgust or amusement. These body movements may indicate whether a person is open and receptive, angry, distracted, or a number of other emotions. Many affect displays are commonly interpreted; for instance, individuals who sit in a slumped position and frown are believed to be disinterested or unhappy. Those who sit upright, smile, and have raised eyebrows, are seen as interested and happy. While these affect displays are often appropriately interpreted, they may not be related to the interaction with another person, and thus may be misread. For instance, if a person has a terrible headache, he may squint, look down, and grimace during a conversation, indicating to the speaker that he disagrees with her, even if he is receptive to and in agreement with the speaker.

Regulator movements are the fourth category. These actions are seen in social interaction, and they are especially important in business and sales situations. Regulator actions are made by the listener to help the speaker improve communication. A listener may nod and move in an interested manner, urging the speaker to continue or give looks of confusion, urging the speaker to explain or repeat. Certain regulator movements can also communicate the listener's desire to end the discussion or embark on a new explanation.

The last category is *adaptor*. Adaptor actions are often unconscious movements made for reasons of comfort or clarity. This includes shifting positions in a chair or scratching an itch. Although these movements have less immediate meaning to the verbal communication, adaptors can still reveal attitudes and feelings that contribute to a mental state. Other examples of adaptors are adjusting one's clothes, biting one's nails, or fidgeting and toying with an object. Adaptors may indicate to others that a person is upset or nervous, and behavior such as this during a job interview or a meeting with a coworker may be interpreted very negatively. A person who engages in such behavior may be seen as preoccupied, anxious, or even as dishonest. As with affect displays, such body language may not convey true feelings; a person who fidgets and bites her nails may be exhibiting such behaviors for innocuous reasons. Thus, while such behaviors are often interpreted correctly as presenting anxiety, they do not necessarily indicate that a person is in any way dishonest.

When listening to others, individuals often convey messages nonverbally. Therefore, care should be taken to avoid the following:

- Sitting or leaning back is a body movement that may convey disinterest in a speaker's words or disagreement with the speaker. Additionally, resting

one's chin on his or her hand may convey boredom. Conversely, leaning forward slightly, raising eyebrows, and making eye contact indicates that one is receptive to the speaker.

- Crossed arms often connote a defensive posture, which can indicate that a person is unhappy with the speaker, feels threatened by the speaker, or does not want to listen to the speaker.

- Adaptors, such as fidgeting or playing with objects, may indicate that one is nervous around the speaker or disinterested in the speaker's message.

FACIAL EXPRESSIONS AND EYE CONTACT

Although facial expressions and eye contact are not kinesics and therefore technically not body language, they are types of nonverbal communication that can have an effect on business relations. Researchers have found that people can identify with great accuracy seven separate human emotions, even after seeing only facial and eye expressions: sadness, happiness, anger, fear, surprise, contempt, and interest. Therefore, without speaking a word, a facial expression can convey a great deal of information to others. Similarly, eye contact or lack of eye contact can also indicate a person's attitudes and emotions.

Research indicates that people use four different facial management techniques to control our facial expressions. First, people intensify their facial expressions, or exaggerate them, in order to show strong emotion. For example, a saleswoman who just made a major sale might intensify her positive expression by smiling more broadly and raising her eyebrows. Second, people may de-intensify their facial expressions when they control or subdue them. For instance, an employee who just found out that he got a raise might smile less or look less happy after finding out that his coworker did not get a raise. Third, a person neutralizes their expressions when they avoid showing any facial expression. A person might not show any emotion when being reprimanded in the workplace or when attempting to negotiate with another businessperson. Finally, humans mask their facial expressions. This occurs when a person hides his or her true emotions and conveys different emotions. For example, an employee might express enthusiasm to a manager who gives him an undesirable task in order to curry favor with that manager. Or, a customer service representative might express concern and caring in her facial expression, when in actuality she is annoyed by the customer. Each of these facial management techniques makes it possible for people to interact with one another in socially acceptable ways.

Making and maintaining eye contact can have positive outcomes in the workplace. Eye contact can be used to indicate receptiveness to what another person is saying.

Additionally, eye contact may indicate the desire to communicate with a person. Finally, eye contact can be used to express respect for a person by maintaining a longer gaze. Interestingly, refraining from making eye contact, such as looking down or away, may indicate a level of respect for someone of higher status. A lack of eye contact, or an unwillingness to maintain that eye contact may indicate discomfort with a situation, a disinterest in the other person's words, or a dislike of the person. However, the degree to which a person does or does not make eye contact may be dependent on their own level of shyness or extraversion and cannot always be interpreted as a reaction to a particular person or situation.

Certain business positions involve a large amount of nonverbal communication connected to the face and the eyes. Positions where interaction with people is common, such as bank tellers, profit by practicing better nonverbal communication. Marketing and auditing positions also go hand-in-hand with proper facial gestures. In William E. Nolen's article "Reading People—Nonverbal communication in internal auditing" (1995), Nolen suggests that smiles and eye contact can be used to relieve tension in normally serious business situations. Jeanne Segal and Jaelline Jaffe, in their 2007 article/resource "Nonverbal Communication: The Hidden Language of Emotional Intelligence," suggest using a digital camera or recorder to self-record one's facial movements and improve them, learning proper smiles and stopping stress signals.

PERSONAL SPACE

Researchers use the term *proxemic* to describe the way that a person uses space in communication. Individuals have a personal space that is like an invisible bubble surrounding them. This bubble becomes larger or smaller, depending on the person with whom we interact. We are comfortable standing or sitting closer to someone we like and more comfortable with someone we dislike or do not know well standing or sitting at a distance. However, the amount of personal space that a person desires depends on many characteristics, including gender and age.

The personal space that a person prefers also depends on the situation. When interacting with friends, relatives, or conducting casual business, most people prefer a distance of one and a half to four feet. When conducting formal or impersonal business, most individuals prefer a personal space of 4 to 8 feet. Therefore, a person is likely to be more comfortable standing closely to a trusted coworker than to a new customer.

Although there are broad norms for a comfortable personal space, it is not uncommon for a person to feel that his or her personal space has been violated when another person sits or stands too closely. When personal

space is violated, there are several reactions that people might have. First, they may withdraw by backing up or leaving the room. Second, if anticipating the possibility of a personal space violation, a person may avoid having their space violated by such actions as staying away from meetings, crowds, and parties. Third, people may insulate themselves from intrusion of personal space. A manager who puts her desk in her office in such a way that no one can sit near her is insulating. An employee who takes a seat at the end of a table during a meeting might be doing so to prevent others from sitting near him. Finally, a person may fight to keep his personal space by asking the other person to back up or move away.

In a business setting, it may be helpful to recognize the behaviors that others engage in when their personal space is violated. That is, if one notices that others step back from them when speaking, they may sit at more of a distance, or if they seem physically uncomfortable, they may have a larger personal space, which should be respected.

TOUCH

In the workplace, people may use touch to communicate nonverbally. The functional-professional touch is businesslike and impersonal. The touch that a physician uses when conducting a physical examination is a functional-professional touch. However, touch is not a part of most professions, and thus, this type of touch is not used often in business settings. The social-polite touch, such as a handshake, is much more common. This type of touch is used to recognize other individuals. It is an expected touch in many business settings. Finally, the friendship-warmth touch shows that one values another as a person. A pat on the back or a hug is a friendship-warmth touch. In most workplaces, the social-polite touch is the only necessary touch, and most managers and employees are encouraged to avoid using touch (particularly the friendship-warmth touch) in the workplace. While many people see a hand on a shoulder or a pat on the back as a useful touch to convey encouragement or concern for another's well-being, sexual harassment fears have made many avoid all types of touch beyond handshakes.

PARALANGUAGE

Often considered part of nonverbal communication, paralanguage involves the sounds and pitch of speech during social interaction. Paralanguage affects many business functions, such as meetings, conference calls, and personal evaluations. Constantly speaking in a shrill voice, for instance, is more likely to provoke irritation and annoyance no matter what is said. Pauses in speech, or sounds such as "ah" and "um", according to Segal and Jaffe, should be monitored and reduced to avoid causing boredom and lapses in attention.

ENVIRONMENT

An important aspect of nonverbal communication is the environment which the subject has control over. Most workers have a workspace that they can change, add items of their own, or organize to their liking. Many managers can decorate their offices and move furniture such as desks and chairs in whatever ways they want. In the 2008 article "Non-verbal Communication" by *bizmove.com*, the office environment is seen as divided into personal and nonpersonal sections. Managers can control communication by controlling the surroundings in which they conduct interviews, meetings, and so forth. This in turn changes the comfort levels of people in the environments.

SILENCE

In addition to using the environment, *bizmove.com* suggests that silence can be an integral part of many social interactions. The silence between phrases, the silence when waiting for questions, and the silence before responding are all examples of how silence can affect communication. Many people interpret silences as signs of emotional states. Does a silence show hesitance, thoughtfulness, or ignorance? This depends on the situation and the speakers. Silence should be considered in all business communication.

CULTURAL DIFFERENCES

Across the United States, most body language is consistently understood. However, in other nations and cultures, what is considered to be appropriate body language in one place, may be seen as highly inappropriate in others. As noted above, the American sign for "ok" may be seen as vulgar in other nations. Similarly, other types of gestures and body movements may convey unwanted negative meanings. Therefore, care should be taken before using gestures in other countries or with business partners from other parts of the world. Body movements can also be misinterpreted based on culture. Although most people in the world understand the movement of the head up and down to mean "yes" or "I agree," this is not the case in all countries.

Norms and expectations regarding facial expressions and eye contact also differ across cultures. Because different cultures have different norms for respect, eye contact that is seen as relationship-building and respectful in the United States may be seen as challenging and disrespectful in other cultures.

Personal space and touch are used differently in different nations. Americans tend to prefer larger amounts of personal space than do some Latin Americans, Italians, and Middle-Easterners. Germans, Chinese, and Japanese prefer larger amounts of personal space, similar to what Americans prefer. Thus, when conducting business with people from other cultures, it is important to understand and respect their personal space needs. Americans who do

business with those who prefer less personal space may have to fight the urge to step back and therefore avoid insulting a business partner.

However, many instances of nonverbal communication are considered to be nearly universal. Paul Ekman, in his 2007 book *Emotions Revealed*, discusses an experiment he helped conduct, in which a series of nine Pidgin speakers (who had limited experience in other languages) made a series of facial gestures. These gestures were in time with a story, the main character of which they were to mirror using nonverbal communication to describe emotion. These gestures, filmed, were then shown to American college students, who tried to define the emotions correctly. Overwhelmingly, the college students were able to perceive the emotions of the Pidgin speakers without flaw. Some of the emotions Ekman found to be easily understood included anger, enjoyment, sadness, and disgust. This study suggests that certain basic nonverbal communications are shared by most cultures throughout the world.

NORTH AMERICAN INDUSTRY CLASSIFICATION SYSTEM

The North American Industry Classification System or NAICS (pronounced "nakes") is a system for organizing data on industries and companies for standardized reporting. Implemented in 1997 for the United States and Canada and in 1998 for Mexico, the classification system replaced the U.S. Standard Industrial Classification (SIC) system, as well as the respective classification systems of the other two nations.

The system provides common industry definitions for Canada, Mexico, and the United States. It replaces the three countries' separate classification systems with essentially one uniform system, while allowing for nation-specific customization at the finest level of detail. This means at the broadest levels of the NAICS hierarchy the three countries share common industry codes, but at the most detailed level (represented by six-digit codes) each country may choose to recognize additional sub-industries that are of particular importance to their national economies, while remaining within the broader framework of the cross-national system.

The NAICS and previous SIC systems are administered by the U.S. Office of Management and Budget, but are used by numerous government agencies along with private firms and nonprofit organizations. The systems describe a company or organization, often termed an establishment, using a numerical code based on its type of economic activity or the kinds of products or services a company provides. Groups of firms in similar lines of business are thus grouped together under the same classification number. Companies are assigned a four-digit to six-digit code, with each additional code number adding more specific data to identify the exact activities of the organization. The first two digits indicate the broad business sector, the third digit designates the sub sector, the fourth digit identifies the industry group, the fifth digit indicates the industry, and the sixth digit designates national industries. For example, the broad category of "information" is winnowed down to groups such as "publishers" and "broadcasters," which are further narrowed to highly specific industry designations like "software publishers" and "radio stations." In light of such specific categories, many large and diversified firms fall into multiple NAICS categories; hence, the category that accounts for the largest share of sales is sometimes known as the company's "primary" industry classification.

Major libraries or the U.S. Government Printing Office in Washington, D.C., maintain detailed information to help researchers determine a particular firm's classification codes. Private publishers also produce listings and rankings of companies by their SIC and NAICS codes. The official NAICS codes assigned to specific companies by government agencies, such as the Census Bureau in its economic censuses, are usually considered confidential, although for the typical company the correct codes can be readily surmised based on public information.

Problems with the SIC system, including the under-reporting of services, led to the adoption of the NAICS

system. When the SIC system was created in the 1930s, the U.S. economy was heavily dependent on manufacturing. By 2000, however, services had grown to represent 80 percent of the U.S. Gross Domestic Product (GDP). As a result, the SIC codes were replaced in part to provide better information on service firms. However, the service-oriented data is not as detailed as it is for manufacturers and does not have the detailed historical data that is available for manufacturers. The NAICS system was also created to recognize developments in high technology—particularly Internet-related businesses—and increases in international trade following the North American Free Trade Agreement (NAFTA). The revised version known as NAICS 2002 included such new industries as Internet Service Providers, Data Processing Services, and Web Search Portals. NAICS classifications do not always correlate directly with the previous SIC codes. In NAICS 2002, 358 additional industry codes were included that had not been represented in the old system.

The NAICS was revised again in 2007, but the changes were minimal. Two new industries—executive search services and biotech research and development—were assigned codes in NAICS 2007. Additionally, some other industries have been integrated into broader classifications. For example, wireless telecommunication now includes paging, and wired telecommunication includes cable program distribution. The U.S. Census Bureau has published a detailed bridge to show the changes that were made to categories between 2002 and 2007.

Furthermore, in 1999 the statistical agencies in Canada, Mexico and the United States began work on the North American Product Classification System (NAPCS) as a complement to NAICS. The NAPCS aims to classify the products of services-producing industries. As of 2007 the services produced by NAICS sectors 48-49 to 81 have been classified. These product lists can be viewed on the U.S. Census Bureau Web site at www.census.gov.

The expanded and standardized coding system aids business reporting as well as assists researchers gathering and studying data across industries. The system provides a consistent framework for industrial statistics and can benefit anyone who uses industry-based data. According to the NAICS Web page sponsored by the Georgetown University Library, the system will most benefit economists, regulators, marketers, and publishers. Because the three governments designed the system jointly, it is expected to provide better standardization and comparability for nearly all North American industry data.

There are many uses of NAICS data. A firm can compare its own sales data in a particular NAICS classification to the total sales of all companies in the classi-

fication to estimate its market share and growth potential, or to gauge its general performance. If competitors have a larger market share, the firm may need to make adjustments in its strategy or target other subgroups within an industry that offer more sales or growth potential. Many organizations use these classifications; for example, Dun & Bradstreet publishes a plant list based on these codes that might be used by marketers or industry analysts to target particular types of firms.

Typical government census data arranged by NAICS classification include the number of establishments in a given category, the number of employees, payroll data, hours worked, value added by manufacturing, the quantity and value of products shipped, materials consumed, and even capital expenditures. Marketers can use the data to determine if categories are growing or not and thus discover new opportunities. Data will also aid in determining where particular industries are clustered.

The NAICS Association, a private company that markets NAICS-related information, lists four key questions that can be answered using their data:

- Who are potential customers?
- What industries should be targeted?
- How are lists of potential customers obtained?
- What are the NAICS or SIC codes of customers?

Manuals of NAICS information released by the U.S. government are available and include alphabetized lists of NAICS and codes. Data is also available on CD-ROM format for ease of database referencing.

O

O*NET

OCCUPATIONAL INFORMATION NETWORK

O*NET, or the Occupational Information Network, is an electronic replacement for the *Dictionary of Occupational Titles* (DOT). Like the DOT, which was last published in 1991, O*NET provides a comprehensive database of worker attributes and job characteristics. By describing the tasks to be performed and the levels of education that must be achieved, the O*NET database can be used as a tool for training and education, career guidance, employment counseling, and for writing job descriptions.

The U.S. Department of Labor developed the DOT in the mid-1930s, soon after the federal-state employment service system was established. O*NET was also developed by and is supported by the U.S. Department of Labor. The main difference between the DOT and the O*NET database is the flexibility of the new database and its depth of information. Rather than having information for 12,000 occupations, as the DOT did, the O*NET database has 974 occupations which are related to a common framework describing job requirements and worker characteristics, the content, and the context of work. A second difference between the DOT and the O*NET database is that O*NET can be updated more frequently; the Department of Labor uses a data collec-

tion program that provides for an update to the database twice annually. The most recent update was in December 2004. Additionally, there is now a Spanish-language version of the O*NET database available.

O*NET USES

O*NET can be used by many different people for a variety of reasons. Some of the uses for managers are:

- Writing and updating job descriptions and job specifications
- Developing criteria for recruitment and selection
- Developing criteria for performance appraisal systems
- Structuring training and development activities
- Structuring compensation systems
- Improving career counseling

O*NET DEVELOPMENT: COMMON LANGUAGE AND THE CONTENT MODEL

The O*NET database provides a common language that can be used to communicate in different areas of the economy and in workforce development efforts. This common language provides definitions and concepts for describing worker attributes and workplace requirements that can be widely understood and accepted. Knowledge, skills, and abilities (KSAs), interests, content, and context of work are described in comprehensive terms, and there is a common frame of reference in O*NET for understanding how these characteristics relate to successful job performance. O*NET's common language is intended to

aid those who communicate about jobs in understanding one another, even when operating in different segments of the economy. The goal is for job descriptions and worker requirements to have the same meaning for human resource professionals, employees, educators, and students.

The conceptual foundation of the O*NET database is the Content Model; it provides a framework that identifies the most important types of information about work, integrating them into one system. Information in the model reflects both the character of occupations and of people, and it allows for information to be applied across jobs, sectors, or industries and within occupations. The Content Model was developed using research on job and organizational analysis, and thus has a strong theoretical and empirical foundation.

The Content Model has six domains:

1. Worker Characteristics—enduring characteristics that might influence job performance and the ability to acquire knowledge and skills used for effective work performance; this includes abilities, interests, values, and work styles.

2. Worker Requirements—work-related attributes gained and/or developed through a worker's education or experience; this includes knowledge, experience, and skills (basic skills and cross-functional skills).

3. Experience Requirements—previous activities, linked specifically to certain types of work activities that are required for effective job performance; this includes formal education, certifications, licensures, and training.

4. Occupational Characteristics—global contextual characteristics that define and describe occupations and that may influence requirements for that occupation.

5. Occupational Requirements—detailed information regarding typical activities required in various occupations; generalized work activities (GWAs), or dimensions that summarize the kinds of tasks that may be performed within a single occupation are identified; additionally, information about the context, such as physical and social elements of the work, that may create specific demands on the worker are included.

6. Occupation-Specific Information—elements that apply only to a single occupation or a narrowly defined job family; this domain provides related information available in other areas of the Content Model, but is used when developing specific applications of O*NET information, such as writing a job description.

The O*NET—SOC taxonomy provides the background information for defining different classes of occupations. The information contained in the O*NET—SOC taxonomy is updated every two years with statistics derived from surveys conducted on serving employees. The 2006 update raised the number of occupations to 812.

The U.S. State Department, in conjunction with the National O*NET Center, are introducing translated versions of O*NET to give better access to populations, that do not speak English very well. For example, the U.S. State Department has released the Spanish O*NET 4.0 Database, a translated version that is designed to enable predominantly-Spanish speaking members of the population of the United States to access the latest career information in the country.

OPEN AND CLOSED SYSTEMS

A system is commonly defined as a group of interacting units or elements that have a common purpose. The units or elements of a system can be cogs, wires, people, computers, and so on. Systems are generally classified as open systems and closed systems and they can take the form of mechanical, biological, or social systems.

Open systems refer to systems that interact with other systems or the outside environment, whereas closed systems refer to systems having relatively little interaction with other systems or the outside environment. For example, living organisms are considered open systems because they take in substances from their environment, such as food and air and return other substances to their environment. Humans, for example, inhale oxygen out of the environment and

exhale carbon dioxide into the environment. Similarly, some organizations consume raw materials in the production of products and emit finished goods and pollution as a result. In contrast, a watch is an example of a closed system in that it is a relatively self-contained, self-maintaining unit that has little interaction or exchange with its environment.

All systems have boundaries, a fact that is immediately apparent in mechanical systems such as the watch, but much less apparent in social systems such as organizations. The boundaries of open systems, because they interact with other systems or environments, are more flexible than those of closed systems, which are rigid, and largely impenetrable.

A closed system perspective views organizations as relatively independent of environmental influences. The closed systems approach conceives of the organization as a system of management, technology, personnel, equipment, and materials, but tends to exclude competitors, suppliers, distributors, and governmental regulators. This approach allows managers and organizational theorists to analyze problems by examining the internal structure of a business with little consideration of the external environment.

The closed-system perspective basically views an organization much as a thermostat; limited environmental input outside of changes in temperature is required for effective operation. Once set, thermostats require little maintenance in their ongoing, self-reinforcing function. While the closed-system perspective was dominant through the 1960s, organization scholarship and research subsequently emphasized the role of the environment. Up through the 1960s, it was not that managers ignored the outside environment such as other organizations, markets, government regulations, and the like, but that their strategies and other decision-making processes gave relatively little consideration to the impact these external forces might have on the internal operations of the organization.

Open systems theory originated in the natural sciences and subsequently spread to fields as diverse as computer science, ecology, engineering, management, and psychotherapy. In contrast to closed systems, the open system perspective views an organization as an entity that takes inputs from the environment, transforms them, and releases them as outputs in tandem with reciprocal effects on the organization itself along with the environment in which the organization operates. That is, the organization becomes part and parcel of the environment in which it is situated and initiates feedback mechanisms to the results achieved by the outputs of the organization on the environment.

As an open-systems approach spread among organizational theorists, managers began incorporating these views into practice. Two early pioneers in this effort, Daniel Katz and Robert Kahn, began viewing organizations as open social systems with specialized and interdependent subsystems and processes of communication, feedback, and management linking the subsystems. Katz and Kahn argued that the closed systems approach fails to take into account how organizations are reciprocally dependent on external environments. For example, environmental forces such as customers and competitors exert considerable influence on corporations, highlighting the essential relationship between an organization and its environment as well as the importance of maintaining external inputs to achieve a stable organization.

Furthermore, the open systems approach serves as a model of business activity; that is, business as a process of transforming inputs to outputs while realizing that inputs are taken from the external environment and outputs are placed into this same environment. Companies use inputs such as labor, funds, equipment, and materials to produce goods or to provide services, and they design their subsystems to attain these goals. These subsystems are thus analogous to cells in the body, the organization itself is analogous to the body, and external market and regulatory conditions are analogous to environmental factors such as the quality of housing, drinking water, air, and availability of nourishment.

The production subsystem, for example, focuses on converting inputs into marketable outputs and often constitutes a primary purpose of a company. The boundary subsystem's goal is to obtain inputs or resources, such as employees, materials, equipment, and so forth, from the environment outside of the company, which are necessary for the production subsystem. This subsystem also is responsible for providing an organization with information about the environment. This adaptive subsystem collects and processes information about a company's operations with the goal of aiding the company's adaptation to external conditions in its environment. Another subsystem, management, supervises and coordinates the other subsystems to ensure that each subsystem functions efficiently. The management subsystem must resolve conflicts, solve problems, and allocate resources, and so on.

To simplify the process of evaluating environmental influences, some organizational theorists use the term "task environment" to refer to aspects of the environment that are immediately relevant to management decisions related to goal setting and goal realization. The task environment includes customers, suppliers, competitors, employees, and regulatory bodies. Furthermore, in contrast to closed-systems, the open-system perspective does not assume that the environment is static. Instead, change is the rule rather than the exception. Consequently, investigation of environmental stability and propensity to change is a key task of a company, making the activities of an organization contingent on various environmental forces.

As an open system, an organization maintains its stability through feedback, which refers to information about outputs that a system obtains as an input from its task environment. The feedback can be positive or negative and can lead to changes in the way an organization transforms inputs to outputs. Collier and Agyei-Ampomah point out that feedback data enable open system organizations to determine the impact of their inputs in the environment and the subsequent action for either maintaining positive impacts or correcting negative impacts.

The difference between closed systems and open systems, then, lies in the complexity of environmental interactions. Closed systems exhibit minimal interaction with the environment because of their tightly guarded and relatively impenetrable boundaries. Consequently, very little information exchange takes place between the organization and the environment in closed systems, a situation that denies management the opportunity to receive feedback from the environment. Moreover, closed systems are generally static and do not provide room for multiple alternatives for accomplishing the same result.

Conversely, open systems such as the human body and modern organizations are more intricately dependent on their environments. Organizations that observe open systems management design their operational strategies along the principles of continuous information exchange, continuous target market evaluation, and multiplicity of alternatives for achieving the same goal. The point is that closed systems and open systems represent a continuum along which organizations are more open or less open to their environments. The key defining variable governing this degree of openness is the complexity of the environment in which the organization is situated.

Managers must take into consideration their organization's position along the open-closed continuum. The Linux computer operating system, for instance, is opensource, and Red Hat, Inc., the corporation selling the bundled revisions—the multiple inputs from geographically dispersed users—represents an organization that would cease to exist if it were not for an open systems perspective. Thus, stable environments with low complexity are more consistent with a relatively closed system or mechanistic management style, while rapidly-changing environments are more consistent with flexible, decentralized, or "organic" management styles.

OPERANT CONDITIONING

Simply put, operant conditioning refers to a systematic program of rewards and punishments to influence behavior or bring about desired behavior. Operant conditioning relies on two basic assumptions about human experience and psychology: (1) a particular act results in an experience that is a consequence of that act, and (2) the perceived quality of an act's consequence affects future behavior. In addition, a central idea of operant conditioning holds that the main influences on behavior are external— that is, it is in a person's external environment that his or her behavior is programmed.

The Harvard psychologist B.F. Skinner pioneered the field of behaviorism in the late 1930s and continued to contribute to it through the mid-1970s. Operant conditioning is one of the key concepts of this school of psychology. Skinner called his brand of conditioning "operant conditioning" to distinguish it from the conditioning theory developed by the Russian physiologist Ivan Pavlov, now referred to as "classical conditioning." Classical conditioning primarily concerned itself with reflexive or unlearned behavior, such as the jerking of a knee upon being tapped with a hammer. In a famous experiment, Pavlov training dogs to salivate in expectation of food at the sound of a bell. Operant conditioning, however, deals with learned, not reflexive behavior; it works by reinforcing (rewarding) and punishing behavior based on the consequences it produces. Reinforcement is used to increase the probability that behavior will occur in the future, whereas punishment aims to decrease that probability. In addition, the process of removing reinforcement from an act is called *extinction*.

Organizational management literature often refers to operant conditioning as part of reinforcement theory and work behavior modification. Unlike other theories of management and motivation, operant conditioning does not rely on attitudes, beliefs, intentions, and motivation for predicting and influencing behavior, although Skinner

and other behaviorists do not suggest that these factors do not exist. Instead, they posit that these notions find their genesis in external conditions and reinforcement. Hence, organizational management theorists who adopt this approach look to external factors—the environment—to explain and influence behavior within the work place. For example, this approach to management views motivation as a product of workers' environments, not as an internal quality of each individual worker's psychological makeup. Therefore, employees are highly motivated whenever quality is reinforced with pay raises, promotions, and other conditions that employees find desirable.

Since most of the behavior taking place in a business is learned rather than reflexive, operant conditioning can be applied to organizational management. Workers learn various kinds of behavior before and after joining a company, and they encounter a host of stimuli in a company setting that can cause them to behave in certain ways with certain consequences. These kinds of behaviors are rewarded and punished depending on their value to a company. The stimuli in the workplace include schedules, corporate structures, company policies, telephone calls, managers, and so on. The consequences of workplace behavior include approval or disapproval from managers and coworkers, promotions, demotions, pay increases, and so forth. When consequences are directly linked to certain kinds of behavior, they are contingent on these kinds of behavior. The classic example is touching a hot stove and experiencing the immediate consequence of being burned.

However, most consequences in a company are only partially contingent on the behavior (performance) of employees, and thus there are often entire networks of relationships between employee behavior and its consequences. These relationships are called *schedules of reinforcement*, and applying operant conditioning to the work place means controlling these schedules.

Reinforcement schedules are either continuous or intermittent (partial). Continuous reinforcement schedules are those situations in which every occurrence of an act is reinforced. In contrast, intermittent schedules are those situations in which only some instances of an act are reinforced. Continuous reinforcement schedules generally facilitate new learning or the acquisition of new skills at the fastest rate. New employees learning how to process customer orders, for example, will learn the proper procedure the fastest if they are reinforced every time they take an order correctly. However, if a continuous schedule is suspended outright after being implemented for any substantial period, the behavior being reinforced might stop altogether. In addition, after a certain kind of behavior has been learned, it will occur more often if reinforced intermittently. Hence, employees who have learned the proper procedure for taking customer orders have the greatest likelihood of continuing to do so correctly if

managers adopt an intermittent schedule after the behavior has been learned.

Moreover, reinforcement can be positive (adding something new, such as a raise or a promotion) or negative (the removal of something from the work environment, such as constant supervision) after new employees demonstrate they have sufficiently learned their jobs. Negative reinforcement, however, should not be confused with punishment, which involves undesirable or aversive consequences and decreases the probability of an act being repeated. Negative reinforcement, rather, is a kind of a reward that removes constraints or other elements from the work environment to encourage employee behavior.

As Nelson and Quick reckon reward systems should have corresponding strategic significance to the organization. Strategically designed reward systems enable organizations to achieve the objectives of motivating behavior and encouraging further accomplishments among employees while advancing the core objectives of the organization at the same time. Managers who adopt a strategic approach in their positive reinforcement actions present employees with rewards that have long–term implications (such as training, educational programs, and awards that demonstrate recognition of achievements made by employees). For example, Marriott International annually honors its best twenty employees with the J. Willard Marriot Award of Excellence.

Organizational behavior modification (OBM) is the most common mode of operant conditioning that is practiced by many organizations because of its relevance to organizational management and wide ranging options for implementation. Social, nonfinancial, and financial reinforcements are the key pillars of the OBM concept. According to Nelson and Quick, a comprehensive review of past research on the impact of OBM in organizations revealed that the concept registered improved performance in organizations in the service and manufacturing sectors that adopted OBM. The review also revealed that monetary-based reinforcement impacted positively on performance more than other forms of rewards and recognition.

Because some behavior is so complex that it does not occur all at once, managers must reinforce progressive approximations of the desired behavior. This process begins with the reinforcement of behavior that may barely resemble the desired behavior, using a continuous reinforcement schedule with a progressive standard. Consequently, behavior must show improvement or greater approximation of the desired behavior to receive reinforcement as time goes on.

When managers wish to discourage certain kinds of behavior or decrease the probability of their occurrence, they can implement a schedule of punishment along the lines of a schedule of reinforcement. Punishment involves

the application of undesirable consequences or the removal of positive consequences following undesired behavior. However, negative consequences must be meted out with consideration of how it will affect individual workers, because what constitutes punishment for one worker may not for another. Ultimately, these consequences or stimuli must be linked to the undesired behavior and decrease the probability of it reoccurring in order for them to constitute punishment in the technical sense of the operant conditioning approach. Moreover, effective punishment usually embodies the following qualities: it is consistent, immediate, impersonal, and contingent on specific behavior. Finally, punishment should be informative— letting employees know why they are being punished— and employees should recognize that future punishment can be avoided by refraining from the undesired behavior.

Operant conditioning has been successfully applied in many settings: clinical, for individual behavior modification, teaching, for classroom management, instructional development, for programmed instruction, and management, for organizational behavior modification.

OPERATING SYSTEMS

A computer's operating system is one of the most important "parts" of the computer. Almost every type of computer— including mobile telephones, video game systems, E-book readers, and DVRs—needs an operating system in order to operate properly. When one turns on a computer, the operating system tells the computer what to do by controlling the system resources such as the processor, memory, disk space, etc. The operating system allows the user to work on the computer without having to know all the details about how the hardware works.

When choosing an operating system for a business, the primary considerations should be the hardware platform used, the number of users and attendant system security requirements, the ease of administration, the adaptability toward different uses, and the different applications that will be employed.

WHAT OPERATING SYSTEMS DO

One of the operating system's main tasks is to control the computer's resources—both the hardware and the software. The operating system allocates resources as necessary to ensure that each application receives the appropriate amount. In addition to resource allocation, operating systems provide a consistent application interface so that all applications use the hardware in the same way. This is particularly important if more than one type of computer uses the operating system or if the computer's hardware is likely to change. By having a consistent application program interface (API), software written on one computer can run on other types of computers. Developers face the challenge of keeping the operating system flexible enough to control hardware from the thousands of different computer manufacturers.

Operating systems must accomplish the following tasks:

1. Processor management. The operating system needs to allocate enough of the processor's time to each process and application so that they can run as efficiently as possible. This is particularly important for multitasking. When the user has multiple applications and processes running, it is up to the operating system to ensure that they have enough resources to run properly.

2. Memory storage and management. The operating system needs to ensure that each process has enough memory to execute the process, while also ensuring that one process does not use the memory allocated to another process. This must also be done in the most efficient manner. A computer has four general types of memory. In order of speed, they are: high-speed cache, main memory, secondary memory, and disk storage. The operating system must balance the needs of each process with the different types of memory available.

3. Device management. Most computers have additional hardware, such as printers and scanners, connected to them. These devices require drivers, or special programs that translate the electrical signals sent from the operating system or application program to the hardware device. The operating system manages the input to and output from the computer. It often assigns high-priority blocks to drivers so that the hardware can be released and available for the next use as soon as possible.

4. Application interface. Programmers use application program interfaces (APIs) to control the computer and operating system. As software developers write applications, they can insert these API functions in their programs. As the operating system encounters these API functions, it takes the desired action, so the programmer does not need to know the details of controlling the hardware.

5. User interface. The user interface sits as a layer above the operating system. It is the part of the application through which the user interacts with the application. Some operating systems, such as Microsoft Windows and Apple Macintosh, use graphical user interfaces. Other operating systems, such as Unix, use shells.

TYPES OF OPERATING SYSTEMS

Most simple, single-function computers (such as in microwave ovens with digital keypads) do not require an operating system. In fact, trying to implement an operating system in these computers would be overkill. On the other hand, all personal desktop and laptop computers and servers do require an operating system. While there are hundreds of operating systems available, the most popular by far are the Microsoft Windows family of operating systems, the Macintosh operating system, and the Unix family of operating systems.

There are four general types of operating systems. Their use depends on the type of computer and the type of applications that will be run on those computers.

1. Real-time operating systems (RTOS) are used to control machinery, scientific instruments, and industrial systems. In general, the user does not have much control over the functions performed by RTOS.

2. Single-user, single-task operating systems allow one user to do one thing at a time. An example of a single-user, single-task operating system is the operating system used by personal digital assistants (PDAs), also known as handheld computers.

3. Single-user, multi-tasking operating systems allow a single user to simultaneously run multiple applica-

tions on their computer. This is the type of operating system found on most personal desktop and laptop computers. Microsoft Windows, Mac OS, and Linux are three well-known examples of this type of system.

4. Multi-user operating systems allow multiple users to simultaneously use the resources on a single computer. Unix is an example of a multi-user operating system.

AVAILABLE OPERATING SYSTEMS

The most popular and widely-known operating system is Windows, a family of operating systems introduced by the Microsoft Corporation in 1985. Windows employs a graphical user interface (GUI), which eliminates the need for the user to learn complex commands. With a GUI, the user instructs the operating system by using a mouse to point and click icons that are displayed on the screen. The first version of Windows, released in November 1985, was designed as a GUI add-on for MS-DOS (short for Microsoft Disk Operating System), Microsoft's original command-line operating system. In order to communicate with the computer, DOS users had to type commands or instructions at a command prompt, and then the command-line interpreter executed those commands. DOS has limited use with modern computer systems and applications because it does not support multiple users or multitasking. It is also not as "user friendly" as a GUI operating system. By the late-1990s, most command-line operating systems had been replaced by user-friendly systems using a GUI.

By the time Windows 3.1 was released in 1991, Windows had gained significantly in market share, and from the mid-1990s on, Microsoft dominated the operating-system market. Microsoft released Windows 95 in August 1995. It was so well marketed and in such high demand that people bought the operating system even if they did not own a home computer. With each new release, from Windows 98 to Windows 2000 to Windows XP to Windows Vista, Microsoft gained popularity. By 2004, Microsoft commanded around 90 percent of the operating-system market. The latest Windows release, Windows Vista, was introduced worldwide in January 2007, five years after the introduction of its predecessor, Windows XP—the longest time between releases of Windows. Vista is only slowly gaining in popularity, while Windows XP remains the world's dominant operating system, commanding 79 percent market share in September 2007 (compared to only 7 percent for Vista).

The second-most popular family of operating systems is the Mac OS. Macintosh is often credited with introducing the GUI-style operating system; Mac OS was not the first graphical user interface, but it was the

first successful one, largely because competitors were so expensive—the Xerox Alto, the first true GUI system, cost $32,000 to build while the Macintosh retailed for $2,500. Because of its relative affordability, it immediately became much more popular than other GUI computers. The first Mac OS, unnamed at the time but now known as "System 1," was introduced in 1984. It had a desktop, windows, icons, a mouse, menus, and scrollbars.

Early versions of the Mac OS could only be used on Apple computers. In 1991, Apple introduced computers with PowerPC hardware; these computers could run either Windows or Mac OS. The latest version of the Mac OS, OS X, was first introduced in 2000. It can be used in computers with both PowerPC and Intel processors, giving it wider applicability and use. However, the Mac OS lags far behind Microsoft Windows. In 2007, it was the world's third-most popular operating system—after Windows XP and Windows Vista—but it commanded only slightly over 3 percent of the operating-system market.

UNIX is a multi-user, multitasking operating system, and was designed to be a small, flexible system used by computer programmers. UNIX is not considered to be very user-friendly for the average person due to its design. However, graphical user interfaces have been developed for UNIX to help alleviate the ease-of-use issue.

Linux is a UNIX variant that runs on several different hardware platforms. Linus Torvalds, a student at the University of Helsinki in Finland, initially created it as a hobby. The kernel, at the heart of all Linux systems, is developed and released under the General Public License (GNU), and its source code is freely available to everyone. There are now hundreds of companies, organizations, and individuals that have released their own versions of operating systems based on the Linux kernel.

Because of its functionality, adaptability, and robustness, Linux is able to compete against the Unix and Microsoft operating systems. IBM, Hewlett-Packard, and other computer giants have embraced Linux and support its ongoing development. More than a decade after its initial release, Linux is being adopted worldwide mainly as a server platform. More and more people are starting to use Linux as a home and office desktop operating system. The operating system can also be incorporated directly into microchips in a process called "embedding." Many appliances and devices are now starting to use operating systems in this way.

OPERATIONS MANAGEMENT

Operations management is the planning, scheduling, and control of the activities that transform inputs (raw materials and labor) into outputs (finished goods and services). Along with marketing and finance, it is one of the three main areas of any business. Operations management is also an academic field of study that focuses on the effective planning, scheduling, use, and control of a manufacturing or service firm and their operations. Operations management is concerned with the efficiency and effectiveness of a firm's operation in support and development of the firm's strategic goals. Other areas of concern to operations management include the design and operations of systems to provide goods and services.

Operations management is a broad framework that includes a set of recognized and well-developed concepts, tools, and techniques. While the term operations management conjures up views of manufacturing environments, many of these concepts have been applied in service settings, with some of them actually developed specifically for service organizations. The field is a synthesis of concepts derived from design and industrial engineering, management information systems, quality, production, and inventory management, accounting, and other functions.

HISTORY OF OPERATIONS MANAGEMENT

During the early Industrial Revolution, manufacturing was often more of an art than a science. This changed with the development of Frederick W. Taylor's method of scientific management and Henry Ford's moving assembly line. These innovations brought the world into an age where management was predominantly centered on the production of goods. In the late 1950s and early 1960s scholars moved from writing about industrial engineering and operations research into writing about production management. Production management had itself become a professional field as well as an academic discipline. As the U.S. economy evolved into a service economy and operations techniques began to be incorporated into

services, the term *production/operations management* came into use. Today, services are such a pervasive part of our life that the term *operations management* is used almost exclusively.

The field of operations management has been gaining increased recognition over the last two decades. One major reason for this is public awareness of the success of Japanese manufacturers and the perception that the quality of many Japanese products is superior to that of American manufacturers. As a result, many businesses have come to realize that the operations function is just as important to their firm as finance and marketing. In concert with this, firms now realize that in order to compete effectively in the global market, they must have an operations strategy to support the mission of the firm and its overall corporate strategy.

Another reason for greater awareness of operations management is the increased application of operations management concepts and techniques to service operations. Finally, operations management concepts are being applied to other functional areas such as marketing and human resources. The term *marketing/operations interface* is often used in twenty-first century management discussions.

WHAT OPERATIONS MANAGERS DO

While operations management may sound like it focuses solely on the mechanics of production, operations managers must actually answer questions on three different levels: the strategic level, the tactical level, and the operational level.

Strategic Level. At the strategic level (long term), operations managers are responsible for or associated with making decisions in four key areas:

- Product development—what shall we make?

- Process and layout decisions—how shall we make it?

- Site location—where will we make it?

- Capacity—how much do we need?

Tactical Level. At the tactical level (intermediate term), operations management addresses the issues relevant to efficiently scheduling material and labor within the constraints of the firm's strategy and making aggregate planning decisions. Operations managers have a hand in deciding employee levels (How many workers do we need and when do we need them?), inventory levels (When should we have materials delivered and should we use a chase strategy or a level strategy?), and capacity (How many shifts do we need and do we need to work overtime or subcontract some work?).

Operational Level. At the operational level, operations management is concerned with lower-level (daily/weekly/monthly) planning and control. Operations managers and their subordinates must make decisions regarding scheduling (What should we process and when should we process it?), sequencing (In what sequence should we process the orders?), loading (What order do we put an item on what machine?), and work assignments (To whom do we assign individual machines or processes?).

A MULTI-FACETED FIELD

Originally, operations managers required only knowledge about productive processes. Today's operations managers must not only have knowledge of advanced operations technology and technical knowledge relevant to their industry, they must also possess interpersonal skills as well as know about other functional areas within the firm. Operations managers must have the ability to manage projects, work on multidisciplinary teams, communicate effectively, and motivate other people. The authors of *Managing Business Process Flows* (2008) describe the scope of operations management as encompassing these multidisciplinary areas:

- Supply Chains—management of all aspects of providing goods to a consumer from extraction of raw materials to end-of-life disposal.

- Operations Management/Marketing Interface—determining what customers value prior to product development.

- Operations Management/Finance Interface—capital equipment and inventories comprise a sizable portion of many firms' assets.

- Service Operations—coping with inherent service characteristics such as simultaneous delivery/consumption, performance measurements, etc.

- Operations Strategy—consistent and aligned with firm's other functional strategies.

- Process Design and Improvements—managing the innovation process.

The authors of *Fundamentals of Operations Management* suggested that the following issues are the major issues for operations management today:

- Reducing the development and manufacturing time for new goods and services

- Achieving and sustaining high quality while controlling cost

- Integrating new technologies and control systems into existing processes

- Obtaining, training, and keeping qualified workers and managers

- Working effectively with other functions of the business to accomplish the goals of the firm

- Integrating production and service activities at multiple sites in decentralized organizations

- Working effectively with suppliers at being user-friendly for customers

- Working effectively with new partners formed by strategic alliances

All of the areas encompassed by operations management are critical to any firm no matter the industry or sector. No longer is operations management considered subservient to marketing and finance; rather, it is a legitimate functional area within most organizations. Also, operations management can no longer focus on isolated tasks and processes but must be one of the architects of the firm's overall business model. The importance of these concerns can be seen in the rise and popularity of various operations doctrines, from Six Sigma and lean manufacturing to total quality management.

OPERATIONS SCHEDULING

Scheduling pertains to establishing both the timing and use of resources within an organization. Under the operations function (both manufacturing and services), sched-

uling relates to use of equipment and facilities, the scheduling of human activities, and receipt of materials.

While issues relating to facility location and plant and equipment acquisition are considered long-term and aggregate planning is considered intermediate term, operations scheduling is considered to be a short-term issue. As such, in the decision-making hierarchy, scheduling is usually the final step in the transformation process before the actual output (e.g., finished goods) is produced. Consequently, scheduling decisions are made within the constraints established by these longer-term decisions. Generally, scheduling objectives deals with tradeoffs among conflicting goals for efficient utilization of labor and equipment, lead time, inventory levels, and processing times.

There are two general approaches to scheduling: forward scheduling and backward scheduling. As long as the concepts are applied properly, the choice of methods is not significant. In fact, if process lead times (move, queue, and setup times) add to the job lead time and process time is assumed to occur at the end of process time, then forward scheduling and backward scheduling yield the same result. With forward scheduling, the scheduler selects a planned order release date and schedules all activities from this point forward in time.

With backward scheduling, the scheduler begins with a planned receipt date or due date and moves backward in time, according to the required processing times, until he or she reaches the point where the order will be released.

Of course there are variables to consider other than due dates or shipping dates. Other factors that directly impact the scheduling process include: the types of jobs to be processed and the different resources that can process each, process routings, processing times, setup times, changeover times, resource availability, number of shifts, downtime, and planned maintenance.

LOADING

Loading involves assigning jobs to work centers and to various machines in the work centers. If a job can be processed on only one machine, no difficulty is presented. However, if a job can be loaded on multiple work centers or machines, and there are multiple jobs to process, the assignment process becomes more complicated. The scheduler needs some way to assign jobs to the centers in such a way that processing and setups are minimized along with idle time and throughput time.

Two approaches are used for loading work centers: infinite loading and finite loading. With infinite loading, jobs are assigned to work centers without regard for capacity of the work center. Priority rules are appropriate for use under the infinite loading approach. Jobs are

loaded at work centers according to the chosen priority rule. This is known as vertical loading.

Finite loading projects the actual start and stop times of each job at each work center. Finite loading considers the capacity of each work center and compares the processing time so that process time does not exceed capacity. With finite loading, the scheduler loads the job that has the highest priority on all work centers it will require. Then the job with the next highest priority is loaded on all required work centers, and so on. This process is referred to as horizontal loading. The scheduler using finite loading can then project the number of hours each work center will operate. A drawback of horizontal loading is that jobs may be kept waiting at a work center, even though the work center is idle. This happens when a higher priority job is expected to arrive shortly. The work center is kept idle so that it will be ready to process the higher priority job as soon as it arrives. With vertical loading the work center would be fully loaded. Of course, this would mean that a higher priority job would then have to wait to be processed since the work center was already busy. The scheduler will have to weigh the relative costs of keeping higher priority jobs waiting, the cost of idle work centers, the number of jobs and work centers, and the potential for disruptions, new jobs, and cancellations.

If the firm has limited capacity (e.g., already running three shifts), finite loading would be appropriate since it reflects an upper limit on capacity. If infinite loading is used, capacity may have to be increased through overtime, subcontracting, or expansion or work may have to be shifted to other periods or machines.

SEQUENCING

Sequencing is concerned with determining the order in which jobs are processed. Not only must the order be determined for processing jobs at work centers, but also for work processed at individual work stations. When work centers are heavily loaded and lengthy jobs are involved, the situation can become complicated. The order of processing can be crucial when it comes to the cost of waiting to be processed and the cost of idle time at work centers.

There are a number of priority rules or heuristics that can be used to select the order of jobs waiting for processing. Some well-known ones are presented in a list adapted from Vollmann, Berry, Whybark, and Jacobs:

- Random (R). Pick any job in the queue with equal probability. This rule is often used as a benchmark for other rules.

- First come/first served (FC/FS). This rule is sometimes deemed to be fair since jobs are processed in the order in which they arrive.

- Shortest processing time (SPT). The job with the shortest processing time requirement goes first. This rule tends to reduce work-in-process inventory, average throughput time, and average job lateness.

- Earliest due date (EDD). The job with the earliest due date goes first. This seems to work well if the firm performance is judged by job lateness.

- Critical ratio (CR). To use this rule, one must calculate a priority index using the formula (due date − now)/(lead time remaining). This rule is widely used in practice.

- Least work remaining (LWR). An extension of SPT, this rule dictates that work be scheduled according to the processing time remaining before the job is considered to be complete. The less work remaining in a job, the earlier it is in the production schedule.

- Fewest operations remaining (FOR). This rule is another variant of SPT; it sequences jobs based on the number of successive operations remaining until the job is considered complete. The fewer operations that remain, the earlier the job is scheduled.

- Slack time (ST). This rule is a variant of EDD; it utilizes a variable known as slack. Slack is computed by subtracting the sum of setup and processing times from the time remaining until the job's due date. Jobs are run in order of the smallest amount of slack.

- Slack time per operation (ST/O). This is a variant of ST. The slack time is divided by the number of operations remaining until the job is complete with the smallest values being scheduled first.

- Next queue (NQ). NQ is based on machine utilization. The idea is to consider queues (waiting lines) at each of the succeeding work centers at which the jobs will go. One then selects the job for processing that is going to the smallest queue, measured either in hours or jobs.

- Least setup (LSU). This rule maximizes utilization. The process calls for scheduling first the job that minimizes changeover time on a given machine.

These rules assume that setup time and setup cost is independent of the processing sequence. However, this is not always the case. Jobs that require similar setups can reduce setup times if sequenced back to back. In addition to this assumption, the priority rules also assume that setup time and processing times are deterministic and not variable, there will be no interruptions in processing, the set of jobs is known, no new jobs arrive after processing begins, and no jobs are canceled. While little of this is true in practice, it does make the scheduling problem manageable.

GANTT CHARTS

Gantt charts are named for Henry Gantt, a management pioneer of the early twentieth century. He proposed the use of a visual aid for loading and scheduling. Appropriately, this visual aid is known as a Gantt chart. This Gantt chart is used to organize and clarify actual or intended use of resources within a time framework. Generally, time is represented horizontally with scheduled resources listed vertically. Managers are able to use the Gantt chart to make trial-and-error schedules to get some sense of the impact of different arrangements.

There are a number of different types of Gantt charts, but the most common ones, and the ones most appropriate to our discussion, are the load chart and schedule chart. A load chart displays the loading and idle times for machines or departments; this shows when certain jobs are scheduled to start and finish and where idle time can be expected. This can help the scheduler redo loading assignments for better utilization of the work centers. A schedule chart is used to monitor job progress. On this type of Gantt chart, the vertical axis shows the orders or jobs in progress while the horizontal axis represents time. A quick glance at the chart reveals which jobs are on schedule and which jobs are on time.

Gantt charts are the most widely used scheduling tools. However, they do have some limitations. The chart must be repeatedly updated to keep it current. Also, the chart does not directly reveal costs of alternate loadings nor does it consider that processing times may vary among work centers.

SCHEDULING SERVICE OPERATIONS

The scheduling of services often encounters problems not seen in manufacturing. Much of this is due to the nature of service (i.e., the intangibility of services and the inability to inventory or store services and the fact that demands for services are usually random.) Random demand makes the scheduling of labor extremely difficult as seen in restaurants, movie theaters, and amusement parks. Since customers do not like to wait, labor must be scheduled so that customer wait is minimized. This sometimes requires the use of queuing theory or waiting-line theory. Queuing theory uses estimate arrival rates and service rates to calculate an optimum staffing plan. In addition, flexibility can often be built into the service operation through the use of casual labor, on-call employees, and cross-training.

Scheduling of services can also be complicated when it is necessary to coordinate and schedule more than one resource. For example, when hospitals schedule surgery, not only is the scheduling of surgeons involved but also the scheduling of operating room facilities, support staff, and special equipment. Along with the scheduling of classes, universities must also schedule faculty, classrooms, labs, audiovisual and computer equipment, and students. To further complicate matters, cancellations are also common and can add further disruption and confusion to the scheduling process.

Instead of scheduling labor, service firms frequently try to facilitate their service operations by scheduling demand. This is done through the use of appointment systems and reservations. This trend is particularly evident in service companies such as airlines and hotels which have adopted the increased use of electronic reservations systems to register demand, track cancellations and determine the supply of services. Advance reservations systems enable companies to significantly reduce random demand, customer wait times, and difficulties in scheduling of labor.

The increased use of electronic reservation systems by businesses has prompted governments and regional bodies around the world to respond by reviewing regulations that govern computerized reservations. In 2008 the Transport Committee of the European Union Parliament offered its full support to proposals by the European Union Commission to replace the old rules that govern Computerized Reservations Systems with new ones. This move was geared towards modernizing regulations and optimizing opportunities for air travel companies and agencies operating within European Union member countries.

Therefore, it is important for managers to pursue technological options when seeking remedies for different problems and difficulties that characterize operations scheduling. In fact, the use of technological alternatives—including software applications and electronic scheduling of services—reduce the levels of labor intensity of operations to the advantage of the company.

Robert Bylett suggests that the use of operations checklist is an effective system for ensuring that all the activities of a business organization are run according to planned sequence and set limits. For example, an operations checklist in a restaurant business facilitates the identification of daily activities, general activities, and special events of the restaurant. Subsequently, it enables employees to execute assigned duties according to the set guidelines, thereby eliminating probabilities of customer delays or wastage of resources.

OPERATIONS STRATEGY

After collectively considering the products and services demanded by customers, strengths and weaknesses of competitors, the environment, and the firm's own strengths, weaknesses, cultures, and resources, proficient firms can formulate their vision as expressed through the mission statement. This statement expresses the organization's values and aspirations; basically its reason or purpose for existence. Based on this mission statement the firm will formulate its business strategy. This business strategy is a long-term plan for accomplishing the mission set forth in the mission statement. Each function within the business can then derive its own strategy in support of the firm's overall business strategy (financial strategy, marketing strategy, and operations strategy).

Operations strategy is the collective concrete actions chosen, mandated, or stimulated by corporate strategy. It is, of course, implemented within the operations function. This operations strategy binds the various operations decisions and actions into a cohesive consistent response to competitive forces by linking firm policies, programs, systems, and actions into a systematic response to the competitive priorities chosen and communicated by the corporate or business strategy. In simpler terms, the operations strategy specifies how the firm will employ its operations capabilities to support the business strategy.

Operations strategy has a long-term concern for how to best determine and develop the firm's major operations resources so that there is a high degree of compatibility between these resources and the business strategy. Very broad questions are addressed regarding how major resources should be configured in order to achieve the firm's corporate objectives. Some of the issues of relevance include long-term decisions regarding capacity, location, processes, technology, and timing.

The achievement of world-class status through operations requires that operations be integrated with the other functions at the corporate level. In broad terms, an operation has two important roles it can play in strengthening the firm's overall strategy. One option is to provide processes that give the firm a distinct advantage in the marketplace. Operations will provide a marketing edge through distinct, unique technology developments in processes that competitors cannot match.

The second role that operations can play is to provide coordinated support for the essential ways in which the firm's products win orders over their competitors, also known as distinctive competencies. The firm's operations strategy must be conducive to developing a set of policies in both process choice and infrastructure design (controls, procedures, systems, etc.) that are consistent with the firm's distinctive competency. Most firms share access to the same processes and technology, so they usually differ little in these areas. What is different is the degree to which operations matches its processes and infrastructure to its distinctive competencies.

KEY SUCCESS FACTORS

Industries have characteristics or strategic elements that affect their ability to prosper in the marketplace (i.e., attributes, resources, competencies, or capabilities). The ones that most affect a firm's competitive abilities are called key success factors (KSFs). These KSFs are actually what the firm must be competent at doing or concentrating on achieving in order to be competitively and financially successful; they could be called prerequisites for success. In order to determine their own KSFs, a firm must determine a basis for customer choice. In other words, how do customers differentiate between competitors offering the same or similar products or services and how will the firm distinguish itself from these competitors? Once this is determined, the firm has to decide what resources and competitive capabilities it needs in order to compete successfully, and what will it take to achieve a sustainable competitive advantage. These KSFs can be related to technology, operations, distribution, marketing, or to certain skills or organizational capability. For example, the firm may derive advantages from superior ability to transform material or information (technology or operations), to quickly master new technologies and bring processes online (technology or organizational capability), or to quickly design and introduce new products, service a broad range of products, customize products or services on demand, or provide short lead times (skills).

The set of KSFs that are delegated totally or substantially to the operations function has been termed the *manufacturing mission.* It represents what top management expects from operations in terms of its strategic contribution.

All decisions made relative to system design, planning, control and supervision must aim at accomplishing the manufacturing mission. As such, the manufacturing mission is the principal driver of the operations function and gives it its reason for existence. All world-class manufacturers have an explicit, formal manufacturing mission.

From the manufacturing mission the operations function derives its distinctive competencies (also called competitive priorities or competitive weapons). Distinctive competence is defined as the characteristic of a given product/service or its producing firm that causes the buyer to purchase it rather than the similar product/service of a competitor. It is generally accepted that the distinctive competencies are cost/price, quality, flexibility, and service/time. Various experts include other competencies, such as location, but these can usually be categorized within one of the generally accepted four. Some experts also feel that innovation is quickly becoming a fifth distinctive competency, if it hasn't already. It should be noted that a firm's position on the product-process matrix is a controlling factor for the manufacturing mission and the firm's competitive priority or priorities.

DISTINCTIVE COMPETENCIES

Details relative to each distinctive competency are provided, along with the implications of each and some examples.

Price/Cost. A firm competing on a price/cost basis is able to provide consumers with an in-demand product at a price that is competitively lower than that offered by firms producing the same or similar good/service. In order to compete on a price basis, the firm must be able to produce the product at a lesser cost or be willing to accept a smaller profit margin. Firms with this competency are generally in a position to mass produce the product or service, thereby giving the firm economies of scale that drive the production cost per unit down considerably. Commodity items are mass-produced at such volume that they utilize a continuous process, thus deriving tremendous economies of scale and very low prices Consumers purchasing commodity-type products are usually not greatly aware of brand difference, and will buy strictly on the basis of price; e.g., as long as it is a major brand of gasoline and location is not a factor, consumers will opt for the lowest price. Wal-Mart is able to offer low prices by accepting a lower profit margin per unit sold. Their tremendous volume more than makes up for the lower profit margin.

Quality. David Garvin lists eight dimensions of quality as follows:

- Performance. Performance refers to a product's primary operating characteristics. For an automobile this could mean fast acceleration, easy handling, a smooth ride, or good gas mileage. For a television it could mean bright color, clarity, sound quality, or the number of channels it can receive. For a service this could merely mean attention to details or prompt service.

- Conformance. Conformance is the degree to which a product's design and operating characteristics meet predetermined standards. When a manufacturer utilizing coils of steel receives a shipment from the mill, it checks the width of the coil, the gauge (thickness) of the steel, and the weight of the coil, and puts a sample on a Rockwell hardness tester to check that the specified hardness has been provided. The receiving inspector will also check to see if specified characteristics are met (e.g., hot-rolled, pickled, and oiled). Services may have conformance requirements when it comes to repair, processing, accuracy, timeliness, and errors.

- Features. Features are the bells and whistles of a product or service. In other words, they are the characteristics that supplement the basic function of the product or service. Desirable, but not absolutely necessary, features on a VCR include four heads, slow-motion capability, stereo or surround sound, split screens or inset screens, and 365-day programming ability. Service examples include free drinks on an airline flight or free delivery of flowers.

- Durability. Durability is defined as mean time until replacement. In other words, how long does the product last before it is worn out or has to be replaced because repair is impossible? For some items, such as light bulbs, repair is impossible and replacement is the only available option. Durability may be had by use of longer life materials or improved technology processes in manufacturing. One would expect home appliances such as refrigerators, washer and dryers, and vacuum cleaners to last for many years. One would also hope that a product that represents a significant investment, such as an automobile, would have durability as a primary characteristic of quality.

- Reliability. Reliability refers to a product's mean time until failure or between failures. In other words, the time until a product breaks down and has to be repaired, but not replaced. This is an important feature for products that have expensive downtime and maintenance. Businesses depend on this characteristic for items such as delivery trucks and vans, farm equipment and copy machines since their failure could conceivably shut down the business altogether.

- Serviceability. Serviceability is defined by speed, courtesy, competence and ease of repair. This can be an extremely important characteristic as witnessed by the proliferation of toll-free hot lines for customer service. A number of years ago, a major television manufacturer advertised that its product had its "works in a box." This meant that the television set was assembled out of modular units. Whenever there were problems with the set, a repairman making a house call simply had to replace the problem module, making the product easily and quickly serviceable.

- Aesthetics. A product's looks, feel, smell, sound, or taste are its aesthetic qualities. Since these characteristics are strictly subjective and captive to preference, it is virtually impossible to please everyone on this dimension.

- Perceived Quality. Perceived quality is usually inferred from various tangible and intangible aspects of the product. Many consumers assume products made in Japan are inherently of high quality due to the reputation of Japanese manufacturers, whereas 50 years ago, the perception was the complete opposite. Other characteristics such as high price or pleasing aesthetics may imply quality.

Firms competing on this basis offer products or services that are superior to the competition on one or more of the eight dimensions. Obviously, it would be undesirable if not impossible for firms to compete on all eight dimensions of quality at once. This would be prohibitively expensive, and there are some limitations imposed by trade-offs that must be made due to the nature of the product. For example, a firm may sacrifice reliability in order to achieve maximum speed.

Service. Service can be defined in a number of ways. Superior service can be characterized by the term "customer service" or it could mean rapid delivery, on-time delivery, or convenient location.

Flexibility. Firms may compete on their ability to provide either flexibility of the product or volume. Firms that can easily accept engineering changes (changes in the product) offer a strategic advantage to their customers. Also, some firms are able to absorb wide fluctuations in volume allowing customers with erratic demand the luxury of not holding excessive inventories in anticipation of change in demand.

Tradeoffs. Firms usually focus on one distinctive competency (rarely more than two). For some competencies there are tradeoffs involved. An automobile manufacturer producing a product that is considered to be of high quality (leather seats, real wood trim, and an outstanding service package) will not be able to compete on a cost/price basis as the cost of manufacture prohibits it. An automotive parts house would like to keep their customers happy by offering the lowest prices possible. However, if the automotive parts house also wants to be able to fill almost every single order from walk-in customers, it must maintain an extensive inventory. The expense of this inventory could preclude the parts house from offering prices competitive with other similar firms not choosing to provide this level of service. Therefore, one parts house is competing on the basis of service (but not cost/price) while the other is competing on the basis of cost/price (but not service). The customer may have to wait a few days to get the desired part; if the customer cannot wait, he or she can pay more and purchase the part immediately from the competitor.

THE NEED FOR AN OPERATIONS STRATEGY

In too many instances, a firm's operations function is not geared to the business's corporate objectives. While the system itself may be good, it is not designed to meet the firm's needs. Rather, operations is seen as a neutral force, concerned solely with efficiency, and has little place within the corporate consciousness. Steven C. Wheelwright and Robert H. Hayes described four generic roles that manufacturing can play within a company, from a strategic perspective. While they specifically discuss the manufacturing function, the term operations can be substituted with no loss in relevance. These generic roles are labeled stages 1 to 4, as explained below.

Stage 1 firms are said to be internally neutral, meaning that the operations function is regarded as being incapable of influencing competitive success. Management, thereby, seeks only to minimize any negative impact that operations may have on the firm. One might say that operations maintain a reactive mode. When strategic issues involving operations arise, the firm usually calls in outside experts.

Stage 2 firms are said to be externally neutral, meaning they seek parity with competitors (neutrality) by following standard industry practices. Capital investments in new equipment and facilities are seen as the most effective means of gaining competitive advantage.

Stage 3 firms are labeled internally supportive, that is, operations' contribution to the firm is dictated by the overall business strategy but operations has no input into the overall strategy. Stage 3 firms do, however, formulate and pursue a formal operations strategy.

Stage 4 firms are at the most progressive stage of operations development. These firms are said to be externally supportive. Stage 4 firms expect operations to make an important contribution to the competitive success of the organization. An operation is actually involved in

major marketing and engineering decisions. They give sufficient credibility and influence to operations so that its full potential is realized. Firms within Stage 4 are known for their overall manufacturing capability.

Since the bulk of many, if not all, firms have the bulk of their labor force and assets tied to the operations function, it makes sense for most firms to strive for a position in Stage 3 or Stage 4. Firms can, of course, evolve from one stage to the next with few, if any, skipping a stage. In fact, most outstanding firms are in Stage 3, as Stage 4 is extremely difficult to reach.

The need for an operations strategy that reflects and supports the corporate strategy is not only crucial for the success of the corporate strategy but also because many decisions are structural in nature. In other words, the results are not easily changed. The firm could be locked into a number of operations decisions, which could take years to change if the need arose. These could range from process investment decisions to human resource management practices. For example, Dell runs a complete chain of operations that links all the key stakeholders right from the customers to the suppliers. In effect, Dell records huge volumes of profits as a result of high levels of responsiveness and product success.

Firms that fail to fully exploit the strategic power of operations will be hampered in their competitive abilities and vulnerable to attack from those competitors who do exploit their operations strategy. To do this effectively, operations must be involved throughout the whole of the corporate strategy.

Bell Helicopter has demonstrated success in incorporating its operations strategy into the overall corporate strategy of the organization. In 2008, the global leader in aircraft manufacturing announced the rationalization of the company's product line through concentrating on the production of the popular models that are in high demand. The management of Bell Helicopters projects to yield significant increase in the production capacity of the company and subsequent increase in its capacity to meet customer demands from this pragmatic strategy.

Corporate executives have tended to assume that strategy has only to do with marketing initiatives. They erroneously make the assumption that operation's role is strictly to respond to marketing changes rather than make inputs into them. Secondly, corporate executives assume that operations have the flexibility to respond positively to changing demands. These assumptions place unrealistic demands upon the operations function. Moreover, some target markets lack the fundamentals of capitalism such as free flow of information. It is therefore incumbent upon corporate executives to pursue operational strategies that create competitive advantage through innovation and increased research and development. For example, Apple

iTunes draws the majority of its market share through strategic and persistent pursuit of competitive advantage.

Operations management's attention must increasingly be toward strategy. The balance and direction of its activity should reflect its impact on the firm's performance toward achieving its goals through its strategy, and on the performance of operations itself, recognizing that both need to be done well. Linda Nielsen-Englyst recommends a four-phase process for formulating and updating operations strategy: learning, reviewing, aligning, and redirecting. Phase one is a learning stage where alternatives to the intended strategy are evaluated in practice. Phase two involves reviewing alternatives over time, allowing ideas to grow and mature. Phase three, the alignment stage, is an analytical process where the firm attempts to identify and document financial rationale for changing the intended strategy. Finally, in the redirecting phase, the firm tests its ideas in practice through local initiatives.

In an article titled *Operational Strategy: Bold Moves, Break out Performance*, Tom Godward and Mark Deck suggest that successful management of operations strategy requires facilitation and integration of key organizational factors that include management systems, organizational culture, information and technology systems, and process innovation. The availability and proper utilization of the key organizational dynamics go a long way in determining the probabilities of success of the operational strategies and the entire corporate strategies of the organization.

OPPORTUNITY COST

An opportunity cost is defined as the value of a forgone activity or alternative when another item or activity is chosen. Opportunity cost comes into play in any decision that involves a tradeoff between two or more options. It is expressed as the relative cost of one alternative in terms of the next-best alternative. Opportunity cost is an important economic concept that finds application in a wide range of business decisions.

Opportunity costs are often overlooked in decision making. For example, to define the costs of a college education, a student would probably include such costs as tuition, housing, and books. These expenses are examples of accounting or monetary costs of college, but they by no means provide an all-inclusive list of costs. There are many opportunity costs that have been ignored: (1) wages that could have been earned during the time spent attending class, (2) the value of four years' job experience given up to go to school, (3) the value of any activities missed in order to allocate time to studying, and (4) the value of items that could have been purchased with tuition money or the interest the money could have earned over four years.

These opportunity costs may have significant value even though they may not have a specific monetary value. The decision maker must often subjectively estimate opportunity costs. If all options were purely financial, the value of all costs would be concrete, such as in the example of a mutual fund investment. If a person invests $10,000 in Mutual Fund ABC for one year, then he forgoes the returns that could have been made on that same $10,000 if it was placed in stock XYZ. If returns were expected to be 17 percent on the stock, then the investor has an opportunity cost of $1,700. The mutual fund may only expect returns of 10 percent ($1,000), so the difference between the two is $700.

This seems easy to evaluate, but what is actually the opportunity cost of placing the money into stock XYZ? The opportunity cost may also include the peace of mind for the investor in having his money invested in a professionally managed fund, compared to the sleep lost after watching his stock fall 15 percent in the first market correction while the mutual fund's losses were minimal. The values of these aspects of opportunity cost are not so easy to quantify. It should also be noted that an alternative is only an opportunity cost if it is a realistic option at that time. If it is not a feasible option, it is not an opportunity cost.

Opportunity-cost evaluation has many practical business applications, because opportunity costs will exist as long as resource scarcity exists. The value of the next-best alternative should be considered when choosing among production possibilities, calculating the cost of capital, analyzing comparative advantages, and even choosing which product to buy or how to spend time. According to Kroll, there are numerous real-world lessons about opportunity costs that managers should learn:

1. Even though they do not appear on a balance sheet or income statement, opportunity costs are real. By choosing between two courses of action, you assume the cost of the option not taken.

2. Since opportunity costs frequently relate to future events, they are often difficult to quantify.

3. Most people will overlook opportunity costs.

As most finance managers operate on a set budget with predetermined targets, many businesses easily pass over opportunities for growth. Most financial decisions are made without the consultation of operational managers. As a result, operational managers are often convinced by finance departments to avoid pursuing value-maximizing opportunities, assuming that the budget simply will not allow it. Instead, workers slave to achieve target production goals and avoid any changes that might hurt their short-term performance, for which they may be continually evaluated.

During the opening years of the twenty-first century, opportunity costs associated with more environmentally sensitive business practices and economic activity—such as combating carbon dioxide emissions through sequestration—came to the fore. Carbon sequestration (capture) is intended to reduce greenhouse gases in the atmosphere and can be achieved several different ways. One U.S. government study of different carbon capture strategies noted some of the opportunity costs. For example, one method of carbon sequestration involves afforestation, or planting trees in an area where there had been none before. Some opportunity costs associated with this type of carbon sequestration might include other profitable activities that could be conducted on that land. For example, the Congressional Budget Office noted that other measures to stop greenhouse gases might make growing crops for biofuels profitable. In this instance, there would be less incentive to devote land to trees for carbon sequestration because of the opportunity costs.

ORDER-QUALIFYING CRITERIA

SEE *Order-Winning and Order-Qualifying Criteria*

ORDER-WINNING AND ORDER-QUALIFYING CRITERIA

The terms "order winners" and "order qualifiers" were coined by Terry Hill, professor at the London Business School, and refer to the process of how internal operational capabilities are converted to criteria that may lead to competitive advantage and market success. In his writings, Hill emphasized the interactions and cooperation between operations and marketing. The operations people are responsible for providing the order-winning and order-qualifying criteria—identified by marketing—that enable products to win orders in the marketplace. This process starts with the corporate strategy and ends with the criteria that either keeps the company in the running (i.e., order qualifiers) or wins the customer's business.

COMPETITIVE ADVANTAGE AND COMPETITIVE PRIORITIES

Many factors shape and form the operations strategy of a corporation. For example, these factors include: the ever increasing need for globalizing products and operations, thus reducing the unit cost; creating a technology leadership position; introducing new inventions; taking advantage of mass customization; using supplier partnering; and looking for strategic sourcing solutions. All of these factors require an external or market-based orientation—these are the changes that take place in the external environment of the company.

Traditionally, strategic decisions were thought of as "big decisions" made by general managers. However, big strategic decisions may not be the only source of competitive advantage for the firm. Jay Barney wrote, "Recent

work on lean manufacturing suggests that it is the simultaneous combination of several factors that enables a manufacturing facility to be both very high quality and very low cost. This complicated system of numerous interrelated, mutually supporting small decisions is difficult to describe, and even more difficult to imitate, and thus a source of sustained competitive advantage." Barney contrasted big and small decisions further, "Recognizing that small decisions may be more important for understanding competitive advantages than big decisions suggests that the study of strategy implementation—the process by which big decisions are translated into operational reality—may be more important for understanding competitive advantage than the study of strategy formulation."

The strategy expressed as a combination of a few big and hundreds of small decisions leads to setting up competitive priorities for improving operational practices through investments in various programs. These competitive priorities place different and diverse demands on manufacturing. These demands, sometimes called manufacturing tasks, can be organized into three distinctly different groups: product-related demands, delivery-related demands, and cost demands.

The emphasis given to these priorities and the state of the organization determine the nature and level of investments deemed necessary to implement the operations strategy. These investments in operational practices are expected to lead to better operational performance, as measured and evaluated internally using indicators like reject rates in the manufacturing process, production schedule fulfillment, and others. Through investments firms create and acquire resources that can isolate them from negative market influences and can serve as a source of competitive advantage for them. These investments can be made in tangible assets (e.g., machinery and capital equipment) and intangible assets (e.g., brand names and the skills of individual employees).

A distinction has to be made between investments aimed at creating resources and those aimed at creating capabilities. Few resources by themselves are productive. Productive activity requires the cooperation and coordination of teams of resources. An operational capability is the capacity for a team of resources to perform some task or activity.

While resources are the source of a firm's capabilities, capabilities are the main source of its competitive advantage. Capabilities are not evaluated in themselves, and they cannot be thought of as absolute values. They have to be evaluated relative to the capabilities of competitors. This is the reason for distinguishing between competitiveness dimensions (like the three Ps from the marketing mix: price, place, and product) and capability-based dimensions (like cost-time-quality measures). They show

the two sides of the same coin: the internal capabilities and their evaluation in the market.

ORDER QUALIFIERS AND ORDER WINNERS

Terry Hill argues that the criteria required in the marketplace (and identified by marketing) can be divided into two groups: order qualifiers and order winners. An order qualifier is a characteristic of a product or service that is required in order for the product/service to even be considered by a customer. An order winner is a characteristic that will win the bid or customer's purchase. Therefore, firms must provide the qualifiers in order to get into or stay in a market. To provide qualifiers, they need only to be as good as their competitors. Failure to do so may result in lost sales. However, to provide order winners, firms must be better than their competitors. It is important to note that order qualifiers are not less important than order winners; they are just different.

Firms must also exercise some caution when making decisions based on order winners and qualifiers. Take, for example, a firm producing a high quality product (where high quality is the order-winning criteria). If the cost of producing at such a high level of quality forces the cost of the product to exceed a certain price level (which is an order-qualifying criteria), the end result may be lost sales, thereby making "quality" an order-losing attribute.

Order winners and qualifiers are both market-specific and time-specific. They work in different combinations in different ways on different markets and with different customers. While, some general trends exist across markets, these may not be stable over time. For example, in the late 1990s delivery speed and product customization were frequent order winners, while product quality and price, which previously were frequent order winners, tended to be order qualifiers. Hence, firms need to develop different strategies to support different marketing needs, and these strategies will change over time. Also, since customers' stated needs do not always reflect their buying habits, Hill recommends that firms study how customers behave, not what they say.

When a firm's perception of order winners and qualifiers matches the customer's perception of the same, there exists a "fit" between the two perspectives. When a fit exists one would expect a positive sales performance. Unfortunately, research by Sven Horte and Hakan Ylinenpaa, published in the *International Journal of Operations and Production Management,* found that for many firms a substantial gap existed between managers' and customers' opinions on why they did business together. The researchers found that favorable sales performance came about when there was a good fit between a firm's perception of the strengths of a product and customer perception of the product. Conversely, when firms with high opinions about their competitive strengths had customers who did not share this opinion, sales performance was negative.

PRODUCT LIFE CYCLE

Over time, product sales follow a pattern called the product life cycle. The different stages of the product life cycle also influence a product's set of order winners and order qualifiers. The length of and the sales at each stage of the cycle, as well as the overall length of the life cycle, vary from product to product and depend on such factors as the rate of technological change, the amount of competition in the industry, and customer preferences.

In the early portion of a product's life, product design is critical. A product's early users are almost always more interested in product performance than in price. This stage is characterized by a large number of product innovations. A considerable amount of product design is undertaken to make the product more useful and desirable for its users. Abernathy referred to this early phase of product technology as the search for dominant design. Dominant designs are those that "make a market," such as Ford's Model T car, the DC-3 airplane, and the IBM PC. At this stage, the production process is most likely to be a job shop or close to a job shop.

As the dominant design gets more accepted, cost reduction becomes increasingly important. Thus, process innovation—geared primarily toward lowering costs, increasing yield, and improving throughput time—becomes more important. Changes become less radical as the product, the process, and the organization become more standardized. The production process moves closer to the continuous flow end of the process spectrum. When this happens, both the product and the process become increasingly vulnerable to the introduction of new offerings of similar function (i.e., substitute products) by other producers. Then, the company has to decide when and how to abandon the product and process that they perfected and in which they invested so much.

As the product moves through its life cycle, the requirements for the product and for the production process change. During the early part of the life cycle a production facility with high flexibility (i.e., a job shop) can generate order winners such as customization. For a mature product a dedicated facility (i.e., a flow shop) can produce high quality and low cost, which are the order winners for many, but not all, mature products.

Terry Hill noted that different product characteristics require different production processes, and without communication between marketing, which identifies the order winners and qualifiers, and operations, which develops the operational capabilities to deliver these characteristics,

market success cannot be achieved. Hill developed a tool—product profiling—to ascertain a certain level of fit between process choices and the order-winning criteria of the products. The purpose of profiling is to provide comparison between product characteristics required in the market and the process characteristics used to manufacture the products and make the necessary adjustments.

Social and cultural changes can also affect order winning and qualifying criteria. For example, midway through the first decade of the twenty-first century, environmental issues became a public concern. This development had vast implications for companies and managers. Medhi Shahbazpour and Rainer Seidel argued that sustainable and environmentally sensitive practices needed to become an integral part of the manufacturing process. Sustainability can be either an order winner or order qualifier. As Shahbazpour and Seidel note, "Whether sustainability is categorized as order or order qualifier depends on the specific market, industry, and society the firm operates in."

ORGANIC ORGANIZATIONS

The term "organic" suggests that, like living things, organizations change their structures, roles, and processes to respond and adapt to their environments. Burns and Stalker noted in *The Management of Innovation* that organic struc-

tures are appropriate in unstable, turbulent, unpredictable environments and for nonroutine tasks and technologies. For organizations coping with such uncertainty, finding appropriate, effective, and timely responses to environmental challenges is of critical importance. Organic organizations are characterized by:

- Decentralization
- Flexible, broadly defined jobs
- Interdependence among employees and units
- Multi-directional communication
- Employee initiative
- Relatively few and broadly defined rules, regulations, procedures, and processes
- Employee participation in problem solving and decision making, often interactively and in groups

In organic organizations, the emphasis is on effectiveness, problem solving, responsiveness, flexibility, adaptability, creativity, and innovation. Such an organization is able to respond in a timely manner to environmental change because employees are empowered to be creative, to experiment, and to suggest new ideas. The process of innovation is triggered by employees throughout the organization in a "bottom-up" manner. The following four sections explain how these characteristics fit together in a cohesive organizational structure that allows for flexibility and ongoing change.

MEETING CHALLENGES

An unstable external environment increases the uncertainty and complexity with which an organization must contend. An organization is continually confronted with a variety of new and unexpected problems and opportunities, of which the nature and relevant factors are initially unclear and for which appropriate responses are not immediately obvious. Further, since the environment changes rapidly, responses to today's problems and opportunities may need to be modified or may even be inappropriate or irrelevant to tomorrow's challenges. In short, the organization cannot keep doing the same old things in the same old ways. Under conditions of uncertainty and complexity, the organization must design its structures and processes to be flexible and responsive to changes in customer desires, technology, governmental regulations, and economic conditions.

FLEXIBILITY AND SHARED AUTHORITY

The need for flexibility and responsiveness leads to the decentralization of decision-making authority in organic organizations. As a result, rules, regulations, procedures,

and policies tend to be few, are defined broadly rather than precisely, loosely rather than rigidly, and are often informal rather than written. Employees are allowed to exercise a great deal of discretion. The authority to identify problems and opportunities and to devise responses is delegated to those best able to respond, regardless of their position, unit, or level in the organization. Emphasis is placed more on individual and group control than on managerial, hierarchical control. Top-level managers in organic organizations are more concerned with coordination and integration as opposed to passing directives down a vertical hierarchy, which is a common task of top-level managers in mechanistic organizations.

The need for flexibility and responsiveness also affects how work is designed and performed in organic organizations. Jobs are not clearly or precisely defined in these organizations. Positions, roles, job descriptions, and standard operating procedures are broad and generalized rather than specific and specialized. Employees accept general responsibility for getting things done, but the manner in which they accomplish their tasks is dictated more by autonomous or semi-autonomous teams than by standard operating procedures. Because the work of organic organizations is often interdependent, specific tasks and responsibilities vary from one situation to another and are refined through direct interaction and mutual adjustment among employees and work units. Too much direction from top-level management may hinder rather than assist the accomplishment of tasks.

A key issue in organic organizations is determining who has the knowledge, perspective, experience, expertise, or skills required to identify opportunities or find solutions to problems. Rather than assuming that top management is the fountainhead of all knowledge and wisdom, organic organizations assume that various people in the organization may have crucial insights or capabilities. Thus, communication is multidirectional, decentralized, and informal rather than hierarchical and formalized. To facilitate the sharing of information and ideas, employees are frequently empowered to communicate across traditional organizational boundaries regardless of position or level or unit.

Going one step further, pharmaceutical firms, for example, may collaborate across corporations and with academic researchers to conduct basic research leading to new drug development. Jack Welch, former CEO of General Electric, referred to this type of company as a "boundaryless organization." Coordination and integration with multiple constituencies beyond traditional organizational boundaries is a necessary component for success, especially in multinational organizations.

Diversity of information and perspectives is often the key to the development of creative responses to vague, complex problems and opportunities. Thus, in organic organizations, much work is done in groups composed of employees with different backgrounds and from different levels, units, or functional areas. Such teams are among the main coordination mechanisms in organic organizations.

THE HUMAN ELEMENT

Human needs and dynamics play an important role in organic organizations. The empowerment and participation of employees is motivational because it meets the human need for autonomy, responsibility, challenge, esteem, social interaction, and personal development. Furthermore, this empowerment and participation helps the organization develop and capitalize on its intellectual capital, which is becoming increasingly valued by many organizations. By emphasizing initiative, direct interaction, open communication, and the creation of teams composed of various members of the organization, organic organizations are able to utilize their internal diversity to foster innovative responses to environmental challenges and changes.

MIXING STYLES

The organic organization is not entirely without hierarchy or formalized rules, regulations, procedures, and processes. Indeed, structural parameters, even if loosely or broadly defined, are necessary to prevent the chaos that would result from absolute decentralization (i.e., where everyone in the organization is completely free to decide what they want to do or not do). As an example of such structural parameters, while employees of Minnesota Mining and Manufacturing (3M) are encouraged to take the initiative in suggesting new products and seeking support from others in the organization, new product teams must still meet specific financial measures at each stage of product development. Nonetheless, the real control is found in constant interaction among peers and the normative rules that develop informally among them.

It is not always necessary for an entire organization to be organic. Some units, such as research and development departments, may benefit from an organic structure because they face an unstable environment. Units that have a more stable environment, such as routine, administrative departments, may favor a mechanistic structure. Some units may borrow from both models. Customer service departments, for example, can build flexibility into responding to exceptional circumstances while maintaining standardized protocols for more typical situations.

The structures of organic organizations are informal, fluid, and constantly changing to identify and develop responses to new problems and opportunities. Authority and responsibility shifts from one situation to another. Groups are established, complete their work, and disband, and a single employee may belong to several temporary

teams at the same time. In organic organizations there is diminished emphasis on superior-subordinate roles in favor of dispersed initiative. Roles, tasks, and responsibilities are not limited by rigid, vertical boundaries of hierarchy for decision-making, communication, coordination, and control. Relations and interactions between personnel and units continually change, and managers and other employees must figure out which relations and interactions will be most effective for each particular problem or opportunity.

In a move that is directly related to organic organizational structure, some companies have adopted a strategy known as a "Results-Only Work Environment" or ROWE. This type of organizational structure emphasizes productivity instead of hours spent at work. The company Best Buy has been a pioneer of this management style. Personnel at its corporate headquarters do not have fixed hours, and they are not required to work from the office. Instead, employees have control over how they manage their time. This policy has much in common with the characteristics of an organic organizational structure, such as a greater degree of individual autonomy and empowerment for employees. A "Results-Only Work Environment" also resembles an organic organization in that it deemphasizes a hierarchical structure.

ORGANIZATION THEORY

Organization theory is a broad field with roots in sociology. Anthropologists, philosophists, and political scientists have contributed greatly to the field. Organization theory as a topic for managers, as opposed to scholars, has come about fairly recently. For example, political scientists trace many ideas back to Ancient Rome or even before. Philosophers reach even farther back in time, and anthropologists have been interested in organization in terms of how groups arrange social systems and status systems as long as there has been a field of anthropology.

Although it is difficult to pinpoint when managers became interested in theories of organization, some suggest it was around the 1940s, when the writings of the German sociologist and engineer, Max Weber, were translated into English. Although Weber's lifework was spent trying to understand why capitalism arose first in Western Europe rather than in Asia, American managers lifted Weber's notion of bureaucracy out of these studies to explain then-modern forms of organizations that coincided with what Weber had described among Western European organizations. These organizations had reduced the influence of patriarchal styles of management to systems in which job positions, rather than the people in those positions, provided the source of authority.

Phillip Selznick became well known for studying goal conflict and power struggles during the U.S. government's subsidy of the Tennessee Valley Authority, which was an effort to put unemployed Americans to work producing electricity for the Tennessee Valley area. In the 1950s Herbert Simon studied how managers make decisions when information is complex but incomplete. The 1960s brought about research elaborating why the closed-system mentality of organizations—the idea that organizations have little reciprocal interaction with their environments—was not accurate. The result was a shift to viewing organizations as open systems that are intertwined with their environments in such a way that reciprocal interdependence is created. Managers began to realize that society has a profound effect on organizations, as organizations also have a profound effect on society.

Taken in total, then, organization theory as a management topic of interest was born out of non-management research. Bureaucracy, authority, goal conflict, power, managerial decision-making, and interaction between organizations and their environments are all topics of concern among today's organization theorists, but none of these ideas arose from management research.

Management research has borrowed from these various fields to attempt to answer two questions that are of specific interest to managers: Why do organizations exist and how do they function? With respect to the first question, it seems reasonable to argue that organizations exist to provide society with a level of goods and services that would otherwise be unattainable. With respect to the second, how organizations function, organizations combine human skills, knowledge, technology, and material resources to produce goods and services.

The broadest variant of organization theory looks at the relationship between organizations and their social and natural environments, as originated by open-system theorists. One branch of Western moral philosophy conceives of organizations as having a social contract with society, whereby they are granted legitimacy for the purpose of serving the social good. This constructive purpose includes the production of goods and services and their fair allocation. Yet organizations can also cause negative social outcomes. Negative externalities include the social problems associated with monopolies, unsafe products, and the unfair treatment of employees, as well as the ecological problems posed by industrial accidents and industry-related pollution of the natural environment.

Because of the existence of negative externalities, organization theory is influenced by the concept of social control that can be found in political science, economics, and sociology. Social control refers to the laws, regulations, and social customs that are meant to minimize the negative impacts of organizational activities. Because organization theorists address social control, they also examine the nature of the relationship between organizations and their regulatory agencies.

The anthropological view derives from the knowledge that standards of social control reflect the underlying assumptions, values, and beliefs of cultures. The restraints or expectations placed on organizations, therefore, can vary across societies. The stakeholder model of organizations is useful for demonstrating this form of cultural relativism. The stakeholder model depicts an organization as surrounded by a variety of constituent groups, such as customers, social activists, regulators, the media, stockholders, and regulatory agencies.

Stakeholder expectations, in turn, can depend upon cultural affiliations. For example, employees in the United States tend to expect more active participation in the work contract than do employees in Japan. Thus, a Japanese firm with operations in the United States may face employment laws and employee views of justice and fairness that differ from those of the home country. When the scope of organization theory is widened to include international issues such as the activities of multinational corporations in host environments, the impact of cultural relativism must be acknowledged.

Although organization theory never loses sight of the importance of the organizational-societal interface (and this is one distinguishing feature between organization theory and organization behavior), it also deals with what goes on inside organizations. Weber's classical theory of bureaucracy, for example, was followed by research on the more informal aspects of organizational life. This line of inquiry is strongly influenced by the insight that organizational activity can involve less-than-rational processes that yield unexpected consequences, including the negative externalities mentioned above. Hence, although organizations ideally exist as tools for constructive social purposes, these purposes can be subverted by the constraints on rational decision processes within organizations.

Contemporary theorists use many metaphors to guide their investigations into the suboptimal and even non-rational decisions enacted in organizations. These metaphors include those that suggest organizations are systems of power and political intrigue, miniature cultures, chaos, temples, theaters, machines, families, and jungles. These metaphors arise through shared meaning that has been socially constructed and generally agreed upon, thus subconsciously institutionalizing the specific, agreed-upon metaphor for certain organizations.

Organization theorists are interested in why organizations exist and how these social systems function. This interest has yielded a body of research on the organizational-societal relationship and the formal and informal aspects of organizational life, yet there is no single answer to either of these root issues.

Since 2001 some management theories have come under criticism for the role they may have played in corporate scandals at firms such as Enron and Tyco. The late London Business School scholar, Sumanatra Ghoshal, argued that business schools and MBA programs taught amoral management ideas that drastically deemphasized responsibility and ethics. Likewise, Malcolm Salter warned that another scandal like Enron could only be avoided if companies created, "organizational processes and structures that promote effective management and ethical behavior." However, these business scandals also yielded new avenues of research. Enron emails that became public after the scandal and subsequent investigations have provided insight into how communication and informal networks function inside an organization.

ORGANIZATIONAL ANALYSIS AND PLANNING

Organizational analysis and planning focuses on cultivating and maintaining an efficient workforce through design and structure of an organization, including the relationship and behavior of individuals within organizations. Specifically, organizational analysis is concerned with developing models and theories that accurately capture the functioning and development of organizations and that account for the ways in which organizations respond to and bring about changes. Organizational planning, on the other hand, involves designing an organization's structure and dividing up the responsibilities of an organization. The goals of organizational analysis and planning typically have been to determine the best way to view and organize a company in order to manage it successfully and to bring about greater efficiency.

MODELS OF OGANIZATIONAL ANALYSIS

One of the basic techniques of organizational analysis is modeling—developing models of organizations that delineate the way they function and evolve in order to identify the best way of managing each one. Modeling enables managers to determine the crucial variables in particular circumstances so they can experiment with different combinations of variables to achieve their desired results. For example, managers can determine the best combination of technology and organizational structure for their company by using organizational models.

Organizational models typically focus on behavior, structure, or technology. In consideration of these variables, four general models of organizational analysis exist: the rational (also called the classical model), the natural system (also called the participative model), the socio-technical, and the cognitive model.

Rational Model. A pioneer of the rational model of organization was Frederick Taylor, who was influential near the start of the twentieth century. Taylor's background in engineering prompted his organizational analysis on efficiency. In Taylor's view, there was one best way—the most efficient way—to perform a task. Scientific management sprang from his work, with resultant time and motion studies in which tasks were timed and employee motions were gauged for efficiency. The best way to perform a task, in Taylor's view, was the way that accomplished the task in the least amount of time. He extended this view from employees to management, suggesting that nearly all organizational tasks could become more efficient if scientific principles were applied.

This was at the dawn of the introduction of the automobile to America. Although many Western European nations began manufacturing automobiles before the early twentieth century, production efficiencies still had a long way to go. Applying scientific management principles helped Ford Motor Company develop the first American, mass-produced automobile. Frederick Taylor, then, was correct. Scientific management did work, but it was not without problems. The main problem was that it ignored the boredom that repetitive tasks created for workers. Workers became simply replaceable parts in the organizational machine.

In addition, the rational model of organization presupposes that decisions about an organization's structure are reached because of the rational assessment of an organization's needs, goals, and external influences. And like Taylor's scientific management, this is true in some situations, but is not comprehensive enough to tell the whole story of how needs, goals and external influences affect organizational analysis and planning.

The rational model assumes that deviations from rationality result from errors in judgment and calculation as well as from ignorance. This model treats organizations as mechanical groups because it conceives of the organization as having a structure of different parts, and that all of these parts can be modified and manipulated in order to improve the efficiency of the entire

organization. Furthermore, individual parts of the organization are viewed as modifiable through deliberate effort. Finally, this model sees the long-term development of the organization as modifiable and controllable through planned modification in order to accomplish definite goals.

The rational model is still pervasive among managers and corresponds to the pyramidal organizational structure, in which top managers are at the apex and employees are at the bottom. Managers possess the authority in this model, defining and assigning tasks to the employees, who are charged with completing the tasks. They must begin by giving employees clear and detailed instructions. After that, managers must evaluate employee performance and distribute rewards and punishments based on the way employees performed their tasks.

Managers assume that worker motivation is directly correlated with economic rewards and punishments meted out by the managers. Motivation, from a rational perspective, simply involves increasing pay or threatening workers with various punishments. Hence, according to this model, managers rely on pay and related forms of compensation to motivate workers to complete their tasks efficiently in order to achieve company goals.

The problem with this assumption is that there are many motivators other than money, there can be many ways to perform a given task, and there are many organizational goals that are not rational. The rational model is thus a starting point for thinking about organizational analysis, but certainly not encompassing enough to provide a complete picture.

Natural System Model. In contrast to the rational model, the natural system model views organizations holistically, that is, as systems. The natural system model sees an organization as not only striving to accomplish its own goals, but also other important goals. An organizational structure is regarded as an institution in its own right that has needs of its own. Hence, according to this model, an organization seeks to maintain a balance of its various needs and goals, which may restrict the way it pursues other goals.

Unlike the rational model of organization, the natural system model sees the modification of an organization as unplanned and adaptive reactions to unstable conditions that threaten the balance of the organization as an entire system. The way an organization responds to problems is characterized as a defense mechanism and as being influenced by the common values ensconced in the members of the organization. This model concentrates on threats to an organization's equilibrium, that is, on events and activities with the potential of disrupting an organization's balance.

When deviations from organizational plans and goals occur, they are seen not as the product of error or ignorance, but as the result of limitations brought about by an organization's social structure. This model generally is based on the concept of organizations as organisms in which all the parts are interconnected and interdependent. Consequently, changes in one part of an organization are thought to have an impact on other parts of the organization, and so planned modification of the organization is difficult.

In practical terms, the natural system model strives to balance the needs of all the members of the organization as well as other stakeholders, such as customers, shareholders, and suppliers. This model holds that organizations function best when members belong to at least one effective work group (department, committee, or staff group), thereby contributing to the goals of organizations. Members who belong to more than one work group help link the different units of the organization together and facilitate communication and the exchange of information throughout the organization.

The natural system model views change as affecting the entire organization, not just individuals or individual units. Consequently, managers cannot change just one small part of an organization; rather, they must change the whole organization. As a result, planning for change must be comprehensive and systematic. Theoretically, the natural system model helps prevent conflicts, in that changes take place only with the involvement of each member of the organization. Therefore, commitment to change is greatly increased and conflict over change is limited.

Sociotechnical Model. Due to the limitations of the previous models of organization, theorists developed other models to capture the essence and functioning of modern organizations. The sociotechnical model does not rely on the mechanical and biological analogies of the rational and natural system models. Instead, the sociotechnical model views organizations as having a greater ability to modify their form and structure. Nevertheless, like the natural system model, the sociotechnical model sees organizations as evolving. An organization changes when the expectations of its members change as a result of their collaboration with other members and the exchange of information.

This model views organizations as systems that interact with their environments. Through the course of this interaction, organizational behavior is affected by human, social, technological, and organizational inputs. These inputs are all interdependent, thus a change in one causes a change in the others. The basic tenets of the sociotechnical model include the belief that behavior in

organizations can have a number of causes, that organizations are systems, and that informal social systems are different from formal social systems.

An organization's main task is accomplished through the process of inputs being converted into outputs. The organization is designed around these tasks. Similarly each unit of the organization is designed around its specific subtask. The sociotechnical model assumes that an organization's effectiveness is determined by its design to perform its main task. Organizations have differentiated, yet integrated, units based on three primary factors: technology (including techniques, skills, and materials), geographic location, and time (work shifts). According to this model, if an organization is effectively designed around its main task and if its units are differentiated and integrated effectively, then the number of conflicts will be reduced.

Cognitive Model. The cognitive model of organization consists of three primary components: cognition, the decision-making or problem-solving process, and an organizational setting. Cognition refers to the information-processing units of an organization and its organizational units. The decision-making or problem-solving component is a series of steps, operations, and procedures that an organizational unit uses to make decisions or solve problems. The organizational setting component is the arrangement of the organization, that is, the way tasks are distributed and the way processes are coordinated.

Although the rational model of organization focuses on clarifying and assigning tasks, it does not address the other aspects of organizations. In particular, it provides little in terms of the ways organizations solve problems once tasks are clarified and assigned. The cognitive model moves beyond this level of organizational analysis by focusing on the processes through which organizations assign specific activities and times for the activities to be performed.

The cognitive model focuses on the decision-making process of an organization. An organization makes decisions in accordance with its objectives and based on available information. Since this model views individuals as having the capacity to do only a few things at a time, the organization functions as the combination of these limited capacities and facilitates the overall completion of a number of complex tasks, which are broken down into a series of subtasks so that individuals can perform them. These subtasks are the areas of specialization within an organization. Specialization, in turn, brings about the flow of specific information to and from specialized units.

This model provides several key insights into the workings of organizations. It conceives of an organization as a process that develops from the interaction of human cognition, organizational structure, and the types of decisions that need to be made. Because of these characteristics, the cognitive model focuses on the development and adaptation of organizations in different circumstances. Furthermore, this model accounts for the way in which specialization affects organizational behavior and coordination.

In conclusion, because each different organization model has its advantages and disadvantages, managers must decide which one (or ones) best captures the workings of their company by evaluating the assumptions and key processes of each, as well as by determining which one can solve the kinds of problems they need to solve.

TYPES OF ORGANIZATIONAL PLANNING STRUCTURES

Organizational planning involves designing an organization's structure to maximize efficiency. This includes dividing a company up into different units, departments, and teams. Prior to this division, managers must consider a company's goals and business obstacles as well as alternative company structures. Business goals may include, for example, increasing the flow of information, promoting teamwork, and reducing redundancy. Next, managers must consider the different organizational structures and select the one that holds the greatest potential for eliminating problems with the current corporate structure or for bringing about the desired structural environment. The selection may be made by taking different organizational models into consideration, as well.

Managers and executives generally divide an organization into different units based on one of the following six criteria:

Function. A manufacturing firm typically includes functional units such as engineering, production, finance, sales, and personnel. These different functions are controlled by managers who head each function. In this organizational structure, each function primarily focuses on its core tasks (e.g., production or finance).

Product. Large, diversified companies may find it advantageous to divide their tasks based on product groups, such as foodstuffs, farm chemicals, and pharmaceuticals. This organizational structure has the benefit of enabling each business unit to produce desired results. However, it can lead to high administrative costs and redundancy.

Customers. Companies may be divided into different units based on target customers. For example, a book publisher may be organized by retail bookstores, mail-order book stores, online book stores, and school system

tier, such as elementary, middle school, high school, and higher education.

Geographic Location. Many sales and service companies use geographic location as the basis for creating departments within the organization. This organizational structure calls for members of each group to concentrate on particular locations for which they are responsible.

Process. Some companies are organized by process. Process organization is common in manufacturing and clerical companies. For example, natural gas companies have different units for exploration, production, and distribution. This type of organizational structure enables each unit to have its own specialists.

Matrix. Matrix organizational structures include not only general functional units like production, sales, and finance, but also product or geographic units. Company executives frequently oversee the product units directly. The product units, in turn, collaborate with and coordinate the functional units. By adopting the matrix arrangement, companies attempt to reap the benefits of the functional and the product or geographic structures, while bypassing the inefficient and redundant aspects of the product structure. A company with a matrix organizational structure has functional units such as development, production, and sales matched in a matrix by product or geographic location.

Since the globalization of companies and businesses, matrix structure has been viewed as a popular option for organizations. As Margaret Oertig and Thomas Buergi note, "Many international companies have projects spanning a variety of nationalities, involving great geographical distance and a range of time zones." However, not all companies consider matrix structure an ideal method of organization. For example, Hewlett Packard CEO, Mark Hurd and former CEO of General Electric Jack Welch have both offered criticisms of matrix organizational structure, arguing that it can create complex reporting and accountability issues for workers within a company.

A *McKinsey Quarterly* article from 2007 notes that matrix organizations seem ideal for a global company while echoing these criticisms of matrix organization. Instead, the article's authors advocate the use of what they term "formal networks" as an organizational structure. While "formal networks" resemble a matrix structure in that they attempt to collect team members from all areas of an organization, the authors point out that "formal networks" are less hierarchical than matrix organizations.

Ultimately, company executives and managers must strive to select the organizational structure that best suits their fields of business; that offers the optimal amount of control, specialization, and cooperation; and that facilitates key business activities while also taking into consideration concerns for efficiency and effectiveness.

ORGANIZATIONAL BEHAVIOR

Organizational behavior is the study of individual behavior in an organizational setting. This includes the study of how individuals behave alone, as well as how individuals behave in groups. Organizational behavior is an interdisciplinary field dedicated to understanding individual and group behavior, interpersonal processes, and organizational dynamics. The purpose of organizational behavior is to gain a greater understanding of those factors that influence individual and group dynamics in an organizational setting so that individuals and the groups and organizations to which they belong may become more efficient and effective.

Organizational behavior is a relatively new field of study that draws most heavily from the psychological and sociological sciences. It also looks to scientific fields such as ergonomics, statistics, and psychometrics. Other topics of interest in the field of organizational behavior include the extent to which theories of behavior are culturally

bound, unethical decision-making, self-management and self-leadership, and work/family conflict.

MULTIPLE LEVELS OF ANALYSIS

One of the main reasons for this interdisciplinary approach is because the field of organizational behavior involves multiple levels of analysis. These different levels of analysis are necessary for understanding individual behavior within organizations because people always act within the context of their environment, which includes both objects and other people. Workers influence their environment and are also influenced by their environment, making the study of organizational behavior a multi-level endeavor. The different levels of analysis used in the field of organizational behavior are: the individual level, the group level, and the organizational level.

Individual Level of Analysis. At the individual level of analysis, organizational behavior involves the study of learning, perception, creativity, motivation, personality, turnover, task performance, cooperative behavior, deviant behavior, ethics, and cognition. At this level of analysis, organizational behavior draws heavily upon psychology, engineering, and medicine. For example, a study of organizational behavior at the individual level of analysis might focus on the impact of different types of overhead lighting on such factors as productivity and absenteeism.

Group Level of Analysis. At the group level of analysis, organizational behavior involves the study of group dynamics, intra- and intergroup conflict and cohesion, leadership, power, norms, interpersonal communication, networks, and roles. At this level of analysis, organizational behavior draws upon the sociological and socio-psychological sciences. For example, a study of how different personality types correspond to different leadership styles and levels of results operates at the group level of analysis.

Organization Level of Analysis. At the organization level of analysis, organizational behavior involves the study of topics such as organizational culture, organizational structure, cultural diversity, inter-organizational cooperation and conflict, change, technology, and external environmental forces. At this level of analysis, organizational behavior draws upon anthropology and political science. The various studies on organizational cultures, from William Ouchi's classic *Theory Z: How American Business Can Meet the Japanese Challenge* (1981) to the more recent *Organizational Culture and Leadership* (2004) are examples of organizational behavior conducted at the organization level of analysis.

ORGANIZATIONAL BEHAVIOR MANAGEMENT

Much of organizational behavior research is ultimately aimed at providing human resource management professionals with the information and tools they need to select, train, and retain employees in a fashion that yields maximum benefit for the individual employee as well as for the organization. As one author has written, "People are an organization's most important assets!" The study of organizational behavior is an attempt to maximize the effectiveness of this asset.

Organizational behavior management utilizes studies of organizational behavior as a tool to improve productivity and profit. There is an attempt to develop scientific principles that improve employee performance. This goes beyond simply understanding the general principles of human behavior in the organizational context and focuses on such specific issues as:

- Employee safety, stress, and health

- Evaluation of employee satisfaction and feedback systems

- Use of monetary and nonmonetary incentives

- Development of self-management procedures

- Programmed instruction, behavioral modeling, and computer-aided instruction

- Positive and negative side effects of management interventions

- Systems analysis of the way in which work gets done, measured, and evaluated

TRENDS

A number of important trends in the study of organizational behavior are the focus of research efforts. First, a variety of research studies have examined topics at the group level of analysis rather than exclusively at the individual level of analysis. For example, while empowerment has largely been investigated as an individual-level motivation construct, researchers have begun to study team empowerment as a means of understanding differences in group performance. Similar research has focused on elevating the level of analysis for personality characteristics and cooperative behavior from the individual level to the group level.

Another research trend is an increasing focus on personality as a factor in individual- and group-level performance. This stems from the movement toward more organic organization designs, increased supervisory span of control, and more autonomous work designs. All of these factors serve to increase the role that personality

plays as a determinant of outcomes such as stress, cooperative or deviant behavior, and performance.

Personality traits that are related to flexibility, stress hardiness, and personal initiative are also the subject of research. Examples of these personality traits include a tendency toward individualism or collectivism, self-monitoring, openness to experience, and a proactive personality. Forms of behavior that are constructive and change-oriented in nature are also studied. These forms of behavior are proactive in nature and act to improve situations for the individual, group, or organization. Examples of these behaviors include issue selling, taking initiative, constructive change-oriented communication, innovation, and proactive socialization.

Organizational behavior is a central concern of human resource managers. Research at all levels of organizational behavior continues to be an active field in both academia and management. A wide variety of issues and concerns are the focus of on-going studies and management techniques.

ORGANIZATIONAL CHART

An organizational chart is a pictorial representation of a company's structure and reporting relationships. This chart can provide a great deal of information and may help organizational members understand the overall structure of the organization and its strategy. This entry describes how organizational charts are constructed, including the software and other applications that can be used to create them; what information the organizational chart provides; the benefits of making the chart available publicly; and the circumstances under which a chart is likely to change.

CONSTRUCTING AN ORGANIZATIONAL CHART

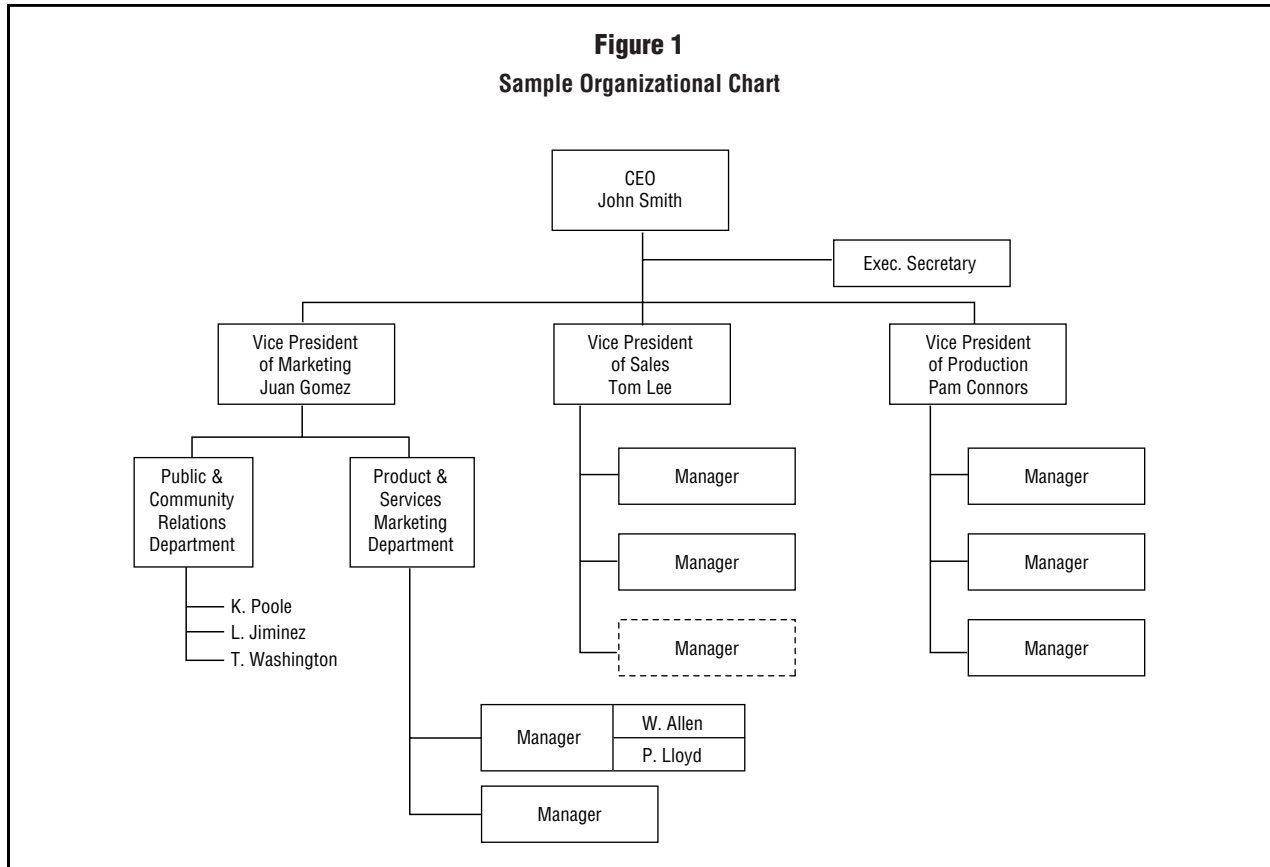
All organizational charts have similar elements that allow them to be easily interpreted and understood by people inside and outside of the organization. Charts consist of shapes and lines that represent work units and their hierarchy. See Figure 1 for an example of an organizational chart.

The basic building block of an organizational chart is the rectangle, which can represent a person or a work unit (e.g., a department). For example, as shown in Figure 1, the CEO position has a separate rectangle that denotes one person, but the entire Public and Community Relations Department is also represented by one rectangle. If the outline of the rectangle is dashed, this means that a position is open and must be filled, as with one of the manager positions. If a rectangle is divided, and two or more names are in it, this may indicate job sharing or that multiple people are responsible for the outcomes associated with this position. In the figure, W. Allen and P. Lloyd are comanagers in one area of the Production and Services Marketing Department, where they have a job-sharing arrangement and each works part-time hours.

The boxes may contain as much or as little information as the organization prefers. They may include a job title, an employee's name, an employee's department, or even information such as job tenure, education, or salary. Alternatively, a chart may be created without rectangles, with names or titles standing alone. The three employees in the Public and Community Relations Department are listed with their names not in rectangles. This often is done to save space on the chart.

Rectangles on an organizational chart are linked with solid or dashed lines. A solid line indicates a formal, direct relationship, and a dashed line indicates that one employee or department advises another or has some other sort of indirect relationship. Note that all but one of the reporting relationships in Figure 1 is formal. L. Jiminez has a dashed line to the Product and Services Marketing Department, which means that she sometimes will work for that department or will report to that department's manager. When lines represent a tree structure—when two or more rectangles are linked to another with multiple lines—this indicates that several individuals or departments report to one supervisor. For instance, the tree structure represents the relationship between the CEO and the three top

Figure 1

Sample Organizational Chart


managers who report to the CEO. Finally, a rectangle that is attached horizontally outside of the vertical hierarchy typically indicates an assistant or staff person. In the example, this is represented by the executive secretary to the CEO.

Computer software is the most common and user-friendly method for creating organizational charts. Organizational charts can be created using drawing tools in a word processing program, but diagramming programs offer more options and ease of use. For example, Microsoft's Visio 2007 presentation software allows for the creation of organizational charts, can be shared with colleagues in various formats, and is compatible with all other Microsoft applications. For creating larger, more complex charts, there are many different programs available for purchase. Some examples are OrgPlus7, Concept-Draw 7.6, SmartDraw 2008.3, and Abra OrgChart. These software programs allow quick, easy chart creation with point-and-click menus, automatic resizing and alignment. Diagramming software programs also allow charts to be easily downloaded into word processing documents, presentations, or Web sites for optimal visibility. Other features include the ability to insert photographs and

information from other human resources programs directly into charts.

Other diagramming software for creating organization charts can be used live on the Internet to allow user interface from business to business. The Google Apps Suite offers Google Docs, a program that allows for the creation and integration of organizational charts directly into documents that are accessible to multiple online users. Users are able to make changes to charts and documents based on a level of access determined by the account's administrator.

INFORMATION IN THE ORGANIZATIONAL CHART

Organizational charts provide a great deal of information about the organization as a whole and the interaction of its parts. From a chart, one can see the organization's structure, its hierarchy, the degree to which it is centralized or decentralized, and its chain of command.

Organizational Structure. First, organizational charts detail an organization's structure. It may be functional, in which work units are divided based on what they do and named after those functions (e.g., research and

development, marketing, sales, etc.). The structure may be divisional, based on product, customers served, or geographic location. Finally, an organizational chart may represent a matrix structure, in which work units are organized by function and division.

Organizational Hierarchy and Centralization. In addition to outlining the type of organizational structure, the organizational chart also indicates the number of management levels, whether the organizational structure is tall or flat, and the span of control at each level. Tall organizations have many levels of middle management and small spans of control. Each manager supervises and directs few employees, and the chain of command has many managers. Conversely, a flat organization has fewer management levels and larger spans of control. Because managers supervise more employees, employees tend to have more autonomy and discretion in their jobs.

Organizational hierarchy and the number of management levels often indicate the degree of centralization within an organization. Centralized organizations are those in which most of the decision making occurs by a few people at the top of the hierarchy. This typically creates a top-down management structure, in which top-level managers strongly control the direction of the workplace through their decisions and supervision. Conversely, an organization with a decentralized structure allows greater decision-making and authority at lower organizational levels. Highly decentralized companies may have units that operate nearly independently of one another. The degree of hierarchy on an organization's chart will help to determine the degree of centralization or decentralization within its structure. Typically, the taller the organization, the more centralized it is. Flatter organizations generally require more decentralization because managers each have broader spans of control and cannot direct and closely supervise so many people. Additionally, as previously described, the organization's structure may indicate the degree of centralization. Functional structures tend to be more centralized than divisional structures.

Chain of Command. The vertical and horizontal lines connecting the rectangles on an organizational chart indicate reporting relationships and chain of command. That is, they indicate which employees are directly responsible for the supervision of others and who has ultimate accountability for a group of employees.

AVAILABILITY OF THE ORGANIZATIONAL CHART

Many companies make their organizational chart available to their employees and to the public either online or in corporate literature. The members of the public who may

have an interest in a company's organizational chart include company shareholders, investors, distributors and suppliers, customers, potential job applicants, and even community members. The chain of command of a publicly traded company can often be found in a company's profile on Yahoo! Finance or Google Finance and are updated regularly. By providing this information, these external stakeholders and other interested parties may gain a better understanding of the organization. The chart may give them a sense of the organization's operations, workforce, or even its strategy.

Employees typically have access to the organizational chart through the employee handbook or a company Web site, generally in the "About Us" or "Investor Relations" sections. Providing the organizational chart to employees allows them to see the structure of the organization and to better understand how their positions fit into the bigger picture. Additionally, observing the chain of command helps an employee to understand to whom they are accountable, making diagnosing organizational problems easier.

CHANGES TO THE ORGANIZATIONAL CHART

The organizational chart must reflect any alterations to the organizational structure. The structure may change due to a company's growth, decline, or restructuring.

Growth or Decline. All organizations have a life cycle of growth, maturity, and decline, and in each stage the organizational structure is likely to be different. In the growth stage, the company is expanding rapidly, gaining customers and market share. Growth takes place when a company is just beginning and products and services are gaining a foothold. It may also occur when an organization develops a new product or expands into new markets, perhaps in other countries. With growth, the organizational chart will change. Levels of management may be added, along with new departments.

In maturity, an organization is no longer growing at a rapid rate and is stable in its production and sales. The organization may introduce minor changes to a product or service, but major changes to its structure are unlikely.

In the decline stage, the organization is losing ground in the marketplace. It may be that its products or services are becoming obsolete or that its competitors are taking over the market. In decline, the organization may shed levels of management or positions in all divisions. Additionally, it may outsource work in some areas and thus remove those departments from its structure. Or, as certain products or services are dropped from the organization, the work units needed for these products and services also may be eliminated. Thus, in the decline stage

the organizational chart is likely to be streamlined or shrunken.

Restructuring. Restructuring occurs when an organization reduces its workforce by eliminating large numbers of management and line employees. Restructuring typically occurs when information technology can be used to achieve the same productivity outcomes with fewer people. With restructuring, management levels may be eliminated entirely, or entire departments may be removed. This is particularly true if outsourcing accompanies the restructuring.

ORGANIZATIONAL CULTURE

An organizational culture is defined as the shared assumptions, values, and beliefs that guide the actions of its members. Large organizations usually have a dominant culture (shared by the majority of the organization) and subcultures (represented by groups of individuals with unique values or beliefs that may or may not be consistent with the dominant culture). Subcultures that reject the dominant culture are called *countercultures*. Organizational culture tends to be shaped by the founders' values, the industry and business environment, the national culture, and the senior leaders' vision and behavior.

THE IMPORTANCE OF ORGANIZATIONAL CULTURE

As people work together to accomplish goals, groups develop into organizations. As goals become more specific and longer-term, and work more specialized, organizations become both more formal and institutionalized. Organizations tend to take on a life of their own and widely held beliefs, values, and practices develop, differentiating one organization from another and often affecting the organization's success or failure. As one commentator has noted, "Most organizational scholars and observers now recognize that organizational culture has a powerful effect on the performance and long-term effectiveness of organizations."

The importance of organizational culture is a relatively new phenomenon. While organizational psychologists began developing theories of organizational behavior during the 1950s and 1960s, it wasn't until the 1980s that the culture of the organization was recognized as a key determinant of behavior and effectiveness. The interest in organizational cultures was largely created by William Ouchi's 1981 best-seller, *Theory Z: How American Business Can Meet the Japanese Challenge.* Ouchi considered organizational culture to be a key factor in creating an effective organization. In 1982 two other best-sellers, Terrance Deal and Allan Kennedy's *Corporate Cultures: The Rites and Rituals of Corporate Life* and Thomas Peters and Robert Waterman's *In Search of Excellence*, supported the idea that excellent companies tended to have strong cultures.

Throughout the 1980s, management scholars began attempting to describe these belief systems, which they referred to as organizational or corporate cultures. Interest in organizational culture has remained strong in subsequent decades as managers and executives continue to recognize the impact an organization's culture can have on such key factors as morale, productivity, and profit.

A STRONG ORGANIZATIONAL CULTURE

Strong organizational cultures are those where the core values of the dominant culture are strongly believed by the great majority of organizational members. A strong culture tends to increase behavior consistency and reduce turnover.

There are many practices within an organization that tend to keep a culture alive and measure the cultural fit between the organization and its employees. Many of the human resource practices such as selection, performance appraisal, training, and career development reinforce the organization's culture. Organizational beliefs also tend to influence the work norms, communication practices, and philosophical stances of employees. Organizations use a process called socialization to adapt new employees to the organization's culture. If employees do not adapt well, they feel increasing pressure from supervisors and from coworkers who are better acculturated. They might stay and fight, stay and become isolated, or leave the organization, voluntarily or involuntarily, and look for a different organization whose culture they fit better.

In contrast, employees who understand and share the organization's values have a better basis for making choices that match the firm's goals. Many organizations compete through innovation. When most employees understand and support the organization's expectations, less time is spent explaining, instructing, and building consensus before trying something innovative. Moreover, the error level will be lower in most cases. Employees who are well acculturated also find their work more meaningful: They are part of, and contributing to, something larger than themselves. Thus, a good cultural fit between employees and the organization contributes to employee retention, organizational productivity, and profit. However, strong cultures may be less adaptive to change, may create barriers to diversity, and may create barriers to successful acquisitions and mergers.

MEANS OF CONVEYING CULTURE

Organizations often convey cultural values explicitly by means of mission statements or corporate credos, or to a lesser extent through slogans, logos, or advertising campaigns. Leaders and managers also show what the organization values by what they say and do, what they reward, who they make allies, and how they motivate compliance. Other elements of culture appear tacitly in symbols and symbolic behavior. For instance, meeting protocols, greeting behavior, allocation and use of space, and status symbols are a few areas where organizational norms often develop. Culture can regulate social norms as well as work or task norms.

The new-employee orientation typically offered by organizations conveys selected cultural elements of which management is both aware and proud. Some cultural elements might be initially unpalatable, however, and some others might be hard to put into words. For instance, an orientation would rarely say outright that the culture rewards neglect of one's personal life and demands a sixty-hour work week, although these expectations are not unknown in corporate life. Perceptive new employees learn about tacit cultural elements through observation and through questioning trusted employees or mentors. This is not one-time learning; employees must continue to watch for signs that the rules are changing.

These organizational rules include explicit policy statements, but also a much larger and less evident set of unwritten organizational expectations. Attentive employees figure them out sooner than others. They listen to the metaphors, images, and sayings that are common in the organization. They watch, for example, the consequences of others' mistakes to reach conclusions about appropriate behavior.

Organizations also communicate values and rules through displayed artifacts. For example, in some organizations, the CEO's office displays many symbols of wealth, such as expensive original art or antiques. In others, the CEO's workspace is very spartan and differs little from that of other executives and higher-level managers. In the former case, a manager with other sources of income might be able to afford similar status symbols but would be unwise to display them since this might be perceived as competing with the CEO. In the latter case, display of personal wealth by people in general would probably be counter to organizational values.

Even the way a physical plant is laid out communicates cultural messages: Is it an open area where everyone can see everyone? Are there cubicles? Are there private offices? Is it easy or difficult to move and communicate between functional areas? Have ergonomics and convenience been considered or ignored? Are there adequate neutral spaces for people to meet to make decisions and solve problems? Do the break rooms and lunch rooms invite or discourage use?

SOME COMPONENTS OF CULTURE

The idea that organizations have cultures came originally from ethnography, the study and description of human social cultures. Researchers in organizational culture have borrowed some of that language. Individuals in societies took on specific "roles," such as ruler, priest, historian, or teacher. In organizations, similar roles emerge. The historian or storyteller, for instance, is usually a longtime employee who narrates inspirational stories about the company's early years or its evolution. Embodied in the stories are many of the core values that permeate the organization. This "organizational folklore" includes oft-repeated stories about the founder, a long-term CEO, a dramatic firing, or an individual who rose through the ranks very quickly owing to some attribute highly valued by the firm. The stars of an organization are comparable to a social culture's heroes. An organization's success stories yield "role models" for the ambitious.

Organizations develop "rites and rituals" comparable to traditional activities within an ethnic culture. Whereas some organizations might emphasize award ceremonies, others might de-emphasize explicit recognition and affiliation behaviors. Still others might foster "management by walking around," whereby managers spend frequent one-on-one time away from their desks giving praise or criticism to individuals. As another example, lunch with the president might be a longstanding tradition, although the amount of actual communication will vary from organization to organization according to unwritten rules about who talks to whom.

Although all organizations have both formal and informal communication networks, organizational culture strongly affects the content, reliability, and influence of

the informal network or "grapevine." When information through formal channels is scarce, the grapevine carries heavier traffic. Leaders aware of culture's importance try to find ways to tap and monitor the grapevine and sometimes use the grapevine by adding information to it.

CULTURE CHANGE

An organization's culture is composed of relatively stable characteristics that are based on deeply held values that are reinforced by many organizational practices. However, an organizational culture can be changed, and increasingly, such changes are becoming more frequent. Because of the fast-paced and dynamic nature of the twenty-first century's global environment, changes in organizational structure are today seen as just as important as constancy and steadfastness were in the previous century. As Cameron and Quinn point out in their 2006 book *Diagnosing and Changing Organizational Culture,* "Stability is interpreted more often as stagnation than steadiness, and organizations that are not in the business of change and transition are generally viewed as recalcitrant."

Beginning in the early 2000s, a number of books were published to guide organizations in changing their cultures. Such works as *Managing Change and Transition, Strategic Organizational Change,* and *The Corporate Culture Handbook: How to Plan, Implement, And Measure a Successful Culture Change Programme* have come to define the discussion of organizational culture. One example of when organizations must adapt their culture is when organizations become multinational. With the increase in global organizations, it has become clear that national cultures impinge on organizational cultures. Besides language differences, employees bring to the job many radically different assumptions about such aspects as the dignity of work, the proper relationship between employee and supervisor, the value of initiative, the treatment of unwelcome information, and the voicing of complaints. Organizations with international customers, and even more, those with global operations, have needed to learn how to adapt to a multicultural environment. Failure to adapt jeopardizes an organization's chance of success abroad.

Despite their importance and even necessity, cultural changes are not necessarily easy to decide upon or implement. Cultural changes are most likely to occur when there is a dramatic setback such as a financial crisis or when there is a turnover in top leadership. Also, younger and smaller organizations and organizations with a weak culture are more amenable to change.

Deliberate and major culture change occurs by executive fiat, by implementation of a plan, or a combination of these means. When leadership changes or when existing leadership commits to change, employees learn that the old assumptions which they were comfortable are no longer safe. After a merger or acquisition, for example, "how we do things here" will change, sometimes quickly and radically. A wise leadership team implements a planned culture-change process. The process usually consists of a series of two-way communications that elicit the prevailing assumptions, reassure employees that the changes can benefit them, introduce (sometimes gradually) the new vision, and work to gain employees' commitment and support. Leaders also must model the new culture for others and change the organization's structure and management practices to support the new culture. If the leaders skip the process or do an inadequate job, employees at all levels experience stress, confusion, and anger. When change is introduced so as not to arouse fear and resentment, however, transition may be relatively smooth.

To summarize, organizational culture is the shared assumptions, beliefs and values held by most members of an organization. Culture is conveyed in both explicit and implicit ways. Newcomers to an organization must quickly assimilate a great deal about the culture. Veteran employees must remain aware of cultural change too, especially when the leadership changes. A strong culture that is aligned with the organization's strategic context and is adaptive to environmental changes can enhance an organization's long-term financial performance.

ORGANIZATIONAL DEVELOPMENT

Organizational development is an ongoing, systematic process to implement effective change in an organization. Organizational development is known as both a field of applied behavioral science focused on understanding and managing organizational change and as a field of scientific study and inquiry. It is interdisciplinary in nature and draws on sociology, psychology, and theories of motivation, learning, and personality.

HISTORY OF ORGANIZATIONAL DEVELOPMENT

In the late 1960s organizational development was implemented in organizations via consultants, but was relatively unknown as a theory of practice and had no common definition among its practitioners. In 1969 Richard Beckhard, an authority on organizational development and change management, defined organizational development as "an effort, planned, organization-wide, and managed from the top, to increase organization effectiveness and health through planned interventions in the organization's processes, using behavioral-science knowledge."

Throughout the 1970s and 1980s organizational development became a more established field with courses and programs being offered in business, education, and administration curricula. In the 1990s and 2000s, organizational development continued to grow and evolve and its influences could be seen in theories and strategies such as total quality management (TQM), team building, job enrichment, and reengineering. The global marketplace and working remotely with telecommuting teams are aspects of business today that are theorized in up-and-coming organizational development ideologies.

RATIONALE AND IMPLEMENTATION

Organizational development takes into consideration how the organization and its constituents or employees function together. Does the organization meet the needs of its employees? Do the employees work effectively to make the organization a success? How can the symbiotic relationship between employee satisfaction and organizational success be optimized? Organizational development places emphasis on the human factors and data inherent in the organization-employee relationship. Organizational development strategies can be used to help employees become

more committed and more adaptable, which ultimately improves the organization as a whole.

The organizational development process is initiated when there is a need, gap, or dissatisfaction within the organization, either at the upper management level or within the employee body. Ideally, the process involves the organization in its entirety, with evidenced support from upper management and engagement in the effort by all members from each level of the organization.

To launch the process, consultants with experience in organizational development and change management are often utilized. These consultants may be internal to the company or external, with the cautionary understanding that internal consultants might be too entrenched in the existing company environment to effectively coordinate and enforce the action plans and solutions required for successful change. Analysts contracted jointly with consultants can also be an effective problem-solving method, and this route is often employed when issues arise among executive leaders.

Data analysis through task forces, interviews, and questionnaires can illuminate likely causes for disconnects throughout an organization. These gaps can then be analyzed, an action plan formed, and solutions employed. This is by no means a linear process, nor is it a brief one. Feedback from all constituents should be elicited throughout the process and used to make adjustments to the action plan as necessary. Constant monitoring during the entire implementation effort is important for its success and acceptance.

THE FUTURE OF ORGANIZATIONAL DEVELOPMENT

There are contradictory opinions about the status and future prospects of organizational development. Is it a theory whose time has come and gone? Does its basis in behavioral science, a "soft" science, make it unappealing? What are the challenges for the future?

An article by Bunker, Alban, and Lewicki proposes six areas that could revitalize the field of organizational development in the future: virtual teams, conflict resolution, work group effectiveness, social network analysis, trust, and intractable conflict. These authors suggest that focusing on these areas will help bridge the gap between research theory (i.e., academics) and practice (i.e., consultants). Getting these two groups to communicate with each other will benefit both groups and promote organizational development efforts.

In a survey conducted by Church, Waclawski, and Berr, twenty individuals involved in the study and practice of organizational development were questioned about their perspectives and predictions on the future of the

field. The most in-demand services, according to those polled, are:

- Executive coaching and development
- Team building and team effectiveness
- Facilitating strategic organizational change
- Systemic integration
- Diversity and multiculturalism

They list the daily challenges in the field as the need for speed, resistance to change, interpersonal skills and awareness, and differentiating organizational development, which refers to the variety of definitions of organizational development among practitioners and how this impacts consultants, clients, and the clients' needs.

The future of organizational development includes an international focus and more thought and theory where multiple cultures collaborate in the world of business. An emphasis on the individual and how he should be counseled will include ideas about ethnicity, culture, and a broader worldview, rather than merely the Euro-American perspective.

The opinions on the future direction of the field vary among its practitioners. Nevertheless, the continuing interest in and value of optimizing an organization's needs and goals with the needs, wants, and personal satisfaction of its employees indicate that organizational development will continue to be relevant to and vital for organizational reform in the future, either in its present form or through evolution into other theories and practices.

ORGANIZATIONAL LEARNING

The importance of learning in organizations has been recognized since the early twentieth century. Organizational learning was implicitly applied by Henry Ford in developing the Model T. This work demonstrated the existence of learning curves, whereby the time and cost needed to assemble products decreased by a constant percentage—usually 20 to 30 percent—for every doubling of output.

The phenomenon of learning curves, also called experience curves, progress curves, or learning by doing, became very popular in the 1960s and 1970s. At that time, many managers were held up to (and fired for not reaching) the 80 percent mark, meaning, with each doubling of output, costs were expected to decrease to 80 percent of the prior cost level. This overly simplistic view of learning curves resulted in disgruntlement with them in the 1980s.

Modern scholars realize that, although the learning curve is present in many organizations, there is great variation in the slope of those learning curves. The disparity in organizational learning rates clearly indicates that productivity rates are not guaranteed to improve as experience increases. Other factors are at play.

The goal of much research on organizational learning, is to determine which characteristics of an organization cause it to be able to continually learn and adapt to new circumstances. Those that are able to do so are called "learning organizations" because they are uniquely capable of improving themselves by learning from experience. Peter Senge popularized the concept of the learning organization in his 1993 book *The Fifth Discipline,* and he identified the following as its core ingredients:

1. Mental models—everyone sets aside old ways of thinking.

2. Personal mastery—everyone becomes self-aware and open to others.

3. Systems thinking—everyone learns how the whole organization works.

4. Shared vision—everyone understands and agrees to a plan of action.

5. Team learning—everyone works together to accomplish the plan.

Organizations that meet Senge's criteria offer work settings in which members develop their abilities to learn and are encouraged and helped to make that learning continuously available to everyone else. These organizations have value-driven organizational cultures that emphasize information sharing, teamwork, empowerment, participation, and learning. According to the 2006 Google Annual Report, the main benefit of the company's corporate culture has been the learning achieved through teamwork. Organized learning has been a natural offshoot of Google's dedication to the creativity and innovation of its collective, making it the most highly sought-after business model of the early twenty-first century.

Importantly, the leaders of learning organizations set an example for others by embracing change and communicating enthusiasm for solving problems and growing with new opportunities. Jack Welch, formerly the CEO of General Electric, communicated his enthusiasm for the learning organization when he once stated in an annual report that this was the company's only competitive advantage.

The imperative for improved learning derives from the emerging global, knowledge-based economy, which focuses on collective, entrepreneurial learning to create continual innovations in products, processes, and services. It is driven by the continuing growth of new technological knowledge. This, in turn, leads to newly definable markets for this knowledge and to changing organizational and network structures, thus enabling organizations to apply new technology in both old and new markets. The organizational learning and information sharing model used by Wikipedia is a good example of the global community organizing, synthesizing, and constantly editing information to the betterment of all who have access to it.

ORGANIZATIONAL STRUCTURE

Organizational structure refers to the way that an organization arranges people and jobs so that its work can be performed and its goals can be met. When a work group is very small, and face-to-face communication is frequent, formal structure may be unnecessary, but in a larger organization decisions have to be made about the delegation of various tasks. Thus, procedures are established that assign responsibilities for various functions. It is these decisions that determine the organizational structure.

In an organization of any size or complexity, employees' responsibilities typically are defined by what they do, who they report to, and for managers, who reports to them. Over time these definitions are assigned to positions in the organization rather than to specific individuals. The relationships among these positions are illustrated graphically in an organizational chart. The best organizational structure for any organization depends on many factors including the work it does; its size in terms of employees, revenue, and the geographic dispersion of its facilities; and the range of its businesses (the degree to which it is diversified across markets).

DEVELOPMENT OF THE TRADITIONAL ORGANIZATIONAL STRUCTURE

Understanding the historical context from which some of today's dominant organizational structures have developed helps to explain why some structures are the way they are. For instance, why are the old, but still operational steel mills such as U.S. Steel and Bethlehem Steel structured using vertical hierarchies? Why are newer steel mini-mills such as Chaparral Steel structured more horizontally, capitalizing on the innovativeness of their employees? Part of the reason, as this section discusses, is that organizational structure has a certain inertia—the idea borrowed from physics and chemistry that something in motion tends to continue on that same path. Changing

an organization's structure is a daunting managerial task, and the immensity of such a project is at least partly responsible for why organizational structures change infrequently.

At the beginning of the twentieth century the United States business sector was thriving. Industry was shifting from job-shop manufacturing to mass production, and thinkers like Frederick Taylor in the United States and Henri Fayol in France studied the new systems and developed principles to determine how to structure organizations for the greatest efficiency and productivity, which in their view was very much like a machine. Even before this, German sociologist and engineer Max Weber had concluded that when societies embrace capitalism, bureaucracy is the inevitable result. Yet, because his writings were not translated into English until 1949, Weber's work had little influence on American management practice until the middle of the twentieth century.

Management thought during this period did match Weber's ideas of bureaucracy, where power is ascribed to positions rather than to the individuals holding those positions. It also was influenced by Taylor's scientific management, or the "one best way" to accomplish a task using scientifically-determined studies of time and motion. Also influential were Fayol's ideas of invoking unity within the chain-of-command, authority, discipline, task specialization, and other aspects of organizational power and job separation. This created the context for vertically-structured organizations characterized by distinct job classifications and top-down authority structures, or what became known as the traditional or classical organizational structure.

Job specialization, a hierarchical reporting structure through a tightly-knit chain-of-command, and the subordination of individual interests to the superordinate goals of the organization combined to result in organizations arranged by functional departments with order and discipline maintained by rules, regulations, and standard operating procedures. This classical view, or bureaucratic structure, of organizations was the dominant pattern, as small organizations grew increasingly larger during the economic boom that occurred from the 1900s until the Great Depression of the 1930s. Henry Ford's plants were typical of this growth, as the emerging Ford Motor Company grew into the largest U.S. automaker by the 1920s.

The Great Depression temporarily stifled U.S. economic growth, but organizations that survived emerged with their vertically-oriented, bureaucratic structures intact as public attention shifted to World War II. Post-war rebuilding reignited economic growth, powering organizations that survived the Great Depression toward increasing size in terms of sales revenue, employees, and geographic dispersion. Along with increasing growth, however, came

increasing complexity. Problems in U.S. business structures became apparent and new ideas began to appear. Studies of employee motivation raised questions about the traditional model. The "one best way" to do a job gradually disappeared as the dominant logic. It was replaced by concerns that traditional organizational structures might prevent, rather than help, promote creativity and innovation—both of which were necessary as the century wore on and pressures to compete globally mounted.

DIFFERENT ORGANIZATIONAL STRUCTURES

There are multiple structural variations that organizations can take on, but there are a few basic principles that apply and a small number of common patterns. The structure of every organization is unique in some respect, but all organizational structures develop or are consciously designed to enable the organization to accomplish its work. Typically, the structure of an organization evolves as the organization grows and changes over time.

Researchers generally identify four basic decisions that managers have to make as they develop an organizational structure, although they may not be explicitly aware of these decisions.

1. Division of labor. The organization's work must be divided into specific jobs.

2. Departmentalization. Unless the organization is very small, the jobs must be grouped in some way.

3. Span of control. The number of people and jobs that are to be grouped together must be decided, which is related to the number of people that are to be managed by one person.

4. Authority. The way decision-making authority is to be distributed must be determined.

In making each of these design decisions, a range of choices are possible. At one end of the spectrum, jobs are highly specialized with employees performing a narrow range of activities; while at the other end of the spectrum employees perform a variety of tasks. In traditional bureaucratic structures, there is a tendency to increase task specialization as the organization grows larger. In grouping jobs into departments, the manager must decide the basis on which to group them. The most common basis, at least until the last few decades, was by function. For example, all accounting jobs in the organization can be grouped into an accounting department, all engineers can be grouped into an engineering department, and so on.

The size of the groupings also can range from small to large depending on the number of people the managers supervise. The degree to which authority is distributed throughout the organization can vary as well, but

traditionally structured organizations typically vest final decision-making authority by those highest in the vertically structured hierarchy. Even as pressures to include employees in decision-making increased during the 1950s and 1960s, top management usually made final decisions. The traditional model of organizational structure is thus characterized by high job specialization, functional departments, narrow spans of control, and centralized authority. Such a structure has been referred to as traditional, classical, bureaucratic, formal, mechanistic, or command and control. A structure formed by choices at the opposite end of the spectrum for each design decision is called unstructured, informal, or organic.

BASIS FOR DEPARTMENTALIZATION

Many organizations group jobs in various ways in different parts of the organization, but the basis that is used at the highest level plays a fundamental role in shaping the organization. There are four commonly used bases: functional, geographic, product, and customer/market.

Functional Departmentalization. Every organization of a given type must perform certain jobs in order to do its work. For example, key functions of a manufacturing company include production, purchasing, marketing, accounting, and personnel. The functions of a hospital include surgery, psychiatry, nursing, housekeeping, and billing. Using such functions as the basis for structuring the organization may, in some instances, have the advantage of efficiency. Grouping jobs that require the same knowledge, skills, and resources allows them to be done efficiently and promotes the development of greater expertise. A disadvantage of functional groupings is that people with the same skills and knowledge may develop a narrow departmental focus and have difficulty appreciating any other view of what is important to the organization; in this case, organizational goals may be sacrificed in favor of departmental goals. In addition, coordination of work across functional boundaries can become a difficult management challenge, especially as the organization grows in size and spreads to multiple geographical locations.

Geographic Departmentalization. Organizations that are spread over a wide area may find advantages in organizing along geographic lines so that all the activities performed in a region are managed together. In a large organization, simple physical separation makes centralized coordination more difficult. Also, important characteristics of a region may make it advantageous to promote a local focus. For example, marketing a product in Western Europe may have different requirements than marketing the same product in Southeast Asia. Companies that market products globally sometimes adopt a geographic structure. In addition, experience gained in a regional division is often excellent training for management at higher levels.

Product Departmentalization. Large, diversified companies are often organized according to product. All the activities necessary to produce and market a product or group of similar products are grouped together. In such an arrangement, the top manager of the product group typically has considerable autonomy over the operation. The advantage of this type of structure is that the personnel in the group can focus on the particular needs of their product line and become experts in its development, production, and distribution. A disadvantage, at least in terms of larger organizations, is the duplication of resources. Each product group requires most of the functional areas such as finance, marketing, production, and other functions. The top leadership of the organization must decide how much redundancy it can afford.

Customer/Market Departmentalization. An organization may find it advantageous to organize according to the types of customers it serves. For example, a distribution company that sells to consumers, government clients, large businesses, and small businesses may decide to base its primary divisions on these different markets. Its personnel can then become proficient in meeting the needs of these different customers. In the same way, an organization that provides services such as accounting or consulting may group its personnel according to these types of customers. Figure 1 depicts an organization grouped by customers and markets.

TRADITIONAL ORGANIZATIONAL STRUCTURE

The traditional approach is the vertically-arranged organizational structure that came to dominate in the first half of the twentieth century. This traditional model is easily represented in a graphical form by an organizational chart. It is a hierarchical or pyramidal structure with a president or other executive at the top, a small number of vice presidents or senior managers under the president, and several layers of management below this, with the majority of employees at the bottom of the pyramid. The number of management layers depends largely on the size of the organization. The jobs in the traditional organizational structure usually are grouped by function into departments such as accounting, sales, human resources, and so on. Figures 2a and 2b illustrate such an organization grouped by functional areas of operations, marketing, and finance.

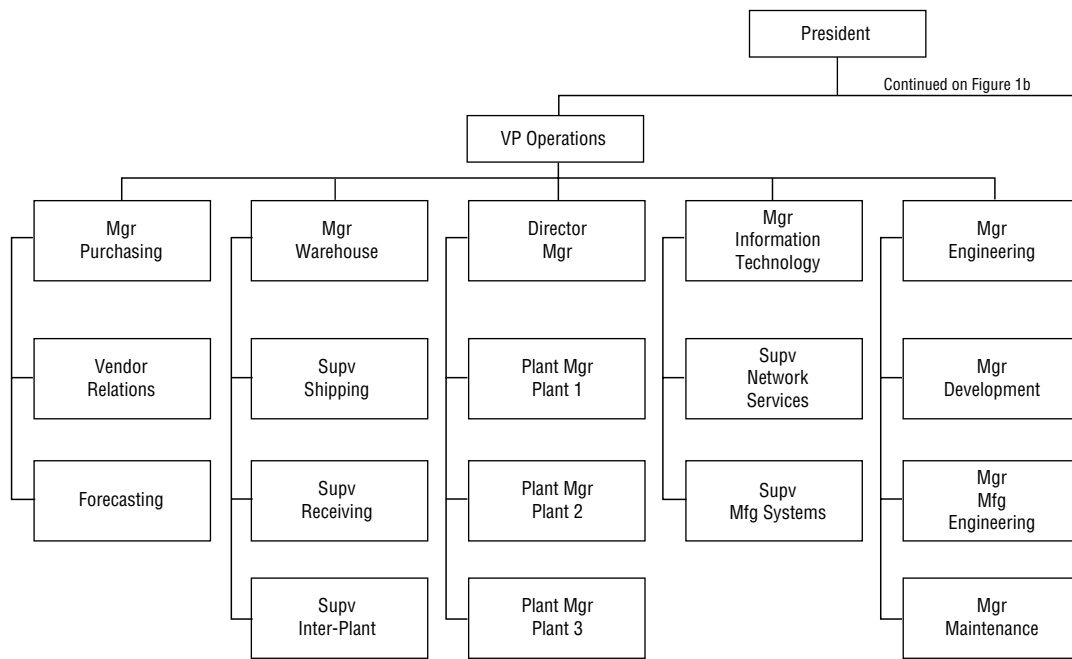
Figure 1a
Organizational Structure


Figure 1b
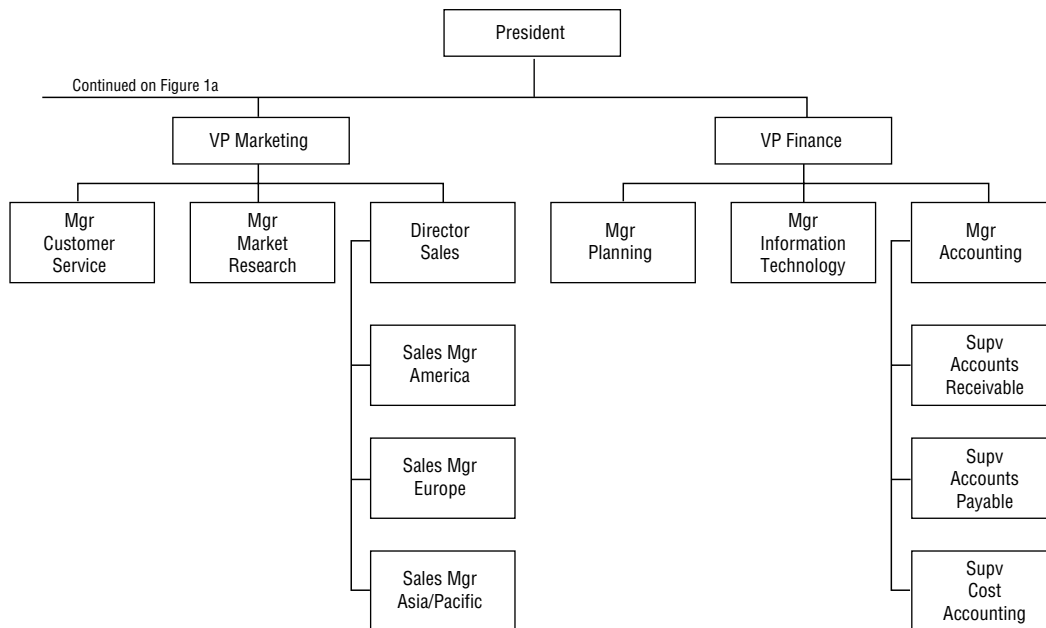
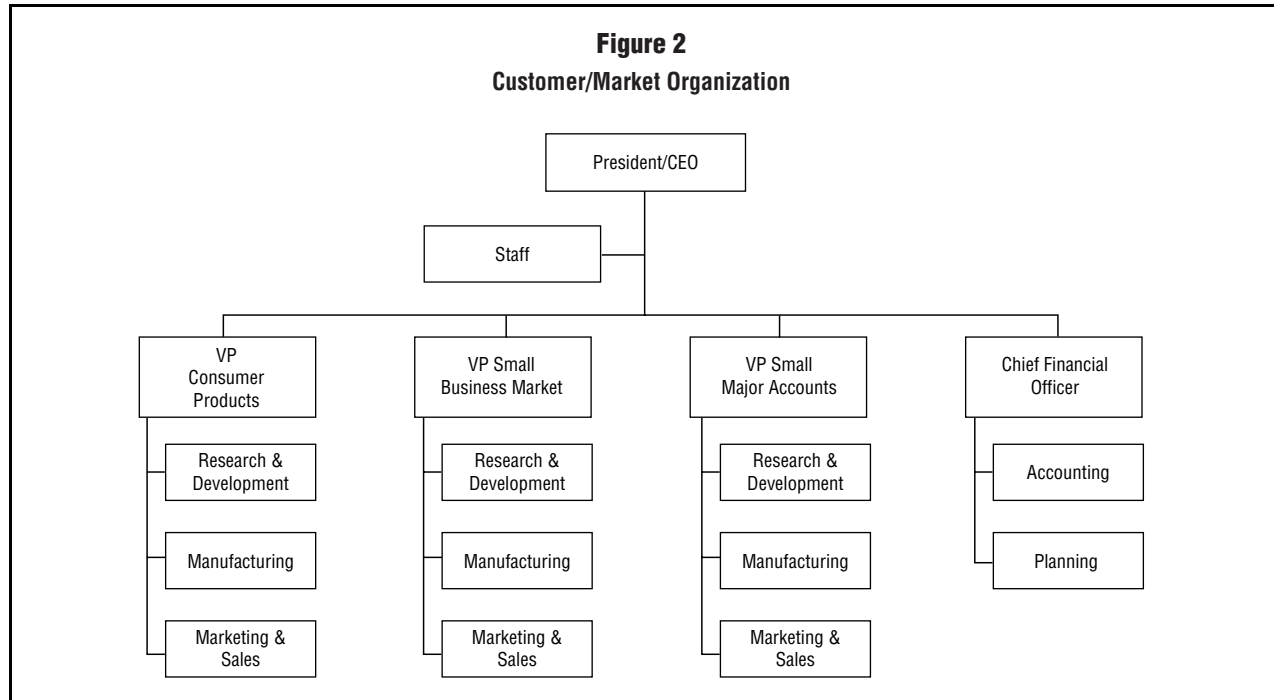
Organizational Structure

Figure 2
Customer/Market Organization




MATRIX ORGANIZATIONAL STRUCTURE

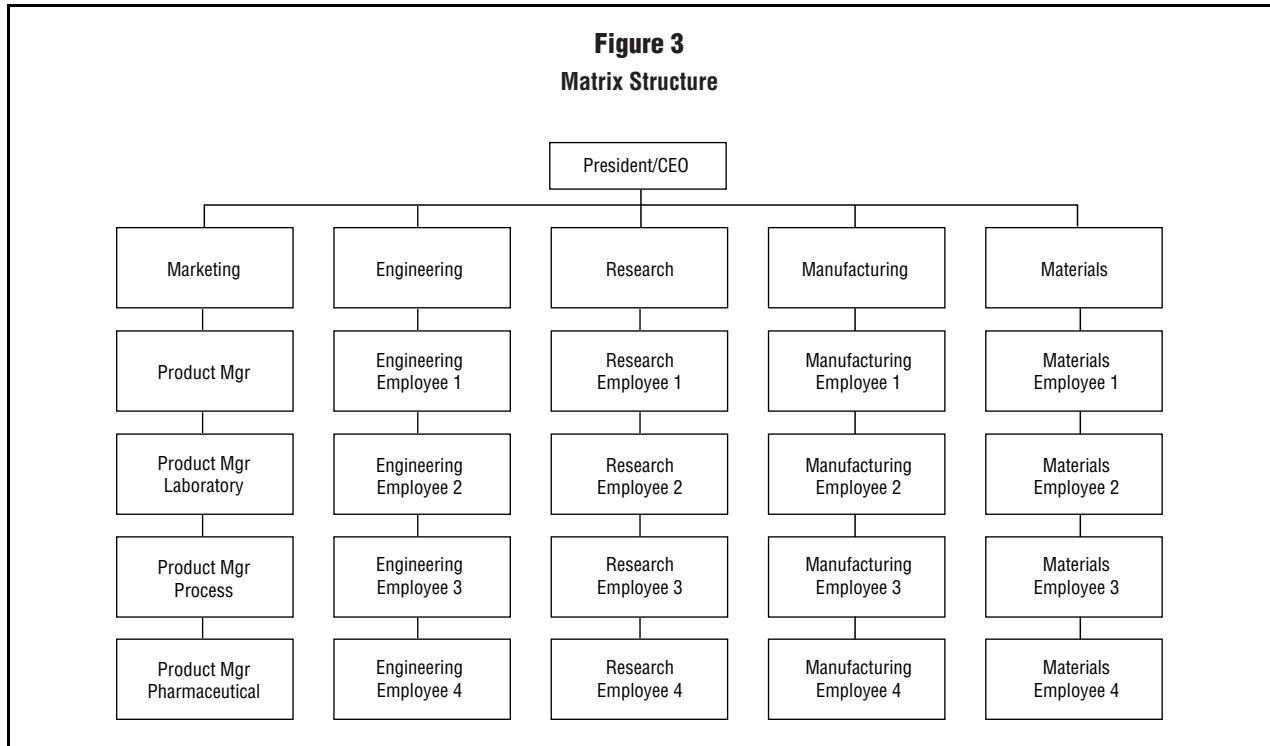
Some organizations find that none of the aforementioned structures meet their needs. One approach that attempts to overcome the inadequacies is the matrix structure, which is the combination of two or more different structures. Functional departmentalization commonly is combined with product groups on a project basis. For example, a product group wants to develop a new addition to its line; for this project, it obtains personnel from functional departments such as research, engineering, production, and marketing. These personnel then work under the manager of the product group for the duration of the project, which can vary greatly. These personnel are responsible to two managers (as shown in Figure 3).

One advantage of a matrix structure is that it facilitates the use of highly specialized staff and equipment. Rather than duplicating functions as would be done in a simple product department structure, resources are shared as needed. In some cases, highly specialized staff may divide their time among more than one project. In addition, maintaining functional departments promotes functional expertise, while at the same time working in project groups with experts from other functions fosters cross-fertilization of ideas.

The disadvantages of a matrix organization arise from the dual reporting structure. The organization's top management must take particular care to establish proper procedures for the development of projects and to keep communication channels clear so that potential conflicts do not arise and hinder organizational functioning. In theory at least, top management is responsible for arbitrating such conflicts, but in practice power struggles between the functional and product manager can prevent successful implementation of matrix structural arrangements. Besides the product/function matrix, other bases can be related in a matrix. Large multinational corporations that use a matrix structure most commonly combine product groups with geographic units. Product managers have global responsibility for the development, manufacturing, and distribution of their own product or service line, while managers of geographic regions have responsibility for the success of the business in their regions.

STRATEGIC BUSINESS UNITS

As corporations become very large they often restructure as a means of revitalizing the organization. Growth of a business often is accompanied by a growth in bureaucracy, as positions are created to facilitate developing needs or opportunities. Continued changes in the organization or in the external business environment may make this bureaucracy a hindrance rather than a help, not simply because of the size or complexity of the organization but due to a sluggish bureaucratic way of thinking. One approach to encourage new ways of thinking and acting

Figure 3
Matrix Structure


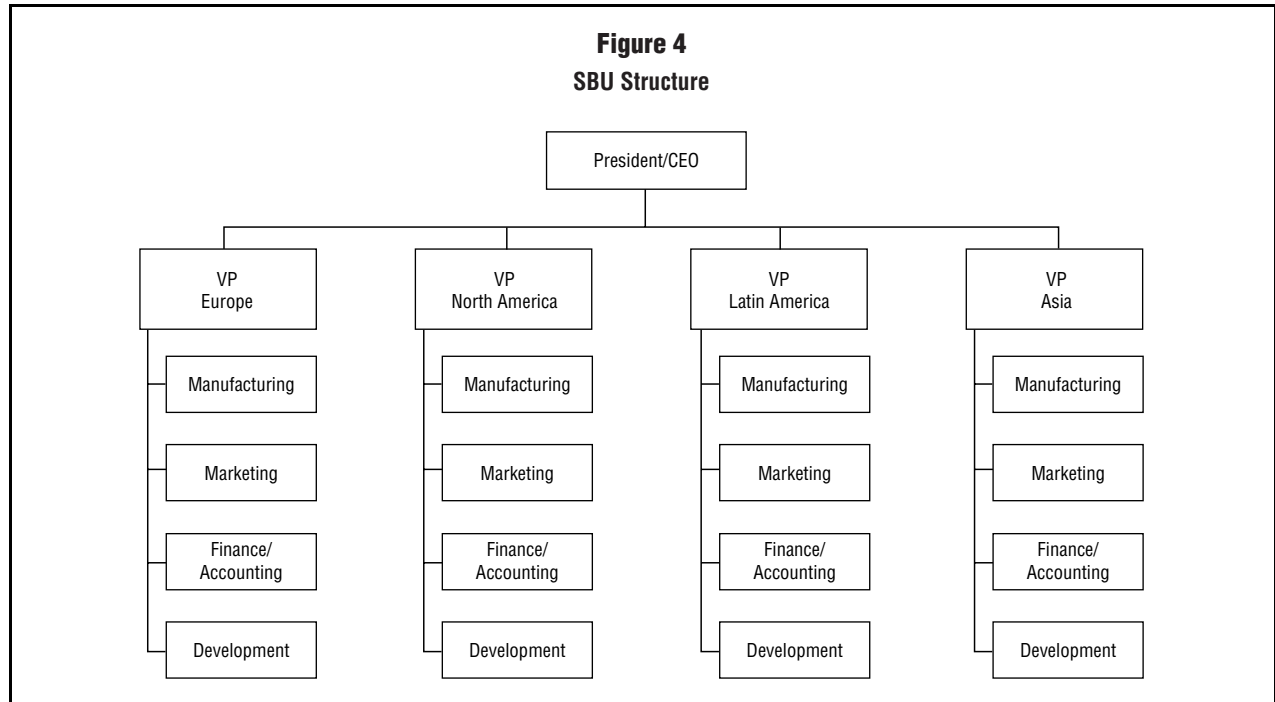
is to reorganize parts of the company into largely autonomous groups, called strategic business units (SBUs). Such units generally are set up like separate companies, with full profit and loss responsibility invested in the top management of the unit—often the president of the unit and/or a senior vice president of the larger corporation. This manager is responsible to the top management of the corporation. This arrangement can be seen as taking any of the aforementioned departmentalization schemes one step further. The SBUs might be based on product lines, geographic markets, or other differentiating factors. Figure 4 depicts SBUs organized by geographic area.

EMERGING TRENDS IN ORGANIZATIONAL STRUCTURE

Except for the matrix organization, all the structures described above focus on the vertical organization; that is, who reports to whom, who has responsibility and authority for what parts of the organization, and so on. Such vertical integration is sometimes necessary, but may be a hindrance in rapidly changing environments. A detailed organizational chart of a large corporation structured on the traditional model would show many layers of managers; decision-making flows vertically up and down the layers, but mostly downward. In general terms, this is an issue of interdependence.

In any organization, the different people and functions do not operate completely independently. To a greater or lesser degree, all parts of the organization need each other. Important developments in organizational design in the last few decades of the twentieth century and the early part of the twenty-first century have been attempts to understand the nature of interdependence and improve the functioning of organizations in respect to this factor. One approach is to flatten the organization, to develop the horizontal connections and de-emphasize vertical reporting relationships. At times, this involves simply eliminating layers of middle management. For example, some Japanese companies—even very large manufacturing firms—have only four levels of management: top management, plant management, department management, and section management. Some U.S. companies also have drastically reduced the number of managers as part of a downsizing strategy; not just to reduce salary expense, but also to streamline the organization in order to improve communication and decision-making.

In a virtual sense, technology is another means of flattening the organization. The use of computer networks and software designed to facilitate group work within an organization can speed communications and decision-making. Even more effective is the use of intranets to make company information readily accessible throughout the organization. The rapid rise of such technology has made virtual organizations and boundaryless organizations possible, where managers, technicians, suppliers, distributors, and customers connect digitally rather than physically.

Figure 4
SBU Structure


A different perspective on the issue of interdependence can be seen by comparing the organic model of organization with the mechanistic model. The traditional, mechanistic structure is characterized as highly complex because of its emphasis on job specialization, highly formalized emphasis on definite procedures and protocols, and centralized authority and accountability. Yet, despite the advantages of coordination that these structures present, they may hinder tasks that are interdependent. In contrast, the organic model of organization is relatively simple because it de-emphasizes job specialization, is relatively informal, and decentralizes authority. Decision-making and goal-setting processes are shared at all levels, and communication ideally flows more freely throughout the organization.

A common way that modern business organizations move toward the organic model is by the implementation of various kinds of teams. Some organizations establish self-directed work teams as the basic production group. Examples include production cells in a manufacturing firm or customer service teams in an insurance company. At other organizational levels, cross-functional teams may be established, either on an ad hoc basis (e.g., for problem solving) or on a permanent basis as the regular means of conducting the organization's work. Aid Association for Lutherans is a large insurance organization that has adopted the self-directed work team approach. Part of the impetus toward the organic model is the belief that this kind of structure is more effective for employee moti-vation. Various studies have suggested that steps such as expanding the scope of jobs, involving workers in problem solving and planning, and fostering open communications bring greater job satisfaction and better performance.

Saturn Corporation, a subsidiary of General Motors (GM), emphasizes horizontal organization. It was started in 1985 with the intention to learn and incorporate the best in business practices in order to be a successful U.S. auto manufacturer. The organizational structure that it adopted is described as a set of nested circles, rather than a pyramid. At the center is the self-directed production cell, called a Work Unit. These teams make most, if not all, decisions that affect only team members. Several such teams make up a wider circle called a Work Unit Module. Representatives from each team form the decision circle of the module, which makes decisions affecting more than one team or other modules. A number of modules form a Business Team, of which there are three in manufacturing. Leaders from the modules form the decision circle of the Business Team. Representatives of each Business Team form the Manufacturing Action Council, which oversees manufacturing. At all levels, decision-making is done on a consensus basis, at least in theory.

Saturn was originally established as an independently administered subsidiary of General Motors. Poor financial performance in the early twenty-first century led to a 2006 decision to reintegrate the company into the traditional GM divisional structure. GM executives hoped that the positive lessons learned from the Saturn experiment

would help improve the rest of GM's operation, making the company as a whole more competitive. In 2008, GM announced plans to sell Saturn. Despite these financial moves, GM has never repudiated the structural experiment, and many commentators continue to laud Saturn for its innovative approach to corporate organization.

RESTRUCTURING

Industry consolidation—creating huge global corporations through joint ventures, mergers, alliances, and other kinds of interorganizational cooperative efforts—has become increasingly important in the twenty-first century. Among organizations of all sizes, concepts such as agile manufacturing, just-in-time inventory management, and ambidextrous organizations are impacting managers' thinking about their organizational structure. Indeed, few leaders were likely to blindly implement the traditional hierarchical structure common in the first half of the twentieth century. The early twenty-first century has been dominated by the thinking that changing organizational structures, while still a monumental managerial challenge, can be a necessary condition for competitive success. As the authors of *Designing Organizations to Create Value* (2003) write, "a poor design can lead to lost profits and even result in the failure of the institution."

Indeed, corporate restructuring has become a popular response to financial difficulties in the twenty-first century. However, there are dangers to following the path of reorganization. Removing layers of bureaucracy to cut costs is tempting, but it can often be the case that removed layers of management creep back into the organization. It can also be difficult to reshape an organization with a strong organizational culture, as many well-established firms have. Further, reorganization may not be an appropriate response to trouble. According to a 2008 article in the *Harvard Business Review*, "in efforts to improve performance, most organizations go right to structural measures because moving lines around the org chart seems the most obvious solution and the changes are visible and concrete." However, the article notes, such changes are generally only short-term and "Several years later, companies usually end up in the same place they started."

Whatever the potential dangers, structural reorganization is likely to remain a popular corporate strategy in the fast-paced global environment of the twenty-first century. Properly handled, restructuring—particularly away from the traditional vertical model—can increase competitiveness and reorient the organizational culture and behaviors to enhance productivity and profits. Even with the attendant dangers, restructuring is a tempting path. As the authors of *Diagnosing and Changing Organizational Culture* (2006) note, "The failure rate of most planned organizational change initiatives is dramatic," but "organ-

izations that are not in the business of change and transition are generally viewed as recalcitrant."

ORGANIZING

Organizing is the managerial function of arranging people and resources to work toward a common goal. The purposes of organizing include, but are not limited to determining the tasks to be performed to achieve objectives, dividing tasks into specific jobs, grouping jobs into departments, specifying reporting and authority relationships, delegating the authority necessary for task accomplishment, and allocating and deploying resources in a coordinated fashion.

Henri Fayol first identified organizing as a function of management in his classic monograph *General and Industrial Administration.* This book was published in France in 1916 but was not translated into English until the 1920s, and it was not published in the United States until 1949. Fayol's monograph has had a profound effect on the teaching and practice of management in the years since. Early "principles of management" texts published

in the 1950s generally were organized around management functions, including organizing, as are most basic management texts from the late 1990s.

Organizing plays a central role in the management process. Once plans are created, the manager's task is to see that they are carried out. Given a clear mission, core values, objectives, and strategy, the role of organizing is to begin the process of implementation by clarifying jobs and working relationships. It identifies roles and how different parts of the organization relate to and work with one another. All of this, of course, can be done in many ways. The strategic leadership challenge is to choose the best organizational form to fit the strategy and other demands.

ORGANIZING DECISIONS

When organizing, managers must make decisions about the division of labor and work specialization, departmentalization, chain of command, span of management, centralization, and formalization. Collectively, these decisions are often called organizational design.

Division of Labor or Specialization. More than two centuries ago, Adam Smith concluded that division of labor contributes to increased productivity and efficiency by allowing workers to specialize and become proficient at a specific task. This principle, coupled with technological advances, made possible the tremendous productivity of industrial companies during most of the twentieth century.

By the 1940s most manufacturing jobs in developed nations were highly specialized, with workers performing specific, standardized, and repetitive tasks. This resulted in reduced staffing, training, and compensation costs, since highly skilled workers were often not necessary. In addition, since employees were doing the same task repetitively, they tended to become very good at it.

Despite the improvements in productivity made possible by the division of labor, managers must be aware of the negative aspects of specialization: fatigue, stress, boredom, low quality products, absenteeism, and turnover. Such problems have led to programs geared toward job enlargement and job enrichment. Many enterprises now cross-train specialized workers to avoid constant repetitive work and reduce the risk of layoffs should one skill become obsolete.

Departmentalization. After the work to be completed is organized into identifiable jobs through a process of dividing labor, jobs are then combined into logical sections or departments. Doing so allows for effective coordination of effort. There are many ways to departmentalize, each of which has important advantages and disadvantages. One of the most common forms is functional departmentalization, which involves grouping similar jobs into a common department, such as accounting, sales, human resources, and engineering. Another form

is product departmentalization, which involves organizing around an enterprise's various product lines. Other ways of departmentalizing include organizing by customer and by geographic territory. In practice, most large companies use a hybrid form of departmentalization, which means they combine one or more of the above methods to form their organizational structure.

Chain of Command. The chain of command is a line of authority extending from the top to the bottom of the organizational structure. Classic principles of organizing emphasize that one must be aware of the need to define the extent of managers' responsibility and authority by specifying their place in the chain of command. Another principle of organizing related to the chain of command is called the unity of command, which states that a person should have only one superior to whom he or she must report.

Span of Management. The span of management, often called the span of control, is the number of individuals who are directly responsible to a particular manager. A classic principle of organizing suggests that there are definite limits to the number of subordinates one manager can supervise effectively. When organizing, managers must keep these limits in mind. Wide spans of management lead to flatter organizational structures with fewer layers of management, and are thus considered more efficient. However, if spans become too wide managers may not be able to provide adequate direction to subordinates. Narrow spans of management lead to tall organizational structures with many layers of management. Although narrower spans of management allow for closer supervision of subordinates they have many drawbacks, including cost, communication problems, and difficulty in developing the initiative and autonomy of subordinates.

In general, the trend is toward wider spans of management, with an accompanying decrease in management hierarchy. Technological advances in information processing and communication have made wider spans of management more feasible.

Chief among these advances is methods of organization that make it possible for multiple users to co-manage projects away from a centralized office. Software (like PeopleReady and SharePoint) helps organize group efforts in communication, building a customer base, finding and sharing information, creating a proactive mobile workforce, and organizing the company's platform.

Degree of Centralization. Another organizing decision is the degree of centralization in the organizational structure. If decision-making authority in an organization is highly centralized, then most major decisions are made at the upper levels of the structure. Conversely, if decision-making

authority is decentralized, important decisions are often made at lower levels of the hierarchy. The degree of centralization that is appropriate for a given organization depends upon many factors, including the nature of the environmental conditions that face the enterprise, the characteristics and abilities of lower-level employees, and the size of the enterprise. Many organizations are favoring a greater degree of decentralization of their decision-making authority.

Formalization. The degree of formalization in an enterprise refers to the degree to which there are standardized rules and procedures governing the activities of employees. A company with a high degree of formalization is characterized by detailed job descriptions and clearly defined policies and procedures covering a wide variety of employee behaviors. Conversely, a company with a low level of formalization is characterized by non-structured jobs and fewer explicit policies and procedures.

As companies grow larger, a certain amount of formalization is inevitable. Employees require some direction in their job responsibilities and in the procedures required for consistency within the organization's production schema. When organizing, however, managers should be aware of the costs of excessive formalization, which may include stifling employee creativity and innovation as well as slowing the organization's responsiveness to critical issues and problems.

FACTORS AFFECTING ORGANIZING DECISIONS

There is no standard formula for the best way to organize an enterprise. Several factors have been shown to influence organizing decisions. Among the most important of these factors are strategy, size, environmental conditions, and technology.

Strategy. Managers organize in order to achieve the objectives of the enterprise for which they work. Thus, the strategy of the enterprise affects organizing decisions. Changes in strategy frequently necessitate changes in the way the enterprise is organized.

Size. Small enterprises tend to exhibit less formalization, centralization, and complexity in their organizational structure. Nevertheless, enterprises of the same size may be organized quite differently because of differences in strategy, environmental conditions, and technology.

Environmental Conditions. The key factor in the external environment that is relevant to organizing is uncertainty. Some enterprises face competitive environments that change rapidly and are quite complex, while others face relatively stable conditions. Generally, turbulent envi-ronments call for organizing decisions that lead to less formalization and centralization in the organizational structure. Companies that wish to be less formal and operate from a less upper-management driven schema will benefit from sharing as much of the information and responsibility as possible with employees at every level in the organization. Weekly newsletters including finance information, town hall-style meetings, an open door policy at all levels of the hierarchy, and an open forum company-wide instant messenger system will all serve to this end.

Technology. The processes by which an enterprise transforms inputs into outputs may also affect organizing decisions. Some research suggests that organizing decisions that lead to high degrees of formalization, centralization, and work specialization are more appropriate for routine technologies and that the converse is true for non-routine technologies. The trend in popular business models shifts constantly, but enterprises of all sizes should take their own needs—not what is popular—into consideration when deciding the degree of formalization and centralization they will implement.

OUTSOURCING AND OFFSHORING

Outsourcing refers to a firm's practice of paying another firm to perform a function or produce a product that could be done or made in-house by the paying firm. It usually involves more information exchange, coordination, and trust than a mere vendor relationship, since a certain amount of management control is transferred to the supplier. Products and services can be outsourced domestically or to a foreign company. Outsourcing is increasingly associated with firms located overseas, where salaries are markedly lower.

Business process outsourcing, or BPO, is the most common type of outsourcing, occurring when businesses outsource a part of their process to another company, with the goal of cutting costs and improving efficiency. Payroll, accounting, and customer service outsourcing are all examples of BPO. There are two classifications of BPOs: front office and back office. Front office BPO refers to outsourcing parts of the process that include customers or visible parts of the company, such as tech support or customer service. Back office BPO refers to activities that are not as visible and that do not come in contact with the customer directly (such as billing supply purchasing and other accounting services).

Outsourcing and offshoring began in the 1960s and 1970s with the transfer of physical manufacturing processes to lower-cost areas. For example, some U.S. companies shifted production to factories in Mexico that were part of a *maquiladora* system. Offshoring of physical products then moved to other low-cost locations such as China, India, the Philippines, and Eastern Europe. Despite increased transportation, dock, duty, and broker costs and loss of supply-chain speed, firms found that a 30 to 50 percent reduction in labor costs more than compensated for these increases.

The information technology revolution has made location much less important since inputs and outputs can be transmitted digitally. This has facilitated the offshoring of many white-collar functions. For example, the computer manufacturer Dell has outsourced its technical support for residential customers. When customers dial the number for technical support they are connected with technicians in India. With the costs of establishing sufficient bandwidth, compatible software connections, and video hookups decreasing rapidly, more employers may embrace the opportunity to replace employees located in the United States with lower-cost workers overseas.

Some analysts foresee a new global division of labor emerging. They propose that the West will focus on the highest levels of product creation, the part that entails artistry, creativity, and empathy with the customer, and the jobs involving turning these concepts into actual products and services will be sent overseas. However, outsourcing is also used for the process of innovation. Some American firms feel that their current spending on research and development is not yielding a sufficient return, so they are turning to "original design manufacturers" (ODMs). These ODMs completely design products that are then sold to firms such as Dell, Motorola, and Philips, who tweak them to their own specifications and label them with their own brand names.

TYPES OF OUTSOURCING

Although all types of outsourcing share similar characteristics already discussed, there are many different types of outsourcing recognized in the business world. Marc

Schniederjans, in his 2008 book, *Outsourcing and Insourcing in an International Context*, gives an excellent list of the most common types of outsourcing, which include:

- *Offshore Outsourcing.* This refers to outsourcing to a firm located in another country. It does not mean that a company opens a branch in a different country—which is actually a form of insourcing, since the business is closer in proximity—but merely that another company enters the supply chain in an international relationship.

- *Nearshore Outsourcing.* This is a type of offshore outsourcing, but occurs when a company outsources to a nation that is nearby. For instance, America outsources many operations to Mexico, a neighboring country. Nearshore outsourcing reduces transportation and often communication costs.

- *Transitional Outsourcing.* This type of outsourcing allows a business to concentrate on a particular part of the business system, while outsourcing older or more traditional models. A company may outsource certain outdated technologies while working to develop a new replacement technology within the organization. Other companies may want to give up a business system entirely to free resources they can use to specialize.

- *Co-sourcing.* Co-sourcing involves paying the providing firm based on their performance, usually in reaching a goal. Companies collaborate on setting expectations and fulfilling them, and the provider is compensated when expectations are met.

- *Spin-Offs.* Spin-offs occur when a company splits and a separate organization is established. Tasks are switched to this new organization.

- *Backsourcing.* Also known as an insourcing activity, backsourcing occurs when a company is displeased with their outsourcing provider, and moves the outsourced tasks back to the original organization. This could involve breaches in the contract, ineptitude, or falling profits, but backsourcing usually means that negative aspects of the relationship caused the company to undo their outsourcing endeavor.

- *Business Process Outsourcing* (BPO). Already mentioned, this type of outsourcing is rising in popularity as companies move particular departments or systems to other firms who can carry them out more efficiently.

- *Business Transformation Outsourcing* (BTO). This process relegates business activities to another firm so that the company can focus on reinventing itself, create a new business model, or enter a different industry. An outside firm is hired to carry on the

necessary systems of the old business while the company explores a new field or another way of conducting business within its industry.

- *Value-added Outsourcing.* This is when a company gains competitive advantage by outsourcing tasks the providing firm can do better or with more efficiency.

- *Netsourcing.* This involves partnering with another company for online interactions, such as renting a Web site or collaborating to create a new program for the company. Some outsource the maintenance of their intranet to other firms.

- *Shared Outsourcing.* This occurs when a provider works on the same outsourced task for multiple companies, such as handling customer service for several similar companies, or working on the same piece of computer code for more than one tech firm.

- *Multisourcing.* This involves a company choosing multiple firms to outsource tasks to, usually to improve quality and gain more flexibility in their outsourcing arrangements. Some companies only begin to multisource to ensure competitive bidding for their outsourcing contract; eventually, they choose one firm at a lower cost.

OUTSOURCING AND MULTISOURCING

How should a company begin to outsource? Most experts agree that the current outsourcing trend involves backing away from large contracts that have high costs and put a hefty amount of the company's production process in other hands. Instead, businesses are backing down, choosing lesser contracts with a variety of other firms, some local and some overseas, in a network-type of relationship, also known as multisourcing. Multisourcing allows businesses more flexibility, letting them solve production problems with greater ease and implement new techniques with less hassle.

What other considerations should companies make when deciding to multisource? Business writer Ephraim Schwartz outlines several important issues to consider in his 2008 article, "Outsourcing: Breaking Up is Hard to Do":

1. The more complicated outsourcing becomes, the more vendors will be present and the more issues that will need to be resolved, especially if a certain part of the company's process is divided up among several different outsourced tasks. Primary concerns will be communication and coordination. It is best to develop a successful integration plan before multisourcing.

2. Bigger companies might be less willing to be multisourcing partners than outsourcing partners. Outsourcing with one sizable contract means that the company carrying out the tasks is guaranteed large payments for a fair amount of time. In multisourcing, companies must be willing to accept shorter contracts and less money. This means large outsourcing-ready firms will not be as likely to participate in the company's outsourcing efforts. Smaller firms may need to be found.

3. Multisourcing, even more than outsourcing, needs talented project managers. Having skilled people on both sides is necessary, especially because of the coordination difficulties in multisourcing. Managers with the ability to field complaints, solve problems, and handle multiple communication efforts are necessary.

4. Costs can come with multisourcing, Although savings is a primary objective when outsourcing, costs can creep up in other areas. The talented managers, large-scale communication efforts, multiple vendors, and multi-level training programs will all eat away at the savings outsourcing gives. Companies should carefully consider how much they will really save—and spend—on multisourcing.

BACKSOURCING AND CONTRACTS

When considering a move toward outsourcing business processes, a company should attempt to protect themselves against the possibility of backsourcing. Backsourcing occurs when a company, disappointed by the results from their provider firm, brings their processes back to the original organization and breaks off their partnership with the providing firm. A final act, backsourcing should be carried out only as a last resort, the end to a failed relationship. This is also known as insourcing, although insourcing typically refers to bringing processes closer to a company for a multitude of reasons, not only negative results.

Business author Addleshaw Goddard has devised a list of suggestions for companies who are considering backsourcing, whether before or after their original outsourcing decision. This comprehensive list includes many of the key backsourcing issues, which should be mentioned:

- Companies should do what they can with their existing contract with the provider when deciding to backsource. Backsourcing requires paying very careful attention to the original contract and often creating a new agreement to help the process.

- Companies should take care of their own employees. Often organizations will find it necessary to send their employees to be a part of the outsourcing

endeavor, for training and knowledge purposes. When backsourcing, companies should ensure they have provided for these employees prior to attempting the backsource. Will the employees still have jobs at their organization? Will they have the same jobs they had prior to outsourcing?

- In the time between outsourcing and backsourcing, the company may have lost the ability to perform the outsourced tasks, especially if they were complex. Companies should be sure they can still perform the necessary processes if they decide to backsource. Losing capability can severely cripple an organization's flexibility when dealing with negative outsourcing.

- When first creating the outsourcing contract, companies should be careful to include provisions in case of backsourcing. Flexibility is very important. Legally, companies need to have enough room to maneuver to a different provider or reassimilate processes in case of failure.

- Reviews help companies judge the performance of their outsourcing providers. Regular reviews should be conducted to ensure the provider is fulfilling the contract and producing satisfactory results. Many companies tie semi-annual reviews into the contract, so they can use the reviews as a basis for backsourcing if necessary.

- Companies may wish to hire third-party reviewers, to analyze the provider and their overall competence.

There are other types of measurement that companies can use to analyze their providers in an outsourcing relationship. Benchmarking measurements, which look at price and quality, can also judge the performance of outsource firms. Other company measurements can be applied to the outsourcing endeavor as well.

Outsourcing and offshoring have caused considerable controversy in the United States, as the country has lost jobs to foreign nations. Forrester Research predicts that 3.3 million white-collar jobs and $136 billion in wages will shift from the United States to lower-wage countries by the year 2015. Despite possible backlash, some feel that outsourcing and offshoring are beneficial to the United States. Nineteenth-century economist David Ricardo proposed that the nation losing jobs will eventually recover its economic loss by developing worldwide markets for its products and services. Outsourcing can also enable firms to spend more time and resources on their core competencies, leading to more innovative goods and services to be sold globally.

P

PARADIGM SHIFT

A paradigm is an overarching theory or viewpoint that a society operates by, accepting it as a basis for understanding. When a paradigm shift occurs, a new theory is proved and established, forcing all members under the old theory to change their perspective. There is often a strong movement against shifting paradigms, since many must restructure their businesses and lives to reflect the new understanding. However, a true paradigm shift will be inevitable, a step in natural progress as knowledge in a particular field increases.

One of the most often cited examples of a paradigm shift is Copernicus's theory that the Earth, along with other planets, revolved around the Sun. It took scientists centuries to fully accept this physical principle which eventually revolutionized many scientific fields. Another paradigm shift occurred at the beginning of the twentieth century, when Newtonian physics began to be replaced by Einstein's theories of relative space and time. As in science, many important paradigm shifts have occurred in the business world as economic principles have been more fully explored and organizational structures attempted. Some of the predicted paradigm shifts for the business world include new management paradigms and revolutionary marketing techniques.

PARADIGM CRISIS

A paradigm shift is often begun by a paradigm crisis, which occurs when the current understanding of a situation is not adequate to explain events. When this happens, people begin seeking other explanations to explain events more clearly and accurately. Changes in international policy or economic situations can begin business paradigm crises, while scientific crises are most often caused by data that cannot fit into the current model. The crisis is resolved when a new model is created that explains current events so well it becomes accepted by the majority in the field, thereby establishing the next paradigm.

BUSINESS PARADIGM SHIFTS

Many business analysts see the arrival of Internet-based collaboration, social networking, and Web 2.0 applications as the beginning of an important business management paradigm shift. For the past couple centuries, managers have produced their own goals and ideas for their companies to follow, creating a top-down system of governance in which employees follow orders from the executives who work on innovation and concepts. Invention was relegated to individual innovators and those with entrepreneurial talent.

While such innovative people are still expected to be necessary, the communication technology of the early twenty-first century is allowing organizations to form ideas in a more fluid, collaborative manner. Concepts are beginning to be formed as a result of employee discussion and customer understanding. Decision making is being spread further throughout the organization, leading to bottom-up strategies formed by the widespread creativity of many organizational members.

To deal with these new methods of creativity, managers must learn to judge incoming data. Widespread collaborative creativity results in a large amount of information, which must be used based on quality and authority. How will managers be able to trust data from so many different sources? What protocols will be established to deal with such employee-generated ideas? These are the

questions the decision-making paradigm shift may bring to the twenty-first century.

PARADIGMS AND IMAGE

Paradigm shifts also apply to marketing principles. This has become an important part of company branding and rebranding, as organizations seek to create a distinctive image for themselves. In this way companies can produce and manage their own paradigm among customers by creating important marketing and innovation strategies. Paradigm shifts can also occur within the organization as new views are accepted concerning branding and image. Sometimes all that is needed is a change in attitudes toward how a company can brand itself and what its brand is founded on.

Managers will encounter paradigm shifts, both large and small, in their organizations. Understanding what decisions are based upon paradigms—and how these decisions will change as the paradigms change—is a vital part of effective leadership.

PARTICIPATIVE MANAGEMENT

Participative (or participatory) management, otherwise known as employee involvement or participative decision making, encourages the involvement of stakeholders at all levels of an organization in the analysis of problems, development of strategies, and implementation of solutions. Employees are invited to share in the decision-making process of the firm by participating in activities such as setting goals, determining work schedules, and making suggestions. Other forms of participative management include increasing the responsibility of employees (job enrichment); forming self-managed teams, quality circles, or quality-of-work-life committees; and soliciting survey feedback.

Participative management, however, involves more than allowing employees to take part in making decisions. It also involves management treating the ideas and suggestions of employees with consideration and respect. The

most extensive form of participative management is direct employee ownership of a company.

Four processes influence participation. These processes create employee involvement as they are pushed down to the lowest levels in an organization. The farther down these processes move, the higher the level of involvement by employees. The four processes include:

1. Information sharing, which is concerned with keeping employees informed about the economic status of the company.

2. Training, which involves raising the skill levels of employees and offering development opportunities that allow them to apply new skills to make effective decisions regarding the organization as a whole.

3. Employee decision making, which can take many forms, from determining work schedules to deciding on budgets or processes.

4. Rewards, which should be tied to suggestions and ideas as well as performance.

BENEFITS OF PARTICIPATIVE MANAGEMENT

A participative management style offers various benefits at all levels of the organization. By creating a sense of ownership in the company, participative management instills a sense of pride and motivates employees to increase productivity to achieve their goals. Employees who participate in the decisions of the company feel like they are a part of a team with a common goal, and find their sense of self-esteem and creative fulfillment heightened. It is important to understand that participative management at one organization is not likely to look the same at the next. Subordinate involvement will vary, and the role of management will have different meanings within different international enterprises.

Managers who use a participative style find those employees are more receptive to change than in situations in which they have no voice. Changes are implemented more effectively when employees have input and make contributions to decisions. Participation keeps employees informed of upcoming events so they will be aware of potential changes. The organization can then place itself in a proactive mode instead of a reactive one, as managers are able to quickly identify areas of concern and turn to employees for solutions.

Participation helps employees gain a wider view of the organization. Through training, development opportunities, and information sharing, employees can acquire the conceptual skills needed to become effective managers or top executives. It also increases the commitment of employees to the organization and the decisions they make.

Creativity and innovation are two important benefits of participative management. By allowing a diverse group of employees to have input into decisions, the organization benefits from the synergy that comes from a wider choice of options. When all employees, instead of just managers or executives, are given the opportunity to participate, the chances are increased that a valid and unique idea will be suggested.

REQUIREMENTS OF PARTICIPATIVE MANAGEMENT

A common misconception by managers is that participative management involves simply asking employees to participate or make suggestions. Effective programs involve more than just a suggestion box. In order for participative management to work, several issues must be resolved and several requirements must be met. First, managers must be willing to relinquish some control to their workers; managers must feel secure in their position in order for participation to be successful. Often managers do not realize that employees' respect for them will increase instead of decrease when they implement a participative management style.

The success of participative management depends on careful planning and a slow, phased approach. Changing employees' ideas about management takes time, as does any successful attempt at a total cultural change from a democratic or autocratic style of management to a participative style. Long-term employees may resist changes, not believing they will last. For participation to be effective, managers must be genuine and honest in implementing the program. Many employees will need to consistently see proof that their ideas will be accepted or at least seriously considered. The employees must be able to trust their managers and feel they are respected.

Successful participation requires managers to approach employee involvement with an open mind. They must be open to new ideas and alternatives for participative management to work. It is important to remember that although the manager may not agree with every idea or suggestion an employee makes, how those ideas are received is critical to the success of participative management.

Employees must also be willing to participate and share their ideas. Participative management does not work with employees who are passive or simply do not care. Many times employees do not have the skills or information necessary to make good suggestions or decisions. In this case, it is important to provide them with information or training so they can make informed choices and offer valid input. Encouragement should be offered in order to accustom employees to the participative approach. One way to help employees engage in the decision-making process is by knowing their individual strengths and capitalizing on them. By guiding employees toward areas in which they

are knowledgeable and by encouraging them to acquaint themselves in areas they feel less knowledgeable, a manager can help to ensure their success.

Before expecting employees to make valuable contributions, managers should provide them with the criteria that their input must meet. This will aid in discarding ideas or suggestions that cannot be implemented, are not feasible, or are too expensive. Managers should also give employees time to think about ideas or alternative decisions. Employees often do not do their most creative thinking on the spot.

Another important element for implementing a successful participative management style is the visible integration of employees' suggestions into the final decision or implementation. Employees need to know that they have made a contribution. Offering employees a choice in the final decision is important because it increases their commitment, motivation, and job satisfaction. Sometimes even just presenting several alternatives and allowing employees to choose from them is as effective as if they thought of the alternatives themselves. If the employees' first choice is not feasible, management might ask for an alternative rather than rejecting the employee input. When an idea or decision is not acceptable, managers should provide an explanation. If management repeatedly strikes down employee ideas without implementing them, employees will begin to distrust management, thus halting participation. The key is to build employee confidence so their ideas and decisions become more creative and sound.

CONCERNS

Participative management is not a magic cure for all that ails an organization. Managers should carefully weigh the pros and the cons before implementing this style of management. Managers must realize that changes will not take effect overnight and will require consistency and patience before employees will begin to see that management is serious about employee involvement. Participative management is probably the most difficult and rewarding style of management to practice. It is challenging not only for managers but for employees as well.

While it is important that management allows employees to participate in decision making and encourages involvement in the organization's direction, managers must be cognizant of the potential for employees to spend more time formulating suggestions and less time completing their work. Upper-level management will not support a participative management program if they believe employees are not meeting their daily or weekly goals. Some suggestions for overcoming this potential problem are to set aside a particular time each week for workers to meet with management to share their ideas, or to allow them to work on their ideas during less busy times of the day or week. Another idea that works for some managers is to allow employees to set

up individual appointments to discuss ideas or suggestions. Generally, a roundtable approach to participative management works best so that all ideas from every party can be heard by management and employees alike.

Managers should remember that participative management is not always the appropriate way to handle a given situation. Employees often respect a manager that uses his or her authority and makes decisions when it is necessary. There are times when, as a manager, it is important to be in charge, make a decision, and accept the responsibility for choices made. For example, participative management is not appropriate when disciplinary action is needed.

When managers look upon their own jobs as a privilege instead of as a responsibility, they will fail at making participative management work. They will be less willing to turn over some of the decision-making responsibility to subordinates. Another reason that participative management fails is that managers do not realize it is not the same as delegating or simply shifting responsibility. Participation alone has no value; it is only an effective tool if it is used to solve problems and meet goals. Some managers believe that inviting employees to join in meetings and form committees will create a successful participative management program. However, these measures are only successful when employees' ideas are accepted by management and implemented.

The larger the organization, the more difficult it becomes to institute a participative management style. Large organizations have more layers and levels, which complicate effective communication and make it difficult to register the opinions and suggestions of a diverse group of employees and managers. The exception to this is when a large organization is set up in participative management style from the onset. Critics argue that unions are often more effective than participative management in responding to employee needs because union efforts can cut through bureaucratic organizations more quickly. However, in many cases, unions themselves can become very bureaucratic, and can often benefit from aspects of participatory management style on the most basic level.

Participative management programs can be threatened by office politics. Due to hidden agendas and peer pressure, employees may keep their opinions to themselves and refuse to tell a manager if they feel an idea will not work. Managers also play a part in politics when they implement participative management programs to impress their own bosses, but have no intention of seeing them through.

Many companies have experienced the positive effects of participative management. Employees are more committed and experience more job satisfaction when they are allowed to participate in decision making. Organizations have reported that productivity improved significantly when managers used a participative style. Participative management is not an easy management style to implement or be consistent with. It presents various challenges and does not succeed overnight. Managers will be more successful if they remember that it will take time and careful planning before they will see results. Starting with small projects that encourage and reward participation is one way to get employees to believe that management is sincere and trustworthy. The challenges are worthwhile when participatory management is seen through to the end, as everyone can be proud of the positive changes they have been a part of implementing.

PATENTS AND TRADEMARKS

Trademarks and patents, along with copyrights, constitute the major forms of legal protection for what is commonly referred to as intellectual property. Although the rights in these three kinds of intellectual property protection are somewhat similar, trademarks, patents, and copyrights differ in what they protect. Patents protect inventions,

while trademarks protect words, phrases, symbols, and designs. Copyrights protect original artistic, musical, and literary works, including software.

PATENTS

A patent is a grant of a property right by the United States government, through the Patent and Trademark Office, to the inventor of an invention. The term of this property right is twenty years from the date the patent is granted, as long as the holder of the patent pays maintenance fees. A patent is not a grant of a right to make, manufacture, use, or sell the invention; rather it secures the right to exclude others from making, manufacturing, using, or selling the invention for the duration of the patent.

A patented invention is no guarantee of future commercial success. Statistically, although millions of patents have been granted, the number of successful inventions is minuscule. One avenue of commercialization open to a patentee is licensing his or her patent to a company, or a number of companies, provided he or she is able to locate a firm that is willing to risk investing in a wholly untried product or process. Upon licensing the patent, however, the patent holder cannot demand that royalties from the product continue beyond the stipulated 20-year patent period, nor can the patentee set the product's price or determine its use.

CREATION OF PATENT RIGHTS

The power to grant rights in patents arises from Article I, section 8 of the United States Constitution, which provides that "Congress shall have power…to promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries." The first patent law was passed in 1790, and the current law governing patents was enacted in 1952 and became effective January 1, 1953. Since the first statute, millions of patents have been granted. The current statute sets forth the subject matters for which patents may be granted and the conditions under which a patent will be issued. It also established the Patent and Trademark Office.

Under the law, anyone who "invents or discovers any new and useful process, machine, manufacture or composition of matter, or any new and useful improvements thereof, may obtain a patent." Courts have interpreted this language to include nearly anything that could be fabricated, although they have not allowed printed matter, such as books to be patented. An invention must meet the test of being new under the standards in the law before a patent will be granted. The subject matter of an invention must be sufficiently different from what has been described in a printed publication of some sort anywhere in the world, or sold in this country, before the date of the application for the patent. In addition, the invention must go beyond what would seem a common-sense or obvious advance-

ment, even to a practitioner or expert in the field. Finally, an invention must be determined "useful" before a patent will issue; this requirement, however, is interpreted very broadly.

Only the inventor may apply for a patent, with two exceptions: (1) if the inventor has died before applying for a patent, the inventor's estate may do so, and (2) if the inventor is insane, the inventor's guardian may apply for the patent.

An inventor applies for a patent by sending to the Commissioner of Patents and Trademarks, at the Patent and Trademark Office, a written specification, which is a description of the invention and of the process in which the invention is made and used. The specification must contain one or more claims about the subject matter that the applicant believes constitute an invention. The specification must be accompanied by a sworn oath or declaration by the inventor that he or she is the original and first inventor of the subject matter of the application. The application must also include drawings, where necessary, and the appropriate filing fee, which the patent statute and rules have established.

THE PATENT AND TRADEMARK OFFICE

The Patent and Trademark Office carries out the patent laws by examining the applications to determine if the inventor is entitled to a patent. The office publishes the specifications and drawings of all patents on the day they are issued. It records assignments of any patents to entities other than the inventors. It maintains a search room for the public to look at issued patents and the office's records.

TRADEMARKS

A trademark is a word, name, phrase, symbol, or design, or a combination of these elements, that identifies and distinguishes the source of goods or services. The term also encompasses service marks. Service marks are the same as trademarks except that they identify and distinguish the source of a service rather than a product. Trademark rights are used to prevent others from making, promoting, or selling goods or services which have a name, symbol, or design that is confusingly similar to that of the trademark. It does not, however, prevent others from making or selling the same goods or services, as long as it is under a different, nonconfusing mark.

CREATION OF TRADEMARK RIGHTS

There are two distinct types of rights in a trademark or service mark: the right to use the mark and the right to register the mark. These rights arise either from using the mark in actual commerce or from filing an application for registration of the mark with the Patent and Trademark Office.

The registration of marks is controlled under the Trademark Act of 1946; the Trademark Rules, 37 C.F.R. Part 2; and the *Trademark Manual of Examining Procedure.* The act covers not only trademarks and service marks, but also certification marks, collective trademarks, and collective membership marks.

The first party who either uses a mark in the course of commerce or business or files an application for registration with the Patent and Trademark Office usually has the right to register that mark. A party can use a mark, or establish rights in it, without filing an application for registration. The registration, however, creates a presumption that the party who has registered the mark is the owner of the mark for the goods and services set forth in the registration application, and therefore has the right to use the mark anywhere in the country. This presumption can become important when two parties unintentionally begin using similar marks and become involved in a lawsuit over who has the sole right to use the mark. The Patent and Trademark Office does not determine this, rather it is the decision of a court, which has the power to issue an injunction to stop a party from using a mark and to award damages for a party's improper use of another's mark.

Similarly, the owner of a mark may use the trademark (^{TM}) or service mark (^{SM}) designation with the mark to make it clear that the owner is claiming rights in the product or service so designated. The ^{TM} and ^{SM} designation may be used without the owner having registered the mark with the Patent and Trademark Office. If it is registered, however, the owner may use the registration symbol (®) with the mark.

Rights embodied in a trademark, unlike those of a copyright or a patent, can last for an indefinite period if the owner of the mark continuously uses the mark for its products or services. Federal registrations last for ten years, but between the fifth and sixth year after the date of the initial registration, the person who registered the mark must file an affidavit with information about the mark and ownership. If the registrant does not file this affidavit, the registration is cancelled. After the initial registration period, the mark can be renewed for successive ten-year terms. Registration of a mark with the Patent and Trademark Office provides protection from others using the mark in the United States and its territories, but does not extend to its use in other countries.

PATENTS AND TRADEMARKS IN THE INTERNET AGE

The growth of Internet technology has affected patent and trademark protection in a number of different ways. For instance, the Internet has made it significantly easier for individuals and companies to conduct searches of patent and trademark databases, whether they are looking to patent an invention or license someone else's invention. The global reach of the Internet has also spurred efforts to harmonize international patent and trademark protection, which may eventually offer firms greater protection in worldwide markets.

In other ways, however, the Internet has made it more difficult for owners to protect their intellectual property rights. The widespread availability of intellectual property in digital form has led to illegal copying of technology, software, music, and other protected materials. Nowhere has this been more prevalent than in the music and newspaper businesses, where the old business models have been turned upside down, and new questions concerning the "fair use" of intellectual property arise continually. Indeed, some of the Internet's most popular sites (such as YouTube) seem to thrive on offering copyrighted material.

In the early twenty-first century, a growing number of technology companies began launching intellectual property licensing programs to turn their accumulated patent bases into revenue. These firms conducted inventories of their patents and identified technologies that were outside the core business, yet still offered some potential for development. They then sought to license these technologies to other firms. IP licensing has proven quite lucrative for a number of large technology firms. IBM, for example, earns over one billion dollars per year from its IP licensing program.

In 2007 the U.S. Supreme Court made a number of decisions concerning patent rights. (These cases were: *MedImmune v. Genentech,* decided 8-1; *KSR International v. Teleflex, decided 9-0;* and *Microsoft v. AT&T,* decided 7-1.) To many observers the overall result of these cases, in the words of the *Washington Post,* "weakened the protection given to patent holders, making it more difficult to get a patent and easier to challenge existing ones."

In 2008 the Supreme Court voted 9-0 in *Quanta Computer, Inc. v. LG Electronics, Inc.* in deciding to limit the reach of patent law regarding the "postsale use" of a product—particularly component parts used in the manufacture of another end product. The Court wrote, "The longstanding doctrine of patent exhaustion provides that the initial authorized sale of a patented item terminates all patent rights in that item."

PATERNALISM

The practice of paternalism has a long history in American business, and it has been both maligned and extolled. Many companies have taken the opportunity to highlight their "fatherly" actions, claiming to be family businesses that take care of their employees through extra benefits and care that their workers would not be able to afford otherwise. Others have complained that paternalistic methods used by businesses form unhealthy environments, creating company towns that are fully dependent on companies to provide too many aspects of their living conditions. Paternalism, according to skeptics, fosters a top-down style of management that hinders creative thought among employees and encourages harmful promises or inconsistent behavior. However, a new style of paternalism has become more common in recent years as companies have begun exploring ways in which to develop employee innovation and social resources by helping their workers live healthier, fuller lives.

In the late 2000s, paternalism often involves offering employees benefit plan advice (instead of only a limited number of available plans) and compensation packages that provide a number of personalized extras. These include fitness gym memberships and other healthy living options. By supporting employees in these socially conscious ways, companies are able to maximize employee retention and maintain favorable, efficient workplaces.

DEVELOPMENT OF PATERNALISM IN AMERICA

Ronald Sims, in his 2003 book *Ethics and Corporate Social Responsibility*, identifies three different stages of development that occurred in the progression of paternalism, as companies explored the meaning of social responsibility and employee welfare in the twentieth century of United States business.

The first stage was **profit maximizing management**, during which business executives decided that their primary goal, for both society and success, was to encourage profit and growth. The American economy was seen as dependent on the wealth of companies, and anything done to encourage that wealth was seen by managers as acceptable. This was before the era of legislation concerning child labor and gender inequality, so some of the accepted methods—while profitable for businesses—were harmful to society. Sims writes that this era ended at the time of the Great Depression (1930s) when the success of business and business practices was called into question.

The second stage was **trustee management**. After the Great Depression, wealth was more spread out, and fewer privately-owned companies existed. Instead, companies were under the control of stockholders and subject to many outside groups such as suppliers, creditors, and of course customers. Government involvement also increased, leading to legislation that established fair labor principles and welfare systems; such legislation also encouraged the protection of employees. Corporate wealth started to be distributed for the purposes of social responsibility, and corporate authority moved away from one or two top executives to corporate boards and trustees. Employee benefits became common in this stage. Unfortunately, several paternistic problems also arose as employees became dependent on their companies, while companies struggled to not misuse their paternistic authority.

The third stage is the **quality-of-life movement**, where corporate social responsibility became a popular topic. Companies began inspecting ways that they could profit by their relationships with employees and employees' relationships throughout society. Social capital, the collective ideas and connections of the society, became important to businesses. Focus moved from purely economic goals to wider initiatives involving care of the environment, employee physical health, employee mental health, and employee emotional security. This is the current state of business paternalism, which is growing into a more complex style of management as organizations realize the marketing and image benefits that can be earned through social responsibility, along with the rewards of employee energy and innovation.

PROBLEMS WITH PATERNALISM

The negative effects of paternalism developed largely in the second stage, as companies began to assume that employees did not have enough knowledge or available information to make wise decisions. Therefore, management took the burden of these decisions away from employees, locking some organizations into dangerous, dependent relationships that could be exploited. However, as electronic communication became more common, the excuse of employee ignorance no longer applied, and companies were able to offer their workers a number of choices, providing them with the necessary education to make wise decisions concerning health plans and benefit options.

One of the most popular current ideas under the heading of "New Paternalism" is the idea of "nudging," or giving employees—and others—small psychological nudges to make the right decisions, rather than forcing them to make certain choices in any direct way. These nudges are designed to help people realize the benefits to choosing health-conscious options without limiting their freedoms. Government nudges include "sin" and "fat taxes" to support beneficial lifestyles. A company interested in "nudging" their employees might offer gym memberships as a part of an attractive and flexible health benefit plan, encouraging workers to maintain physical well-being without requiring it.

PERFORMANCE APPRAISALS

SEE *Employee Evaluation and Performance Appraisals*

PERFORMANCE MEASUREMENT

Improvement in individual, group, or organizational performance cannot occur unless there is some way of getting performance feedback. Feedback is having the outcomes of work communicated to the employee, work group, or company. For an individual employee, performance measures create a link between their own behavior and the organization's goals. For the organization or its work units, performance measurement is the link between decisions and organizational goals.

It has been said that before you can improve something, you have to be able to measure it, which implies that what you want to improve can somehow be quantified. Additionally, it has also been said that improvement in performance can result just from measuring it. Whether or not this is true, measurement is the first step in improvement. But while measuring is the process of quantification, its effect is to stimulate positive action. Managers should be aware that almost all measures have negative consequences if they are used incorrectly or in the wrong situation. Managers have to study the environmental conditions and analyze these potential negative consequences before adopting performance measures.

TYPES OF PERFORMANCE MEASURES

Performance measures can be grouped into two basic types: those that relate to results (outputs or outcomes, such as competitiveness or financial performance) and those that focus on the determinants of the results (inputs such as quality, flexibility, resource utilization, and innovation). This suggests that performance measurement frameworks can be built around the concepts of results and determinants.

Measures of performance of a business usually embrace five fundamental, but interlinking areas:

1. Money, usually measured as profit

2. Output/input relationships or productivity

3. Customer emphasis such as quality

4. Innovation and adaptation to change

5. Human resources

Within the operations area, standard individual performance measures could be productivity measures, quality measures, inventory measures, lead-time measures, preventive maintenance, performance to schedule, and utilization. Specific measures could include:

1. Cost of quality: measured as budgeted versus actual

2. Variances: measured as standard absorbed cost versus actual expenses

3. Period expenses: measured as budgeted versus actual expenses

4. Safety: measured on some common scale, such as number of hours without an accident

5. Profit contribution: measured in dollars or some common scale

6. Inventory turnover: measured as actual versus budgeted turnover

While financial measures of performance are often used to gauge organizational performance, some firms have experienced negative consequences from relying solely on these measures. Traditional financial measures are better at measuring the consequences of yesterday's actions than at projecting tomorrow's performance. Therefore, it is better that managers not rely on one set of measures to provide a clear performance target. Many firms still rely on measures of cost and efficiency, when at times such indicators as time, quality, and service would be more appropriate measures.

To be effective, performance yardsticks should continuously evolve in order to properly assess performance and focus resources on continuous improvement and motivating personnel. To incorporate various types of performance measures some firm's developed performance measurement frameworks. These frameworks appear in the literature and vary from Kaplan and Norton's balanced scorecard to Fitzgerald's framework of results and determinants.

Kaplan and Norton's balanced scorecard approach operates from the perspective that more than financial data is needed to measure performance and that non-financial data should be included to adequately assess performance. They suggest that any performance measurement framework should allow managers to ask the following questions:

- How do we look to our shareholders? (financial perspective)

- What must we excel at? (internal business perspective)

- How do our customers see us? (customer perspective)

- How can we continue to improve and create value? (innovation and learning perspective)

However, the balanced scorecard is flawed as it does not allow for one of the most important questions of all:

- What are our competitors doing? (the competitor perspective)

Keegan proposed a similar, but lesser known, performance measurement framework titled the "performance matrix." The performance matrix is more flexible, as it is able to integrate different dimensions of performance and employs generic terms such as internal, external, cost, and noncost.

DESIGNING THE PERFORMANCE MEASUREMENT SYSTEM

A number of suggestions have been offered by various experts on the subject of designing performance measurement systems. Below is a list of suggestions derived from a number of these experts. Some of these apply to all measures and some apply to a limited number of a firm's measures. A firm's performance measures should:

- Be simple and easy to use.

- Have a clear purpose.

- Provide fast feedback.

- Cover all the appropriate elements (internal, external, financial and non-financial).

- Relate to performance improvement, not just monitoring.

- Reinforce the firm's strategy.

- Relate to both long-term and short-term objectives of the organization.

- Match the firm's organization culture.

- Avoid conflict with one another.

- Be integrated both horizontally and vertically in the corporate structure.

- Be consistent with the firm's existing recognition and reward system.

- Focus on what is important to customers.

- Focus on what the competition is doing.

- Lead to identification and elimination of waste.

- Help accelerate organizational learning.

- Help build a consensus for change when customer expectations shift or strategies and priorities call for the organization to behave differently.

- Evaluate groups, not individuals, for performance to schedule.

- Establish specific numeric standards for most goals.

- Be available for constant review.

Other recommendations for organizations that are developing performance measures include:

1. Data collection and methods of calculating the performance measure must be clearly defined.

2. Objective performance criteria are preferable to subjective ones.

3. Measures may vary between locations; avoid a "one size fits all" mentality.

Wisner and Fawcett provide a nine-step process for developing a performance measurement system:

1. Clearly define the firm's mission statement.

2. Identify the firm's strategic objectives using the mission statement as a guide (profitability, market share, quality, cost, flexibility, dependability, and innovation).

3. Develop an understanding of each functional area's role in achieving the various strategic objectives.

4. For each functional area, develop global performance measures capable of defining the firm's overall competitive position to top management.

5. Communicate strategic objectives and performance goals to lower levels in the organization. Establish more specific performance criteria at each level.

6. Assure consistency with strategic objectives among the performance criteria used at each level.

7. Assure the compatibility of performance measures used in all functional areas.

8. Use the performance measurement system to identify competition, locate problem areas, assist the firm in updating strategic objectives and making tactical decisions to achieve these objectives, and supply feedback after the decisions are implemented.

9. Periodically reevaluate the appropriateness of the established performance measurement system in view of the current competitive environment.

Finally, it is important that the performance measurement systems used by managers be continually reviewed and revised as the environment and economy changes. For example, newer measurements might include the measurement of the linkage between customer and employee satisfaction, or ways in which to measure the progress of new product innovations, or that of e-commerce, or perhaps the work performed by "knowledge workers." Obviously, failure to make the necessary modifications can inhibit the ability of the organization to be an effective and efficient global competitor in fast-changing marketplaces.

PERSONALITY AND PERSONALITY TESTS

Personality is a set of enduring traits and characteristics that relate to a person's emotions, motivations, interpersonal interactions, and attitudes. Personality testing is an attempt to determine the personality traits of an individual to better understand how that individual will behave in certain situations and how well suited a particular individual is for a specific job or task. Because of its usefulness in making these determinations, personality testing is of great interest to employers, particularly human resource managers.

THE NATURE OF PERSONALITY

Research into the human personality has been conducted for many decades, and much of this work has focused on defining personality and understanding how many dimensions of personality there are. One primary area of agreement about personality is that it is a trait. That is, personality is enduring and unlikely to change substantially in one's adult life. This does not mean that a person cannot or will not adapt to a change in circumstances (e.g., behavior at work versus behavior in social situations), but that, on average, a person demonstrates similar personality across all situations and may behave differently from those with dissimilar personality characteristics.

A major debate in the area of personality research is where personality originates, which is often described as the "nature vs. nurture" argument. Some researchers believe that individuals are born with a personality that is determined by genetics and remains unchanged regardless of environment; this group subscribes to the "nature" theory of the origin of personality. The "nurture" perspective is that personality is not determined by genetics, but rather by a host of environmental forces and personal experiences

(such as geography, socio-economic status, and parental upbringing). Most scholars now agree that personality is determined by a combination of both genetics and environment, and that neither is solely responsible for personality.

PERSONALITY TESTING

Despite the various debates about the nature and source of personality, psychologists have both categorized personality types and sought out ways to test individuals for their conformity with such types. These tests can give the individuals as well as their employers useful insights into the personality traits of those tested.

Since employees' personalities may dictate how well they perform their jobs, such personality testing is meaningful to and useful for management. Personality may indicate how hard a person will work, how organized he is, how well he will interact with others, and how creative he is. In recent years, more organizations have been using self-reporting personality tests to identify personality traits as part of their hiring or management development processes. Employers recognize that experience, education, and intelligence may not be the only indicators of who the best hire might be. Additionally, understanding one's own personality characteristics may improve one's ability to develop as an employee and manager.

There are a number of different ways in which personality has been categorized, and different opinions exist about the number of dimensions of personality. Early tests of personality were developed to diagnose mental illness, and while some of these tests were used in employment settings, their acceptability and applicability were questionable. However, there are now tests specifically for use in normal adult populations, each of which is based on different conceptions of the dimensionality of personality.

MINNESOTA MULTIPHASIC PERSONALITY INVENTORY AND CALIFORNIA PSYCHOLOGICAL INVENTORY

Some of the earlier tests used to assess the personality of job applicants and employees were the Minnesota Multiphasic Personality Inventory (MMPI) and the California Psychological Inventory (CPI), which is based on the MMPI.

The MMPI was developed for psychological clinical profiling and includes ten clinical scales. While some of these scales may be applicable to predicting job performance in a selection tool, others are not. Additionally, the items used in the MMPI may be off-putting to job applicants. However, before personality tests became commercially available for use in a business setting, organizations often used the MMPI to assess the personality characteristics of applicants and employees.

Using the psychological basis of the MMPI, the CPI was created to assess the personality of normal adult populations. It assesses seventeen different dimensions of performance, including dominance, responsibility, empathy, and sociability. The CPI is much more appropriate for business settings than the MMPI, but was not created for use in business hiring.

FIVE-FACTOR MODEL

A different conception of personality is captured in the Sixteen Personality Factor Questionnaire, also called the 16 PF. It yields scores of sixteen different personality traits, including dominance, vigilance, and emotional stability. These sixteen factors can be combined to express five "global factors" of personality. These five global factors are often called the Big Five or the Five-Factor Model.

Most researchers agree that while more than five dimensions of personality are present in human beings, nearly all of them can be subsumed within five: emotional stability, conscientiousness, agreeableness, extraversion, and openness to experience. They are summarized in Table 1.

In addition to the 16 PF instrument, the Revised NEO Personality Inventory (NEO PI-R), developed by Costa and McCrae, assesses the five personality dimensions of the Five-Factor Model and thirty additional traits used to create the scores on these dimensions. For instance, to determine scores on the Neuroticism (i.e., Emotional Stability) scale, the following facets are measured: anxiety, angry hostility,

Table 1		
Personality Factor	**Characteristics of Individuals High in Factor**	**Characteristics of People Low in Factor**
Emotional Stability	• Calm • Resistant to stress • Secure • Stable	• Anxious • Depressed • Insecure • Susceptible to stress
Conscientiousness	• Dependable • Organized • Persevering • Punctual	• Disorganized • Easily discouraged • Unpredictable • Unreliable
Agreeableness	• Amiable • Cooperative • Flexible • Trusting	• Aloof • Contrary • Suspicious • Unfriendly
Extraversion	• Active • Assertive • Excitable • Sociable	• Apprehensive • Dull • Shy • Timid
Openness to Experience	• Creative • Curious • Insightful • Intellectual	• Bored • Intolerant • Routine-oriented • Uninterested

depression, self-consciousness, impulsiveness, and vulnerability. This NEO PI-R was developed specifically for use in business settings.

Emotional Stability. Emotional stability (also called neuroticism, when scored oppositely) involves a person's ability to remain stable and balanced. A person who is high in emotional stability is even-tempered, calm, and somewhat resistant to stress. A person who is low in emotional stability tends to be moody, depressed, and very susceptible to stress. In most professions, a person who is high in emotional stability is preferred. Employees with low emotional stability are more likely to be distracted from work by stress, deadlines, or situations in their personal lives, whereas those with high levels of this trait are more able to control their emotions and feelings at work.

Conscientiousness. Conscientiousness is a person's ability to be dependable, organized, punctual, and to persist in the face of setbacks. Research indicates that conscientiousness is the personality characteristic that is most related to job performance across a variety of jobs. Thus, in nearly every situation, a person who is high in conscientiousness will be better suited to perform a job. Individuals who are low in conscientiousness do not give much attention to detail, are likely to overlook deadlines, or may lose important documents. Additionally, individuals low in conscientiousness are more likely to give up when faced with challenges or difficulties in their work, whereas employees with high conscientiousness will continue to persist.

Agreeableness. Agreeableness, when high, indicates that a person is warm, friendly, and tactful. Low agreeableness is demonstrated when employees are cold, abrasive, and unfriendly. Preference on whether to hire an employee high in agreeableness or low in agreeableness is somewhat dependent on the type of job.

In general, a person with high agreeableness can be easier to work with, because they tend to be easier to talk to and interact within a group setting. And, in some jobs, being highly agreeable is an advantage, such as in sales, or in other jobs that require patient and friendly interactions with people. However, there are some jobs in which being too warm and friendly can be a detriment, such as a collections agent; and in these jobs, being low in agreeableness could be advantageous.

Extraversion. Extraversion is how outgoing and social a person is. Someone high in extraversion enjoys crowds, social gatherings, and working in groups. A person low in extraversion is more comfortable working on his or her own and is less gregarious. As with agreeableness, the level of extraversion that is desired in an employee is dependent on the job. In jobs that involve interacting with others, such as sales, teaching, or public relations, high extraversion may be helpful. However, if a job requires independent work and solitude, such as computer programming, having a person high in extraversion may be difficult, and thus a person lower in extraversion would be preferred.

Openness to Experience. Openness to experience refers to the open-mindedness of a person. An individual who is high in openness to experience is curious, imaginative, open-minded, and enjoys trying new things. People who are low in openness to experience are routine-oriented, close-minded, literal, and prefer not to try new things.

As with agreeableness and extraversion, the degree to which an employee is benefited by openness depends on the job. High openness is important in jobs that require creativity and flexibility; one would definitely prefer to have high openness in advertising or research positions. However, some jobs reward routine work, and in those jobs in which creativity is not needed or desired, a person low in openness may find these jobs more rewarding.

In summary, high emotional stability and conscientiousness are desirable in nearly all jobs, and the level of agreeableness, extraversion, and openness to experience are dependent on the job duties and requirements. While personality can relate to how well a person performs a job, it is not the only characteristic upon which a hiring decision should be made. Ideally, a person's education, experience, and intelligence should be evaluated for a position, with personality being part of the criteria considered.

MYERS-BRIGGS TYPE INDICATOR

The Myers-Briggs Type Indicator (MBTI) is a very popular test, primarily used in organizations to develop managers, improve employee performance, and build teams. It is very different from the other personality tests. Rather than tapping the Big Five personality characteristics, the MBTI is based on the work of Jung and addresses four areas of personality to create sixteen distinct types. The four areas of personality are:

- Perception—sensing vs. intuiting
- Judgment—thinking vs. feeling
- Extraversion—extraversion vs. introversion
- Orientation towards the outer world—perceiving vs. judging

The scores along these four dimensions can be combined to create sixteen different "types." The scores on each dimension represent the strength of dimension; so a person might be "sensing, thinking, introverted, and perceiving" and very strong in sensing, but somewhat less strong in thinking.

While the other personality inventories are often used as a selection tool in the organization, the MBTI is best used for career development, counseling, and team selection. Another difference between the MBTI and other personality tests is that strengths on the different dimensions are all seen as valuable. So, a person who is strong in "thinking" is seen as just as skilled an employee as one who is strong in "feeling," but is believed to be more suited to different types of tasks and duties. Contrast this with the NEO-PI: on that instrument, a low score on some dimensions, like conscientiousness, would be undesirable to an organization.

While the Myers-Briggs Type Indicator is used in many organizations and is very popular among employers and employees, there is not as much empirical evidence of its validity and usefulness compared to other personality inventories. Several studies have shown that about 50 percent of people who are retested only several weeks later are classified as a different type; that percentage increases to over 60 percent when people are tested over nine months later. Thus, it is typically not recommended as a tool for employee selection, but rather is best suited for employee self-development, team-building, and managerial information.

USING PERSONALITY TESTS FOR SELECTION

When employers first began to learn about personality and the impact that it could have on job performance, they did not have specific employment tests to measure personality. Therefore, many turned to psychologists and existing personality tests (e.g., the MMPI) to determine the characteristics of job applicants. Unfortunately, the purpose of some of these tests was to diagnose mental illness or psychological disorders, and although they could provide some information related to personality, the test items were likely to seem strange and intrusive to job applicants.

Furthermore, because the tests were not written in an employment context, the information that they provided typically went beyond what was needed to make an informed hiring decision. For these reasons, many managers had negative experiences with personality testing in the workplace and thought it to be inappropriate and useless. However, there are now tests designed specifically for business hiring needs. These tests tap into the Big Five personality characteristics and are written in such a way as to not offend the average job applicant.

Because of the availability of several different tests, human resources departments need to investigate which tests are available and most appropriate to their company before adopting personality testing. Before adopting a particular personality test for employee screening and selection processes, human resources managers need to evaluate its reliability, validity, and acceptability.

Reliability. Reliability, or the degree to which a test measures some characteristic consistently, is a necessary requirement for a selection test. If a test does not measure consistently, then it cannot be valid; thus, assessing the reliability of personality tests is crucial for accurate selection. In general, most commercial personality tests have demonstrated high reliability, though as noted above, the MBTI has been shown to have a low level of testing consistency.

Reliability can be assessed in several different ways. The test-retest method of assessing reliability involves giving one group the same test twice and statistically evaluating the consistency of scores. Because personality tests are intended to measure stable, enduring personality traits, the test-retest reliability of these tests should be high.

The equivalent measures method of determining reliability involves creating two tests that evaluate the same content domains, giving them to the same group, and statistically comparing the scores of each individual. If the two tests truly are equal in content, then high reliability will be indicated by very similar scores on both tests.

Finally, internal consistency is one of the most used measures of reliability. An assessment of internal consistency only requires one version of a test and one sample of people; the test is then broken into two parts, and the consistency of responses on the two parts is determined. A well-known form of the internal consistency approach, called coefficient alpha, averages the correlations between all possible splits of a test, and therefore results in a highly accurate assessment of reliability.

Validity. The validity, or accuracy, of personality tests has been measured in a number of research studies and can be assessed in two main ways: content validity and criterion-related validity. Additionally, meta-analysis has been used to understand the validity of personality tests.

Content validity is an assessment of the degree to which the items on a test capture the domain of interest. This assessment is made by subject matter experts, such as trained psychologists or expert managers. While content validity is an important assessment of the usefulness of a selection test, criterion-related validity provides empirical evidence as to a test's accuracy.

Criterion-related validity indicates how well a test predicts job performance, and it can be evaluated concurrently or predictably. In a concurrent criterion-related validity study of a personality test, job incumbents are given the personality test, and their job performance is measured at the same time. A correlation between test scores and job performance indicates the level of validity of the new test.

With predictive criterion-related validity, job applicants are given the new personality test, but it is not used when making the hiring decisions. After a certain time period, the scores on the personality test are correlated with job performance scores of the new employees to determine the validity of the test. While concurrent validity studies are often preferred because they can be done quickly, the motivation of current employees to do well on these tests may not be high, or at least not as high as the motivation of job applicants.

With predictive validity, the benefit occurs with the use of actual job applicants; however, the time lag involved is often a major drawback.

In both cases, a big concern is range restriction; that is, because the full range of scores on the test is not evaluated (since not all applicants are hired and, presumably, current employees would have high scores on the personality test), the actual validity of a test may be underestimated.

Meta-analysis is a statistical technique that can be used to further explore the validity of selection tests. Meta-analysis combines individual research studies to indicate an overall average validity for most jobs; using this, the general validity of selection tests can be estimated. Based on information from meta-analysis, most personality tests have low to moderate validity, as compared to other selection methods such as intelligence tests, work samples, and structured interviews. However, they are still useful for hiring in many jobs because the information they provide is unique.

Intelligence tests and work samples cannot indicate a person's level of different personality traits, and although structured interview questions may be written to capture some elements of personality, such as conscientiousness, or agreeableness, typically, a personality test will provide information above and beyond other employment tests. Therefore, the inclusion of a validated personality test may increase the overall validity of the selection battery for certain jobs.

There are three major threats to the validity of personality tests: faking, socially desirable responding, and careless responding. While all occur for different reasons, the effects of these types of responses can reduce the validity of personality tests.

Faking occurs when a job applicant purposely attempts to score more positively than he or she would if answering items truthfully. Because many personality inventories include response choices that are easily seen as more desirable than others, applicants may be able to deliberately misrepresent themselves to look more favorable, or "fake good."

Although most personality tests include instructions that request that applicants answer truthfully, they may choose not to follow these instructions. There are no firm conclusions on the amount of faking that occurs, or its effect on test scores, but many researchers argue that when faking occurs, it is unlikely to skew test results appreciably.

Socially desirable responding is similar to faking in that the applicant answers items falsely in order to look better; however, unlike faking, socially desirable responding is not deliberate. These unconscious and unintended responses are chosen in order to conform to social norms. For instance, an applicant may overestimate his punctuality or organization skills on a personality test because these are skills that the employer wants. However, this decision would not be conscious, but instead would represent a generous view of one's own habits.

Response carelessness occurs when an applicant does not pay careful enough attention to the items on the test and therefore responds incorrectly. This occurs when the applicant has poor reading skills, is in a hurry, is bored, or is not motivated to take the test. Careless responses can harm the reliability and the validity of the test because they lack consistency and accuracy.

To avoid these problems, many personality inventories now include scales to detect faking, socially desirable responding, and response carelessness from which scores can be used to adjust the scores on the other scales. Thus, most published personality inventories have the means to avoid and/or correct for these threats to validity.

Acceptability. Acceptability is an assessment made by job applicants. Their reaction to taking the personality test may have an influence on their motivation to take the test, their continuation in the hiring process, or their opinions about the company. For example, if a job applicant is asked a number of questions on a personality test that she believes to be invasive and too personal, she may be offended and therefore not accept a job offer. She may then complain to friends about the company's selection tests—reducing the number of people who might have applied for jobs with the organization. Additionally, prospective employees may take legal action against companies using tests with invasive or offensive questions. Any of these outcomes are likely to hurt recruitment and selection efforts, and thus, only tests with high levels of acceptability should be used.

Understanding the personality traits of employees can be useful in the workplace. In recent decades, a number of personality tests have been developed and are now commercially available. These tests are easily accessed, purchased, and administered on the Internet. The easy availability and affordableness of a great range of personality tests makes it easy for employers to select and administer one or more tests to employees or prospective employees. Because of this, more and more firms are turning to some kind of personality testing as part of their selection and employee-development processes. While hard data on the use of personality testing is hard to come by, estimates

within the testing industry indicate that between 60 and 90 percent of companies now use some form of employee assessment testing.

While the ease of administration makes testing far more common in the twenty-first century than it was in previous decades, companies seem to be reasonably selective in basing important decisions on these tests. Research into validity and reliability supports the use of tests based on the Five-Factor Model of personality for selection. The Myers-Briggs Type Indicator, a very popular inventory, can be useful for development and team-building in the organization, but its low level of reliability makes it inappropriate for employee screening and selection.

PIONEERS OF MANAGEMENT

The study of management as a discipline is relatively new, especially when compared with other scientific disciplines. Yet, to truly understand current management thought it is necessary to examine the historical links. It is best to consider not only the theories of management pioneers, but also the contextual and environmental factors that helped to clarify the developmental process behind the theories. Therefore, management pioneers may be easily placed along a historical timeline.

Using the work of Daniel Wren as a guide, the following categories are employed: (1) early management thought; (2) the scientific management era; (3) the social man era; and (4) the modern era.

EARLY MANAGEMENT THOUGHT: THE ECONOMIC FACET

Adam Smith and James Watt have been identified as the two men most responsible for destroying the old England and launching the world toward industrialization. Adam Smith brought about the revolution in economic thought, and James Watt's steam engine provided cheaper power that revolutionized English commerce and industry. In doing so, they also laid the foundation for modern notions of business management theory and practice.

Adam Smith. Adam Smith (1723—1790) was a Scottish political economist. His *Wealth of Nations,* published in 1776, established the "classical school" and with its publication, he became the father of "liberal economics." Smith argued that market and competition should be the regulators of economic activity and that tariff policies were destructive. The specialization of labor was the mainstay of Smith's market system. According to Smith, division of labor provided managers with the greatest opportunity for increased productivity.

James Watt and Matthew Boulton. Aided by Matthew Boulton (1728—1809), James Watt (1736—1819) built on the work of his predecessors and developed his first workable steam engine in 1765. Together, the partners founded the engineering firm of Boulton, Watt, and Sons.

Recognized as his greatest breakthrough, Watt developed a steam engine with rotary, rather than the traditional up-and-down, movement in 1771. This made the engine more adaptable to factory uses as the engine replacing waterwheel power for grinding grain, driving textile machines, and operating bellows for iron works.

Steam power lowered production costs, lowered prices, and expanded markets. In 1800 the sons of Boulton and Watt took over the management of the company and instituted one of the first complete applications of scientific management. In this plant there is evidence of market research, including machine layout study involving workflow, production standards, cost accounting, employee training, employee incentives, and employee welfare programs.

EARLY MANAGEMENT THOUGHT: MANAGEMENT PIONEERS IN THE FACTORY SYSTEM

The division of labor, combined with the advances in technology, provided the economic rationale for the factory system. However, the factory system brought new problems for owners, managers, and society. Four management pioneers proposed solutions for coping with the pressures of the new large-scale industrial organizations. They were Robert Owens, Charles Babbage, Andrew Ure, and Charles Dupin.

Robert Owens. Robert Owens (1771—1858) was a successful Scottish entrepreneur and a utopian socialist who sowed the first seeds of concern for factory workers. Repulsed by the working conditions and poor treatment of workers in the factories across Scotland, Owen became a reformer. He reduced the use of child labor and used moral persuasion rather than corporal punishment in his factories. He chided his fellow factory owners for treating their equipment better than they treated their workers.

Owen deplored the evils of the division of labor; in his ideal system, he believed each man would do a number of different jobs, switching easily from one job to another. Additionally, Owen hated the modern factory system, so he decided to revolutionize it. In 1813 he proposed a factory bill to prohibit employment of children under the age of ten and to limit hours for all children to 10 ½ hours per day with no night work. The bill became law six years later, but was limited to cotton mills, reduced the age limit to nine, and included no provision for inspections; therefore, the law had little impact.

Feeling frustrated in his attempts to reform Britain, Owen traveled to America in 1824. He continued on to New Harmony, Indiana, where he had purchased a large plot of land. New Harmony was the first and most famous of sixteen U.S.-based Owenite communities appearing between 1825 and 1829. None, however, lasted more than a few years as full-fledged socialist communities.

Charles Babbage. Charles Babbage (1792—1871) is known as the patron saint of operations research and management science. Babbage's scientific inventions included a mechanical calculator (his "difference engine"), a versatile computer (his "analytical engine"), and a punch-card machine. His projects never became a commercial reality; however, Babbage is considered the originator of the concepts behind the present day computer.

Babbage's most successful book, *On the Economy of Machinery and Manufacturers,* described the tools and machinery used in English factories. It discussed the economic principles of manufacturing, and analyzed the operations; the skills used and suggested improved practices.

Babbage believed in the benefits of division of labor and was an advocate of profit sharing. He developed a method of observing manufacturing that is the same approach utilized today by operations analysts and consultants analyzing manufacturing operations.

Andrew Ure and Charles Dupin. Andrew Ure (1778—1857) and Charles Dupin (1784—1873) were early industrial educators. Ure provided academic training at Anderson's College in Glasgow for managers in the early factory system. He published a text in 1835 that dealt mainly with the technical problems of manufacturing in the textile industry, but also dealt with problems of managing.

Obviously pro-management, Ure advocated an "automatic plan" to provide harmony and to keep any individual worker from stopping production. He was a defender of the factory system and believed workers must recognize the benefits of mechanization and not resist its introduction.

Dupin was a French engineer and professor who pioneered industrial education in France. He is credited with having a great influence on the writings of Henri Fayol. Dupin published *Discours sur le Sort Des Ouvriers,* translated Discourse on the Condition of the Workers, in 1831. This manuscript included concepts such as time study and the need to balance workloads after introducing division of labor. He wrote of the need for workers to receive concise instructions and the need to discover and publish the best way to perform work with the least amount of worker energy.

THE SCIENTIFIC MANAGEMENT ERA

Since management relied heavily on engineers for advice in the new factories, it is not surprising that associations of engineers were some of the first to examine and write about management problems. The American Society of Mechanical Engineers (ASME) was founded in 1880 and was one of the first proponents of the search for scientific management.

Henry Towne. Henry Towne, president of the Yale and Towne Manufacturing Company, began applying systematic management practices as early as 1870. In 1866 he wrote a paper, *The Engineer as an Economist,* that suggested that ASME become a clearinghouse for information on managerial practices, since there was no management association.

Towne also published several papers and a book, *Evolution of Industrial Management,* on the use of "gain sharing" to increase worker productivity. In his last book Towne contrasted the status of scientific management in 1886 and in 1921, noting the establishment of industrial

management courses, and crediting Frederick Taylor as the apostle of the scientific movement.

Frederick A. Halsey. Frederick A. Halsey was another engineer who wrote papers presented to ASME outlining his ideas about wages. He attacked the evils of profit sharing and proposed a special "premium plan" for paying workers based on time saved. Halsey proposed incentives based on past production records, including a guaranteed minimum wage and a premium for not doing work. Halsey's plan, along with Taylor's ideas on piece rates, had a major influence in the United States and Great Britain on the design of pay schemes.

Henry Metcalfe. Another early application of the scientific principles of management occurred when Captain Henry Metcalfe developed a system of controls that he applied to the management of the Frankford Arsenal. In 1885, Metcalfe published *The Cost of Manufactures and the Administration of Workshops, Public and Private.* This book is considered a pioneer work in the area of management science.

Daniel McCallum. Unlike many industries, the railroad industry forced managers to develop special ways of managing a labor force that was dispersed over a wide geographical area. Daniel McCallum (1815—1878) became general superintendent of the Erie Railroad in 1854. He developed principles of management that included discipline, division of labor, detailed job descriptions, promotion and pay based on merit, frequent and accurate reporting of worker performance, and a clearly defined chain of command.

McCallum also designed a formal organizational chart and a sophisticated information management system using the telegraph. His system and rules, however, ran afoul of the militant union and he resigned after a six-month strike. Later, McCallum successfully ran the Northern railroads during the Civil War. He also served as a management consultant for several railroads after the war.

Frederick Taylor. Probably the most famous management pioneer of all is Frederick W. Taylor (1856—1915), the father of scientific management. Taylor rose from common laborer to chief engineer in six years, and completed a home study course to earn a degree in mechanical engineering in 1883.

In trying to overcome soldiering by the workers, Taylor began a scientific study of what workers ought to be able to produce. This study led to the beginnings of scientific management. Taylor used time studies to break tasks down into elementary movements, and designed complementary piece-rate incentive systems.

Taylor believed management's responsibility was in knowing what you want workers to do and then seeing that they do it in the best and cheapest way. He developed many new concepts such as functional authority. In other words, Taylor proposed that all authority was based on knowledge, not position. He wrote *Shop Management* in 1903, became the president of the American Society of Mechanical Engineers in 1906, and was a widely traveled lecturer, lecturing at Harvard from 1909 to 1914.

Taylor published *Principles of Scientific Management* in 1911. Its contents would become widely accepted by managers worldwide. The book described the theory of scientific management. Scientific management was defined as methods aimed at determining the one best way for a job to be done.

During this same period, organized labor waged an all-out war on Taylorism resulting in a congressional investigation. In February of 1912, however, the committee reported finding no evidence to support abuses of workers or any need for remedial legislation. Taylor did not neglect the human side of work, as often suggested. He simply emphasized the individual worker not the group. Taylor called for a revolution that would fuse the interests of labor and management into a mutually rewarding whole.

Henry Gantt. Henry Gantt (1861—1919) worked with Taylor at the Midvale Steel Company and was considered a Taylor disciple. Gantt felt the foreman should teach the workers to be industrious and cooperative which, in turn, would facilitate the acquisition of all other knowledge.

Gantt also designed graphic aids for management called Gantt charts using horizontal bars to plan and control work. Similar to Taylor, Gantt called for the scientific study of tasks, movements, working conditions, and worker cooperation. He also focused on the connection between the involvement of management and financial interests.

Frank Gilbreth. Frank Gilbreth (1868—1924) and Lillian Gilbreth (1878—1972) were a husband and wife team that brought many significant contributions, as well as color, to scientific management. Frank began working at age seventeen as an apprentice bricklayer, and later became a chief superintendent and independent contractor. Frank's early work parallels Taylor's and, in later years, Frank formed his own management consulting company, which was closely associated with scientific management methods.

Frank Gilbreth published a series of books describing the best way of laying bricks, handling materials, training apprentices, and improving methods while lowering costs and paying higher wages.

In 1907 Frank Gilbreth met Frederick Taylor and soon became one of Taylor's most devoted advocates.

Frank turned his attention away from construction, and extended his interest in motion study (similar to Taylor's time study) to the general field of management.

To supplement the human eye, Gilbreth used motion picture cameras, lights, and clocks calibrated in fractions of minutes to create "micromotion" study. Gilbreth also developed a list of seventeen basic motions he called "therbligs" (Gilbreth spelled backwards) to help analyze any worker movement. Unfortunately, the partnership of Frank and Lillian came to an end in 1924 when Frank died of a heart attack. Lillian continued their work through motion study seminars and consulting, later becoming a professor of management at Purdue University (1935—1948).

Lillian Gilbreth. Dr. Lillian Gilbreth, known as the first lady of management, played an important role in Frank's research and made many contributions of her own. Lillian pursued a degree in psychology, and in addition to her marriage and family of twelve, she assisted Frank with his work. Lillian's thesis-turned-book, *The Psychology of Management,* is one of the earliest contributions to understanding the human side of management.

Lillian faced many incidents of discrimination during her life, including the fact that her book could only be published if her initials were used so readers would not know she was a woman. Dr. Gilbreth's work was always more management than psychology. Her work illustrated concern for the worker and attempted to show how scientific management would benefit the individual worker, as well as the organization. Lillian wrote about reduction of worker fatigue, how to retool for disabled veteran workers returning to the workplace, and how to apply principles of scientific management to the home. The Gilbreth's partnership and their family was made famous by the 1946 book *Cheaper by the Dozen,* written by son, Frank Gilbreth Jr. and daughter, Ernestine Gilbreth Carey.

Harrington Emerson. Harrington Emerson (1853—1931) was educated in Germany and symbolized a new breed of "efficiency engineers" who were bringing new methods of time and cost savings to American industry. Emerson practiced his system as general manager of the Burlington Railroad, but saw the need for applications of his system in other industries.

The Engineering Magazine published a series of articles by Emerson in 1908 and 1909 that were later issued as a single volume. To Emerson, organization was one of the greatest problems that led to inefficiency. Emerson embraced the general staff concept where each firm was to have a chief of staff and four major sub groupings of staff under him: one for employees, one for machines, one for materials, and one for methods. Staff advice was available to all levels and focused on planning.

Emerson made other contributions in the areas of cost accounting and in setting standards for judging workers and shop efficiency. In 1913 Emerson published *Twelve Principles of Efficiency.* This publication became a landmark in the history of management thought. Harrington Emerson achieved renown in his time and his legacy lives on today.

Morris Cooke. While Taylor, the Gilbreths, Gantt, and Emerson were working with industrial enterprises, Morris Cooke (1872—1960) was extending the gospel of efficiency in non-industrial organizations. Cooke focused his attention on educational and municipal organizations.

Cooke conducted a study of administration in educational organizations funded by the Carnegie Foundation for the Advancement of Teaching. The resulting study was a bombshell in the academic world. Cooke's findings included, among other things, widespread use of inbreeding (hiring your own graduates), inefficient committee management, autonomous departments working against university coordination, and pay based on tenure.

In 1911 Cooke was selected as director of public works and brought scientific management to the governance of Philadelphia. In four years he saved the city over one million in garbage collection costs alone. Cooke wrote *Our Cities Awake* (1918) to put forth his case for using scientific management for better-managed municipalities.

Cooke became a close friend of Samuel Gompers, president of the American Federation of Labor, and tried to bring labor and management together in a time when they were becoming more antagonistic.

Hugo Munsterberg. While the efficiency engineers studied mechanical efficiency, the industrial psychologists studied human efficiency, with the same goal in mind of improving productivity. The father of industrial psychology was Hugo Munsterberg (1863—1916). In 1892 Munsterberg established his psychological laboratory at Harvard, which was to become the foundation stone in the industrial psychology movement.

Munsterberg published *Psychology and Industrial Efficiency* (1913), which included theories directly related to Taylor's scientific management. The book contained three parts. Part one, the "best possible man," was a study of the demand jobs made on people, and the importance of finding people whose mental capabilities made them well-matched for the work. Part two, the "best possible work," described the psychological conditions under which the greatest output might be obtained from every worker. Part three, the "best possible effect," examined the necessity of creating the influences on human needs that were desirable for the interests of business.

Munsterberg's proposals were based on his own evidence from studies involving telephone operators, trolley drivers, and naval officers.

Walter Dill Scott. Walter Dill Scott (1869—1955) taught at Northwestern University from 1901 to 1920 and then served as president of the university for nineteen years. Scott was interested in employee attitudes and motivation in production and devised a system, adopted by the army, for classifying personnel and testing officer candidates. In fact, he was awarded the Distinguished Service Medal for his work.

From March 1910 until October 1911, Scott wrote a series of articles entitled *The Psychology of Business* later published in *System* magazine. These articles were based on actual business cases and represented one of the earliest applications of the principles of psychology to motivation and productivity in industry.

THE EMERGENCE OF ADMINISTRATIVE THEORY

Henri Fayol. Two contributors to the administrative theory of management are Henri Fayol (1841—1925) and Max Weber (1864—1920). Both wrote during the scientific management era in America, but neither was accorded the full measure of his contribution until some decades after his death.

Fayol was trained as a mining engineer and became the managing director of a coal-mining and iron foundry combine. From his own experience, he formulated and wrote papers about his ideas of administrative theory as early as 1900. His first mention of the "elements" of administration came in a book published in 1916. However, America was not thoroughly exposed to Fayol's theory until the book was translated in 1949 and titled *General and Industrial Management.*

Fayol identified the major elements or functions of management as planning, organization, command, coordination, and control. Planning and organization received the majority of his attention in his writings. Fayol believed that management could be taught, that managerial ability was sorely needed as one moved up the ladder, and that management was a separate activity applicable to all types of undertakings.

Fayol's fourteen principles of management included: division of labor, authority, discipline, unity of command, unity of direction, subordination of individual interests to the general interest, remuneration, centralization, scalar chain, order, equity, stability of tenure of personnel, initiative, and *esprit de corps* (morale).

Max Weber. The work of Max Weber (1864—1920) runs chronologically parallel to that of Fayol and Taylor.

Weber was a German intellectual with interests in sociology, religion, economics, and political science. He was a professor, editor, government consultant, and author. Weber used the concept of "bureaucracy" as an ideal organizational arrangement for the administration of large-scale organizations. His work was not translated into English until 1947.

Weber's concept of the best administrative system was actually similar to Taylor's. Some of Weber's essential elements included division of labor, and chain of command. He also believed that selection should be based on technical qualifications, officials'/managers' appointments should be based on qualifications, managers should not be owners, and impersonal and uniform rules should be applied.

Peter Drucker. Peter Drucker (1909—2005) made an enduring contribution to understanding the role of manager in a business society. Unlike the previous Fayolian process texts, Drucker, author of more than thirty-five books, developed three broader managerial functions: (1) managing a business; (2) managing managers; and (3) managing workers and work. He proposed that in every decision, the manager must put economic considerations first. Drucker recognized that there may be other non-economic consequences of managerial decision, but that the emphasis should still be placed on economic performance. Known as the "father of modern management," Drucker later was a critic of excessive executive pay.

As noted in *Business Week*, Drucker introduced the following ideas between the 1940s and the 1970s: the decentralization of large organizations (1940s); the corporation as a "human community," where workers were viewed as assets of and not liabilities to the organization, a view which gained him a strong following in Japan (1950s); using substantive institutional practices and policies over "charismatic cult leaders" in shaping the direction of the organization (1960s); and the realization of the growing importance of "knowledge capital" in the evolving economy. In fact, Drucker is credited with coining the term "knowledge worker" in the 1970s.

THE SOCIAL MAN ERA

The behavioral school of management thought began late in the scientific management era, but did not achieve large-scale recognition until the 1930s. The real catalyst for the emergence of the behavioral school was a series of research studies conducted at the Hawthorne plant of Western Electric between 1924 and 1932. This research became known as the Hawthorne experiments.

Elton Mayo and the Hawthorne Studies. Elton Mayo (1880—1949) joined the Harvard faculty in 1926 as associate professor of industrial research, and two years

later was asked to work with Western Electric, as part of the Harvard research group, to continue the Hawthorne studies.

Mayo was intrigued by the initial results of the early illumination studies that showed output had increased upon changes in illumination—either brighter or darker—but no one knew why. Mayo believed the increased output came from a change in mental attitude in the group as the workers developed into a social unit.

Other experiments included the piecework experiment, the interviewing program, and the bank wiring room experiments. From these experiments the Mayoists concluded that employees have social needs as well as physical needs, and managers need a mix of managerial skills that include human relations skills.

Mary Parker Follett. Another contributor to the behavioral school of thought was Mary Parker Follett. Follett (1868—1933) was trained in philosophy and political science, and became interested in vocational guidance and the emerging field of social psychology. She had an international reputation as a political philosopher and in 1924 published *Creative Experience,* a book that was widely read by businessmen of the day.

Follett advocated a business philosophy that embraced integration as a way to reduce conflict without compromise or domination. She also proposed the "law of the situation," where parties agree to take their orders from the situation instead from an individual.

Another facet of her philosophy focused on coordination as a fundamental principle of organization. Follett believed the primary leadership task was to define the purpose of the organization and integrate that purpose with individual and group purposes. In other words, she thought that organizations should be based on a group ethic rather than individualism. Thus, managers and employees should view themselves as partners rather than adversaries.

Chester Barnard. Chester Barnard (1886—1961) was a self-made scholar who attended Harvard on a scholarship, but never graduated because he lacked a laboratory science course. He joined the AT&T system in 1909 and became the president of New Jersey Bell in 1927.

Barnard is best-known for his 1938 work, *The Functions of the Executive,* a collection of eight lectures in which he described a theory of organizations in order to stimulate others to examine the nature of cooperative systems. Looking at the disparity between personal and organizational motives, Barnard described an "effective-efficient" dichotomy.

According to Barnard, effectiveness deals with goal achievement, and efficiency is the degree to which individual motives are satisfied. He viewed formal organizations as integrated systems where cooperation, common purpose,

and communication are universal elements, whereas the informal organization provides communication, cohesiveness and maintenance of feelings of self-worth. Barnard also developed the "acceptance theory of authority" based on his idea that bosses only have authority if subordinates accept that authority.

THE MODERN ERA: TOTAL QUALITY MANAGEMENT

A quality revolution swept through the business sector during the latter part of the twentieth century. The universal term used to describe this phenomenon was "total quality management" or TQM. This revolution was led by a small group of quality gurus; the most well known were W. Edwards Deming (1900—1993) and Joseph Juran (b. 1904).

W. Edwards Deming. Deming, an American, is considered to be the father of quality control in Japan. In fact, Deming suggested that most quality problems are not the fault of employees, but the system. He emphasized the importance of improving quality by suggesting a five-step chain reaction. This theory proposes that when quality is improved, (1) costs decrease because of less rework, fewer mistakes, fewer delays, and better use of time and materials; (2) productivity improves; (3) market share increases with better quality and prices; (4) the company increases profitability and stays in business; and (5) the number of jobs increases. Deming developed a 14-point plan to summarize his teachings on quality improvement. These fourteen points are listed in Table 1.

Table 1
Deming's 14 Points

1. Create consistency of purpose toward the improvement of product and service, and communicate this goal to all employees.
2. Adopt the new philosophy of quality throughout all levels with the organization.
3. Cease dependence on inspection to achieve quality; understand that quality comes from improving processes.
4. No longer select suppliers based solely on price. Move towards developing a long-term relationship with a single supplier.
5. Processes, products, and services should be improved constantly; reducing waste.
6. Institute extensive on-the-job training.
7. Improve supervision.
8. Drive out fear of expressing ideas and concerns.
9. Break down barriers between departments. People should be encouraged to work together as a team.
10. Eliminate slogans and targets for the workforce.
11. Eliminate work quotas on the factory floor.
12. Remove barriers that rob workers of their right to pride of workmanship.
13. Institute a program of education and self-improvement.
14. Make sure to put everyone in the company to work to accomplish the transformation.

Joseph M. Juran. Joseph Juran's experience led him to conclude that more than 80 percent of all quality defects are caused by factors within management's control. He referred to this as the "Pareto principle." From this theory, he developed a management trilogy that included quality planning, control, and improvement. Juran suggested that an area be selected which has experienced chronic quality problems. It should be analyzed, and then a solution is generated and finally implemented.

The quality work of Joseph Juran and W. Edwards Deming changed the way people looked at business.

THE MODERN ERA: CONTEMPORARY MANAGEMENT HISTORIANS

The following group of individuals have proven themselves to be great teachers and intellectual leaders in matters of fundamental concern to management history. Their leadership and research have contributed greatly to our understanding of the evolution of management.

Arthur Bedeian. Arthur Bedeian, a management professor at Louisiana State University, is a management historian with universal interests. He has written on a variety of management-related topics, many of which fall within the area of management history. Bedeian has made several significant contributions to management history. These include his research into specific areas of inquiry such as scientific management and his bibliographic investigations and memoriams. However, perhaps his most important contribution to the field is his editorship of the four volumes of the *Management Laureates: A Collection of Autobiographical Essays.*

Alfred Bolton. Alfred Bolton was born in Canada in 1926. At the age of fifty-four, he began work on his doctorate at Nova University. It was during this time that he developed an interest in management history. His most significant contribution to the body of management history knowledge is his work with Ron Greenwood regarding the Hawthorne study participants. The work resulting from this collaborative effort has provided a unique glimpse into the groundbreaking experiments at Western Electric.

Daniel Wren. Daniel Wren (b. 1932) is considered one of the leading authorities on the history of management thought. He is one of the most prolific writers in this field. His textbook, *The Evolution of Management Thought,* focuses on describing management history by providing a conceptual framework for understanding the evolution of management. Both his research and teaching in this area have led many to consider Wren as one of the management history gurus of the twentieth century.

PLANNING

Planning is the management function that involves setting goals and deciding how to best achieve them. Setting goals and developing plans helps the organization to move in a focused direction while operating in an efficient and effective manner. Long-range planning essentially is the same as strategic planning; both processes evaluate where the organization is and where it hopes to be at some future point. Strategies or plans are then developed for moving the organization closer to its goals. Long-range plans usually pertain to goals that are expected to be met five or more years in the future.

People often confuse the roles of planning and scheduling. They are different methodologies and utilize different sets of tools. Planning takes a futuristic view and sets anticipated timelines, while scheduling focuses on an organization's day-to-day activities. For example, most enterprise

resource planning (ERP) systems are good at the planning function, but are very poor at the scheduling function. A tool like finite capacity scheduling (FCS) is necessary to facilitate the daily tracking of material and labor movements.

LONG-RANGE PLANNING AND STRATEGIC MANAGEMENT

Since the purpose of strategic management is the development of effective long-range plans, the concepts often are used interchangeably. The traditional process models of strategic management involve planning organizational missions; assessing relationships between the organization and its environment; and identifying, evaluating, and implementing strategic alternatives that enable the organization to fulfill its mission.

One product of the long-range planning process is the development of corporate-level strategies. Corporate strategies represent the organization's long-term direction. Issues addressed as part of corporate strategic planning include questions of diversification, acquisition, divestment, and formulation of business ventures. Corporate strategies deal with plans for the entire organization and change relatively infrequently, with most remaining in place for five or more years.

Long-range plans usually are less specific than other types of plans, making it more difficult to evaluate the progress of their fulfillment. Since corporate plans may involve developing a research-intensive new product or moving into an international market, which may take years to complete, measuring their success is rarely easy. Traditional measures of profitability and sales may not be practical in evaluating such plans.

Top management and the board of directors are the primary decision makers in long-range planning. Top management often is the only level of management with the information needed to assess organization-wide strengths and weaknesses. In addition, top management typically is alone in having the authority to allocate resources toward moving the organization in new and innovative directions.

WHY ENGAGE IN LONG-RANGE PLANNING?

Research has found that firms engaged in strategic planning outperform firms that do not follow this approach. Because planning helps organizations to consider environmental changes and develop alternative responses, long-range planning seems particularly useful for firms operating in dynamic environments.

A review of studies regarding long-range and strategic planning and performance allows a number of generalizations to be made about how long-range planning can contribute to organizational performance.

1. Long-range plans provide a theme for the organization. This theme is useful in formulating and evaluating objectives, plans, and policies. If a proposed objective or policy is not consistent with the existing theme, it can be changed to better fit the organization's strategies.

2. Planning aids in the anticipation of major strategic issues. It enhances the ability of a firm to recognize environmental changes and begin courses of action to prevent potential problems. Rewarding employees for recognizing and responding to environmental changes sensitizes employees to the need for planning.

3. Planning assists in the allocation of discretionary resources; future costs and returns from various alternatives can be more easily anticipated. Strategies also reflect priorities resulting from multiple objectives and business-unit interdependencies.

4. Plans guide and integrate diverse administrative and operating activities. The relationship between productivity and rewards is clarified through strategic planning, guiding employees along the path to the desired rewards. Strategies also provide for the integration of objectives, avoiding the tendency for subunit objectives to take precedence over organizational objectives.

5. Long-range planning is useful for developing prospective general managers. Strategic planning exposes middle managers to the types of problems and issues they will have to face when they become general managers. Participation in strategic planning also helps middle managers to see how their specialties fit into the total organization.

6. Plans enable organizations to communicate with groups in the environment. Plans incorporate the unique features of the product or company that differentiate it from its competitors. Branding communicates to the public an image of product attributes (e.g., price, quality, and style). Similarly, dividend policies make a difference in the attractiveness of a stock to blue-chip, growth, and speculative investors.

THE STRATEGIC MANAGEMENT/ LONG-RANGE PLANNING PROCESS

The first basic step in long-range planning, is the definition of the organization's mission. Essentially, the mission is what differentiates the organization from others providing similar goods or services. Strategies are developed from mission statements to aid the organization in operationalizing its mission.

Long-range planning primarily is the responsibility of boards of directors, top management, and corporate planning staffs. Strategic decision makers are responsible for identifying and interpreting relevant information about the business environment. Thus, a key part of strategic management involves identifying threats and opportunities stemming from the external environment and evaluating their probable impact on the organization.

Environmental analysis, another key component of long range-planning, identifies issues to be considered when evaluating an organization's environment. The environment consists of two sets of factors. These include the macro-environment, consisting of factors with the potential to affect many businesses or business segments, and the task environment, with elements more likely to relate to an individual organization. Industry analysis is an especially important part of analyzing the specific environment of an organization.

Internal characteristics of an organization must be thoroughly identified and accounted for in order to effect long-term planning. Internal factors can represent either strengths or weaknesses. Internal strengths provide a basis upon which strategies can be built. Internal weaknesses represent either current or potential problem areas that may need to be corrected or minimized by appropriate strategies. Internal planning issues commonly involve the functional areas of finance, marketing, human resource management, research and development, operations/production, and top management.

Once the organization's mission is determined and its internal and external strengths and weaknesses are identified, it is possible to consider alternative strategies that provide the organization with the potential to fulfill its mission. This process essentially involves the identification, evaluation, and selection of the most appropriate alternative strategies. Strategic alternatives include strategies designed to help the organization grow faster, maintain its existing growth rate, reduce its scope of operations, or a combination of these alternatives. Corporate grand strategies are evaluated later in this discussion.

Strategy implementation is another important part of long-range planning. Once a strategic plan has been selected, it must be operationalized. This requires the strategy to be implemented within the existing organizational structure, or the modification of the structure so that it is consistent with the strategy. Implementing a strategy also requires integration with the organization's human component.

A final element of long-range planning is strategic control, which evaluates the organization's current performance and compares this performance to its mission. Strategic control essentially brings the strategic management process full circle in terms of comparing actual results to intended or desired results.

CORPORATE-LEVEL PLANS

Corporate-level plans are most closely associated with translating organizational mission statements into action. In a multi-industry or multiproduct organization, managers must juggle the individual businesses to be managed so that the overall corporate mission is fulfilled. These individual businesses may represent operating divisions, groups of divisions, or separate legal business entities. Corporate-level plans primarily are concerned with:

1. Scope of operations. What businesses should we be in?

2. Resource allocation. Which businesses represent our future? Which businesses should be targeted for termination?

3. Strategic fit. How can the firm's businesses be integrated to foster the greatest organizational good?

4. Performance. Are businesses contributing to the organization's overall financial picture as expected, in accordance with their potential? The business must look beyond financial performance to evaluate the number and mix of business units. Has the firm been able to achieve a competitive advantage in the past? Will it be able to maintain or achieve a competitive advantage in each business in the future?

5. Organizational structure. Do the organizational components fit together? Do they communicate? Are responsibilities clearly identified and accountabilities established?

CORPORATE PORTFOLIO ANALYSIS

The Boston Consulting Group (BCG) Model is a relatively simple technique for helping managers to assess the performance of various business segments and develop appropriate strategies for each investment within the corporate portfolio.

The BCG Model classifies business unit performance on the basis of the unit's relative market share and the rate of market growth. Products and their respective strategies fall into one of four quadrants. The typical starting point for a new business is as a *question mark*. If the product is new, it has no market share but the predicted growth rate is good. What typically happens is that management is faced with a number of these types of products, but with too few resources to develop all of them. Thus, long-range planners must determine which of the products to attempt to develop into commercially viable products and which ones to drop from consideration. Question marks are cash users in the organization. Early in their life, they contribute no revenues and require expenditures

for market research, test marketing, and advertising to build consumer awareness.

If the correct decision is made and the product selected achieves a high market share, it becomes a *star* in the BCG Model. Star products have high market share in a high growth market. Stars generate large cash flows for the business, but also require large infusions of money to sustain their growth. Stars often are the targets of large expenditures for advertising and research and development in order to improve the product and to enable it to establish a dominant industry position.

Cash cows are business units that have high market share in a low-growth market. These often are products in the maturity stage of the product life cycle. They usually are well-established products with wide consumer acceptance and high sales revenues. Cash cows generate large profits for the organization because revenues are high and expenditures are low. There is little the company can do to increase product sales. The plan for such products is to invest little money into maintaining them, and to divert the large profits generated into products with more long-term earnings potentials (i.e., question marks and stars).

Dogs are businesses with low market share in low-growth markets. These often are cash cows that have lost their market share or are question marks the company has elected not to develop. The recommended strategy for these businesses is to dispose of them for whatever revenue they will generate and reinvest the money in more attractive businesses (question marks or stars).

Another, later form of the BCG Model is the GE/McKinsey Matrix, which differs in three ways from the BCG Model: (1) a broader measurement—competitive strength—is used instead of market share in order to assess the business unit's relative industry performance; (2) market industry attractiveness is used as a measurement of the product's performance, instead of just market growth; and (3), instead of using a two-by-two matrix in which to place the product—as used in the BCG Model—the GE/McKinsey Matrix uses a three-by-three matrix, which allows for a middle category for measuring product attractiveness.

CORPORATE GRAND STRATEGIES

Corporate strategies can be classified into three groups or types. Collectively known as grand strategies, these involve efforts to expand business operations (growth strategies), maintain the status quo (stability strategies), or decrease the scope of business operations (retrenchment strategies).

Growth Strategies. Growth strategies are designed to expand an organization's performance, usually as measured by sales, profits, product mix, or market coverage.

Typical growth strategies involve one or more of the following:

1. Concentration strategy, in which the firm attempts to achieve greater market penetration by becoming very efficient at servicing its market with a limited product line.

2. Vertical integration strategy, in which the firm attempts to expand the scope of its current operations by undertaking business activities formerly performed by one of its suppliers (backward integration) or by undertaking business activities performed by a business in its distribution channel.

3. Diversification strategy, which the firm moves into different markets or adds different products to its mix. If the products or markets are related to its existing operations, the strategy is called *concentric diversification.* If the expansion is in products and markets unrelated to the existing business, the diversification is called *conglomerate.*

Stability Strategies. When firms are satisfied with their current rate of growth and profits, they may decide to employ a stability strategy. This strategy basically extends existing advertising, production, and other strategies. Such strategies typically are found in small businesses in relatively stable environments. The business owners often are making a comfortable income operating a business that they know, and see no need to make the psychological and financial investment that would be required to undertake a growth strategy.

Retrenchment Strategies. Retrenchment strategies involve a reduction in the scope of a corporation's activities. The variables to be considered in such a strategy primarily involve the degree of reduction. Retrenchment strategies can be subdivided into the following:

1. Turnaround strategy, in which firms undertake a temporary reduction in operations to make the business stronger and more viable in the future. These moves are popularly called downsizing or rightsizing. The hope is that a temporary belt tightening will allow the firm to pursue a growth strategy at some future point.

2. Divestment, in which a firm elects to spin off, shut down, or sell a portion of its business. This strategy would commonly be used with a business unit identified as a dog by the BCG Model. Typically, a poor performing unit is sold to another company and the money is reinvested in a business with greater potential.

3. Liquidation strategy, which is the most extreme form of retrenchment. Liquidation involves the selling or

closing of the entire business operation, usually when there is no future for the business. Employees are released, buildings and equipment are sold, and customers no longer have access to the product. This generally is viewed as a strategy of last resort, and is one that most managers work hard to avoid.

The purpose of an organization is its role as defined by those who maintain authority over it. How the organization elects to fulfill this role constitutes its plan. Mission statements differentiate the organization from other organizations providing similar goods or services. Objectives are the intermediate goals or targets to be completed as the organization fulfills its mission. Plans outline how a firm intends to achieve its mission. Policies provide guidelines or parameters within which decisions are made so that decisions are integrated with other decisions and activities.

POISON PILL STRATEGIES

Poison pill strategies are defensive tactics that allow companies to thwart hostile takeover bids from other companies. Many companies may find themselves unprepared when facing such bids. By adopting a poison pill strategy, a company can be somewhat reassured that acquiring companies will approach its board of directors, not the shareholders. Poison pill strategies are also known as shareholders' protection rights plans.

HISTORY

During the late 1950s and early 1960s, several large corporations began acquiring other companies to diversify their operations. Diversification allowed them to offset their losses in a failing industry with profits from other unrelated, successful industries. Such phenomena caused concerns about the potential of conglomerates to concentrate excessive economic power in the hands of a few corporations. This led to the passage of the Williams Act in 1968, which required the acquiring company to fully disclose the terms of an impending acquisition and to allow a period for competing offers for the target company to be made.

By the late 1970s, the pace of acquisitions nearly came to a halt. In 1982, however, the U.S. Supreme Court passed a landmark ruling in the case of *Edgar v. MITE Corp* that invalidated the basis for anti-takeover laws in thirty-seven states. Furthermore, under the Reagan administration, the U.S. Department of Justice followed a lax policy towards enforcing anti-takeover laws. No longer able to shelter themselves against unfriendly takeover bids, many companies opted to devise anti-takeover strategies. At that time there was a significant increase in poison pill adoptions. However, in light of recent corporate scandals and an overall perception of poor corporate ethics poison pills began to show a decline in the early twenty-first century.

TYPES OF POISON PILL STRATEGIES

"Flip-Over" Rights Plan. Most poison pill strategies involve some form of discrimination against the acquiring company. The most commonly used strategy is called the "flip over," or the shareholder rights plan. Under this strategy, the holders of common stock of a company receive one right for each share held, which allows them an option to buy more shares in the company. The rights have a set expiration date and do not carry voting power. They are worthless at the time of the offering because the exercise price is set well above the going market price of common shares. A shareholder cannot sell these rights independently as they trade together with the shares. When a suitor company makes an unwelcome bid, the rights begin trading separately from the shares. If the takeover bid is successful, the shareholder rights may be exercised to purchase shares at a discount of as much as 50 percent from the going market price. All the shareholders except the acquirer can exercise their rights to purchase shares at discount. This results in a significant dilution in the share holdings of the acquirer, possibly placing the control of the firm in jeopardy. The attempted takeover bid becomes expensive. If the takeover bid is abandoned, the company might redeem the rights, usually at five cents per share.

"Flip-in" Rights Plan. A variation of the flip over is the "flip-in" plan. The plan allows the rights holder to purchase shares in the target company at a discount upon the mere accumulation of a specified percentage of stock by a potential acquirer. For example, the rights become exercisable to purchase the target company's common stock at

50 percent discount from market price in the event the acquirer purchases more than, say, 30 percent ownership in the target company. The acquirer is precluded from exercising flip-in rights. This strategy allows more power than the "flip-over" rights plan and, therefore, has become a common form of poison pill adopted by many U.S. corporations.

Poison Debt. The target company issues debt securities on certain stipulated terms and conditions to discourage a hostile takeover bid. Examples include covenants that severely restrict the company's ability to sell assets, an increase in the interest rates, an acceleration of the maturity date, a conversion of debt to equity at favorable rates, and rights to buy notes at a substantial premium to the prevailing market price at the time of the takeover bid.

"Put Rights" Plan. Under this plan, the target company issues rights to its stockholders in the form of a dividend. When an acquirer purchases a specified percentage ownership in the target company, the target shareholders, excluding the acquirer, are entitled to sell their common stock back to the company for a specified sum of cash, debt securities, preferred stock, or some combination thereof. This form of poison pill strategy is rarely used by the U.S. corporations.

Voting Poison Pill Plan. This poison pill strategy is designed to dilute the controlling power of the acquirer. Under this plan, the target company issues a dividend of securities, conferring special voting privileges to its stockholders. For example, the target company might issue shares that do not have special voting privileges at the outset. When a potential hostile bid occurs, the stockholders, other than the acquiring party, receive super voting privileges. Alternately, the target company's stockholders might receive securities with voting rights that increase in value over period.

Examples of Rights Plans. On 5 November 1998, Motorola, Inc. adopted a new rights plan to replace an existing plan. Under the plan, one right attaches to each existing share of common stock. If a person or group acquires a 10 percent stake, all other right holders will be entitled to purchase the company's stock at a 50 percent discount. Motorola may redeem the new rights at one cent per right at any time before a person or group takes a 10 percent stake.

On 13 October 1998, Baldwin Piano & Organ Company announced a shareholder rights plan by declaring a dividend of one stock purchase right for each share of common stock owned. Unlike rights plans adopted by other companies, Baldwin's innovative plan would permit a qualified offer to go forward without the board's approval. A qualified offer must be all cash, made to all share-

holders, contain a firm financing commitment, and a fairness opinion from an investment bank. A qualified offer must result in the acquirer gaining at least 70 percent of Baldwin's then outstanding shares.

In late 2004, PeopleSoft management attempted to use a poison pill that would be triggered when 20 percent of the company was acquired. However, shareholder interest in accepting the takeover by Oracle Corp. led to an eventual merger of the two companies.

Cisco had implemented a poison pill plan triggered when an individual or group acquired more than 15 percent of the company. The plan was set to expire in 2008; however, in March 2005 Cisco decided to end the shareholder rights' program, citing revision of its corporate governance procedures.

Yahoo instituted a poison pill strategy in 2001, also triggered when a buyer acquired 15 percent of the company. This came to light during Microsoft's attempt to buy Yahoo in 2008, and allowed shareholders to acquire more stock once the 15 percent threshold was breached by a buyer. In February 2008, Yahoo expanded the poison pill by increasing severance packages to its employees in the event of an acquisition. As a result of the proposed severance packages, Yahoo stockholder and corporate investor Carl Icahn initiated a proxy fight in an attempt to replace Yahoo's board of directors. Subsequently, a group of institutional stockholders filed suit to block the February expansion of the poison pill.

In June 2008, the *Wall Street Journal* reported that at least two companies, Louisiana-Pacific Corp. and Micrel Inc., announced they would take into account derivatives holdings when calculating "beneficial ownership" levels that trigger their respective poison pills.

THE NET EFFECTS OF POISON PILL STRATEGIES

The net effect of a poison pill strategy is to make it prohibitively expensive for an acquirer to buy the control of a company. The underlying assumption is that the board will always act in the best interest of the shareholders, a view that is explicitly rejected by agency theorists. Agency theorists have argued that the practice of allowing management to adopt poison pill strategy has reduced the number of potential offers and actual takeovers. In doing so, they have protected incumbent management at the expense of shareholders. It is argued that poison pills have the effect of perpetuating inefficiencies and poor management that ultimately is reflected in lower stock values.

Boards of directors invariably argue that poison pill strategies have exactly the opposite effect on stock values. They help maintain their independent decision making power to run their companies in the best interests of the shareholders. Poison pill strategies also provide bargaining

strength to the board in order to extract the most value for the stock from a potential acquirer.

While there are merits to the arguments on both sides, an efficient allocation of resources through merger and acquisition activities can only enhance shareholders' wealth no matter how hostile the tender offers of corporate raiders. Many of the defensive tactics of management should be opposed by the shareholders as they might cause a loss of their wealth, although other defensive actions—for example, by soliciting competitive bids—can increase their wealth.

POKA-YOKE

Poka-yoke is a technique for avoiding simple human error in the workplace. Also known as mistake-proofing, goof-proofing, and fail-safe work methods, poka-yoke is simply a system designed to prevent inadvertent errors made by workers performing a process. The idea is to take over repetitive tasks that rely on memory or vigilance and guard against any lapses in focus. Poka-yoke can be seen as one of the three common components of Zero Defect Quality Control performed by Japanese companies (source inspection and feedback are the other two).

Poka-yoke can be applied in physical, operational, and philosophical aspects of either manufacturing or service firms. Physical mistake-proofing involves establishing automated mechanisms that eliminate conditions that are prone to errors from a system. Mistake-proofing of operations is achieved through modification of systems with relevant devices which monitor the proper sequences for procedures. Philosophical approach to mistake-proofing involves addressing situations that impede quality and efficiency in production processes (such as inadequate or unskilled workforce).

Dr. Shigeo Shingo, a renowned authority on quality control and efficiency originally developed the mistake-proofing idea. Realizing its value as an effective quality control technique, he formalized its use in Japanese manufacturing as the poka-yoke system. One hundred percent inspections catch unacceptable products but do nothing to improve the process. Shingo was emphatic that the purpose of this system be to improve the process not sort out defective parts.

The poka-yoke concept is in wide use in Japan and other countries throughout the world. Toyota Motor Corporation, whose production system Shingo helped design, averages twelve poka-yoke devices per machine in their manufacturing plants, statistics that clearly validate the concept as beneficial to industry. Patel, Dale, and Shaw, in the article "Set-Up Time Reduction and Mistake Proofing Methods: An Examination in Precision" list the potential benefits as:

- Elimination of set-up errors and improved quality

- Decreased set-up times with associated reduction in production time and improved production capacity

- Simplified and improved housekeeping

- Increased safety

- Lower costs

- Lower skill requirements

- Increased production flexibility

- Improved operator attitudes

In a *Quality* magazine article, Melissa Larson provides interesting details about benefits resulting from the implementation of poka-yoke systems at the Supply Support Activity (SSA) at Fort Carson, Colorado, a military retail supply operation of the U.S. Army.

Inventory, receipt, and batch processing all improved quantifiably. Location survey accuracy was approximately sixty-five percent prior to implementation. After implementing the use of the bar-code readers location accuracy increased to ninety-eight percent. Inventory adjustments

averaged $3,000 a month. Inventory adjustments dropped to an average of $250 per month.

The rate of incorrect receipt closures to the supplier had been ninety percent. This rate dropped to zero percent. Batch processing was also significantly improved. Traditionally, the SSA had approximately fifteen to twenty batch processing failures per month, and a myriad of system file failures due to operators performing the process out of proper sequence. Since the poka-yoke implementations, there have been zero batch process failures.

Catalog update improvements also resulted. The error rate was twenty-two percent but dropped to zero percent. Original request processing time was 12.5 days, but with the new request processing time is 1.6 days. Actual dollars invested in these activities totaled less than $1,000.

TYPES OF POKA-YOKES

Poka-yoke is based on prediction and detection. That is, recognizing that a defect is about to occur or recognizing that a defect has occurred. Consequently, there are two basic types of poka-yoke systems. The control poka-yoke does not allow a process to begin or continue after an error has occurred. It takes the response to a specific type of error out of the hands of the operator. For example, a fixture on a machine may be equipped with a sensing device that will not allow the process to continue unless the part is properly inserted. A second type of poka-yoke provides some type of warning when an error occurs. This does not prevent the error, but immediately stops the process when an error is detected. This type of poka-yoke is useful for mass production environments with rapid processing as the device prevents mass production of scrapped material. For environments where large losses of time or resources do not result, a warning poka-yoke is warranted. All that is needed is a way to ensure that the error is investigated and corrected in a timely manner.

Poka-yokes can be as simple as a steel pin on a fixture that keeps incorrectly placed parts from fitting properly, or they can be as complex as a fuzzy logic neural network used to automatically detect tool breakage and immediately stop the machine. Surprisingly, the simple low-cost devices tend to be in the majority. Regardless of degree of simplicity, all poka-yokes fall into one of three categories: contact methods, fixed-value methods, and motion-step methods. Each is briefly discussed.

Contact Methods. Contact methods are based on some type of sensing device which detects abnormalities in the product's shape or dimension and responds accordingly. Interference pins, notches with matching locator pins, limit switches and proximity switches are sometimes used to ensure that a part is positioned correctly before work occurs. Asymmetric parts with matching work fixtures can

also alleviate incorrect positioning. If orientation is not critical, symmetrical designs can then be used to prevent defects.

Contact methods are useful in situations which encourage mistakes. Such situations involve rapid repetition, infrequent production, or environmental problems such as poor lighting, high or low heat, excess humidity, dust, noise, or anything which distracts a worker. Paul Dvorak, in "Poka-Yoke Designs Make Assemblies Mistake-proof," an article appearing in *Machine Design,* recommends that the maintenance engineer investigate at least four areas for potential problems that require contact method solutions.

1. Look for where the product will fail if parts are assembled incorrectly.

2. Look for small features critical to proper assembly.

3. Beware of relying on subtle differences to determine top from bottom or front from back, especially if the parts are painted dark colors.

4. Beware of designs so complicated that they confuse inexperienced operators.

Fixed-Value Methods. Fixed-value methods are used in processes where the same activity is repeated several times, such as tightening of bolts. This method frequently involves very simple techniques, such as methods that allow operators to easily track how often this activity has been performed. Dvorak gives the example of an operator who is responsible for tightening down six bolts on a product. Before passing the product on, the tightening process is performed a fixed number of times (six). A simple poka-yoke device would incorporate the use of a wrench dipped in diluted paint. Since loose bolts will not have paint on them, the operator can easily see if he or she has performed the process the required number of times. A second example (from Dvorak) would be the use of packaged material in the exact (fixed) quantities needed to complete the process. If the bolts were stored in containers of six, the operator could easily see when the process was still incomplete as the box would still contain one or more bolts.

Motion-Step Method. The motion-step method is useful for processes requiring several different activities performed in sequence by a single operator. This is similar to the fixed-value situation in that the operator is responsible for multiple activities but instead of performing the same activity multiple times the operator performs different activities. First, each step in the process is identified by the specific motions needed to complete it. Then devices are created to detect whether each motion is performed and then alert the operator when a step is skipped. An assembly process could utilize a device that

Table 1

Examples of Poka-Yokes

	Contact Type	Warning Type
Contact Method	A steel pin on a fixture keeps incorrectly placed parts from fitting properly.	A device on a drill counts the number of holes drilled in a work piece; a buzzer sounds if the work piece is removed before the correct number of holes have been drilled.
Fixed-value Type	Light sensors determine if each crayon is present in each box; if a crayon is missing, the machines will stop automatically.	Bolts are tightened with a wrench dipped in paint. Bolts with no paint on them are still un-tightened.
Motion-Step Method	A simple proximity switch opens after all components are loaded in the proper order.	A device detects when each component is removed from a dispenser; if a component is not removed, the device alerts the assembler before he can move on to another unit.

senses when all required components are present at the start of the process for each unit. The devices could then detect when each component is removed from its dispenser, if a component is not removed, the sensing device alerts the assembler before he/she can move on to another unit.

SELF CHECKS

Poka-yoke devices which provide the fastest possible feedback about defects and allow workers to assess the quality of their own work are referred to as self-checks. Self-checks can be used to allow workers to rapidly identify slips or work errors such as incomplete or omitted operations and to verify the existence or absence of an attribute. For example, at Brigham and Women's Hospital, a computer system is used to check and process doctors' prescriptions.

Examples. A number of "real world" applications are presented in the business and engineering literature. Below is a list of examples of poka-yoke applications. James R. Evans and William M. Lindsay present these examples in their book *The Management and Control of Quality:*

- Color-coding a wiring template to assist the worker.

- Installing a device on a drill to count the number of holes drilled in a work piece; a buzzer sounds if the work piece is removed before the correct number of holes has been drilled.

- Cassette covers were frequently scratched when the screwdriver slipped out of the screw slot and slid against the plastic covers. The screw design was changed to prevent the screwdriver from slipping.

- A metal roller is used to laminate two surfaces bonded with hot melted glue. The glue tended to stick to the roller and cause defects in the laminate surface. An investigation showed that if the roller were dampened the glue would not stick. A secondary roller was added to dampen the steel roller during the process, preventing the glue from sticking.

- One production step at Motorola involves putting alphabetic characters on a keyboard, then checking to make sure each key is placed correctly. A group of workers designed a clear template with the letters positioned slightly off center. By holding the template over the keyboard, assemblers can quickly spot mistakes.

John Grout presented these examples in "Mistake-Proofing Production," an article written for *Production and Inventory Management Journal:*

- Trinity Industries Railcar Division workers created a layout jig to avoid having to use a tape measure and chalk to position subassemblies on each car individually. The jig has tops that allow it to be quickly positioned correctly on the car's chassis. Each component that is to be attached to the car has a corresponding cutout on the jig. The jig eliminates two modes of worker error. It eliminates incorrect measurements and inaccurate positioning of parts. It also eliminates the worker vigilance required to ensure all of the components are attached. Omitted parts are made very obvious because an empty space exists on the layout jig. Without the jig, there would be no indication that anything is missing. Once parts are spot-welded in place, the jig is lifted off and welding is completed. Not only is dependence on worker vigilance reduced, cost savings result from the simplified, accelerated process.

- Binney and Smith, maker of Crayola Crayons, uses light sensors to determine if each crayon is present in each box of crayons they produce. If a crayon is

missing, the machines will stop automatically. Producing complete boxes of crayons right the first time is the preferred outcome.

- A mail-order computer company has designed its boxes and packing material to avoid mistakes. The inner flaps of the box bottom have a large brightly colored warning to "Stop! Open the other side." When the correct side is opened, a book titled "Setting Up Your Computer" is on top of the packing material. The sequence of the book matches the arrangement of the contents of the box. Each instruction involves the next item from the box.

- Airplane lavatory lights come on only when the door lock is engaged. This keeps customers from failing to lock the door.

- John Deere produced a gearbox that was assembled without oil, mounted on a machine, and required replacement after factory tests. A team streamlined production with a simple proximity switch that opens after all components were loaded into an assembly fixture. The switch prevents workers from using air wrenches to tighten bolts on the assembly until they cycle an oil gun into the gearbox. After filling the gearbox a solenoid releases the interlock sending air to the wrench. Then workers can tighten cover bolts and send the box to the next station.

- The electrical connectors in one machine control formerly used only three-pin connectors to join each in a series. Labels instructed assemblers which boards went where and which connectors should be joined. However, in the field, assemblers connecting and disconnecting them wear or bend the pins, which meant putting on a new plug. Soon the label was gone. The simple solution involved three-, four-, and five-pin connectors that cannot join others and demand a single assembly sequence.

- Ficarra's solution to labels that come off is to machine them into parts, especially when the function is to determine the correct orientation.

- On Varian machines, assemblers are guided by small machined-in pictures that cannot wear off.

SERVICE APPLICATIONS

Poka-yoke can also be applied to service-based organizations. The following is summarized from the paper "Using Poka-Yoke Concepts to Improve a Military Retail Supply System," which was printed in *Production and Inventory Management Journal*.

While manufacturing typically only considers errors made by the producer, service industries must consider errors from both the server and the customer. Additionally, service organizations interface in many different ways to transfer a service to the customer. Because of the possibility that service errors can be created by both the customer and the server, service poka-yokes are grouped into two categories: fail-safing the server and fail-safing the customer.

SERVER POKA-YOKES

There are three types of poka-yoke systems that can be used to fail-safe the server: task poka-yokes, treatment poka-yokes, and tangible poka-yokes.

Task poka-yokes. Task poka-yokes focus on server tasks and common mistakes servers make while performing the service/task for the customer. A good example of a control-oriented, task poka-yoke is the coin return machine used in many fast-food restaurants. The coin portion of a customer's change from payment is returned automatically through these machines. This takes the control out of the hands of the cash register operator, eliminating errors and speeding up the processing of customers.

Treatment poka-yokes. Treatment poka-yokes focus on the social interaction between the customer and the server (i.e., eye contact, greeting). By mistake-proofing/standardizing what servers say and do to customers, managers can reasonably ensure that customers receive proper, fair, and consistent treatment. Burger King utilized warning-oriented, treatment poka-yokes by placing "cue cards" at the service point, ensuring that servers know what to say the minute they interface with the customer. Automated teller machines (ATM) in banks are programmed with sequenced interactive response systems that guide customers through the process of withdrawing or depositing money; they prevent occurrence of errors such as use of wrong secret identification numbers by customers or withdrawal of more money than what is available in a bank account.

Tangible poka-yokes. Tangible poka-yokes attempt to improve the tangible, physical impression and experience for the customer in addition to the direct task of the server (i.e., dirty office, unkempt server, sloppy documents). Motorola uses a control-oriented poka-yoke in the legal department by having a second lawyer inspect all legal work for spelling, presentation, and arithmetic. In this way, the legal department is ensuring that the "tangibles" of the service are satisfactory in addition to the task of the service (legal work).

CUSTOMER POKA-YOKES

Fail-safing the customer also consists of three of poka-yoke systems: preparation poka-yokes, encounter poka-yokes, and resolution poka-yokes.

Preparation poka-yokes. Preparation poka-yokes attempt to fully prepare the customer before they even enter the service. An example of a warning-oriented, preparation poka-yoke is the notice a university sends to each student prior to registration for the next semester detailing the courses he needs to finish his degree. This system could be converted to a control system by having an automated registration process which would not allow students to sign up for classes out of sequence or until all prerequisites are met.

Encounter poka-yokes. Encounter poka-yokes attempt to fail-safe a customer at a service who may misunderstand, ignore, or forget the nature of the service or their role in it. A good example of a control-oriented, encounter poka-yoke is the use of concrete curbing at an oil and lubes shop that directs customers so that they do not/cannot pull the wrong way into the station. This system also assists in the selection process so that customers are not served out of order.

Resolution poka-yokes. Resolution poka-yokes attempt to remind customers of the value of their input to the continuous improvement of a service. A hotel which uses an automated check-out system through the television in each room could attach a few questions to the check-out process to ensure the customer provides feedback on key issues. This would be a control-oriented resolution poka-yoke. Obviously, one of the keys to the success of any customer-oriented poka-yoke is to obtain willing customer participation.

BARRIERS TO IMPLEMENTATION AND RECOMMENDATIONS

Patel, Dale and Shaw note that there are a number of barriers a firm may face when implementing poka-yoke devices within their system. These include:

- Difficulty in accepting change
- Justification of the investment
- Using inappropriate and ineffective methods
- Time requirements
- Difficulty encountered as a result of continuous process

Stewart and Grout, in an article titled "The Human Side of Mistake-Proofing," make the following recommendations for the implementation of poka-yoke devices:

1. The outcome of the process or routine must be known in advance so as to have a standard for comparison.

2. The process must be stable, i.e., outcomes are not changing.

3. There must be an ability to create a break between cause and effect in the process so as to provide an opportunity to insert a poka-yoke.

4. Environments requiring substantial operator skill are prime locations for poka-yoke devices.

5. Environments where training or turnover cost is high are prime locations for poka-yoke devices.

6. Environments with frequent interruptions and distractions are prime locations for poka-yoke devices.

7. Environments with a consistent set of mixed products are prime locations for poka-yoke devices.

8. The beginning of any process where there are multiple other possible processes that could be initiated are a prime location for poka-yoke devices.

9. Locations in the process with similarly positioned or configured parts, controls or tools are prime locations for poka-yoke devices.

10. Any point in the process requiring replacement or orientation of parts in order to prevent wrong positioning is a prime location for poka-yoke devices.

11. Any point in the process where adjustments are made for machine or process setups is a prime location for poka-yoke devices.

John Grout attributed defects to three sources: variance, mistakes, and complexity. Complexity requires techniques which simplify the process while managing variance can be accomplished by utilizing statistical process control (SPC). However, if quality problems are the result of mistakes, poka-yoke devices are the appropriate technique to use. In this case, poka-yoke provide an even more effective quality improvement tool than SPC. Other poka-yoke benefits include reduced training costs and the advantage of freeing workers' time and minds for more creative and value-adding activities.

As a key component of the Zero Defect Quality Control, poka-yoke is widely applied in the design and development of modern software and other information technology processes. Software developers incorporate clear warning signals that aid end users and client-developers in identifying errors in a system before they occur, as is usually the case with the automated warnings that computer software generate upon expiry of anti-virus certificates. Poka-yoke systems facilitate the achievement of lean software development initiatives in information technology processes.

Manivannan is categorical that the application of poka-yoke in analytical processes—such as failure mode and effects analysis (FMEA)—aids the identification and implementation of appropriate mistake-proofing mechanisms that ensure process improvement and efficiency.

FMEA is an analysis tool that is applied by the functional teams across a firm to evaluate manufacturing and process-related activities with the objective of quantifying results in terms of risk priorities.

Circumstances where poka-yoke is not the appropriate response are situations involving high speed production, situations where X-bar ($\bar{X}$) and R charts are effective, and use in destructive testing. Other situations, however, provide opportunities for simple, inexpensive, and fail-safe devices to improve performance. Grout relates the example of Lucent Technologies, which reported that half of their 3,300 mistake-proof devices cost less than $100. However, they estimate a net savings of $8.4 million or about $2,545 per device. Poka-yoke is a most impressive and powerful tool.

POPULAR PRESS MANAGEMENT BOOKS

The past several decades have witnessed a profusion of management books published in the popular press, many becoming best sellers. This trend often starts during economic hard times, when managers search for some easy-to-understand cures for their organizations' financial woes. Even when the overall economy improves, managers continue to look for new insights that might help them improve their own or their organizations' fortunes.

Despite their enormous sales, popular management books must weather a rather severe image problem. They are often perceived as hastily assembled tracts that do little more than attempt to capitalize on a hot (and usually short-lived) management fad. They are borne of managers' frazzled attempts to overcome obstacles and challenges that do not generalize well for a wide audience, but the books hide these faults behind hyperbolic and trendy word spinning. Typically relying as much on their style as on their substance, popular management books are criticized for lacking both empirical and rational justification, assuming factors that one would be ill-advised to assume, and excessively simplifying very complex problems. Lastly, critics skeptically eye the sheer volume of such books, along with the frequency with which new ones arrive in bookstores before sliding into the background, typically just in time for a new generation of popular books to detail the next fad.

Since a systematic analysis of popular-press management books would be an endless odyssey, what follows are brief summaries of fourteen quite popular titles. The purpose is not so much to critically examine the books, since the criticisms, like the books themselves, do not generalize reliably; rather, the more modest goal is to lay the foundation for what a reader can expect from popular-press management books, from which one can deduce the degree of usefulness therein for one's own purposes.

COMPETITIVE ADVANTAGE THROUGH PEOPLE

Stanford professor Jeffrey Pfeffer in his book *Competitive Advantage Through People* has described the potential impact of human resource management practices on competitive advantage. Based on his study of popular and

academic business literature and interviews with people from a wide range of the business community, Pfeffer identified sixteen human resource management practices that, in his opinion, can enhance a firm's competitive advantage, including employment security, high wages, incentive pay, employee ownership, team and job redesign, and symbolic egalitarianism.

THE ONE-MINUTE MANAGER

Written by Kenneth Blanchard and Spencer Johnson, *The One-Minute Manager* warns managers of the perils of treating employees too harshly or too softly. In the first instance, the employer wins; in the latter, the employee wins. The ideal is to manage employees in a way that both parities win. This aim can be accomplished if managers use three techniques: goal setting, positive reinforcement, and verbal reprimand, each of which can be implemented within one minute.

The use of one-minute goals helps clarify the employees' specific responsibilities and lets them know performance standards to which they will be held. The manager should then frequently review the employees' goal achievements to ensure they remain on target. Moreover, managers should focus their time on catching their employees doing something right, rather than something wrong. Immediate praise should accompany these behaviors. Finally, when seen doing something wrong, employees should receive immediate feedback, indicating exactly what was done wrong and how the manager feels about it. Following the reprimand, the manager should praise the individual as a person, thus establishing a clear separation between the person and the problem behavior.

WHO MOVED MY CHEESE?

Written by Spencer Johnson, M.D., *Who Moved My Cheese?* is a simple parable that reveals profound truths about change. It is an amazing and enlightening story of four characters that live in a "Maze" and look for "Cheese" to nourish them and make them happy. Two mice are named Sniff and Scurry—nonanalytical and nonjudgmental, they just want cheese and are willing to do whatever it takes to get it. Hem and Haw are "little people," mouse-size humans who have an entirely different relationship with cheese. It's not just sustenance to them; it's their self-image. Their lives and belief systems are built around the cheese they've found.

Most of us reading the story will see the cheese as something related to our livelihoods—our jobs, our career paths, the industries we work in—although it can stand for anything, from health to relationships. In the story, the characters are faced with unexpected change. Eventually, one of them deals with it successfully, and writes what he has learned from his experience on the maze walls. When the reader sees the "handwriting on the wall," he or she can

discover for him or herself how to deal with change more effectively. One of the most eloquent of the wall sayings is "what would you do if you weren't afraid?" The point of the story is that we have to be alert to changes in the cheese, and be prepared to go running off in search of new sources of cheese when the cheese we have runs out.

GUNG HO!

Blanchard (*The One-Minute Manager,* 1984), along with co-author Bowles (*Raving Fans,* Morrow, 1993), recounts an organizational turnaround based on three Native American lessons. This inspirational story of business leaders Peggy Sinclair and Andy Longclaw uses allegory to explain fundamental techniques to boost enthusiasm and performance.

Meet Peggy Sinclair, the newly promoted factory manager who was sent to the worst plant of the thirty-two owned by the company, with the expectation to shut it down in six months—and Andy Longclaw, who is pointed out to her the first day, in spite of his area's remarkable performance, as a "troublemaker" by one of her executive staff. Longclaw patiently shows Sinclair Native American principles that help turn Walton Works #2 from the worst plant in the company to a workplace recognized by the White House as one of the nation's finest workplaces. Those three important principles are as follows:

1. "The Spirit of the Squirrel" teaches a lesson of the power of worthwhile work.
2. "The Way of the Beaver" showcases empowerment.
3. "The Gift of the Goose" shows the exponential factor of motivation.

GOOD TO GREAT

Jim Collins' book, *Good to Great,* is based on extensive research on a set of companies that moved from mediocre performance to great results and sustained those results for at least fifteen years. (The good-to-great companies generated cumulative stock returns that beat the general stock market by an average of seven times in fifteen years.)

The findings of the *Good to Great* study:

1. Level 5 Leaders: During the transition years, all of the companies were led by humble individuals who channel their ego needs away from themselves and into the larger goal of building a great company. It is not that Level 5 leaders have no ego or self-interest. Indeed, they are incredibly ambitious—but their ambition is first and foremost for the institution, not themselves.
2. First Who Then What: The good-to-great leaders began the transformation by first getting the right people on the bus (and the wrong people off the bus) and then figured out where to drive it. The

comparison companies frequently followed the "genius with a thousand helpers" model where the leader sets a vision and then enlists a crew of highly capable "helpers" to make the vision happen. This model fails when the genius departs.

3. Confront the Brutal Facts (Yet Never Lose Faith): Create a culture where people have a tremendous opportunity to be heard, and where, ultimately, the truth is heard. Leadership begins with getting people to confront the brutal facts and to act on the implications. Retain absolute faith that you can and will prevail in the end, regardless of the difficulties.

4. Hedgehog Concept: See what is essential and ignore the rest. Hedgehog companies understand what they can be the best at, what they can feel passionate about, and what drives their economic engine.

5. A Culture of Discipline: Good-to-great firms have a high ethic of responsibility and a high culture of discipline. Get disciplined people to engage in disciplined thought and take disciplined action.

6. Technology Accelerators: Good-to-great companies avoid technology fads and yet they become pioneers in the application of carefully selected, relevant technologies.

7. The Flywheel and the Doom Loop: Good-to-great companies follow a pattern of buildup leading to breakthrough. They accumulate successes and use the cumulative consistent momentum to push them yet further out in front. There is no dramatic, revolutionary event.

THE TIPPING POINT

Malcolm Gladwell's bestseller of 2000 explores the difference between trends that take hold and attempts at fame that dissolve into failure. The tipping point itself is the key factor or group of factors that propels an idea into fame and fortune, often a smaller or subtle quality. *The Tipping Point* explores these subtleties and how they can effect products, companies, and innovation.

By studying the way events slowly link together before bursting into success, Gladwell was able to come up with several theories on what makes a difference (also handily divided into the names of chapters), such as the Law of the Few, The Stickiness Factor, and The Power of Context, what are called collectively the Three Rules of Epidemics, epidemics being a good thing in terms of successful marketing.

The first rule, the Law of the Few, says that all trends begin with a small number of people—certain types of people especially. Gladwell identifies these people based on their parts in the marketing framework, and calls them Connectors, Mavens, or Salesmen. Connectors unite dem-

ographic markets, while Mavens inform consumers as to their choices, and Salesmen influence people to make particular choices. These three groups are instrumental.

The second rule, the Stickiness Factor, theorizes that certain qualities about products or services themselves allow them to develop into trends. These qualities are usually unique, going against prevailing notions and giving people memorable impressions. If something is memorable and defiant, it becomes sticky—people remember it, and often take it into consideration in future decision-making.

The third rule is the Power of Context. This rule states that not only the right people and the right idea are necessary, but also the right time and place. Innovations should be introduced into the market when the market is prepared. There may be an obvious need, a large demographic who is willing to try a new concept, a particular economic or environmental pressure, or other effects which make the timing for trend-setting products perfect.

FIRST, BREAK ALL THE RULES

First, Break All the Rules was written by Marcus Buckingham and Curt Coffman as a summary of research done among approximately 80,000 different managers. The book draws conclusions from the research and gives several methods for achieving results when working with goal-oriented employees. It contains many suggestions for achieving status as a relational and effective manager, such as "reject conventional wisdom," "treat every employee as an individual," "focus on strengths, not weaknesses," and "know you are on stage every day." More than a book on breakthrough behavior or marketing, *First, Break All the Rules* is a book on treating employees the right way in order to maximize organizational success.

21 LEADERS FOR THE 21ST CENTURY

This book, by famed management consultants Fons Trompenaars and Charles Hampden-Turner, is a series of interviews and studies with the most successful leaders in the world, including Michael Dell of Dell Computers and Karrel Vursteen of the Heineken Company. *21 Leaders* is a unique book, not necessarily for its management advice, but because it tries to give an outline of successful management procedures and attitudes in an international market. Some nations can have legislation, economies, and goals so different from each other that conducting business with them can be a trial. Trompenaars and Hampden-Turner address this problem with the insights of global executives and studies of their companies.

In certain places the book's advice is simple and well-placed, suggesting to hold back quick judgments when meeting other cultures that express emotion differently, and other such common-sense ideas. Other ideas are more

complex, such as the literary gaffe of "surfing on a three-legged stool," which is used as a metaphor to show how business leaders can please multiple parties at the same time using creative resolution techniques.

BECOMING A SUCCESSFUL MANAGER

Grossman and Parkinson's *Becoming a Successful Manager* acts as a personal training guide to someone new to the management experience, from beginning a shift as a supervisor to moving up to middle or top management teams. It starts with the line, "Congratulations on being promoted to manager!" and moves on from there, breaking down departmental and employee needs into lessons on how to succeed in the management world.

Much of the book focuses on the differences between Professional and Nonprofessional managers, and how to become the former. A Nonprofessional manager is one without experience, who fumbles decisions and acts without confidence. When questioned or given advice, nonprofessionals tend to be defensive, refusing help and causing others to mistrust their judgments. A Professional manager, on the other hand, is in full control, acts with confidence, and concentrates much more on producing results and mastering their responsibilities than on maintaining a particular image or facade. Most of the book's department-maintaining and trust-building advice is centered around this concept.

BROKEN WINDOWS, BROKEN BUSINESS

In 1982, two criminologists by the names of Wilson and Kelling published a famous paper dealing with crime concepts and the "Broken Window" theory. This theory, applied to cities, said that if smaller laws were enforced, such as laws against graffiti or other vandalism, and basic living standards were maintained (broken windows were fixed), then large-scale crimes and gang-related activity would decrease as a natural, trickle-down reaction. This theory single-handedly changed the landscape of New York City crime in the 1990s.

In 2005, Michael Levine wrote *Broken Windows, Broken Business* as an application of the Broken Window theory to the world of business. If companies tend to the small needs of the customers, then a natural attitude will be installed, resulting in good treatment of customers in key areas and a successful business. For this reason, Levine recommends a rigorous employee satisfaction strategy, including regular mystery-shoppers and highly skilled, happy customer service people. The worst attitude a business can have, according to Levine, is broken window hubris, or a top-down view that the company is so successful that they do not need to pay attention to what the customer wants.

THE LEADERSHIP PIPELINE

Charan, Dotter, and Noel wrote this book to train managers in developing their skills to peak condition. The Leadership Pipeline goes through several phases as the manager progresses in talent and experience. First, the manager must learn to apply lessons learned in managing one's self to managing other people (the employees). This includes basic delegation and analysis. Then the manager moves from managing others to managing managers, who have a set of needs different from regular employees. Then the manager learns about Functional managers, or those who run the departments. This requires a broader view of the company. After that, the manager moves to join Business managers or into a more theoretical framework where the company's larger operations become even more important. Next are the Group managers, where managers learn to help others succeed at running their part of the business and become adept at creating and running other operations. The last stage occurs when managers become Enterprise managers, or the CEOs and presidents of companies.

SACRED COWS MAKE THE BEST BURGERS

According to David Brandt and Robert Kriegel, a company can be ruined by its sacred cows, and it can profit by finding and reinventing them. A sacred cow is defined as a business operation or process that the company finds too valuable or traditional to change; Brandt and Kriegel propose that those are the parts of the business most in need of change. They give many examples of managers who challenged sacred cows and either transformed a business operation or saved their companies significant profits by disbanding the cow and replacing it with a more efficient process.

The book gives several ways to spot sacred cows and go on a "cow hunt." Challenging authority and outdated practices is encouraged, while other steps are suggested, such as fostering an environment of change, creating a cow-finding event for employees (including rewards), and training both one's self and others to keep an eye out for any part of the business about which can be asked, "Why do we do that?"

BEFORE THE BRAND

Alycia Perry and David Wisnom put this book together to help companies create a powerful brand identity before they actually implement it, focusing on key issues such as the difference between identity and image, and the necessary long-term strategies associated with owning a brand. Some companies have their name and their image, but are not sure how to broadcast themselves—what can they say about themselves? *Before the Brand* gives methods through which businesses can advertise through effective messages as well as image. It also deals with digital identity and the effect of

various names in today's society (what can be descriptive? Is there such a thing as a good acronym?). Perry and Winsom also include several different brand formulas, such as Ingredient branding and Technology branding.

THE SEVEN HABITS OF HIGHLY EFFECTIVE PEOPLE

Though it was first published in 1989, Stephen Covey's bestselling book has remained a core training tool in the business management world (an anniversary edition was printed in 2004). The book gives seven different suggestions that are meant to be adopted as a holistic approach to self-improvement:

- Be proactive.
- Begin with the end in mind.
- Put first things first.
- Think win-win.
- Seek first to understand, then to be understood.
- Synergize by working in teams with other talented people.
- Sharpen the saw, or be sure to rest, but rest in healthy ways.

PORTER'S FIVE-FORCES MODEL

Porter's five-forces model is a strategy framework that provides corporations with clear analysis of their competitive strategies. The model was developed and advanced by Michael Porter, a renowned marketing strategist. Porter's five-forces model looks at the strength of five distinct competitive forces, which when taken together, determine long-term profitability and competition. Porter's work has had a greater influence on business strategy.

The five-forces model was developed in Porter's 1980 book, *Competitive Strategy: Techniques for Analyzing Industries and Competitors.* To Porter, the classic means of developing a strategy—a formula for competition, goals, and policies to achieve those goals—was antiquated and in need of revision. Porter was searching for a solution between the two schools of prevailing thought. One was centered on the Harvard Business School, and it urged firms to adjust to a unique set of changing circumstances. The other strategy, championed by the Boston Consulting Group, was based on the experience curve, whereby the more a company knows about the existing market, the more its strategy can be directed to increase its share of the market. Porter applied microeconomic principles to business strategy and analyzed the strategic requirements of industrial sectors, not just specific companies.

THE FIVE FORCES

The five forces are competitive factors, which determine industry competition and include: suppliers, rivalry within an industry, substitute products, customers or buyers, and new entrants (see Figure 1).

Although the strength of each force can vary from industry to industry, the forces, when considered together, determine long-term profitability within the specific industrial sector. The strength of each force is a separate function of the industry structure, which Porter defines as "the underlying economic and technical characteristics of an industry." Collectively, the five forces affect prices, necessary investment for competitiveness, market share, potential profits, profit margins, and industry volume. The key to the success of an industry, and thus the key to the model, is analyzing the changing dynamics and continuous flux between and within the five forces. Porter's model depends on the concept of power within the relationships of the five forces.

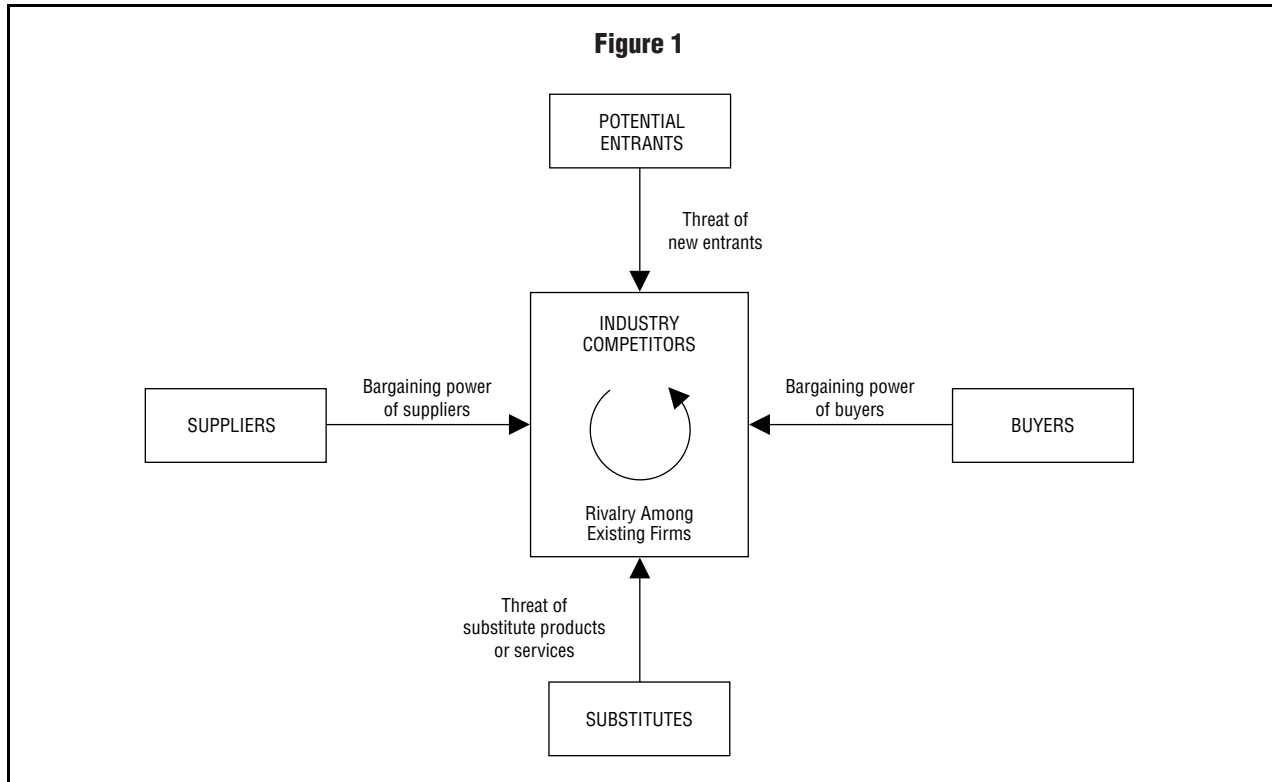
BUYERS

Rivalry Among Existing Firms

Threat of substitute products or services

SUBSTITUTES


Industry Competitors. Rivalries naturally develop between companies competing in the same market. Competitors use means such as advertising, introducing new products, more attractive customer service and warranties, and price competition to enhance their standing and market share in a specific industry. To Porter, the intensity of this rivalry is the result of factors like equally balanced companies, slow growth within an industry, high fixed costs, lack of product differentiation, overcapacity and price-cutting, diverse competitors, high-stakes investment, and the high risk of industry exit. There are also market entry barriers.

Pressure from Substitute Products. Substitute products are the natural result of industry competition, but they place a limit on profitability within the industry. A substitute product involves the search for a product that can do the same function as the product the industry already produces. Porter uses the example of security brokers, who increasingly face substitutes in the form of real estate, money-market funds, and insurance. Substitute products take on added importance as their availability increases.

Bargaining Power of Suppliers. Suppliers have a great deal of influence over an industry as they affect price increases and product quality. A supplier group exerts even more power over an industry if it is dominated by a few companies; there are no substitute products; the industry is not an important consumer for the suppliers; their product is essential to the industry; and forward integration potential of the supplier group exists. Labor supply can also influence the position of the suppliers. These factors are generally out of the control of the industry or company but strategy can alter the power of suppliers.

Bargaining Power of Buyers. The buyer's power is significant in that buyers can force prices down, demand higher quality products or services, and, in essence, play competitors against one another, all resulting in potential loss of industry profits. Buyers exercise more power when they are large-volume buyers, the product is a significant aspect of the buyer's costs or purchases, the products are standard within an industry, there are few changing or switching costs, the buyers earn low profits, potential for backward integration of the buyer group exists, the product is not essential to the buyer's product, and the buyer has full disclosure about supply, demand, prices, and costs. The bargaining position of buyers changes with time and a company's (and industry's) competitive strategy.

Potential Entrants. Threats of new entrants into an industry depend largely on barriers to entry. Porter identifies six major barriers to entry:

- Economies of scale, or decline in unit costs of the product, which force the entrant to enter on a large

scale and risk a strong reaction from firms already in the industry, or accepting a disadvantage of costs if entering on a small scale.

- Product differentiation, or brand identification and customer loyalty.

- Capital requirements for entry; the investment of large capital, after all, presents a significant risk.

- Switching costs, or the cost the buyer has to absorb to switch from one supplier to another.

- Access to distribution channels. New entrants have to establish their distribution in a market with established distribution channels to secure a space for their product.

- Cost disadvantages independent of scale, whereby established companies already have product technology, access to raw materials, favorable sites, advantages in the form of government subsidies, and experience.

BARRIERS TO ENTRY STRATEGY

The six factors identified by Porter can be narrowed down into two major categories of barriers to entry; market barriers to entry and mobility barriers to entry. Market barriers to entry are the structural characteristics of a market, which favor established firms to the disadvantage of new entrants in the market in such a way that established firms enjoy the flexibility of raising prices over costs without attracting new entrants. Mobility barriers shield a firm operating in one segment of the market from entry by other firms operating in different segments of the same market.

Armstrong and Kotler reckon that barriers to entry as a strategy does not occur naturally and has to be initiated by organizations through anticipatory approach. The major strategies of barriers to entry commonly employed by established firms include adoption of sunk costs, squeezing of new entrants, and raising the costs of competitors.

Sunk costs are one of the most effective barriers to entry strategies that a firm can adopt. This is done by locking itself into a market in such a way that new entrants find it difficult to initiate and enforce counter strategies that would kick the incumbent firm out of business. A firm sinks costs through commitment of substantial capital towards purchasing, expanding, and sustaining its investment resources such as plant, machinery, equipments, and acquisition of advanced technologies which enable the firm to draw the advantages of low pricing through economies of scale. Dell, a leading manufacturer of personal computers, is one of the best examples of companies that have successfully applied this strategy. Dell has been able to retain the lion's share of the personal computer market for many years despite

the entry of Macintosh Computers and even the subsequent merger of Hewlett-Packard and Compaq Computers because of the low pricing advantage that it draws from the economies of scale of its vast resources.

Squeezing of new entrants and raising the costs of a competitor are closely related strategies, which focus on creation of a difficult market environment; this denies competitors the likelihood of achieving positive returns on their investments. These strategies of barrier to entry involve introduction of measures such as increased expenditures on advertising, heavy research and development, minimization of access to channels of distribution, patenting of innovations, lowering of prices, optimization of government subsidies, and development of cheaper alternative product ranges in the same market.

New entrants can also expect a barrier in the form of government policy through federal and state regulations and licensing. New firms can expect retaliation from existing companies and also face changing barriers related to technology, strategic planning within the industry, and manpower and expertise problems. The entry deterring price or the existence of a prevailing price structure presents an additional challenge to a firm entering an established industry.

Whereas established firms may find it easy to manipulate the different strategies of barriers to entry according to prevailing market conditions, new entrants always find it difficult to break these barriers and may even run the risks of incurring heavy losses during the efforts to establish favorable market share for their products. It is equally important for management of established firms to adopt a balanced approach when implementing market barrier techniques against competitors and imitators by ensuring that additional costs incurred are appropriately recovered through increased sales volumes.

In summary, Porter's five-forces model concentrates on five structural industry features that comprise the competitive environment, and hence profitability, of an industry. Applying the model means, to be profitable, the firm has to find and establish itself in an industry so that the company can react to the forces of competition in a favorable manner. For Porter, *Competitive Strategy* is not a book for academics but a blueprint for practitioners—a tool for managers to analyze competition in an industry in order to anticipate and prepare for changes in the industry, new competitors and market shifts, and to enhance their firm's overall industry standing.

Throughout the relevant sections of *Competitive Strategy,* Porter uses numerous industry examples to illustrate his theory. Although immediate praise for the book and the five-forces model was exhaustive, critiques of Porter have appeared in business literature. Porter's model does not, for example, consider nonmarket changes, such as events in

the political arena that impact an industry. Furthermore, Porter's model has come under fire for what critics see as his under-evaluation of government regulation and anti-trust violations. Overall, criticisms of the model find their nexus in the lack of consideration by Porter of rapidly changing industry dynamics. In virtually all instances, critics also present alternatives to Porter's model.

Yet, in a *Fortune* interview in early 1999, Porter responded to the challenges, saying he welcomed the "fertile intellectual debate" that stemmed from his work. He admitted he had ignored writing about strategy in recent years but emphasized his desire to reenter the fray discussing his work and addressing questions about the model, its application, and the confusion about what really constitutes strategy. Porter's publications on competitive strategies span across all spheres of business as demonstrated by his 2006 book titled *Redefining Health Care: Creating Value-Based Competition on Results.*

PRICING POLICY AND STRATEGY

Managers should start setting prices during the development stage as part of strategic pricing to avoid launching products or services that cannot sustain profitable prices in the market. This approach to pricing enables companies to either fit costs to prices or scrap products or services that cannot be generated cost-effectively. Through systematic pricing policies and strategies, companies can reap greater profits and increase or defend their market shares. Setting prices is one of the principal tasks of marketing and finance managers in that the price of a product or service often plays a significant role in that product's or service's success, not to mention in a company's profitability.

Generally, pricing policy refers to how a company sets the prices of its products and services based on costs, value, demand, and competition. Pricing strategy, on the other hand, refers to how a company uses pricing to achieve its strategic goals, such as offering lower prices to increase sales volume or higher prices to decrease backlog. Despite some degree of difference, pricing policy and strategy tend to overlap, and the different policies and strategies are not necessarily mutually exclusive.

After establishing the bases for their prices, managers can begin developing pricing strategies by determining company pricing goals, such as increasing short-term and long-term profits, stabilizing prices, increasing cash flow, and warding off competition. Managers also must take into account current market conditions when developing pricing strategies to ensure that the prices they choose fit market conditions. In addition, effective pricing strategy involves considering customers, costs, competition, and different market segments.

Pricing strategy entails more than reacting to market conditions, such as reducing pricing because competitors have reduced their prices. Instead, it encompasses more thorough planning and consideration of customers, competitors, and company goals. Furthermore, pricing strategies tend to vary depending on whether a company is a new entrant into a market or an established firm. New entrants sometimes offer products at low cost to attract market share, while incumbents' reactions vary. Incumbents that fear the new entrant will challenge the incumbents' customer base may match prices or go even lower than the new entrant to protect its market share. If incumbents do not view the new entrant as a serious threat, incumbents may simply resort to increased advertising aimed at enhancing customer loyalty, but have no change in price in efforts to keep the new entrant from stealing away customers.

The following sections explain various ways companies develop pricing policy and strategy. First, cost-based pricing is considered. This is followed by the second topic

of value-based pricing. Third, demand-based pricing is addressed followed by competition-based pricing. After this, several strategies for new and established pricing strategies are explained.

COST-BASED PRICING

The traditional pricing policy can be summarized by the formula:

Cost + Fixed profit percentage = Selling price

Cost-based pricing involves the determination of all fixed and variable costs associated with a product or service. After the total costs attributable to the product or service have been determined, managers add a desired profit margin to each unit such as a 5 or 10 percent markup. The goal of the cost-oriented approach is to cover all costs incurred in producing or delivering products or services and to achieve a targeted level of profit.

By itself, this method is simple and straightforward, requiring only that managers study financial and accounting records to determine prices. This pricing approach does not involve examining the market or considering the competition and other factors that might have an impact on pricing. Cost-oriented pricing also is popular because it is an age-old practice that uses internal information that managers can obtain easily. In addition, a company can defend its prices based on costs, and demonstrate that its prices cover costs plus a markup for profit.

However, critics contend that the cost-oriented strategy fails to provide a company with an effective pricing policy. One problem with the cost-plus strategy is that determining a unit's cost before its price is difficult in many industries because unit costs may vary depending on volume. As a result, many business analysts have criticized this method, arguing that it is no longer appropriate for modern market conditions. Cost-based pricing generally leads to high prices in weak markets and low prices in strong markets, thereby impeding profitability because these prices are the exact opposites of what strategic prices would be if market conditions were taken into consideration.

While managers must consider costs when developing a pricing policy and strategy, costs alone should not determine prices. Many managers of industrial goods and service companies sell their products and services at incremental cost, and make their substantial profits from their best customers and from short-notice deliveries. When considering costs, managers should ask what costs they can afford to pay, taking into account the prices the market allows, and still allow for a profit on the sale. In addition, managers must consider production costs in order to determine what goods to produce and in what amounts.

Nevertheless, pricing generally involves determining what prices customers can afford before determining what amount of products to produce. By bearing in mind the prices they can charge and the costs they can afford to pay, managers can determine whether their costs enable them to compete in the low-cost market, where customers are concerned primarily with price, or whether they must compete in the premium-price market, in which customers are primarily concerned with quality and features.

VALUE-BASED PRICING

Value prices adhere to the thinking that the optimal selling price is a reflection of a product or service's perceived value by customers, not just the company's costs to produce or provide a product or service. The value of a product or service is derived from customer needs, preferences, expectations, and financial resources as well as from competitors' offerings. Consequently, this approach calls for managers to query customers and research the market to determine how much they value a product or service. In addition, managers must compare their products or services with those of their competitors to identify their value advantages and disadvantages.

Yet, value-based pricing is not just creating customer satisfaction or making sales; customer satisfaction may be achieved through discounting alone, a pricing strategy that could also lead to greater sales. However, discounting may not necessarily lead to profitability. Value pricing involves setting prices to increase profitability by tapping into more of a product or service's value attributes. This approach to pricing also depends heavily on strong advertising, especially for new products or services, in order to communicate the value of products or services to customers and to motivate customers to pay more if necessary for the value provided by these products or services.

DEMAND-BASED PRICING

Managers adopting demand-based pricing policies are, like value prices, not fully concerned with costs. Instead, they concentrate on the behavior and characteristics of customers and the quality and characteristics of their products or services. Demand-oriented pricing focuses on the level of demand for a product or service, not on the cost of materials, labor, and so forth.

According to this pricing policy, managers try to determine the amount of products or services they can sell at different prices. Managers need demand schedules in order to determine prices based on demand. Using demand schedules, managers can figure out which production and sales levels would be the most profitable. To determine the most profitable production and sales levels, managers examine production and marketing cost estimates at different sales levels. The prices are determined

by considering the cost estimates at different sales levels and expected revenues from sales volumes associated with projected prices.

The success of this strategy depends on the reliability of demand estimates. Hence, the crucial obstacle manager's face with this approach is accurately gauging demand, which requires extensive knowledge of the manifold market factors that may have an impact on the number of products sold. Two common options managers have for obtaining accurate estimates are enlisting the help from either sales representatives or market experts. Managers frequently ask sales representatives to estimate increases or decreases in demand stemming from specific increases or decreases in a product or service's price, since sales representatives generally are attuned to market trends and customer demands. Alternatively, managers can seek the assistance of experts such as market researchers or consultants to provide estimates of sales levels at various unit prices.

COMPETITION-BASED PRICING

With a competition-based pricing policy, a company sets its prices by determining what other companies competing in the market charge. A company begins developing competition-based prices by identifying its present competitors. Next, a company assesses its own product or service. After this step, a company sets it prices higher than, lower than, or on par with the competitors based on the advantages and disadvantages of a company's product or service, as well as on the expected response by competitors to the set price. This last consideration—the response of competitors—is an important part of competition-based pricing, especially in markets with only a few competitors. In such a market, if one competitor lowers its price, the others will most likely lower theirs as well.

This pricing policy allows companies to set prices quickly with relatively little effort, since it does not require as accurate market data as the demand pricing. Competitive pricing also makes distributors more receptive to a company's products because they are priced within the range the distributor already handles. Furthermore, this pricing policy enables companies to select from a variety of different pricing strategies to achieve their strategic goals. In other words, companies can choose to mark their prices above, below, or on par with their competitors' prices and thereby influence customer perceptions of their products.

For example, if a Company A sets its prices above those of its competitors, the higher price could suggest that Company A's products or services are superior in quality. Harley-Davidson used this with great success. Although Harley-Davidson uses many of the same parts suppliers as Kawasaki, Yamaha, and Honda, they price

well above the competitive price of these competitors. Harley's high prices—combined with its customer loyalty and mystique—help overcome buyer resistance to higher prices. Production efficiencies over the last two decades, however, have made quality among motorcycle producers about equal, but pricing above the market signals quality to buyers, whether or not they get the quality premium they pay for.

STRATEGIES FOR NEW AND ESTABLISHED PRODUCTS

Product pricing strategies frequently depend on the stage a product or service is in its life cycle; that is, new products often require different pricing strategies than established products or mature products.

New Product Pricing Strategy. Entrants often rely on pricing strategies that allow them to capture market share quickly. When there are several competitors in a market, entrants usually use lower pricing to change consumer spending habits and acquire market share. To appeal to customers effectively, entrants generally implement a simple or transparent pricing structure, which enables customers to compare prices easily and understand that the entrants have lower prices than established incumbent companies.

Complex pricing arrangements, however, prevent lower pricing from being a successful strategy in that customers cannot readily compare prices with hidden and contingent costs. The long-distance telephone market illustrates this point; large corporations have lengthy telephone bills that include numerous contingent costs, which depend on location, use, and service features. Consequently, competitors in the corporate long-distance telephone service market do not use lower pricing as the primary pricing strategy as they do in the consumer and small-business markets, where telephone billing is much simpler.

In a book titled *Pricing Policies and Strategies*, Brassington and Pettitt warn that low-pricing strategy for new products should be designed to achieve the right impressions in the target market or else consumers may interpret the low prices as constituting low quality value of the products on offer. Managers can overcome such hurdles by employing low introductory prices on a promotional basis and adjust the prices once a product achieves considerable market share.

Market skimming also serves as a reliable strategy for pricing new products. Market skimming involves setting high initial prices for new products to optimize revenue earnings and gradually reduce the prices as a product gains greater market share. Market skimming pricing strategy is particularly suitable to high technology products that have unique qualities and high entry barriers that dissuade competitors from making entry with undercut prices.

Established Product Pricing Strategy. Sometimes established companies need not adjust their prices at all in response to entrants and their lower prices, because customers frequently are willing to pay more for the products or services of an established company to avoid perceived risks associated with switching products or services.

However, when established companies do not have this advantage, they must implement other pricing strategies to preserve their market share and profits. When entrants are involved, established companies sometimes attempt to hide their actual prices by embedding them in complex prices. This tactic makes it difficult for customers to compare prices, which is advantageous to established companies competing with entrants that have lower prices.

In addition, established companies also may use a more complex pricing plan, such as a two-part pricing tactic. This tactic especially benefits companies with significant market power. Local telephone companies, for example, use this strategy, charging both fixed and per-minute charges. In a strategy aimed at protecting its market share, 3 Group, the 3G mobile broadband operator in the United Kingdom launched the "3 Like Home" in 2007, a pricing policy that allows 3G customers to utilize other 3G networks for a price similar to that on their home network. This is a rare pricing strategy through which the 3 Group extends transparent and attractive pricing on an established product while expanding its market share among customers who are frequent travelers.

MARKET SEGMENTATION

Because all customers do not have the same needs, expectations, and financial resources, managers can improve their pricing strategies by segmenting markets. Successful segmentation comes about when managers determine what motivates particular markets and what differences exist in the market when taken as a whole. For example, some customers may be motivated largely by price, while others are motivated by functionality and utility. The idea behind segmentation is to divide a large group into a set of smaller groups that share significant characteristics such as age, income, geographic location, lifestyle, and so on. By dividing a market into two or more segments, a company can devise a pricing scheme that will appeal to the motivations of each of the different market segments or it can decide to target only particular segments of the market that best correspond to its products or services and their prices.

Managers can use market segmentation strategically to price products or services in order to attain company objectives. Companies can set prices differently for different segments based on factors such as location, time of sale, quantity of sale, product design, and a number of others, depending on the way companies divide up the market. By doing so, companies can increase their profits, market share, cash flow, and so forth.

PRIVACY, PRIVACY LAWS, AND WORKPLACE PRIVACY

Privacy, privacy laws, and workplace privacy are issues of major concern to individuals and organizations in the modern world. Privacy violation and encroachment have become a norm as a result of the surveillance capabilities of the new and emerging electronic gadgets and information technology (IT) systems. This trend has prompted many countries to pass laws that govern the handling and collection of personal information of individuals and organizations with the use of electronic instruments.

WHAT IS PRIVACY?

What constitutes an encroachment to an individual's or an organization's rights to privacy? In legal terms, privacy simply refers to the accepted standards of related rights that safeguard human dignity. Definitions of privacy vary according to the environment, the participating interests, and the contextual limits. In many countries, the concept of data protection is included in the definition of privacy to achieve an interpretation that views privacy in terms of boundaries to an individual's personal information or an organization's data.

The subject area of privacy is concerned with wide-ranging issues that include rights to information privacy, bodily privacy, territorial privacy, and privacy of communications. Information privacy is defined by regulations governing the handling of the private data of individuals such as company, employees, business partners, or owners. Bodily privacy spells out the aspects of privacy that concern trespass of the physical selves of individuals through invasive procedures (such as blood tests). Territorial privacy defines the limits of intrusion across physical boundaries of physical properties belonging to private individuals or firms, whereas privacy of communications defines the limits of intrusions in other people's communication processes such as telephone conversations, e-mails, or ordinary mail.

Privacy is definitely a fundamental human right that underpins the values of human dignity curved around the principles of freedom of association, freedom of expression, and freedom of speech. These values are entrenched in international covenants and protected by specific laws and constitutional provisions in different countries. Privacy is a subject that is always characterized by many controversies that arise from varying interpretations of what constitutes privacy.

PRIVACY LAWS

Privacy law is a concept that has experienced a long history of constitutional declarations as well as landmark court rulings and interpretations. In the book titled *Essentials of Human Rights*, Rhoda Smith and Christian Anker note that the concept can be traced to as far back as the fourteenth century, when the Justices of the Peace Act in England provided for the arrest of peeping toms and eavesdroppers. The preceding years have seen the development of specific protections for privacy in many countries throughout the world.

Privacy laws form the basis of protection for privacy rights, which are seen as the boundaries that determine the allowable levels of intrusion that an individual, a society, or an organization can commit into the activities of an individual or any legally recognized entity. In the United States, the historical transformations of protection of privacy rights can be traced in numerous constitutional declarations and Supreme Court rulings. For example, the Declaration of the Rights of Man and the Citizen of 1792 recognized the sanctity of private property and outlawed violations to private property.

In their 2006 book titled *Constitutional and Administrative Law, Second Edition*, Joanne Coles and Jane Reynolds point out that the benchmark for modern privacy laws can be traced in the 1948 Universal Declaration of Human Rights, which particularly advocates for communications privacy and territorial privacy. Article 12 of the articles clearly states that "At no one time should an individual's privacy, family, home, or correspondence be subjected to arbitrary interference, and neither should the reputation or honor of an individual be subjected to attacks as well, because everyone has the right to enjoy the protection of law against such arbitrary attacks or interference." The authors also note that the declaration is further reinforced by the International Covenant on Civil and Political Rights and the European Declaration of Human Rights which expand the boundaries of the rights to privacy.

Countries such as the United States, Sweden, Germany, and France introduced amendments in their privacy laws in the 1970s and 1980s that broadened data protection rights to include electronic data.

Sniffing. Sniffing of messages on the Internet is one of the ways through which state intelligence agencies monitor public e-mail communications. In the book titled *Internet Literacy,* Fred T. Hofstetter defines sniffing as the act of intercepting information by hacking into gateways that link the networks to the information superhighway. In the United States, for example, the Federal Bureau of Investigation (FBI) uses Carnivore, a customizable intelligence gadget with the capacity to break Internet security and encryption codes and to monitor multiple forms of Internet communications such as e-mails, chats, file transfers, and instant messaging. Carnivore churns through Internet communications and automatically forwards to the FBI messages that may contain clues to cases the intelligence organization is dealing with.

FBI computerized monitoring intensified in 2001 with the passing of the USA Patriot Act of 2001 which introduced amendments to the Electronic Communications Privacy Act of 2006 and Computer Matching and Privacy Protection Act of 1988 to allow the FBI to issue National Security Letters to Internet Service Providers demanding the disclosure of personal information and data about their clients. The USA Patriot Act of 2001 also introduced amendments to the Right to Financial Privacy Act of 1978 that mandated the access of intelligence agencies to private financial information. In a move geared towards protecting U.S. citizens from arbitrary monitoring by state intelligence agencies such as the FBI, the United States passed the USA Patriot Improvement and Reauthorization Act of 2005, which outlawed the provisions in the USA Patriot Act of 2001 that provided FBI with unlimited access to private information and data of US citizens.

INTERNATIONAL INSTRUMENTS OF PRIVACY LAWS

The Council of Europe's Convention on the Protection of Individuals with Regard to the Automatic Processing of

Personal Data and the Organization for Cooperation and Development (OECD) Guidelines Governing the Protection of Privacy and Cross Border Data Flows are the main international law instruments that stipulate specific guidelines concerning the handling of electronic data across international borders. The two documents form the basis for laws that govern the protection of data in many countries, because they provide adequate description of personal information that is subject to protection at every stage of collecting, storing, and disseminating data. The underlying principle of the international privacy and data protection laws is that personal information should be obtained accurately, lawfully, and subjected only to the original purpose for which it was intended.

The European parliament further enhanced the levels of protection for each of its states in the 1990s by passing the Europe-Wide Directive on the Protection of Individuals with regard to the processing of personal data, which provides citizens of member countries with protection against a wider range of privacy and data abuse. Each of the European Union (EU) member countries has passed legislations that compliment the directive to ensure harmonious application of privacy protection laws concerning the flow of data throughout the EU.

EMPLOYEE MONITORING AND WORKPLACE PRIVACY

Workplace privacy is a very important yet controversial issue that dogs the modern workplace environment. Computer-based technologies are increasingly providing government agencies and organizations in the private sector with technologically advanced channels for conducting mass surveillance on people both at the workplace and on the streets, developments that have led to the transformation of privacy into a crucial concern for individual rights.

Employee monitoring in organizations has become a prominent practice with many organizations crafting policies that regulate employee behaviors and use of equipment and facilities. E-mail communications and use of the system's computers, Internet, and telephones are usually the most monitored employee activities in organizations. For example, Continental Airlines IT policies clearly stipulate that all e-mail and other Internet-based communications of employees are subject to monitoring with the objective of ensuring that they meet the requirements of the company.

The modern work environment is always characterized by ever-evolving information technology systems and equipment that employers keep on acquiring with the objective of facilitating speed, convenience, and productivity in organizational work processes. Employers are reaping enhanced benefits from these systems as they can comfortably utilize the multimedia capacities of these technological systems to track and monitor the activities

of employees in the systems. As much as organizations cite workplace security as the main reason behind the practice of monitoring employees through technological devices, there is much concern that the organizations are openly breaching the privacy rights of the employees.

Workplace security is a critical issue in organizations that subject the properties and business interests of employers to extreme protection from misuse and unauthorized exposure to competitors. Moreover, employee productivity may be hampered if employees use the IT systems of the organization to gamble, run private businesses, play computer games, or log on to sites with adult content. Therefore, workplace policing often focuses on protecting the organization from employee actions that may result in the misuse of the company's physical and intellectual properties, use of company database for personal purposes, revelation of trade secrets to competitors, or the transmssion of malicious and damaging information through the organization's IT systems.

But the big question is; how far should organizations extend their protection? There is genuine need for organizations to draw a balance between security of information policies and the privacy of employees. Managers take advantage of company policies to intercept employee communications at will without regard to the privacy rights of the employees. In fact, employers have the leeway to even incorporate the rights for filming employees at their work stations. Nonetheless, whatever employers deem fit and good for the organization, managers should always provide clear company policy guidelines concerning extents and limits of employee monitoring, taking into account that privacy is a fundamental component of human rights.

There is prevailing urgency for increased privacy protection legislation as a result of the increased sophistication of information technology which enhances the capacity for state authorities and organizations to collect, analyze, and share information on individuals without infrastructural constraints. Emerging information technologies link chains of computers through high-speed networks equipped with high-speed processors capable of creating comprehensive dossiers on any individual without the need for particular central computer control systems.

ETHICAL APPROACH TO WORKPLACE PRIVACY

Protection of workforce data can be observed through enforcement of codes of practice within both private and public organizations. Organizational managers can choose to observe either the rights-view approach or the utilitarian approach when dealing with issues that concern workplace privacy. Respect and recognition of individual privileges and liberties, with due regard to the rights of employees to privacy and due process, form the cornerstone principles

for managers who observe the rights-viewpoint of workplace privacy ethics. However, this approach is not favored by many managers because it creates a burdensome legalistic work environment that can encourage inefficiency and unproductive practices among employees.

A utilitarian approach to ethical issues concerning workplace privacy requires managers to base their decisions on the consequences that employee actions portend to the organization. Managers seek to achieve the most favorable results for their organizations by implementing policies that portend greater good in terms of productivity and efficiency in the organizations, with little regard to the punitive measures such policies may bear upon employees. The utilitarian approach toward workplace ethics is favored by many organizations because it mainly focuses on maximum utility of resources and maximization of profits.

Managers should pursue policies that achieve a balance between organizational policies and employee privacy rights. Appropriate IT systems technologies—such as encryption and firewall protection—should be employed to protect employees' use of Internet-based communications from unauthorized access by individuals both within and outside the organization.

PROBLEM SOLVING

A managerial problem can be described as the gap between a given current state of affairs and a future desired state. Problem solving may then be thought of as the process of analyzing the situation and developing a solution to bridge the gap. While it is widely recognized that different diagnostic techniques are appropriate in different situations, problem solving as a formal analytical framework applies to all but the simplest managerial problems. The framework is analogous to the scientific method used in chemistry, astronomy, and the other physical sciences. In both cases, the purpose underlying

the analytic process is to minimize the influence of the investigator's personal biases, maximize the likelihood of an accurate result, and facilitate communication among affected parties.

Problem solving was popularized by W. Edwards Deming and the expansion of the total quality management movement in the 1980s. While Deming described what he called the Shewhart cycle, the technique is more commonly known as the Deming Wheel or simply as the PDCA cycle. Regardless of the name, a problem solver is urged to follow a step-by-step approach to problem solving—plan, do, check, act (hence the PDCA acronym).

In the planning stage, a manager develops a working hypothesis about why a given problem exists and then develops a proposed solution to the problem. The second step is to implement, or do, the proposed remedy. Next, the manager studies or checks the result of the action taken. The focus of this review is to determine whether the proposed solution achieved the desired result—was the problem solved? The fourth step then depends upon the interpretation of the check on results. If the problem was solved, the manager acts to institutionalize the proposed solution. This might mean establishing controls or changing policy manuals to ensure that the new way of doing business continues.

However, if the check indicates that either the problem was not solved or was only partially corrected, the manager should act by initiating a new cycle. Indeed, the technique is represented as a cycle based on the belief that many problems are never fully solved. For example, suppose that the problem in a given manufacturing facility is determined to be that labor productivity is too low. A change in processing methods may be found to successfully increase labor productivity. However, this does not preclude additional increases in labor productivity. Therefore, the PDCA cycle suggests that managers should pursue a course of continuous improvement activity.

The problem-solving framework can be used in a wide variety of business situations, including both large-scale management-change initiatives and routine improvement or corrective activity. Indeed, management consultants may be thought of as professional problem solvers. By relying on the proven problem-solving framework, external consultants are often able to overcome their lack of specific industry experience or knowledge of an organization's internal dynamics to provide meaningful analysis and suggestions for improvement. To more fully explore the issues presented by problem solving, the four-step PDCA cycle is expanded to a nine-step framework in the next section.

Perhaps the only generalizable caveat regarding problem solving is to guard against overuse of the framework. For example, Florida Power & Light became well known for their problem-solving ability in the late 1980s. One of their most successful initiatives was to institute an aggressive tree-

trimming program to anticipate and prevent power failure due to downed limbs falling on electrical lines during storms. They were so successful that they integrated the problem-solving framework into their day-to-day managerial decision-making and organizational culture.

While this resulted in well-reasoned decisions, it also meant that implementing even simple changes (like moving a filing cabinet closer to the people using it) required an overly bureaucratic approval process. This phenomenon is commonly referred to as paralysis of analysis. Therefore, managers should remain aware of the costs in both time and resources associated with the problem-solving framework. Accordingly, the nine-step framework described below is offered as a suggested guide to problem solving. Managers should feel free to simplify the framework as appropriate given their particular situation.

THE PROBLEM-SOLVING FRAMEWORK

Although business problems in the form of a broken piece of machinery or an irate customer are readily apparent, many problems present themselves in a more subtle fashion. For example, if a firm's overall sales are increasing, but its percentage of market share is declining, there is no attention-grabbing incident to indicate that a problem exists. However, the problem-solving framework is still helpful in analyzing the current state of affairs and developing a management intervention to guide the firm toward the future desired state. Therefore, a solid approach to problem solving begins with a solid approach to problem identification.

Problem Identification. Whatever techniques are used, a firm's approach to problem identification should address three common identification shortfalls. First and most obviously, the firm wants to avoid being blindsided. Many problems develop over time; however, unless the firm is paying attention, warning signals may go unheeded until it is too late to effectively respond.

A second common error of problem identification is not appropriating properly. This means that although a firm recognizes that an issue exists, they do not recognize the significance of the problem and fail to dedicate sufficient resources to its solution. It can be argued that not prioritizing properly has kept many traditional retail firms from responding effectively to emerging internet-based competitors.

Finally, a third common error in problem identification is overreaction—the Chicken Little syndrome. Just as every falling acorn does not indicate that the sky is falling, neither does every customer complaint indicate that a crisis exists. Therefore, a firm's problem identification methods should strive to present an accurate assessment of the problems and opportunities facing the firm.

While no specific problem-identification technique will be appropriate for every situation, there are several techniques that are widely applicable. Two of the most useful techniques are statistical process control (SPC) and benchmarking.

SPC is commonly used in the repetitive manufacturing industries, but can also prove useful in any stable production or service-delivery setting. A well formulated SPC program serves to inform managers when their operational processes are performing as expected and when something unexpected is introducing variation in process outputs. A simplified version of SPC is to examine performance outliers-those instances when performance was unusually poor or unusually good. It is believed that determining what went wrong, or conversely what went right, may inspire process or product modifications.

Benchmarking may take the form of either competitive analysis or best practices evaluation of competitors. Competitive benchmarking allows managers to keep tabs on their competition and thereby gauge their customers' evolving expectations. For instance, benchmarking might involve reverse engineering-disassembling a competitor's product-to study its design features and estimates the competitor's manufacturing costs. Best practices benchmarking is a qualitative intelligence approach that allows a manager to focus on a particular aspect or phase of the production processes, methodologies, or systems of a competitor. This is done in order to compare and gauge the competitive capabilities of their own company.

Additional listening and problem identification techniques include the time-tested management-by-walking-around, revamped with a Japanese influence as "going to the gemba." (The *gemba* is the "real place.") The technique suggests that managers go to where the action is—to the production floor, point of delivery, or even to the customer's facilities to directly observe how things are done and how the product is used. Other methods include active solicitation of customer complaints and feedback as well as persistent research and development practices. ARDEC, the 2007 winner of the coveted Malcolm Baldrige National Quality Award, involves its Picatinny-based customers in its transformational life-cycle lethality research and technology in a bid to elicit independent judgments about the effectiveness of the company's products.

Problem Verification. The amount of resources that should be dedicated to verification will vary greatly depending upon how the problem itself is manifested. If the problem is straightforward and well defined, only a cursory level of verification may be appropriate. However, many business problems are complex and ill defined. These situations may be similar to the case of a physician who is confronted with a patient that has self-diagnosed his medical condition. While

considering the patient's claim, the doctor will conduct her own analysis to verify the diagnosis.

Similarly, the need for verification is especially important when a manager is asked to step in and solve a problem that has been identified by someone else. The introduction of the manager's fresh perspective and the possibility of a hidden agenda on the part of the individual who initially identified the issue under consideration suggest that a "trust, but verify" approach may be prudent. Otherwise, the manager may eventually end up spending a great deal of time and effort pursuing a solution to the wrong problem.

In the case of particularly ambiguous problems, McKinsey & Company, a management-consulting group, uses a technique they call Forces at Work. In this analysis, McKinsey's consultants review the external pressures on the client firm arising from suppliers, customers, competitors, regulators, technology shifts, and substitute products. They then attempt to document the direction and magnitude of any changes in the various pressures on the firm. In addition, they review any internal changes, such as shifts in labor relations or changes in production technology.

Finally, they look at how the various factors are impacting the way the firm designs, manufactures, distributes, sells, and services its products. Essentially, McKinsey attempts to create comprehensive before-and-after snapshots of their client's business environment. Focusing on the differences between the two, they hope to identify and clarify the nature of the challenges facing the firm.

Problem Definition. The next step in problem solving is to formally define the problem to be addressed. This is a negotiation between the individuals tasked with solving the problem and the individuals who oversee their work. Essentially, the parties need to come to an agreement on what a solution to the problem will look like. Are the overseers anticipating an implementation plan, a fully operational production line, a recommendation for capital investment, or a new product design? What metrics are considered important—cycle time, material costs, market share, scrap rates, or warranty costs?

Complex problems may be broken down into mutually exclusive and collectively exhaustive components, allowing each piece to be addressed separately. The negotiation should recognize that the scope of the problem that is defined will drive the resource requirements of the problem solvers. The more focused the problem definition, the fewer resources necessary to generate a solution.

Finally, the time frame for problem analysis should also be established. Many business problems require an expedited or emergency response. This may mean that the problem solvers need to generate a temporary or interim solution to the problem before they can fully explore the underlying causes of the problem. Ensuring that the over-

seers recognize the limitations inherent in an interim solution serves to preserve the credibility of the problem solvers.

Root-Cause Analysis. Now that the problem has been formally defined, the next step is for the problem solvers to attempt to identify the causes of the problem. The ultimate goal is to uncover the root cause or causes of the problem. The root cause is defined as that condition or event which, if corrected or eliminated, would prevent the problem from occurring. However, the problem solver should focus on potential root causes that are within the realm of potential control. For example, findings that a particular weight of motor oil is insufficient to protect an engine from overheating readily leads to an actionable plan for improvement. Finding that the root cause of a problem is gravity does not.

A common technique for generating potential root causes is the cause-and-effect diagram (also known as the fishbone or Ishikawa diagram). Using the diagram as a brainstorming tool, problem solvers traditionally review how the characteristics or operation of raw materials, labor inputs, equipment, physical environment, and management policies might cause the identified problem. Each branch of the diagram then becomes a statement of a causal hypothesis. For example, one branch of the diagram might suggest that low salaries are leading to high employee turnover, which in turn results in inexperienced operators running the machinery, which leads to a high scrap rate and ultimately higher material costs. This analysis suggests that to address the problem of high material costs, the firm may have to address the root cause of insufficient salaries.

Collection and examination of data may also lead the problem solver toward causal hypotheses. Check sheets, scatter plots, Pareto diagrams, data stratification, and a number of other graphical and statistical tools can aid problem solvers as they look for relationships between the problems identified and various input variables. Patterns in the data, changes in a variable over time, or comparisons to similar systems may all be useful in developing working theories about why something is happening. The problem solver should also consider the possibility of multiple causes or interaction effects. Perhaps the problem manifests only when a specific event occurs and certain conditions are met-the temperature is above 85 degrees or the ambient humidity is abnormally low.

Once the problem solver has identified the likely root causes of the problem, an examination of the available evidence should be used to confirm or disconfirm which potential causes actually are present and impacting the performance under consideration. This might entail developing an experiment where the candidate cause is controlled to determine whether its manipulation influences the

presence of the problem. At this stage of the analysis, the problem solver should remain open to disconfirming evidence. Many elegant theories fail to achieve the necessary confirmation when put to the test. Also, at this stage of the analysis it is common for the problem solver to discover simple, easily implemented actions that will solve all or part of the problem. If this occurs, then clearly the problem solver should grasp the opportunity to "pick the low hanging fruit." Even if only a small component of the problem is solved, these interim wins serve to build momentum and add credibility to the problem-solving process.

Alternative Generation. Once the root causes of the problem have been identified, the problem solver can concentrate on developing approaches to prevent, eliminate, or control them. This is a creative process. The problem solver should feel free to challenge assumptions about how business was conducted in the past. At times, an effective approach is to generalize the relationship between the cause and the problem. Then the problem solver can look for similar relationships between other cause and effects that might provide insight on how to address the issues at hand. In general, it is useful to attempt to generate multiple candidate solutions. By keeping the creative process going, even after a viable solution is proposed, the problem solver retains the possibility of identifying a more effective or less expensive solution to the problem.

Evaluation of Alternatives. Assuming that the problem was well defined, evaluation of the effectiveness of alternative solutions should be relatively straightforward. The issue is simply to what extent each alternative alleviates the problem. Using the metrics previously identified as important for judging success, the various alternatives can generally be directly compared. However, in addition to simply measuring the end result, the problem solvers may also want to consider the resources necessary to implement each solution. Organizations are made up of real people, with real strengths and weaknesses. A given solution may require competencies or access to finite resources that simply do not exist in the organization. In addition, there may be political considerations within the organization that influence the desirability of one alternative over another. Therefore, the problem solver may want to consider both the tangible and intangible benefits and costs of each alternative.

Implementation. A very common problem-solving failure is for firms to stop once the plan of action is developed. Regardless of how good the plan is, it is useless unless it is implemented. Therefore, once a specific course of action has been approved, it should continue to receive the necessary attention and support to achieve success. The

work should be broken down into tasks that can be assigned and managed. Specific milestones with target dates for completion should be established. Traditional project management techniques, such as the critical path method (CPM) or the program evaluation and review technique (PERT) are very useful to oversee implementation efforts.

Post-Implementation Review. Another common failure is for firms to simply move on after a solution has been implemented. At a minimum, a post-implementation evaluation of whether or not the problem has been solved should be conducted. If appropriate, and using the metrics that were established earlier, this process should again be relatively straightforward—were the expected results achieved? The review can also determine whether additional improvement activities are justified. As the PDCA cycle suggests, some problems are never solved, they are only diminished. If the issue at hand is of that nature, then initiating a new cycle of problem-solving activity may be appropriate.

A secondary consideration for the post-implementation review is a debriefing of the problem solvers themselves. By its very nature, problem solving often presents managers with novel situations. As a consequence, the problem-solving environment is generally rich in learning opportunities. To the extent that such learning can be captured and shared throughout the organization, the management capital of the firm can be enhanced. In addition, a debriefing may also provide valuable insights into the firm's problem-solving process itself. Given the firm's unique competitive environment, knowing what worked and what did not may help focus future problem-solving initiatives.

Institutionalization and Control. The final step in problem solving is to institutionalize the results of the initiative. It is natural for any system to degrade over time. Therefore, any changes made as a result of the problem-solving effort should be locked in before they are lost. This might entail amending policy manuals, establishing new control metrics, or even rewriting job descriptions. In addition, the firm should also consider whether the problem addressed in the initiative at hand is an isolated incident or whether the solution can be leveraged throughout the organization. Frequently, similar problems are present in other departments or other geographic locations. If this is the case, institutionalization might involve transferring the newly developed practices to these new settings.

The overall success of problem-solving activities in organizations is determined by the levels of anticipatory mechanisms and subsequent response measures set up by the management of the organizations. Managers can achieve much success in problem solving by fostering an

organizational culture that encourages continuous adaptation to new situations and creates mechanisms for instant response to unanticipated occurrences. The involvement of employees in problem solving processes is of paramount importance for managers seeking to perpetuate a problem-solving culture defined by teamwork and the tenets of collective responsibility.

PROCESS MANAGEMENT

Process management is a concept that integrates quality/performance excellence into the strategic management of organizations. It is Category 6.0 of the Malcolm Baldrige National Quality Award. Process management includes (1) process design or engineering, which is the invention of new processes; (2) process definition, which requires the description of existing processes; (3) process docu-

mentation; (4) process analysis and control; and (5) process improvement.

Process design and definition includes describing what must be done and how it is to be accomplished. After defining a process, it must be documented using a flow-chart, a process map, or even a simple checklist. Until the process is described and documented, one cannot be assured that a process is in place. At that point, the process can be analyzed and improved.

There are many process analysis tools, including cause-and-effect diagrams, statistical process control, and trend analyses. Process improvement may result from gradual, continuous improvement or a dramatic reinvention or reengineering of the process.

HISTORICAL PERSPECTIVE

Process management can trace its roots back to the early days of industrial engineering and quality management (quality control and quality engineering). The earliest focus was on streamlining factory processes to increase productivity. However, process management concepts are now used in all types of organizations to improve process baselines (safety, quality, cycle time, productivity, on-time delivery, etc.), as well as to improve financial and operational results.

In 1911, Frederick Taylor published *The Principles of Scientific Management.* Some of his ideas are the predecessors for modern industrial engineering tools and concepts that are used to reduce cycle time and/or improve productivity. Frank and Lillian Gilbreth also used time and motion studies to improve processes and to increase productivity by evaluating how much time it took to do each task within a process, and the best way to do each task (the motions involved). (The Gilbreths' work and personal lives were publicized in the book, *Cheaper by the Dozen.*)

One of the world's leading experts on improving the manufacturing process, Shigeo Shingo, created—with Taiichi Ohno—many of the features of just-in-time (JIT) manufacturing methods, systems, and processes that constitute the Toyota Production System. Much of Shingo's work is documented in books he has written, such as *A Study of the Toyota Production System from An Industrial Engineering Viewpoint* (1989).

Experts in the field of quality developed many process-management concepts and tools. Some well-known experts include the following:

1. Dr. W. Edwards Deming (1900—1993) is famous for his work in Japan in the 1950s and for theories such as his Fourteen Points and Plan-Do-Check-Act (PDCA) Cycle (also referred to as the Shewhart Cycle). He also refined and publicized other concepts and tools, including statistical process control. Many of Dr. Deming's theories are contained in his book, *Out of the Crisis.*

2. Dr. Joseph Juran (1904—2008) also worked with the Japanese beginning in the 1950s. Some of his theories supporting process management are Juran's Trilogy (process planning, process control, and process improvement); Big Q (the quality department is responsible for quality) vs. Little Q (everyone is responsible for quality); and the Quality Planning Roadmap. Juran's books include *Juran's Quality Control Handbook* and *A History of Managing for Quality.*

3. Dr. Kaoru Ishikawa (1915—1989), author of *Guide to Quality Control,* invented the cause-and-effect diagram and taught people involved in teams (quality circles) to ask what caused each effect.

4. Dr. Walter Shewhart (1891—1967), a statistician who worked at Western Electric and Bell Laboratories, and who used statistics to explain process variability, first published his theories in his book *Economic Control of Quality of Manufactured Product* (1931).

PROCESS THINKING

Examples of simple, essential questions in process thinking are:

1. What is a process?
2. Who are the internal and external customers of a process?
3. Who are the process owners?
4. Who improves processes—process owners, customers, suppliers?
5. How do you improve processes?
6. What might not add value for customers?
7. What role does measurement play?

WHAT IS A PROCESS?

A process is a series of connected steps or actions with a beginning and an end that can be replicated. Organizations should be viewed as a set or hierarchy of processes that produce outputs of value to a customer, as well as a set of functions such as engineering, manufacturing, accounting, and marketing.

The most successful organizations are managed from a horizontal (process) perspective, as well as from a vertical (function) perspective. Understanding an organization from the process perspective will cause changes in the way one thinks about people and processes as depicted in Figure 1.

Examples of processes in various organizations are included in the following list. Please note that many of the processes could be found in all the various organization types.

Figure 1	
Functional Focus	**Cross-Functional (Process) Focus**
Employees are the problem.	The process is the problem.
Measure individuals.	Measure process results.
Motivate people.	Remove process barriers and constraints.
Who made this error?	What caused the error?
Evaluate employees.	Evaluate the process.
Vertical organizations.	Cross-functional (horizontal) organizations.

1. University
   - Teaching students
   - Paying for classes
2. Hospital
   - Emergency care
   - Payroll
3. Factory
   - Purchasing material
   - Training workers
4. Federal Agency
   - Procurement
   - Hiring new employees
5. Retail Store
   - Selling products
   - Employee scheduling
6. Bank
   - Opening new accounts
   - Statement distribution
7. Church
   - Recruiting members
   - Maintaining facilities
8. Restaurant
   - Preparing meals
   - Advertising
9. Construction
   - Budgeting
   - Managing subcontractors
10. Not for Profit
    - Distribution of funds
    - Employee recruitment

A process involves the steps or stages by which inputs such as people, materials, methods, machines, and environment are transformed into outputs (products and services).

WHO ARE THE CUSTOMERS OF A PROCESS?

Because a transformation process exists to satisfy customer requirements, process owners need to understand who their customers are, what they want, and how to provide what they want. The customers of a process are the people who require the products and services that are the result of the process or one phase of the process. They are classified as: (1) external customers—people who ultimately use the products and/or services (process outputs or work results) of an organization; and (2) internal customers—the owners of the next phases in the process who must wait for the delivery of a product or service before completing work.

External and internal customers must be satisfied if organizations are to experience the highest levels of success. Individuals and teams must understand their roles as suppliers to internal and external customers if customer satisfaction is to be a reality. At the same time, individuals and teams must act as internal customers who communicate requirements to internal suppliers.

Customer/Supplier Relationships. Concepts relating to customer/supplier relationships and satisfaction are as follows:

- Customers (internal and external) have a right to expect quality products and services.

- Every member of an organization has an internal customer—the next phase in the process.

- If each team member treats other team members like valuable customers, relationships and work results (individual and team performance) will improve.

- The customer determines if the product or service is what he or she ordered and if it has the value expected and promised by the supplier.

Individuals and team members should ask internal customers and suppliers, "How am I doing?" and "What did you expect compared to what I gave you?" The answer will assist in improving processes, products, services, and relationships.

Basically, customers want to be their suppliers' first priority. They want (and deserve) perfect products and services delivered on or ahead of schedule at the lowest possible cost. They expect suppliers to be in the improvement mode of operation so that the customers are assured of paying a competitive price.

Perfection is the aspiration; level-improvement is the goal. Whatever today's standard is, tomorrow's customers will require more. It is the responsibility of the supplier to remain on a journey toward perfection; to determine current baselines for important customer requirements such as safety, quality, schedule, and cost; and to determine what process and relationship improvements are necessary to improve those baselines.

Relationships Among Quality, Schedule, and Cost. One of the things that must be done when evaluating and improving processes is to establish process baselines. The baselines for quality, schedule, and cost are so interwoven that it is difficult to measure and improve one of them without considering the other. This is as it should be, since customers want the highest quality products and services on or ahead of schedule and at the lowest possible price.

If you improve the quality of processes and relationships, you can expect other baselines (e.g., quality, schedule, and cost) to improve. While quality, schedule, and cost are measured as separate baselines, long-term improvement is interdependent and process focused.

Customers expect speed of delivery as well as quality. Therefore, objectives of process management are customer satisfaction and retention through the improvement of quality and cycle time. In order to satisfy and retain external customers, suppliers should:

1. Be competitive based on speed as well as quality.

2. Provide real-time information to internal and external customers.

3. Design and streamline processes so that they are free of defects, constraints, and activities that do not add value for the customer.

4. Eliminate procrastination.

5. Change paradigms based on sequential decision making to paradigms that include concurrent decision making, as well as concurrent engineering.

6. Empower workers to dismantle time-wasting bureaucracy.

WHO ARE THE PROCESS OWNERS?

The process owners (the people who actually do the jobs) are the most knowledgeable about the processes by which they accomplish their work. Therefore, if process evaluation and improvement becomes an integral part of daily work, safety improvement, defect prevention, and cycle-time reduction can become a reality. Process owners are those empowered to do work, improve how they do the work, and accept accountability as process owners.

Process Evaluation and Improvement. An essential concept in process management is that all processes have improvement potential. If organizations only focus on current

Figure 2

Area of Difference	Continuous Improvement	Reengineering
Reason for change	Desire to improve baselines	Compelling (rapid process redesign for survival)
Targets	Small improvement in every process; cumulative effects	Aggressive (e.g., 10 times or more, six sigma, etc.)
Approach	Nonstructured	Structured and disciplined
Scope	Evaluation of all steps in all processes	Broad cross-functional processes
Focus	Parts of a system	Relations in system
Level of change	Incremental and continuous	Order of magnitude
Organizational structure	Vertical or horizontal	Flattened, horizontal
Involvement of executives	Important up-front; support throughout	Intensive long-term involvement
Involvement of all employees	Gradual voluntary involvement	Nonvoluntary
Use of terms	Work teams and cross-functional team	Cross-functional teams
Role of information	Incidental	Cornerstone

processes, current problems, and doing the things that are currently done, they may eventually encounter a variety of problems, such as:

- They may continue making a product (e.g., buggy whips) long after the market is gone. These perfect products may have no customers.

- They may do everything in a process perfectly, but they may be doing many things that do not need to be done at all.

- They may be focusing only on quality when speed is also important.

- They may miss opportunities to improve products, services, processes, and relationships.

WHO IMPROVES PROCESSES?

People who know the most about processes and who are most capable of evaluating and improving them are process owners—people who are accountable for process output or results. However, feedback from customers and suppliers contributes a great deal to improvement.

Examples of data a customer could provide include (1) whether the product or service meets the customer's needs/expectations; (2) whether there are any defects or discrepancies; and (3) whether the product or service is delivered on-time or early.

Examples of data suppliers could provide are (1) whether the customer's requirements (e.g., purchase orders) were clear and understandable; and (2) whether customers met lead-time requirements when placing orders.

HOW DO YOU IMPROVE PROCESSES?

Improvement may be gradual and continuous (i.e., kaizen, continuous process improvement), or it may be dramatic process redesign (i.e., process reengineering). The differences between the two are depicted in Figure 2.

Both gradual, continuous improvement and process reengineering should be an integral part of process management and improvement. Chaffey suggests that the objectives for process re-engineering should be designed to facilitate both significant and radical changes in business processes, such as customer care or manufacturing in observable and measurable terms. Process reengineering should demonstrate significant improvement in performance and achieve desired results in the quality, quantity, speed, and costs of processes. Business process reengineering should also involve automation of business processes through employment of innovative technology and knowledge transfer.

In a research article titled *Defining a Knowledge Strategy Framework for Process Aligned organizations: An IBM Case*, McLaughlin and Paton emphasize that innovation and knowledge transfer stand to play important roles in process performance of organizations. However, this is only valid if managers share and promote clear understanding of the impacts of knowledge and innovation on the organizational core processes relative to the improvement of the overall objectives of the organizations.

The following are some of the things people can do to improve processes:

- Use a structured methodology such as the Golden-Pryor Improvement Checklist.

- Eliminate activities that do not add value for the customer. Ask yourself: "Would the customer want to pay for this activity?" If the answer is no, ask yourself: "Why are we doing this? Is it a federal law? A state law?" If the answer is no, ask yourself: "What benefit do we gain by doing this?" At this point, you are coming close to eliminating the activity.

- Eliminate constraints—things that frustrate employees and slow processes.

- Streamline/simplify processes. It is difficult to document and teach people complex processes.

- Once processes are streamlined, computerize them if feasible.

- Provide leadership in a positive direction. Function as a strategist. Envision and invent the future with streamlined processes and relationships.

- Act empowered; be accountable. As individuals and members of teams, function as process owners and consider process management and improvement an integral part of daily work. Don't say, "They won't let us...." Make decisions, not excuses.

- Document and publicize improvements. Success breeds success.

- Continue to monitor and evaluate processes to identify additional opportunities for improvement.

- Ask (and teach others to ask) what, where, why, who, when, and how questions about each step in a process (or job).

Process Questions.

What:

- is there to do?

- is being done?

- should be done?

- can be done?

- constraints keep us from doing it?

Who:

- does this job?

- should do this job?

- knows how to do it?

- should know how to do it?

Where:

- is this job done?

- should it be done?

- can it be done?

When:

- is this job done?

- should it be done?

- can it be done?

When process-improvement efforts fail, it is generally because people have a deficiency in knowledge—they do not know what actions to take. They should be trained on specific improvement methodologies, and they should be held accountable for documenting improvement results.

Improvement team members generally need a model that provides them common knowledge about what they are required to do individually and as a team, such as the Golden Pryor Improvement Checklist in Figure 3.

WHAT MIGHT NOT ADD VALUE?

The concept of value implies worth; value is something that a customer would expect to pay for, such as labor to design, build, and deliver a product or service. Customers want to pay for perfect products and services delivered on or ahead of schedule at the lowest reasonable cost. They only want to pay for activities that add value to products and services, and to processes and relationships that impact the products and services.

WHAT ROLE DOES MEASUREMENT PLAY?

Organizational leaders are accustomed to measuring things that are important to themselves. They also need to measure items that are important to customers. Improving process results does not require sophisticated measurements. It requires systematic identification and elimination of root causes of problems, process constraints, and activities that do not add value. It is as much continuous learning as it is continuous improvement. Improvement results from learning that is fed back and used as the basis for the next decisions.

Quality products and services are the result of quality processes that exist because of quality people who build quality relationships and streamline processes. Specific measurements must be established for individual phases of a process in addition to the final process output. The following can apply in any organization in any industry:

- Quality—first pass yield, scrap, rework, repair.

- Productivity/Use of Time—cycle time, on-time delivery, non-value-added activities, overtime.

- Environmental and Safety—injuries, compliance, ergonomics, discipline problems, incidents of violence.

- People Issues—absenteeism, turnover, morale, grievances, skill levels, stakeholder satisfaction.

- Customer Satisfaction—new and repeat business, customer returns, warranty costs, field service reports/data, involvement.

- Supplier Performance—rating system, quality, capabilities, conformance to requirements.

Figure 3
Golden Pryor Process Improvement Checklist

   I. Determine what work processes you own and list them. Classify them as critical or ancillary.

   II. Describe and flowchart each process.

      A. Choose which process to evaluate first.

         1. Identify and list process and decision steps.

         2. Identify and remove non-value-added steps.

         3. Identify and remove process constraints for each phase of the process.

         4. If flowcharts do not reflect requirements, change the process or change the requirement documents (directives, procedures, etc.)

      B. Using flowcharts, determine the customer and suppliers for each process.

   III. Establish quality measurements. Define quality for the output(s) of each process and identify data sources.

   IV. Establish time measurements (cycle-time, on-time delivery, etc.)

      A. Determine static cycle time (process flow time).

         1. Compute cycle time for sub-processes and total process cycle time.

         2. Identify slack time/queue time.

         3. Establish perfect cycle times (no constraints, bottlenecks, or excess queue time).

         4. Search a second time for non-value-added-activities and eliminate those that still exist. Examples: redundant inspection, unnecessary documentation, unnecessary handling, meetings without agendas.

      B. Identify other measurements relating to time and establish process baselines.

   V. Establish other baselines and measurements.

      A. Safety (e.g., classrooms, discipline problems, acts of violence).

      B. Customer satisfaction (e.g., level of satisfaction with products or services and trends).

      C. Human resources (hours of training, % multiple skills/job rotations, absenteeism, etc.)

   VI. Identify process baselines with greatest improvement potential.

   VII. Use TQM/SPC tools to determine system improvement/problem resolution options.

   VII. Select best improvement option(s) and implement.

   IX. Measure, monitor/track and feedback results to process owners, management, et al. Determine whether process baselines–safety, quality, cycle time–are getting better or worse. Analyze the trends and do root cause analysis.

   X. Continue improvement efforts.

   XI. Publicize improvements.

ESSENTIAL ELEMENTS

This essay focused on process management as it relates to existing processes, not the invention of new processes, products, and services. Process management requires process design (new processes) or definition (existing processes); process documentation; process analysis and control; and process improvement.

Essential elements in process management include: (1) Understanding process thinking, including process ownership; (2) Identifying and satisfying customers' requirements; (3) Establishing process baselines and measurement; (4) Analyzing and improving processes through the use of quality and industrial engineering concepts and tools; and (5) Understanding how to use gradual, continuous process improvement and rapid, dramatic process redesign or reengineering.

Process management is the job of every employee of every organization in every industry. Organizational culture and structure, in conjunction with technological innovation, are the main levers for change and process management in business organizations.

PRODUCT DESIGN

Product design is cross-functional, knowledge-intensive work that has become increasingly important in today's fast-paced, globally competitive environment. It is a key strategic activity in many firms because new products contribute significantly to sales revenue. When firms are able to develop distinctive products, they have opportunities to command premium pricing. Product design is a critical factor in organizational success because it sets the characteristics, features, and performance of the service or good that consumers demand. The objective of product design is to create a good or service with excellent functional utility and sales appeal at an acceptable cost and within a reasonable time. The product should be produced using high-quality, low-cost materials and methods. It should be produced on equipment that is or will be available when production begins. The resulting product should be competitive with or better than similar products on the market in terms of quality, appearance, performance, service life, and price.

THE INCREASING IMPORTANCE OF PRODUCT DESIGN

Product design is more important than ever because in the twenty-first century, customers demand greater product variety and near-constant innovation. It is common for consumers to switch quickly to products with state-of-the-art technology. The impacts of greater product variety and shorter product life cycles have a multiplicative effect on the number of new and derivative products that need to be designed. For example, just a few years ago, a firm may have produced four different products and each product may have had a life cycle of ten years. In this case, the firm must design four new products every ten years. Today, in order to be competitive, this firm may produce eight different products with a life cycle of only five years; this firm must introduce eight new products in five years. That represents sixteen new products in ten years or one product every seven and one-half months. In this fast-paced environment, product design ceases to be an ad hoc, intermittent activity and becomes a regular and routine action. For an organization, delays, problems, and confusion in product design shift from being an annoyance to being life threatening.

PRODUCT DESIGN AND SUPPLY CHAIN MANAGEMENT

Product design can also be an important mechanism for coordinating the activities of key supply chain participants. As organizations outsource the production of subassemblies and components, they also may be asking suppliers to participate in product design. As they outsource design capabilities it is essential that they manage and coordinate the flow of information among the supply chain participants. This can be especially important as firms outsource components to two or more suppliers. Now, there may be important design interfaces among two, three, or more suppliers. These interfaces must be properly managed to ensure cost effective and timely

designs. Clearly, information and communication technologies become important parts of this effort.

A recent development in maintaining supply-chain integrity while pursuing a vigorous strategy of product innovation is an increase in acquisitions that support a program of vertical integration. For example, in 2008 Apple acquired P.A. Semi, a small chip manufacturer that could supply exclusive new chips for Apple's line of iPods and iPhones. Microsoft pursued a similar strategy throughout the 2000s, acquiring software companies for technologies that could be incorporated into existing and developing Microsoft products. Successful companies such as these can turn their high cash-flow into acquisitions that improve the product-design and manufacturing processes.

PRODUCT DESIGN: A KEY TO ORGANIZATIONAL SUCCESS

Product design is an essential activity for firms competing in a global environment. Product design drives organizational success because it directly and significantly impacts nearly all of the critical determinants for success. As the authors of *Product Development* (2008) put it, "The key in new product development is the information that indicates what people want, what features of the product are considered absolutely essential, what price they are willing to pay for it, what features are desirable but can be sacrificed for a lower price, [who are the] current and potential competitors, and [what are the] likely changes in the market size."

In the fast-paced, high-technology business environment of the twenty-first century, customers demand greater product variety and are quick to shift to new, innovative, full-featured products. The sudden success of Apple's iPhone is an excellent case in point. Introduced for the first time in 2007, Apple sold 270,000 iPhones during the first thirty hours of their availability. Over a million iPhones were sold in less than three months, giving the iPhone over a quarter of the U.S. smartphone market. Only a year later, Apple released the iPhone 3G, the next generation of this extremely popular product line, and once again customers lined up early. Apple's corporate strategy is driven by its introduction of such market-changing products as the iPhone—and earlier, the iMac and iPod—and other companies are eager to duplicate this success.

In addition, customers make purchase decisions based on a growing list of factors that are affected by product design. Previously, customers made purchase decisions based primarily on product price and/or quality. While these factors are still important, customers are adding other dimensions such as customizability, order-to-delivery time, product safety, and ease and cost of maintenance. Environmental concerns are expanding to include impacts during production, during the product's operating life, and at the end of its life (recycle-ability). In addition, customers demand greater protection from defective products, which leads to lower product liability losses. Safer and longer-lasting products lead to enhanced warrantee provision, which, in turn, impact customer satisfaction and warrantee repair costs.

Programs and activities are being put in place so organizations can cope with these dimensions. Organizations are embracing concepts such as *mass customization, design for manufacturing and assembly, product disposal, quality function deployment, and time-based competition.* They are using technology such as *rapid prototyping* and *computer-aided design* to examine how products function, how much they may cost to produce, and how they may impact the environment. Firms are searching for and implementing new technologies to determine ways to design better products. They are examining legal and ethical issues in product design as well as the impact of product design on the environment.

MASS CUSTOMIZATION

Mass customization is the low-cost, high-quality, large volume delivery of individually customized products. It is the ability to quickly design and produce customized products on a large scale at a cost comparable to non-customized products. Customization, cost effectiveness is the ability to produce highly differentiated products without increasing costs, significantly. Consumers expect to receive customized products at close to mass-production prices. Customization volume effectiveness is the ability to increase product variety without diminishing production volume. As markets become more and more segmented and aggregate demand remains constant or increases, firms must continue to design and produce high volumes across the same fixed asset base. Customization responsiveness is the ability to reduce the time required to deliver customized products and to reorganize design and production processes quickly in response to customer requests. It would be counter-productive to pursue mass customization if a customized product takes too long to produce. Speed in product design and production is an indispensable criterion for evaluating an organization's mass customization capability.

DESIGN FOR MANUFACTURING AND ASSEMBLY

Improving manufacturability is an important goal for product design. A systems approach to product design that was developed by two researchers from England, Geoffrey Boothroyd and Peter Dewhurst, is called design for manufacturability and assembly (DFMA). It can be a powerful tool to improve product quality and lower manufacturing cost. The

approach focuses on manufacturing issues during product design. DFMA is implemented through computer software that identifies design concepts that would be easy to build by focusing on the economic implications of design decisions. These decisions are critical even though design is a small part of the overall cost of a product because design decisions fix 70 to 90 percent of the manufacturing costs. In application, DFMA has had some startling successes. With the DFMA software, Texas Instruments reduced assembly time for an infrared sighting mechanism from 129 minutes to twenty minutes. IBM sliced assembly time for its printers from thirty minutes to three minutes.

Firms are recognizing that the concept behind DFMA can also be extended beyond cost control to design products that are easy to service and maintain. To do this effectively, service and maintenance issues should be considered at the earliest stages of the design. Also, firms will be required to examine disposal during product design as they become liable for recycling the products they make. It can be easier to recycle products if those factors are part of the product design paradigm.

DISPOSAL AND PRODUCT DESIGN

Disposal is becoming an increasingly important part of product design. The European Union is taking the lead by requiring that most of an automobile is recycled by the year 2010. This requirement has a major impact on product design. The most obvious effect is to change the notion that a consumer is the final owner for a product. With this approach, the product returns to the manufacturer to be recycled and the recycling process should begin in product design. Vehicles should be designed so they can be disassembled and recycled easily. The designers should avoid exotic materials that are difficult to recycle. For example, parts that have plastic and metal fused together should not be used in applications where they are difficult to separate. The designers should determine which parts can be refurbished and reused, and which can be discarded, broken down, and recycled. All this should be done without adding costs or reducing product quality.

QUALITY AND QUALITY FUNCTION DEPLOYMENT

Product design shapes the product's quality. It defines the way that good and service functions. Quality has at least two components. First, the product must be designed to function with a high probability of success, or reliability; that is, it will perform a specific function without failure under given conditions. When product reliability increases, the firm can extend the product's warranty without increasing customer claims for repairs or returns. Warranties for complex and expensive items such as appliances are important selling points for customers. Second, quality improves

when operating or performance characteristics improve even though reliability does not. The goals of product design should be greater performance, greater reliability, and lower total production and operating costs. Quality and costs should not be viewed as a trade-off because improvements in product and process technologies can enhance quality and lower costs.

Quality function deployment is being used by organizations to translate customer wants into working products. Sometimes referred to as the house of quality, quality function deployment (QFD) is a set of planning and communication routines that focus and coordinate actions and skills within an organization. The foundation of the house of quality is the belief that a product should be designed to reflect customers' desires and tastes. The house of quality is a framework that provides the means for interfunctional planning and communications. Through this framework, people facing different problems and responsibilities can discuss various design priorities.

PROTOTYPING

Engineering and operations combine to develop models of products called prototypes. These may be working models, models reduced in scale, or mock-ups of the products. Where traditional prototype development often takes weeks or months, the technology for rapid prototyping has become available. Some companies are using the same technology that creates virtual reality to develop three-dimensional prototypes. Other firms employ lasers to make prototypes by solidifying plastic in only a few minutes; this process can produce prototypes with complex shapes. Prototyping should increase customer satisfaction and improve design stability, product effectiveness, and the predictability of final product cost and performance.

COMPUTER-AIDED DESIGN

Currently, business managers and engineers perceive computer-aided design (CAD) as a tool to assist engineers in designing goods. CAD uses computer technology and a graphic display to represent physical shapes in the same way that engineering drawings have in the past. It is used in the metalworking industry to display component parts, to illustrate size and shape, to show possible relationships to other parts, and to indicate component deformation under specified loads. After the design has been completed, the engineer can examine many different views or sections of the part and finally send it to a plotter to prepare drawings. This capability greatly reduces engineering time and avoids routine mistakes made in analysis and drawing. It significantly increases productivity and reduces design time, which allows faster delivery.

Applications of CAD systems are not limited to producing goods. While it is true that services do not have

physical dimensions, the equipment and facilities used to produce services do. For example, the service stalls in an automotive center or rooms in an emergency medical center have physical characteristics that can be represented by the interactive graphics capabilities of a CAD system.

LEGAL AND ETHICAL ISSUES IN PRODUCT DESIGN

What is the responsibility of an organization and its managers to see that the goods and services they produce do not harm consumers? Legally, it is very clear that organizations are responsible for the design and safe use of their products. Consumers who believe they have been damaged by a poorly designed good or service have legal recourse under both civil and criminal statutes. Often, however, only the most serious and obvious offenses are settled in this way.

More difficult ethical issues in product design result when the evidence is not as clear. For example, what responsibilities does a power tool manufacturer have with respect to product safety? Does a power saw manufacturer have the responsibility to design its product so that it is difficult for a child to operate? Suppose a parent is using a power saw and is called away to the telephone for a few minutes. A ten-year-old may wander over, press the trigger, and be seriously injured. Designing the saw so it has a simple and inexpensive lockout switch that would have to be pressed simultaneously when the trigger is pressed would make it more difficult for the accident to happen. What is the responsibility of the parent? What is the responsibility of the company?

PRODUCT DESIGN AND THE ENVIRONMENT

Organizations consider product design a critical activity to the production of environmentally-friendly products. Organizations increasingly recognize that being good corporate citizens increases sales. Fast-food restaurants have begun recycling programs and redesigned packaging materials and systems in response to customer concerns. In other cases, being a good corporate citizen and protecting a company's renewable resources go well together; there are win-win opportunities where an organization can actually design products and processes that cut costs and increase profits by recapturing pollutants and reducing solid waste.

By the late 2000s many firms had adopted environmentally-friendly and -responsible mission statements. Hewlett-Packard's statement is typical: "Our policy is to design products and services that are environmentally sound and safe throughout their life cycle." This significantly impacts the product-design process, as Apple's statement indicates: "Apple strongly believes that reducing the environmental impact of our business starts with the design of our products. We set high standards—based on our own requirements and those set by programs such as ENERGY STAR—in an effort to create products that offer excellent environmental performance throughout their life cycle." These efforts have spread throughout the corporate community quite rapidly and are a common feature of the product design process in the twenty-first century.

OVERVIEW OF PRODUCT DESIGN PROCESS

Product design time can be reduced by using a team approach and the early involvement of key participants including marketing, research and development, engineering, operations, and suppliers. Early involvement is an approach to managing people and processes. It involves an upstream investment in time that facilitates the identification and solution of downstream problems that would otherwise increase product design and production costs, decrease quality, and delay product introduction.

Time-based competitors are discovering that reducing product design time improves the productivity of product design teams. To reduce time, firms are reorganizing product design from an "over-the-wall" process to a team-based concurrent process. Over-the-wall means to proceed sequentially with the limited exchange of information and ideas. When this approach is used, problems are often discovered late because late-stage participants are excluded from decisions made early in the process. As a result, poor decisions are often made.

Product design is a labor-intensive process that requires the contribution of highly trained specialists. By using teams of specialists, communications are enhanced, wait time between decisions is reduced, and productivity is improved. Participants in this team-based process make better decisions faster because they are building a shared knowledge base that enhances learning and eases decision-making. By sharing development activities, design decisions that involve interdependencies between functional specialists can be made more quickly and more effectively. This reorganized process creates a timely response to customer needs, a more cost-effective product design process, and higher-quality products at an affordable price.

There are several reasons why early involvement and concurrent activities bring about these improvements. First, product design shifts from sequential—with feedback loops that occur whenever a problem is encountered—to concurrent, where problems are recognized early and resolved. The ability to overlap activities reduces product design time. Second, when a team of functional specialists works concurrently on product design, the participants learn from each other and their knowledge base expands. People are better able to anticipate conflicts and can more easily arrive

at solutions. As a result, the time it takes to complete an activity should decline. Third, fewer changes later in the process results in faster and less expensive product design. When problems are discovered late, they take more time and money to solve.

Product design requires the expertise and decision-making skills of all parts of the organization. Marketing, engineering, operations, finance, accounting, and information systems all have important roles. Marketing's role is to evaluate consumer needs, determine potential impact of competitive pressure, and measure the external environment. Engineering's role is to shape the product through design, determine the process by which the product will be made, and consider the interface between the product and the people. Operations' role is to ensure that the product can be produced in full-scale production. Finance's role is to develop plans for raising the capital to support the product in full-scale production and to assist in the evaluation of the product's profit potential. Accounting and information systems provide access to information for decision-making. Cross-functional teamwork and knowledge sharing are thus keys to success.

PRODUCT LIFE CYCLE AND INDUSTRY LIFE CYCLE

The life cycle is a basic concept in biology. All living things go through a cycle of birth, growth, maturity, and death. The life-cycle concept is an appropriate description of what happens to products, industries, and businesses over time. When applied to this context, the life cycle contains four stages: introduction, growth, maturity, and decline.

This concept is much more than an interesting analogy of business and biology. In biology, a living organism's position in its life cycle leads to different courses of action concerning the organism's future. An industry's position and a product's position in their life cycles also lead to very different decisions concerning their futures. The life-cycle concept was adopted from biology for use as a strategic planning tool for products, industries, and businesses.

DEFINITIONS

The life cycle can be used to observe the behavior of many concepts in business. In its classic form, it is best applied to products and industries, though it can also be applied to individual businesses. A product is not an individual item but a group of similar products. For example, the Chevrolet Malibu, Ford Taurus, and Honda Accord are a product group of mid-sized sedans. Industry is a much broader classification than product; an industry consists of many similar groups of products. The product groups of mid-size sedan, pickup truck, and sport-utility vehicle all belong to the automobile industry. A business is, of course, a firm operating within one or more industries, such as Ford or General Motors in the automobile industry.

Generally, industries have longer life cycles than products. For example, the large family-sedan appears to be well into the decline stage. After decades of dominance in the automobile industry, only a few large cars, such as Ford's Crown Victoria, are being manufactured. The automobile industry, on the other hand, has lasted more than one hundred years and shows no signs of declining even with concerns about the declining world supply of oil; with alternative-fuel research getting started in earnest, the automobile industry will likely outlast even the oil industry upon which it is currently based.

Businesses may have an even longer life cycle than its original industry if decline is turned into transformation. For example, NCR began as a company producing cash registers, and while that industry still exists, NCR has become a leading technology company within the newer IT industry. Similarly, oil companies such as BP are moving heavily into alternative energy solutions in order to outlast the decline of the oil industry.

The life-cycle concept also describes individual brand products, such as the Ford Taurus. However, individual products in a group of products usually have much shorter life cycles, and they do not always follow the classic shape of the product life cycle. They may be introduced and die, and then be reintroduced again at a latter point. For example, the Chevrolet Nova has had more than one life cycle. Consequently, products are defined as groups of similar products, and industries are defined as a collection of comparable product groups.

The discussion that follows is applicable to industries, products, and individual businesses. The terms product life cycle, industry life cycle, and business life cycle refer to the four stages of introduction, growth, maturity, and decline. To simplify the discussion, the focus will be on the product life cycle with indication as to where the industry and business life cycles differ in important ways.

RATIONALE FOR THE PRODUCT LIFE CYCLE

Since products are not living beings, why do they have life cycles? The reason is that society accepts products at different rates, but all go through similar stages of societal acceptance. This acceptance of innovations by societies is called the diffusion of innovations. As society begins to adopt and accept an innovation, the new product grows, eventually reaching maturity. When there is a better alternative to the product or when public preference changes, the product will enter a decline, possibly ending with its death.

The diffusion-of-innovations concept categorizes society by the speed with which the individual members adopt a new product. It classifies people into the five categories of innovators, early adopters, early majority, late majority, and laggards.

Innovators. The first people in a society to adopt a new product are the innovators. These people are risk takers and may be looking for new products to try. They represent only 2.5 percent of the population. Though these people are the first to try a product, they are not usually opinion leaders. Consequently, they do not pass information about the product to the rest of the population.

Early Adopters. The early adopters have many opinion leaders in their ranks. They are the first people in the neighborhood to try a new product, and many of them willingly pass the information about the product onto other people. Their experiences can determine whether a product will have a long or short life cycle. They represent about 13.5 percent of the population.

Early Majority. Once the early adopters have tried and given their approval to a product, the early majority will begin to follow. Thirty-four percent of the population is in this category. Since they represent such a large percent of the population, the adoption by the early majority causes the new product to enter a period of rapid growth.

Late Majority. After a significant portion of the population has adopted a product, the late majority will consider its use. These people are not risk takers; they typically wait until they see the product approved by others. They also represent about 34 percent of the population. Once they have adopted the product, the innovators, early adopters, early majority, and late majority represent a total of about 84 percent of the population. By this point, the new product will have reached its maturity.

Laggards. The last category of society to adopt a new product is generally fearful about trying new things. Often, they wait until being forced to adopt because the alternate product is no longer being produced. The laggards represent about 16 percent of the population.

NEW PRODUCT DEVELOPMENT

Although product development is not usually recognized as a formal stage in the product life cycle, many ideas for long-term product planning are derived from the concepts that are generated through this preliminary process. Product development is defined as a strategy for company growth by offering modified or new products to current market segments. Additionally, product development focuses on turning product concepts into a physical reality, while ensuring that that the idea can be turned into a workable product through each stage.

In the product development stage, costs begin to accumulate due to the investment in proposed concepts and ideas. Before introduction, a successful product in the

marketplace will go through the following eight distinct stages of new product development: idea generation, idea screening, concept development, marketing strategy, business analysis, product development, test marketing, and commercialization.

Idea generation usually stems from the organization's internal sources (R&D, engineering, marketing). Company employees will brainstorm new ideas to generate viable product concepts. Additionally, a company may also analyze their competition's new product offerings with the intention of differentiating and improving on existing designs.

Ideas are ultimately screened, reducing the number of unrealistic concepts and focusing on realistic, attainable ones. A single idea is developed into a product concept. Concepts are then tested to measure how appealing the product might be to consumers from the anticipated target market. Testing may range from focus groups to random surveys.

After concept testing, a marketing strategy is needed to define how the product will be positioned in the marketplace. Identifying the product's anticipated target market, financial expectations, distribution channels, and pricing strategy are also determined at this time.

Business analysis, including sales forecasting, determines if the product will be profitable to the manufacturer. Many factors are considered when judging the products anticipated profitability. Managers will look at the length of time it takes for the product to be profitable, cost of capital, and other financial considerations when deciding weather to proceed with development. If the concept is approved, a prototype is created from the product concept.

The prototype undergoes rigorous testing to ensure safety and effectiveness of the product. These tests are a good measure for determining whether or not a product is safe and if the designers should move forward with its creation.

Once a successful prototype is developed, companies perform test marketing on the product. Typically, a company will conduct formal research on a product concept to see if the proposed idea has validity with the targeted audience. Again, customer surveys and focus groups are conducted with the intention of testing the product on a sample of the targeted demographic. The testing is then analyzed to measure consumer reaction to the product. Once all the information is available and the company decides to introduce the item, high commercialization costs are incurred.

STAGES OF THE LIFE CYCLE

As stated above, the product life cycle consists of four stages: introduction, growth, maturity, and decline. Figure A illustrates the product life cycle. Determination of a product's stage in its life cycle is not based on age, but on

Figure A
Product Life Cycle
the relationship of sales, costs, profits, and number of competitors. Each of these stages is described below.

Introduction. When a new product is introduced to a market, the innovators may be the only people aware of the new product. If the product is a new product class, the innovators may not know what the product uses are. Recalling that the innovators represent only a small percent of the population, the sales of the new product will be low. However, there is an advantage in this situation in that the new product does not yet have any competition. During the introduction stage of a new product, the developer enjoys a monopoly.

Unfortunately, the product monopoly does not usually translate to immediate profits. The product may have been in development for a long time and considerable development costs are still in the recovery phase. Also, an expensive marketing effort may be needed to introduce the product to the public. With low sales and high expenses, the introduction stage of the life cycle is usually a money loser for the company. However, the hope is for the future of the product, and the company usually is more than willing to incur the losses.

The life cycle of an industry begins in a similar way, with the introduction of an entirely new type of product, such as the automobile or personal computer. The business life cycle begins more simply, involving the start-up of a new enterprise. This can be as small as a sole proprietorship or involve forming a partnership or corporation. Many businesses never make it past the start-up phase; the failure rate of new restaurants is particularly dramatic.

Growth. As the early adopters begin to try the product, sales begin to grow and profits usually start to follow. This is a great time for a company introducing a new product because the company still enjoys a monopoly early in the growth stage. The company is reaping all the sales and profits of the new product. When Chrysler introduced the

idea of the minivan, they were in this enviable position of having the only minivan on the market.

As the early adopters begin influencing the early majority, sales and profits soar. The competition has also been watching from the new product's inception. Unfortunately for the original firm, the competition has also noticed the new product's success. Although they cannot be the first, the competition races to offer their own products and gain a share of a growing market. Chrysler's minivan did not maintain its monopoly for long; soon, the other major automobile manufacturers offered models to compete with Chrysler. Although total sales and profits continue to grow throughout the growth stage, they are divided among many manufacturers.

Maturity. By the end of the growth stage of the life cycle, the market is beginning to become very competitive, and this trend continues into the early period of the maturity stage. Besides many more manufacturers offering their products, the producers continue the product-differentiation process begun in the growth stage. The result is a market saturated with many manufacturers offering many models of the product. These manufacturers produce a multitude of models, from desktop computers to notebooks.

With so many companies now in the market, the competition for customers becomes fierce. Although total sales continue to grow during the first part of the maturity stage, the increased competition causes profits to peak at the end of the growth stage and beginning of the maturity stage. Profits then decline during the remainder of the maturity stage. The declining profits mean that the market is not as attractive to companies as it was in the growth stage.

In the growth stage, even inefficient companies made money. However, only the best companies and their products survive the maturity stage. Manufacturers begin to drop out as they see profits turn to losses. Though there is still competition in the computer industry, for example, companies such as Dell and Apple have emerged as the leaders in the market. During the later part of the maturity stage, even sales begin to dip, putting more pressure on the remaining manufacturers.

Decline. The number of companies abandoning the market continues and accelerates in the decline stage. Not only does the efficiency of the company play a factor in the decline, but also the product category itself now becomes a factor. By this time, the market may perceive the product as "old," and it may no longer be in demand. For example, the public replaced their preference for station wagons with their desire for minivans. Advancing technology may also bypass and replace a product, as when tapes and CDs replaced the vinyl record.

The product will continue to exist as long as a few manufacturers can maintain profitability. The laggards will resist switching to the alternative, and manufacturers who can profitably serve this niche will continue to do so. Eventually, even the laggards will switch, and the last companies producing the product will be forced to withdraw, thereby killing the product group. It should be noted that even these last companies producing a product group are not necessarily in the decline stage of their life cycle. Even companies that started up and burgeoned on one now-extinct product group will likely have diversified during the maturity stage, and they may be in a position to transfer to another product or industry instead of just decline.

PRODUCT STRATEGIES DURING THE PRODUCT LIFE CYCLE

Depending on the stage of the product life cycle, the marketing strategy should vary to meet the changing conditions. The marketing mix consists of the product, promotion, price, and distribution. Each element must change with the product life cycle if the company expects to maximize sales and profits. It is important to note that as products move through each stage of the life cycle, they should be monitored and re-evaluated in terms of reducing both production costs and the time it takes to make a product or service profitable with its new position.

Strategic options for products during the product life cycle are examined below.

Introduction Stage. In the introduction stage, the product's novelty and lack of competition dominate the marketing strategy. The public is not aware of the product and does not know what benefits it offers them.

Product strategy is focused on introducing one model. Since the public is unaware of the product, to offer more models could confuse them as they learn the purpose of the product. This model may offer various options, but there are usually no major variations on the basic idea of the product. The cost of development may also prohibit the company from developing more models for introduction. With no competition yet in the product category, one model is adequate for introduction.

Since the product is new, persuading the market to buy the product is of secondary importance to informing the public that the product exists. It is the innovators who will begin to buy the product, and they need to be informed. With only one company offering the product, those innovators that decide to purchase the product have only one company from which they can purchase it. Consequently, the promotion efforts concentrate on informing the public of the benefits of the product and the company producing it. Persuasion to buy a particular brand is not needed in the introduction stage.

The pricing policy offers the company an opportunity to regain some development costs through the use of a skimming pricing strategy; that is, a very high price for the new product due to the introduction and newness of the product to the company as well as to the marketplace. Though the high price of the new product may deter some potential customers, many innovators and early adopters will pay the high price to own the new product. The first electronic calculators, for example, were quite expensive. If the product is easily copied, however, the developer may want to use a low-price penetration policy to deter future competition.

Since there are few purchasers in the introduction stage, the distribution does not need to be widespread. The innovators are risk takers and desire to purchase something new. Consequently, they may seek out the distributors carrying the new product, and only a few distributors will suffice.

Growth Stage. In the growth stage, the early adopters, followed by the early majority, begin to consume the product in growing numbers. The increasing sales result in the emergence of profits rather than losses.

During the early part of the growth stage, the company can continue its product policy of offering one basic model. However, if the new product group is successful, eventually competitors will offer their own products to compete in the new category. At that point, the original company will need to offer more models. The models should be differentiated from one another so that the company can continue to attract the new customers coming into the market.

Even with competition beginning to offer their products in the new category, the original company still dominates the market. However, as the market leader rather than a monopoly, the company will need to change its promotion policy of informing the public about their new product and new product category.

With an informing policy, the market leader would still receive the majority of new sales. Unfortunately for the original company, the competition will not be using an informative policy. They will be trying to persuade the public as to why their product is better than the market leader's product. Consequently, the market leader should switch to a persuasive promotion policy.

As the competition enters the market, they will probably be offering products at prices lower than the price of the original product. This is a penetration pricing policy designed to take sales away from the market leader. If the original company used a skimming pricing policy, its continued use would surely lead to a rapid loss in sales to the competition unless it is altered. Prices should be lowered so that sales can continue to grow, and the competition kept at bay.

In a growing market, the company's exclusive distribution policy would limit the potential growth for the firm, and sales would go to the competition. Consequently, the company must increase its product distribution to maintain its leadership in the market.

Maturity Stage. Many competitors characterize the maturity stage. With the large number of firms producing products, the competition for customers becomes quite intense, and profits decline. The strategy for firms during the maturity stage becomes one of survival, as many competitors will eventually withdraw from the market.

With many companies offering several models of the product, the number of products on the market becomes tremendous. The original company must continue differentiating their models so that the market is aware of the differences in the company's products and the competitors' products. The customers are going to ask why they should buy a particular company's product; just being first on the market is not going to persuade customers to continue buying a product. Quality, styling, and product features are a few of the means of differentiating the product from the competition.

During the maturity stage, the need to inform the public has long since passed. Now, the promotion strategy focus is on continuing the persuasion tactics started during the growth stage. The purpose of persuasion is to position the product to the market, which involves creating an image for a product. The image should not be an advertiser's creation, but based on the reality of the product.

The differentiation methods of quality, styling, and features are excellent means of positioning a product. For example, a Chevrolet Corvette and Porsche Boxster are both sports cars, but consumers see the different positions of the cars. The company differentiates its products and uses promotion to create the different position image. Each company hopes that its position is preferred by the consumers.

With the intense competition, management keeps the price of the product to its lowest possible level. For example, the competition for entry-level personal computers has now shifted to offering the lowest price. All of the companies in a mature market must now watch costs carefully.

Every aspect from development through production through marketing is designed to offer the lowest cost possible. A cost and a price advantage over competitors in this stage are significant competitive advantages. Consumers are aware of prices and will reward the company with the lower price, all else being equal. The firm that does not have a significant cost advantage risks losing customers and going out of business.

The absence of a company's product in a particular location may result in lost sales during the maturity period. Widespread distribution is essential. If the company's

product is not in a particular location, one or more of the competitors' products are likely to be there. The firm cannot risk losing sales simply because their products were not available.

Decline Stage. During the decline stage, sales and profits begin an even sharper drop, and the number of competitors is reduced even further. With public preference for this product waning, the decline stage continues until the last of the producers cannot make a profit, and the product category dies.

The product strategy now becomes one of reducing the number of models offered. With the public abandoning the product and competition declining, the need for many models is no longer there. The company now focuses its attention on the costs and profitability of the remaining models. Costs, such as research and development and production, are cut to the minimal amount necessary. After the cost cuts, management eliminates those products that are no longer profitable.

The promotion efforts also include an examination of costs. Only the minimal amount of promotion necessary to keep the product selling is done. The remaining people in the market want the product and do not need to be convinced that they should buy the product. They only need to know that the product is still available. Consequently, the promotion effort shifts to reminder promotion.

Products' prices are also kept as low as possible during the decline stage. Since the number of competitors has dropped, it may seem that a company could raise prices. If the remaining customers maintain strong brand loyalty, this policy might be possible. However, the product has fallen out of favor, and customers have other product alternatives. A price increase that could not be justified by cost increases runs the risk of alienating even the few customers left purchasing the product. Consequently, the strategy should be to keep the prices as low as possible.

Cost is also an overriding factor in the distribution of the product during the decline stage. The declining sales may not justify the widespread distribution reached during the maturity stage. Only those areas or markets that are still profitable should be covered, and the unprofitable distribution outlets eliminated. Hopefully for the last companies producing the product, the brand-loyal customers or laggards will seek out the limited locations of the products and continue purchasing it.

Decline-Stage Trap. Just because a product's sales begin to decline does not mean that the product life cycle has reached the decline stage. However, if the company believes that the product is in a decline, the implementation of the decline-stage strategies may lead to the death of the product long before its time.

Before the strategies for declining products are tried, the company should definitely establish that the product is in decline. The company should first follow strategies to boost sales and not resign themselves to the cost-cutting strategies of the decline stage. For example, Arm & Hammer could have easily decided that their baking soda was dying and implemented decline-stage strategies. However, they chose to fight for its life. They differentiated the product by finding new uses—for instance, as a deodorizer and an ingredient in toothpaste. They so successfully repositioned the product that many people now think about baking soda as a deodorizer first and disregard its original use in baking.

INDUSTRY AND BUSINESS LIFE CYCLES.

The previous discussion focused on the product life cycle. Both industries and businesses can be seen to go through an analogous life cycle. For industries, the time frame is generally much longer, since new product groups are developed within the framework of the industry as a whole. Once again, the automobile industry provides a good case in point. While many product groups have come and gone, the automobile industry continues to pioneer new products in order to remain viable and profitable. The SUV was introduced in the 1980s and had a particularly rapid life cycle. Even though much of the American automobile industry's profits throughout the 1990s were based on SUV sales, rapidly rising oil prices in the mid-2000s rapidly advanced this product life cycle. Automobile companies are continuing to introduce new product groups, such as hybrids and electric cars, and to research others, including hydrogen-powered vehicles. These innovations are likely to keep the automobile industry in its mature stage and fend off the inevitable decline for many more years to come.

There is much more diversity and volatility in the life cycle of businesses than for either products or industries. Some businesses, as noted earlier, never make it out of the start-up stage, while others grow and mature extremely quickly. Microsoft is an excellent example of the latter. Formed in 1975 Microsoft grew to dominate the operating-system industry in less than two decades, rapidly surpassing such mature giants as Xerox and IBM in both profits and industry power. Other high-tech companies, such as Dell and Google, underwent similarly rapid development. Some of the Internet businesses introduced prior to the dot-com bust of the late 1990s also had a very rapid rise but experienced decline and death just as quickly.

Borrowed from biology, the life-cycle concept has been adapted and applied to products, industries, and businesses. The product life cycle maintains that products and industries move through the stages of introduction, growth, maturity, and decline. By viewing a product from the perspective of its product-life-cycle position, management

can use the product life cycle as a valuable decision-making tool. As the product moves through its life cycle, the appropriate strategies for its future development vary greatly. Knowledge of the appropriate strategies can help guide management actions. Industry leaders and business owners and managers can similarly benefit from understanding the life cycle and making appropriate strategic moves based on their understanding of this concept.

PRODUCT-PROCESS MATRIX

The product-process matrix is a tool for analyzing the relationship between the product life cycle and the technological life cycle. The matrix consists of two dimensions: product structure/product life cycle and process structure/process life cycle. The production process used to manufacture a product moves through a series of stages, much like the stages of products and markets, which begins with a highly flexible, high-cost process and progresses toward increasing standardization, mechanization, and automation, culminating in an inflexible but cost-effective process. The process structure/process life cycle dimension describes the process choice and process structure a while the product structure/product life cycle describes the four stages of the product life cycle and product structure.

A company can be characterized as occupying a particular region on the matrix (see accompanying Figure). This region is determined by the firm's stage in the product life cycle and the firm's choice of production process. At the upper left extreme, firms are characterized as process oriented or focused while the lower right extreme holds firms that are said to be product focused. The decision of where a firm locates on the matrix is determined by whether the production system is organized by grouping resources around the process or the product. Note from the figure that the vertices of the matrix result in four distinct types of operations (described by the appropriate process choice) located on the diagonal of the matrix.

BACKGROUND

The concept of the product-process matrix was introduced by Robert H. Hayes and Steven C. Wheelwright in two classic management articles published in *Harvard Business Review* in 1979: "Link Manufacturing Process and Product Life Cycles" and "The Dynamics of Process-Product

Product-Process Matrix

Process structure Process life cycle stage ↓	Product structure Product life cycle stage →	Low volume Unique (one of a kind)	Low volume Multiple products	Higher volume Standardized product	Very high volume Commodity product
	(Project)				
Jumbled flow (job shop)		Job shop			
Disconnected line flow (batch)			Batch		
Connected line flow (assembly line)				Assembly line	
Continuous flow (continuous)					Continuous

Life Cycles." The authors used this matrix to examine market-manufacturing congruence issues and to facilitate the understanding of the strategic options available to a company. The matrix has remained more or less unchanged, though some later writers insert "the project" as an additional stage in the extreme upper-left corner of the matrix.

PROCESS CHOICES

The first aspect of the process structure/process life cycle dimension of the matrix is the process choice, which is either job shop, batch, assembly line, or continuous flow. (As noted above, some authors include project at the upper-left). The process choice has important implications for production choice by managers. The matrix is designed not only to describe production choices but to guide managers in making manufacturing decisions.

Project. Projects include large-scale, one-time, unique products such as civil-engineering contracts, aerospace programs, construction, etc. They are typically customer-specific and often too large to be moved, such that practicality dictates that project is the process of choice.

Job Shop. If a manufacturer had broken a large cog on an outdated (i.e., replacement parts are no longer available) but still useful machine, he or she would take the broken cog to a machine shop where they would manufacture a new one from scratch. This machine shop (along with tool and die manufacturers) is probably the primary example of manufacturing job shops. A job shop is the producer of unique products; usually this product is of an individual nature and requires that the job shop interpret the customer's design and specifications, which requires a relatively high level of skill and experience. Once the design is specified, one or a small number of skilled employees are assigned to the task and are frequently responsible for deciding how best to carry it out. Generally, resources for processing have limited availability with temporary in-process storage capability needed while jobs wait for subsequent processing. If the product is not a one-time requirement, it is at least characterized by irregular demand with long periods of time between orders. Efficiency is difficult since every output must be treated differently.

In a job shop, the outputs differ significantly in form, structure, materials, and/or processing required. Each unique job travels from one functional area to another according to its own unique routing, requiring different operations, using different inputs, and requiring varying amounts of time. This causes the flow of the product through the shop to be jumbled, following no repetitive pattern.

Job shops and batch operations (upper-left quadrant of the matrix) are usually organized around the function

of the individual machines. In other words, machinery is grouped according to the purpose it serves or the capabilities it possesses. For example, in a machine shop, hydraulic presses would be grouped in one area of the shop, lathes would be grouped into another area of the shop, screw machines in another area, heat or chemical treatment in still another, and so on (also contributing to the jumbled flow). This is labeled a *process layout.*

In addition to machine shops and tool and die manufacturers, job shops are also appropriate for use in service operations, since the product is customized and frequently requires different operations. Service examples include law offices, medical practices, automobile repair, tailor shops, and so forth.

Batch. Firms utilizing batch processes provide similar items on a repeat basis, usually in larger volumes than that associated with job shops. Products are sometimes accumulated until a lot can be processed together. When the most effective manufacturing route has been determined, the higher volume and repetition of requirements can make more efficient use of capacity and result in significantly lower costs.

Since the volume is higher than that of the job shop, many processes can be utilized in repetition, creating a much smoother flow of work-in-process throughout the shop. While the flow is smoother, the work-in-process still moves around to the various machine groupings throughout the shop in a somewhat jumbled fashion. This is described as a disconnected line flow or intermittent flow.

Examples of batch processing operations include printing and machine shops that have contracts for higher volumes of a product. Services utilizing batches could be some offices (processing orders in batches), some operations within hospitals, classes within universities (how many classes have only one pupil?), and food preparation.

Assembly Line. When product demand is high enough, the appropriate process is the assembly line. Often, this process (along with continuous; both are in the lower-right quadrant of the matrix) is referred to as mass production. Laborers generally perform the same operations for each production run in a standard and hopefully uninterrupted flow. The assembly line treats all outputs as basically the same. Firms characterized by this process are generally heavily automated, utilizing special-purpose equipment. Frequently, some form of conveyor system connects the various pieces of equipment used. There is usually a fixed set of inputs and outputs, constant throughput time, and a relatively continuous flow of work. Because the product is standardized, the process can be also, following the same path from one operation to the next. Routing, scheduling, and control are facilitated since each individual unit of

output does not have to be monitored and controlled. This also means that the manager's span of control can increase and less skilled workers can be utilized.

The product created by the assembly-line process is discrete; that is, it can be visually counted (as opposed to continuous processes which produce a product that is not naturally divisible). Almost everyone can think of an example of assembly-line manufacturing (automobile manufacturing is probably the most obvious). Examples of assembly lines in services are car washes, class registration in universities, and many fast-food operations.

Because the work-in-process equipment is organized and sequenced according to the steps involved to produce the product and is frequently connected by some sort of conveyor system, it is characterized as flowing in a line. Even though it may not be a straight line (some firms utilize a U-shaped assembly line) we say that it has a connected line flow. Also, firms in the lower-right quadrant (line and continuous) are classified as having a *product layout.*

Continuous manufacturing involves lot-less production wherein the product flows continuously rather than being divided. A basic material is passed through successive operations (i.e., refining or processing) and eventually emerges as one or more products. This process is used to produce highly standardized outputs in extremely large volumes. The product range is usually so narrow and highly standardized that it can be characterized as a commodity.

Considerable capital investment is required, so demand for continuous process products must be extremely high. Starting and stopping the process can be prohibitively expensive. As a result, the processes usually run twenty-four hours a day with minimum downtime (hence, continuous flow). This also allows the firm to spread their enormous fixed cost over as large a base as possible.

The routing of the process is typically fixed. As the material is processed it usually is transferred automatically from one part of the process to the next, frequently with self-monitoring and adjusting. Labor requirements are low and usually involve only monitoring and maintaining the machinery.

Typical examples of industries utilizing the continuous process include gas, chemicals, electricity, ores, rubber, petroleum, cement, paper, and wood. Food manufacture is also a heavy user of continuous processing; especially water, milk, wheat, flour, sugar and spirits.

USING THE MATRIX

The product-process matrix can facilitate the understanding of the strategic options available to a company, particularly with regard to its manufacturing function. A firm may be characterized as occupying a particular region in the matrix, determined by the stages of the product life cycle and its choice of production process(es) for each individual product. By incorporating this dimension into its strategic planning process, the firm encourages more creative thinking about organizational competence and competitive advantage. Also, use of the matrix provides a natural way to involve manufacturing managers in the planning process so they can relate their opportunities and decisions more effectively with those of marketing and of the corporation itself, all the while leading to more informed predictions about changes in industry and the firm's appropriate strategic responses.

Each process choice on the matrix has a unique set of characteristics. Those in the upper-left quadrant of the matrix (job shop and batch) share a number of characteristics, as do those in the lower-right quadrant (assembly line and continuous). Upper-left firms employ highly skilled craftsmen (machinists, printers, tool and die makers, musical instrument craftsmen) and professionals (lawyers, doctors, CPAs, consultants). Hence upper-left firms can be characterized as labor intensive. Since upper-left firms tend to utilize general-purpose equipment, are seldom at 100 percent capacity, and employ workers with a wide range of skills, they can be very flexible. However, there is a difficult trade-off between efficiency and flexibility of operations. Most job shops tend to emphasize flexibility over efficiency. Since efficiency is not a strong point of upper-left firms, neither is low-cost production. Also, the low volume of production does not allow upper-left firms to spread their fixed costs over a wide enough base to provide for reduced costs. Finally, upper-left firms are also more likely to serve local markets.

Lower-right firms require production facilities that are highly specialized, capital intensive, and interrelated (therefore, inflexible). Labor requirements are generally unskilled or semi-skilled at most. Much of the labor requirement deals with merely monitoring and maintaining equipment. Lower-right firms are also more likely to serve national markets and can be vertically integrated.

Hayes and Wheelwright relate three areas affected by the use of the product-process matrix: distinctive competence, management, and organization.

Distinctive Competence. Distinctive competence is defined as the resources, skills, and organizational characteristics that give a firm a comparative advantage over its competitors. Simply put, a distinctive competence is the characteristic of a given product that causes the buyer to purchase it rather than the similar product of a competitor. It is generally accepted that the distinctive competencies are cost/price, quality, flexibility, and service/time. By using the product-process matrix as a framework, a firm can be more precise about its distinctive competence and can concentrate its attention on a restricted set of process decisions and

alternatives and a restricted set of marketing alternatives. In our discussion, we have seen that the broad range of worker skills and the employment of general-purpose equipment give upper-left firms a large degree of flexibility while the highly specialized, high-volume environment of lower-right firms yields very little in the way of flexibility. Therefore, flexibility would be a highly appropriate distinctive competence for an upper-left firm. This is especially true when dealing with the need for flexibility of the product/service produced. Lower-right firms find it very difficult to sidetrack a high-volume operation because of an engineering change in the product. An entire line would have to be shut down while tooling or machinery is altered and large volumes of possibly obsolete work-in-process are accounted for. Upper-left firms, however, would have none of these problems with which to contend. It must be noted though that lower-right firms may possess an advantage regarding flexibility of volume.

Quality may be defined a number ways. If we define quality as reliability, then lower-right firms could claim this as a distinctive competence. Lower-right firms would have the high volume necessary to quickly find and eliminate bugs in their product, yielding more reliability to the end user. However, if we define quality as quality of design (that is, "bells and whistles"—things that embody status, such as leather seats in an automobile or a handcrafted musical instrument), then quality would be seen as a possible distinctive competence of upper-right firms.

Service may also be defined in more ways than one. If one defines service as face-to-face interaction and personal attention, then upper-left firms could claim service as a distinctive competence. If service is defined as the ability to provide the product in a very short period of time (e.g., overnight), then service as a distinctive competence would belong to lower-right firms.

Finally, remember that high volume, economies of scale, and low cost are characteristics of firms in the lower-right quadrant of the matrix. Upper-left firms produce low volumes (sometimes only one) and cannot take advantage of economies of scale. (Imagine, for instance, what you would have to pay for a handcrafted musical instrument.) Therefore, it is obvious that price or cost competitiveness is within the domain of lower-right firms.

Management. In general, the economics of production processes favor positions along the diagonal of the product-process matrix. That is, firms operating on or close to the diagonal are expected to outperform firms choosing extreme off-diagonal positions. Hayes and Wheelwright provide the example of a firm positioned in the upper-right corner of the matrix. This would appear to be a commodity produced by a job shop, an option that is economically unfeasible. A firm positioned in the lower-left corner would represent a unique one-time product produced by a continuous process, again not a feasible option. Both examples are too far off the diagonal. Firms that find themselves too far off the diagonal invite trouble by impairing their ability to compete effectively. While firms operating in the near vicinity, but not exactly on the diagonal, can be niche players, positions farther away from the diagonal are difficult to justify. Rolls Royce makes automobiles in a job shop environment but they understand the implications involved. Companies off the diagonal must be aware of traps it can fall into and implications presented by their position.

Also, a firm's choice of product-process position places them to the right or left of competitors along the horizontal dimension of the matrix and above or below its competitors along the vertical dimension of the matrix. The strategic implications are obvious. Of course, a firm's position on the matrix may change over time, so the firm must be aware of the implications and maintain the capability to deal with them appropriately. The matrix can provide powerful insights into the consequences of any planned product or process change.

Use of the product-process matrix can also help a firm define its product. Hayes and Wheelwright relate the example of a specialized manufacturer of printed circuit boards who produced a low-volume, customized product using a highly connected assembly-line process. Obviously, this would place them in the lower-left corner of the matrix; not a desirable place to be. This knowledge forced the company to realize that what they were offering was not really circuit boards after all, but design capability. So, in essence, they were mass-producing designs rather than the boards themselves. Hence, they were not far off the diagonal at all.

Organization. Firms organize different operating units so that they can specialize on separate portions of the total manufacturing task while still maintaining overall coordination. Most firms will select two or more processes for the products or services they produce. For example, a firm may use a batch process to make components for products, which are constructed on assembly lines. This would be especially true if the work content for component production or the volume needed was not sufficient for the creation of a dedicated line process. Also, firms may need separate facilities for different products or parts, or they may simply separate their production within the same facility. It may even be that a firm can produce the similar products through two different process options. For example, Fender Musical Instruments not only mass produces electric guitars (assembly line) but also offers customized versions of the same product through the Fender Custom Shop (job shop). Again, the matrix provides a valuable framework for diagnostic use in these situations.

OTHER USES OF THE PRODUCT-PROCESS MATRIX

Additional uses of the matrix include:

- Analyzing the product entry and exit.

- Determining the appropriate mix of manufacturing facilities, identifying the key manufacturing objectives for each plant, and monitoring progress on those objectives at the corporate level.

- Reviewing investment decisions for plants and equipment in terms of their consistency with product and process plans.

- Determining the direction and timing of major changes in a company's production processes.

- Evaluating product and market opportunities in light of the company's manufacturing capabilities.

- Selecting an appropriate process and product structure for entry into a new market.

EMPIRICAL ANALYSIS OF THE MATRIX

In 1996, Safizadeh et al. conducted an empirical analysis of the product-process matrix to determine whether firms link their process choices to product customization and other competitive priorities as hypothesized by Hayes and Wheelwright's model. Their analysis of data from over 100 U.S. manufacturing plants showed a strong correlation between process choice, product customization, and competitive priorities.

More recent research by Sohel Ahmad and Roger G. Schroeder, published in 2002, found the proposed relationship between product structure and process structure to be significant but not strong, with less than half of the 128 plants studied operating near the diagonal of the matrix. They proposed that a third dimension be added to the product-process matrix to measure how proactively firms adopt and implement innovative initiatives.

In 2006, Lummus, Vokurka, and Duclos noted that because of changes in manufacturing technology and practice, the Hayes and Wheelwright model may no longer be suitable for describing the environment in some rapidly-changing industries, such as electric tools.

PRODUCTION PLANNING AND SCHEDULING

Production planning is the function of establishing an overall level of output, called the production plan. The process also includes any other activities needed to satisfy current planned levels of sales, while meeting the firm's general objectives regarding profit, productivity, lead times, and customer satisfaction, as expressed in the overall business plan. The managerial objective of production planning is to develop an integrated game plan where the operations portion is the production plan. This production plan, then, should link the firm's strategic goals to operations (the production function) as well as coordinating operations with sales objectives, resource availability, and financial budgets.

THE PRODUCTION-PLANNING PROCESS

The production-planning process requires the comparison of sales requirements and production capabilities and the inclusion of budgets, pro forma financial statements, and supporting plans for materials and workforce requirements, as well as the production plan itself. A primary purpose of the production plan is to establish production rates that will achieve management's objective of satisfying customer demand. Demand satisfaction could be accomplished through the maintaining, raising, or lowering of inventories or backlogs, while keeping the workforce relatively stable. If the firm has implemented a just-in-time philosophy, the firm would utilize a chase strategy, which would mean satisfying customer demand while keeping inventories at a minimum level.

The term *production planning* is really too limiting, since the intent is not to purely produce a plan for the operations function. Because the plan affects many firm functions, it is normally prepared with information from marketing and coordinated with the functions of manufacturing, engineering, finance, materials, and so on. Another term, *sales and operations planning,* has recently come into use, more accurately representing the concern with coordinating several critical activities within the firm.

Production planning establishes the basic objectives for work in each of the major functions. It should be based on the best tradeoffs for the firm as a whole, weighing sales and marketing objectives, manufacturing cost, scheduling and inventory objectives, and the firm's financial objectives. All these must be integrated with the strategic view of where the company wants to go.

The production-planning process typically begins with an updated sales forecast covering the next six to eighteen months. Any desired increase or decrease in inventory or backlog levels can be added or subtracted, resulting in the production plan. However, the production plan is not a forecast of demand. It is planned production, stated on an aggregate basis. An effective production-planning process will typically utilize explicit time fences for when the aggregate plan can be changed (increased or decreased). Also, there may be constraints on the degree of change (amount of increase or decrease).

The production plan also provides direct communication and consistent dialogue between the operations function and upper management, as well as between operations and the firm's other functions. As such, the production plan must necessarily be stated in terms that are meaningful to all within the firm, not just the operations executive. Some firms state the production plan as the dollar value of total input (monthly, quarterly, etc.). Other firms may break the total output down by individual factories or major product lines. Still other firms state the plan in terms of total units for each product line. The key here is that the plan be stated in some homogeneous unit, commonly understood by all, that is also consistent with that used in other plans.

PRODUCTION SCHEDULING

The production schedule is derived from the production plan; it is a plan that authorized the operations function to produce a certain quantity of an item within a specified time frame. In a large firm, the production schedule is drawn in the production planning department, whereas, within a small firm, a production schedule could originate with a lone production scheduler or even a line supervisor.

Production scheduling has three primary goals or objectives. The first involves due dates and avoiding late completion of jobs. The second goal involves throughput times; the firm wants to minimize the time a job spends in the system, from the opening of a shop order until it is closed or completed. The third goal concerns the utilization of work centers. Firms usually want to fully utilize costly equipment and personnel.

Often, there is conflict among the three objectives. Excess capacity makes for better due-date performance and reduces throughput time but wreaks havoc on utilization. Releasing extra jobs to the shop can increase the utilization rate and perhaps improve due-date performance but tends to increase throughput time.

There are fundamental differences between production scheduling and production planning. While planning models often utilize aggregate data, cover multiple stages in a medium-range time frame, in an effort to minimize total costs, scheduling models use detailed information, usually for a single stage or facility over a short-term horizon, in an effort to complete jobs in a timely manner. Despite these differences, planning and scheduling often have to be incorporated into a single framework, share information, and interact extensively with one another. They also may interact with other models such as forecasting models or facility location models.

DEVELOPMENTS

Recent research on scheduling methods has resulted in a major shift in direction. Many production planning and scheduling processes were originally developed for job shops, but many job shops have been configured to become lines. Innovations such as computer-integrated manufacturing (CIM) and just-in-time (JIT) production have led to new processes that can capture the benefits of repetitive manufacturing and continuous flow manufacturing. The authors of the 2005 book *Manufacturing Planning and Control for Supply Chain Management* have noted that "Fundamental changes are occurring in the relationships between firms and their suppliers" and that "just-in-time manufacturing and just-in-time purchasing are growing in importance." This trend appears to be continuing, as noted in 2008's *Operations Research and Management Science Handbook*: "managerial focus has shifted to just-in-time (JIT)."

Much of the new scheduling research concerns new concepts and techniques for repetitive manufacturing-type operations. In addition, many of today's firms cannot plan and schedule only within the walls of their own factory as most are an entity with an overall supply chain. Supply chain management requires the coordination and integration of operations in all stages of the chain. If successive stages in a supply belong to the same firm, then these successive stages can be incorporated into a single planning and scheduling model. If not, constant interaction and information sharing are required to optimize the overall supply chain.

PRODUCTIVITY CONCEPTS AND MEASURES

Productivity is an overall measure of the ability to produce a good or service. More specifically, productivity is the measure of how specified resources are managed to accomplish timely objectives as stated in terms of quantity and quality. Productivity may also be defined as an index that measures output (goods and services) relative to the input (labor, materials, energy, etc., used to produce the output). There are two major ways to increase productivity: increase the numerator (output) or decrease the denominator (input). A similar effect would be seen if both input and output increased with output increasing faster than input; or if both input and output decreased with input decreasing faster than output. Productivity can be expressed as:

$$\text{Productivity} = \frac{\text{Output}}{\text{Input}}$$

Organizations can use this formula in many areas: labor productivity, machine productivity, capital productivity, energy productivity, and so on. A productivity ratio can be computed for a single operation, a department, a facility, an organization, or even an entire country.

CONCEPTUAL ASPECTS OF PRODUCTIVITY

Productivity is an objective concept, which can be measured, ideally against a universal standard. As such, organizations can monitor productivity for strategic reasons such as corporate planning, organization improvement, or comparison to competitors. It can also be used for tactical reasons such as project control or controlling performance to budget.

Productivity is also a scientific concept, and hence can be logically defined and empirically observed. It can also be measured in quantitative terms, which qualifies it as a variable. Therefore, it can be defined and measured in absolute or relative terms. However, an absolute definition of productivity is not very useful; it is much more useful as a concept dealing with relative productivity or as a productivity factor.

Productivity is useful as a relative measure of actual output of production compared to the actual input of resources, measured across time or against common entities. As output increases for a level of input, or as the amount of input decreases for a constant level of output, an increase in productivity occurs. Therefore, a "productivity measure" describes how well the resources of an organization are being used to produce input.

Productivity is often confused with efficiency. Efficiency is generally seen as the ratio of the time needed to perform a task to some predetermined standard time. However, doing unnecessary work efficiently is not exactly being productive. It would be more correct to interpret productivity as a measure of effectiveness (doing the right thing efficiently), which is outcome-oriented rather than output-oriented.

EXPRESSIONS OF PRODUCTIVITY

Productivity is usually expressed in one of three forms: partial-factor productivity, multifactor productivity, and total-factor productivity.

Partial-Factor Productivity. The standard definition of productivity is actually what is known as a partial-factor measure of productivity, in the sense that it only considers a single input in the ratio. The formula then for partial-factor productivity would be the ratio of total output to a single input or:

$$\text{Productivity} = \frac{\text{Total output}}{\text{Single input}}$$

Managers generally utilize partial-factor productivity measures because the data is readily available. Also, since the total of multifactor measures provides an aggregate perspective, partial-factor productivity measures are easier to relate to specific processes. Labor-based hours (generally, readily available information) is a frequently used input variable in the equation. When this is the case, it would seem that productivity could be increased by substituting machinery for labor. However, that may not necessarily be a

wise decision. Labor-based measures do not include mechanization and automation in the input; thus when automation replaces labor, misinterpretation may occur.

Other partial-factor measure options could appear as output/labor, output/machine, output/capital, or output/energy. Terms applied to some other partial factor measures include capital productivity (using machine hours or dollars invested), energy productivity (using kilowatt hours), and materials productivity (using inventory dollars).

Multifactor Productivity. A multifactor productivity measure utilizes more than a single factor, for example, both labor and capital. Hence, multifactor productivity is the ratio of total output to a subset of inputs:

$$\text{Multifactor productivity} = \frac{\text{Total output}}{\text{Subset of inputs}}$$

A subset of inputs might consist of only labor and materials or it could include capital. Examples include:

$$\frac{\text{Output}}{\text{Labor} + \text{Machine}}$$

or

$$\frac{\text{Output}}{\text{Labor} + \text{Capital} + \text{Energy}}$$

or

$$\frac{\text{Quantity of production at standard price}}{\text{Labor cost} + \text{Materials cost} + \text{Overhead}}$$

Obviously, the different factors must be measured in the same units, for example dollars or standard hours.

Total-Factor Productivity. A broader gauge of productivity, total-factor productivity is measured by combining the effects of all the resources used in the production of goods and services (labor, capital, raw material, energy, etc.) and dividing it into the output. As such the formula would appear as:

$$\text{Total productivity} = \frac{\text{Total output}}{\text{Total input}}$$

or

$$\text{Total productivity} = \frac{\text{Goods or services produced}}{\text{All inputs used to produce them}}$$

One example: a ratio computed by adding (1) standard hours of labor actually produced plus (2) the standard machine hours actually produced in a given time period divided by the actual hours available for both labor and machines in the time period.

Total output must be expressed in the same unit of measure and total input must be expressed in the same unit of measure. However, total output and total input need not be expressed in the same unit of measure. Resources are often converted to dollars or standard hours so that a single figure can be used as an aggregate measure of total input or output. For example, total output could be expressed as the number of units produced, and total input could be expressed in dollars, such as tons of steel produced per dollar input. Other varieties of the measure may appear as dollar value of good or service produced per dollar of input, or standard hours of output per actual hours of input.

Total productivity ratios reflect simultaneous changes in outputs and inputs. As such, total productivity ratios provide the most inclusive type of index for measuring productivity and may be preferred in making comparisons of productivity. However, they do not show the interaction between each input and output separately and are thus too broad to be used as a tool for improving specific areas.

Total-factor productivity is a measure favored by the Japanese, whereas labor productivity is the measure favored by the United States. As such, the individual "productivity" of the American employee tends to be the best in the world, in that an American employee can purchase more eggs per one hour of work than anyone else in the world. But as a measure of national productivity, the Japanese have, in the past, tended to be better performers.

PRODUCTIVITY MEASURES

It has been said that the challenge of productivity has become a challenge of measurement. Productivity is difficult to measure and can only be measured indirectly, that is, by measuring other variables and then calculating productivity from them. This difficulty in measurement stems from the fact that inputs and outputs are not only difficult to define but are also difficult to quantify.

Any productivity measurement system should produce some sort of overall index of productivity. A smart measurement program combines productivity measurements into an overall rating of performance. This type of system should be flexible in order to accommodate changes in goals and policies over time. It should also have the ability to aggregate the measurement systems of different units into a single system and be able to compare productivity across different units.

The ways in which input and output are measured can provide different productivity measures. Disadvantages of productivity measures have been the distortion of the measure by fixed expenses and also the inability of productivity measures to consider quality changes (e.g., output per hour might increase, but it may cause the defect rate to skyrocket). It is easier to conceive of outputs as tangible units such as number of items produced, but other factors such as quality should be considered.

Experts have cited a need for a measurement program that gives an equal weight to quality as well as quantity (productivity). If quality is included in the ratio, output may have to be defined as something like the number of defect-free units of production or the number of units that meet customer expectations or requirements.

The determination of when productivity measures are appropriate performance measures depends on two criteria. The first is the independence of the transformation process from other processes within the organization. Second is the correspondence between the inputs and outputs in the productivity measurement process.

USE OF PRODUCTIVITY MEASURES

Productivity is a required tool in evaluating and monitoring the performance of an organization, especially a business organization. When directed at specific issues and problems, productivity measures can be very powerful. In essence, productivity measures are the yardsticks of effective resource use.

Managers are concerned with productivity as it relates to making improvements in their firm. Proper use of productivity measures can give the manager an indication of how to improve productivity: either increase the numerator of the measure, decrease the denominator, or both.

Managers are also concerned with how productivity measures relate to competitiveness. If two firms have the same level of output, but one requires less input thanks to a higher level of productivity, that firm will be able to charge a lower price and increase its market share or charge the same price as the competitor and enjoy a larger profit margin.

Within a time period, productivity measures can be used to compare the firm's performance against industry-wide data, compare its performance with similar firms and competitors, compare performance among different departments within the firm, or compare the performance of the firm or individual departments within the firm with the measures obtained at an earlier time (i.e., is performance improving or decreasing over time?).

Productivity measures can also be used to evaluate the performance of an entire industry or the productivity of a country as a whole. These are aggregate measures determined by combining productivity measures of various companies, industries, or segments of the economy.

PRODUCTIVITY INDEX

Since productivity is a relative measure, for it to be meaningful or useful it must be compared to something. For example, businesses can compare their productivity values to that of similar firms, other departments within the same firm, or against past productivity data for the same firm or department (or even one machine). This allows firms to measure productivity improvement over time, or measure the impact of certain decisions such as the introduction on new processes, equipment, and worker motivation techniques.

In order to have a value for comparison purposes, organizations compute their productivity index. A productivity index is the ratio of productivity measured in some time period to the productivity measured in a base period. For example, if the base period's productivity is calculated to be 1.75 and the following period's productivity is calculated to 1.93, the resulting productivity index would be 1.93/1.75 = 1.10. This would indicate that the firm's productivity had increased 10 percent. If the following period's productivity measurement fell to 1.66 the productivity index of 1.66/1.75 = 0.95 it would indicate that the organization's productivity has fallen to 95 percent of the productivity of the base period. By tracking productivity indexes over time, managers can evaluate the success, or lack thereof, of projects and decisions.

FACTORS AFFECTING PRODUCTIVITY

There is quite a variety of factors that can affect productivity, both positively and negatively. These include:

1. Capital investments in production
2. Capital investments in technology
3. Capital investments in equipment
4. Capital investments in facilities
5. Economies of scale
6. Workforce knowledge and skill resulting from training and experience
7. Technological changes
8. Work methods
9. Procedures
10. Systems
11. Quality of products
12. Quality of processes
13. Quality of management
14. Legislative and regulatory environment
15. General levels of education
16. Social environment
17. Geographic factors

The first 12 factors are highly controllable at the company or project level. Numbers 13 and 14 are marginally controllable, at best. Numbers 15 and 16 are controllable only at the national level, and 17 is uncontrollable.

IMPROVING PRODUCTIVITY

Productivity improvement can be achieved in a number of ways. If the level of output is increased faster than that of input, productivity will increase. Conversely, productivity will be increased if the level of input is decreased faster than that of output. Also, an organization may realize a productivity increase from producing more output with the same level of input. Finally, producing more output with a reduced level of input will result in increased productivity.

Any of these scenarios may be realized through improved methods, investment in machinery and technology, improved quality, and improvement techniques and philosophies such as just-in-time, total quality management, lean production, supply chain management principles, and theory of constraints.

A firm or department may undertake a number of key steps toward improving productivity:

- Develop productivity measures for all operations; measurement is the first step in managing and controlling an organization.

- Look at the system as a whole in deciding which operations are most critical, it is overall productivity that is important.

- Develop methods for achieving productivity improvement, such as soliciting ideas from workers (perhaps organizing teams of workers, engineers, and managers), studying how other firms have increased productivity, and reexamining the way work is done.

- Establish reasonable goals for improvement.

- Make it clear that management supports and encourages productivity improvement. Consider incentives to reward workers for contributions.

- Measure improvements and publicize them.

- Don't confuse productivity with efficiency. Efficiency is a narrower concept that pertains to getting the most out of a given set of resources; productivity is a broader concept that pertains to use of overall resources. For example, an efficiency perspective on mowing the lawn given a hand mower would focus on the best way to use the hand mower; a productivity perspective would include the possibility of using a power mower.

As a cautionary word, organizations must be careful not to focus solely on productivity as the driver for the organ-ization. Organizations must consider overall competitive ability. Firm success is categorized by quality, cycle time, reasonable lead time, innovation, and a host of other factors directed at improving customer service and satisfaction.

PRODUCTIVITY AT THE NATIONAL LEVEL

Since productivity is one of the basic variables governing economic production activity some mention of national productivity concerns would be appropriate. As a matter of fact, productivity may be the most important variable governing economic production activity. It is the fundamental controllable factor in wealth production. Since other economic variables depend on it, increasing productivity tends to have a beneficial multiplying effect on other economic variables. This is generally true at every level of economic aggregation.

During the 1970s and 1980s, productivity growth in the United States lagged behind that of other leading industrial countries. Although U.S. productivity was still the world's highest, the fact that it was losing ground to other nations—most notably Japan, Korea, the United Kingdom, and West Germany—caused concern among government officials and business leaders. The United States reversed this trend beginning in the mid-1990s with a shift from a reliance on manufacturing and agriculture to the "new economy" focus on service and high-technology. Since then, the United States has witnessed a sustained productivity growth from the late-1990s through the mid-2000s.

Although economists and business analysts disagree about the specific causes of this reversal, most point to successful investments in information and communication technology as well as increased automation and productivity-enhancing organizational innovations. The contribution of technology to U.S. productivity is nothing new. It has been estimated that technology was responsible for at least half of the growth in productivity in the United States between 1948 and 1966. Technology continues to be seen as the key to sustaining increases in productivity.

Improving productivity is of national importance because, for a society to increase its standard of living, it must first increase productivity. Overall productivity for individual countries is calculated by dividing output, as measured by Gross Domestic Product (GDP) or Gross National Product (GNP), by the country's total population. Thus, productivity is measured as the dollar value per capita outputs. An increase in this measure of productivity means that each person in the country, on average, produced more goods and services. Also if productivity increases, then profits increase. The resulting profits can then be used to pay for wage increases

(inherent in inflation) without having to raise prices. In this way, productivity gains actually help curb inflation.

PROFIT SHARING

Profit sharing is an organizational incentive plan whereby companies distribute a portion of their profits to their employees in addition to prevailing wages. Profit sharing can generate benefits to the company by fostering greater employee cooperation, reducing labor turnover, raising productivity, cutting costs, and providing retirement security. Profit sharing gives employees a direct stake in the profitability of a company, creating an atmosphere in which employees want the business to succeed as much as management does.

HISTORY

Profit sharing was quite common in primitive fishing and farming economies; in fact, it still persists among fisherman in many parts of the world. Albert Gallatin, Secretary of the Treasury under Presidents Jefferson and Madison, introduced profit sharing into his New Geneva, Pennsylvania, glassworks in the 1790s. Profit-sharing plans as we know them today were developed in the nineteenth century, when companies such as General Foods and Pillsbury distributed a percentage of their profits to their employees as a bonus. The first deferred profit-sharing plan was developed in 1916 by Harris Trust and Savings Bank of Chicago. Profit sharing was also instrumental during World War II, enabling wartime employers to provide additional compensation to their employees without actually raising their wages.

FORMS OF PROFIT SHARING

There are three basic types of profit-sharing plans: cash plans, deferred plans, and combination plans. Cash plans distribute cash or stock to employees at the end of the year. The main drawback of this plan is that employee profit-sharing bonuses are taxed as ordinary income. Even if the distribution takes the form of stock or some other payment, it becomes taxable as soon as the employee receives it.

Deferred plans direct profit shares into a trust fund on behalf of individual employees and distribute them at a later date, often at retirement. The Internal Revenue Service (IRS) allows immediate taxation to be avoided in this plan. The deferred profit-sharing plan is a type of defined-contribution plan. A separate account is established for every employee. The accounts increase as contributions are made to them, earning interest or capital gains. Qualified deferred profit-sharing plans give employees a variety of investment choices for their accounts; these choices are common when outside firms manage the accounts. These plans are often used in conjunction with a 401(k) plan, a common retirement plan for U.S. employers. Combination plans pay part of the profit share out directly in cash and defer the remainder into a trust fund.

VESTING REQUIREMENTS

It is becoming less common for companies to manage their own accounts, due to the fiduciary responsibilities and liabilities involved with them. Instead, companies typically contract the responsibility to financial management firms. The amount of future benefits depends on the performance of the account. The balance of the account will include the employer's contributions from profits, any interest earned, any capital gains or losses, and possibly any forfeiture from other plan participants, which may occur when participants leave the company before they are vested (that is, eligible to receive the funds in their accounts); the funds in their accounts are then distributed to the other employees' accounts.

The time required to become fully vested varies from company to company. Immediate vesting means employees are entitled to the funds in their accounts as soon as their employer makes the contribution. Some companies utilize partially vested schedules, entitling employees to, say, 20 percent of the account before gradually becoming fully vested over a period of time. Establishing a vesting schedule is one way to limit access to the account. Another way is to create strict rules as to when payments can be made from employees' accounts, such as at retirement, death, disability, or termination of employment.

CONTRIBUTION LIMITS

The IRS limits the amount that employers may contribute to their profit-sharing plans. In 2002, the federal

government increased the maximum profit-sharing contribution from 15 percent to 25 percent, with a specific dollar-amount cap that may vary by year; as of 2008, the 25 percent contribution is capped at $46,000.

Individual companies may determine the amount of their contributions in one of two ways. One is a set formula written into the plan document. Formulas are commonly based on the company's pre-tax net profits, earnings growth, or another measure of profitability. Some companies determine a certain amount to contribute each year, settled on by the board of directors.

Many companies incorporate profit-sharing plans when economic times are hard and they are unable to provide guaranteed wage increases. Chrysler Corporation, for example, developed a profit-sharing plan for its union and non-union employees in the economic recession of 1988. The plan was incorporated into the union contract in exchange for wage concessions made by its workers. Although harsh economic times made contributions small, by 1994 (when the economy had recovered) Chrysler was paying an average bonus of $4,300 per person to 81,000 employees, for a total of about $348 million.

Many companies are also encouraged to develop profit-sharing programs because they provide significant tax advantages, which can benefit higher-paid as well as lower-paid employees. IRS regulations allow the deductibility of the employer's profit-sharing contributions as a business expense and also allow the deferral of this money into a trust without any tax liabilities until the money is received (usually at retirement, disability, death, severance of employment, or under withdrawal provisions), at which point the employee is usually in a lower tax bracket.

The Employee Retirement Income Security Act of 1974 (ERISA) is the primary legislation regulating the standards for pension plans and other employee-benefit plans. The intent of the ERISA was to protect employee rights under plans such as corporate pensions, deferred profit sharing, stock-bonus plans, and welfare. ERISA does not mandate companies to establish a profit-sharing plan, nor does it require any minimum benefit levels. ERISA did, however, establish guidelines for participation, vesting, funding, fiduciary standards, reporting/disclosing, and plan-termination insurance.

ADVANTAGES AND DISADVANTAGES

Profit sharing has become one of a new breed of incentives called *total system incentives.* These incentives link all of the employees of a company to the pursuit of organizational goals. A common misconception of profit sharing is that it is more suited for smaller companies where employees can more easily see the connection between their efficiency and company contributions. In actuality,

profit sharing is being successfully utilized in large and small companies, labor-intensive and capital-intensive industries, mass production and job-shop situations, and industries with volatile profits as well as those with stable profits. Profit sharing can reward employee performance, seniority, and thrift, depending on the design of the plan.

Although the concept has experienced a tremendous growth rate, profit-sharing plans do not always work. Roughly 2 percent of deferred plans are terminated annually—some as a result of mergers, others because companies are liquidated or sold. The majority of terminations tend to occur after consecutive years of losses, when investment performance is poor, or when ineffective communication has resulted in lack of employee understanding, appreciation, or interest. Profit sharing may also entail some disadvantages for a company. Such plans may limit the company's ability to reward the performance of individual employees, for example, since the pay for all employees moves up or down according to a formula. At smaller companies, tying employee compensation to often uncertain profits may result in drastic income swings from one year to the next. Finally, some critics claim that profit sharing may encourage employees to focus only on increasing profitability, perhaps at the expense of quality or other goals.

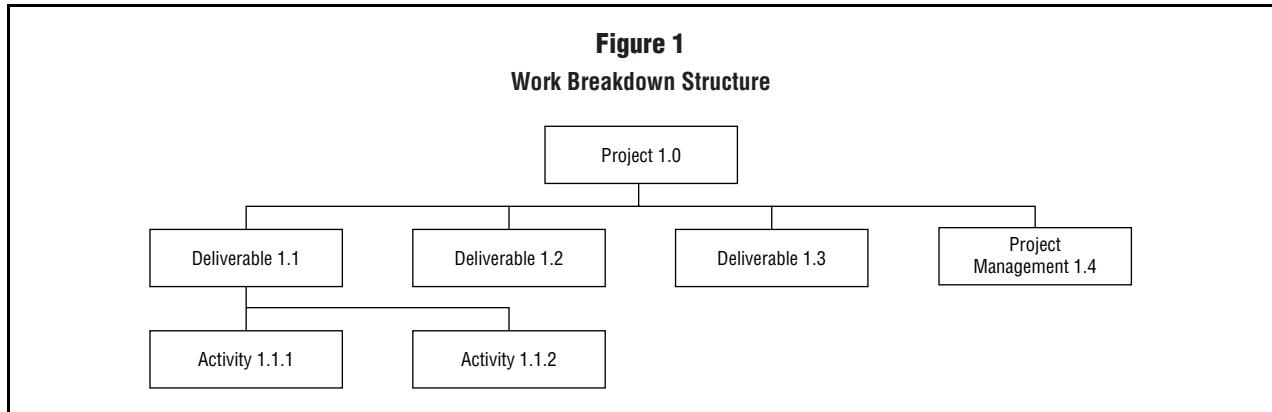
PROJECT MANAGEMENT

Project management is the application of relevant logic and tools to planning, directing, and controlling a temporary endeavor. Almost all companies encounter the need for project management at some point. The need may arise for a new physical plant, an expansion of office space, or a move to a new location. Reengineering may suggest a change in processes, with an accompanying equipment

Figure 1
Work Breakdown Structure


rearrangement and retraining to ensure the effectiveness of the change. The present-day speed of technology change often forces companies to adopt new hardware and software to stay current. Softer issues, such as the implementation of quality programs, also are within the project management purview. While some organizations specialize in projects, others may require project management skills only occasionally to effect a change, either physical or sociological in nature, from the norm.

DEFINING A PROJECT

A project is typically defined as a set of interrelated activities having a specific beginning and ending, and leading to a specific objective. Probably the most important concept in this definition is that a project is intended as a temporary endeavor, unlike ongoing, steady state operations. Secondary is the uniqueness of the output.

To ensure that a project is temporary, it is necessary to define the ending explicitly. The outputs of the project, or deliverables, may be tangible (a new heating system) or intangible (a retrained workgroup), but in either case should be defined in measurable terms (completed installation or documented level of expertise). While the reason for undertaking the project may have been to reduce utility costs by 10 percent or to increase productivity by 20 percent, achieving such goals may be outside the scope of the project.

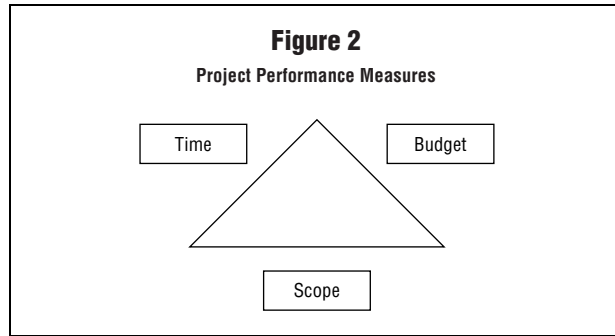
Each project requires specific definition of its goals. In a training project example, the project manager may be given responsibility for identifying and implementing a training system that will enhance productivity by 15 percent; in this case, the project is not complete until the 15 percent goal is reached. If the initial training program enhances productivity by only 12 percent, the project manager is obligated to provide additional training, or the project may be terminated as a failure. Note that a 12 percent increase in productivity was something to celebrate, but did not meet the hurdle rate of acceptability. If instead the project is to implement a previously

identified training program, known to achieve excellent results, then the project is finished when the trainees achieve the test scores known to correlate with a specified level of improvement in productivity. At this point, the project manager has achieved the deliverable, as measured in specific terms; the project is a success. Whether or not the desired improvement in productivity follows is outside the scope of the project.

Obviously, it behooves the project manager to have a well-defined scope for the project. The more nebulous the assignment, the more the project is subject to "scope-creep," or the tendency for the project to acquire additional duties. A "statement of work" document or charter, outlining the relevant specifications of deliverables, helps to keep a project clearly defined. Once the work is completely specified, the requisite activities can be identified and assigned.

The work breakdown structure (WBS) is one of the tools used by project managers to ensure that all activities have been included in planning. By numbering the project "1.0." the implication is that this is the first project for the company; subsequent projects would be numbered sequentially. In the illustrated example, the deliverables are specified on the second layer of the WBS, along with an overhead allocation for the project management team. Under each deliverable is an increasingly specified description of the activities involved in achieving the deliverable. Alternatively, the second line may be functional headings (finance, marketing, operations) or time periods (January, February, March). The objective of the WBS is to clarify that all activities have been addressed and assigned.

While the definition of a project also tends to include the word *unique,* this may be true only in a narrowly defined sense. A company that builds a new branch location (first project) has a template for the construction of a second branch location (second project). In the marketing field, subsequent product rollouts can learn

Figure 2
Project Performance Measures


from the initial product introduction. To the extent that the project is repetitive, the planning process, WBS, and cost estimates can provide a valuable template for future projects.

PROJECT SCHEDULING

Scheduling is an important part of the planning of any project. Program Evaluation and Review Technique (PERT) and Critical Path Method (CPM) are tools widely used in project scheduling. Both are based on network diagrams applicable for both the planning and control aspects of production. Visual display of the network enhances the communication and highlights the interdependency of the various activities required for project completion. Perhaps the greatest contribution of these tools is the identification of sequentially time-critical activities that require the closest monitoring.

It is first necessary to develop a list of all the activities required, as listed in the work breakdown structure. Activities require both time and the use of resources. Typically, the list of activities is compiled with duration estimates and immediate predecessors. Some expertise is required in the planning stage. The concept of concurrent engineering makes the planning stage even more important, as enhanced expertise is needed to address which stages of the project can overlap, and how far this overlap can extend.

Both PERT and CPM rely heavily on time estimates, as derived from local experts, to determine the overall project time. These two project management tools, frequently used together, can assist the project manager in establishing contract dates for project completion, in estimating the risks and costs of contingencies, and in monitoring project progress. Many commercial software packages exist to support the project manager in tracking both costs and time incurred to date throughout the project duration.

Using CPM to Schedule and Control a Project. CPM uses the concept of the critical path to estimate project-completion time. The critical path is the longest path through the system, defining the minimum completion time for the overall project. This generally depends on which activities must be done in sequence so that there is no way to shorten the overall time. Note that this critical path is not dependent on the number of activities, but is rather dependent on the total time for a specific sequence of activities.

The managerial importance of this critical path is that any delay to the activities on this path will delay the project completion time. It is important to monitor this critical set of activities to prevent the missed due-date of the project. Other paths tend to require less monitoring, as these sets of activities have slack, or a cushion, in which activities may be accelerated or delayed without penalty. Total slack for a given path is defined as the difference in the critical path time and the time for the given path.

Slack for the individual activities is calculated by taking the difference between the late-start and early-start times (or, alternatively, between the late-finish and early-finish times) for each activity. If the difference is zero, then there is no slack; the activity is totally defined as to its time-position in the project and must therefore be a critical path activity. For other activities, the slack defines the flexibility in start times, but only assuming that no other activity on the path is delayed.

CPM was designed to address time-cost tradeoffs, such as the use of additional resources to speed the overall process. The project manager should perform contingency planning early in the project to identify potential problems and solutions and the costs associated with employing extra resources. Cost-benefit analysis should be used to compare the missed due-date penalty, the availability and cost of resources, and the effect of these resources on the required quality of the output.

Using PERT to Schedule and Control a Project. In repetitive projects, or in projects employing well-known processes, the duration of a given activity may be estimated with relative confidence. In less-familiar territory, however, it may be more appropriate to forecast a range of possible times for activity duration. The estimated time and or standard deviation for each activity (E) are calculated from the formula for the flexible beta distribution. With a reasonably large number of activities, summing the means tends to approximate a normal distribution, and statistical estimates of probability can be applied.

The mean is calculated as [($a + 4m + b$)÷6], an average heavily weighted toward the most likely time, m. The standard deviation for an activity is [($b − a$) ÷ 6], or one-sixth of the range. Managers with a basic understanding of statistics may relate this to the concept of the standard deviation in the normal distribution. Since ±3 standard deviations comprise almost the entire area under the normal curve, then

there is an intuitive comparison between a beta standard deviation and the normal standard deviation.

From a managerial viewpoint, it should be reiterated that there is only a 50/50 chance of completing the project within the sum of the activity-time estimates on the critical path (T). This perspective is not emphasized in the CPM analysis, but is likely relevant in that context also. Adding a buffer to the promised due date (where $C > T$) enhances the probability that the project will be completed as promised.

There may be competitive advantages to bidding a project on the basis of a nearer-term completion date (where $C < T$), but managers can assess the risks involved using PERT analysis. By using PERT, managers can allocate the resources on a more informed basis.

PROJECT PERFORMANCE MEASURES

The traditional measures for judging project success are: scope, time, and budget. This is frequently depicted as a triangle.

Increasing any of the triangle's sides inherently changes at least one of the other sides. Thus, increasing the scope of the project will necessarily increase either the time required to complete the project or the budget allocated to the project. Unfortunately, the expanded scope can cause both time and budget to escalate simultaneously, as constrained resources come into conflict. Some project contracts have penalty clauses that elicit hefty payments if the project completion is past the contract date. Similarly, when the scope is decreased, the requisite time and budget may be reduced; resources may be assigned elsewhere.

The triangle analogy breaks down when the time factor is reduced, i.e., the project completion date is moved up. An unexpected deadline change may necessitate the use of overtime resources. Overtime hours strain the budget, and may still be insufficient to complete the project within the specified time. Managers attempting to respond to deadline changes should note the relative costs

Figure 3

Performance Measures When Scope is Increased (A)

of time-intensive expenses (such as weekly rental of equipment) and of resource-intensive expenses (wages).

The schedule and budget are developed subsequent to the work breakdown structure, so that all activities and resources are identified. The budget is typically developed by estimating expenses at the bottom layer of the WBS, then rolling up the expenses to a project total. The numbering system in the WBS can be tailored to form a chart of accounts for tracking expenses associated with each activity. The project management heading is appropriate under any of these alternatives to ensure that staff salaries/wages are suitably allocated to the project. Earned value analysis incorporates both on-time and within-budget concepts of tracking the costs incurred to date on a project.

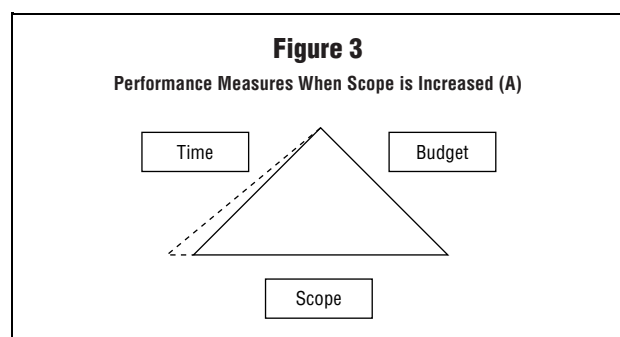
While customer satisfaction is sometimes added as a fourth factor in the list of project performance measures, this complicates the evaluation. If the project manager brings in the project according to scope specifications, on time, within budget, then customer dissatisfaction may be due to the customer's inability to define the scope in terms that would achieve the objective. Customer service in the project management context should include adequate discussion of alternative outcomes at the scope development stage.

ROLES IN THE PROJECT MANAGEMENT ENVIRONMENT

Who is the customer of a project? Generally, the customer is the entity to which the deliverables are actually delivered. In an externally contracted project, the customer is easily identified. In an in-house project, the customer is the executive authorizing both the initiation of the project and the money allocated to it. In either case, the customer is the one with the right to complain when the performance measures of scope, time, and budget are not met.

Ideally, a project will have a sponsor, an intermediary between the customer and the project manager. This individual can help to define the scope for optimal delivery of results, to allocate appropriate funding, to resolve conflicts during the execution of the project.

The project champion is the source of the idea for the project. While the champion is frequently an individual, the idea may originate with the board of directors or the safety committee in a company. The project champion, however, may not be the ideal choice for project manager.

The project manager is in charge of the work to be accomplished. This is not to say that the manager actually does the work, but rather that he/she is the coordinator of all relevant activities through delegation. In many cases, this manager may not possess expertise in the field, but rather possesses the skills to oversee a large number of diverse tasks and to identify the best-qualified employees to carry out the


tasks. The manager should exercise judgment in assigning tasks; seasoned professionals will expect to accomplish the tasks according to their knowledge and experience, while others may require much definition and direction. In some cases, the project manager's ability to accomplish the job depends on negotiating and persuasive skills.

The authority of the project manager depends heavily on the organizational structure. In the "projectized" organization, resources are assigned exclusively to the project, then returned to a pool and assigned to a new project. The manager has near absolute authority and responsibility. In the functional organization (finance, marketing, operations, etc.), the project manager must negotiate with the functional manager for resources obtained from the department. Individuals tend to feel a greater responsibility to the functional manager. In this organization, the project manager has responsibility for the project, but relatively little authority without interference by the sponsor. The matrix organization is a managerial attempt to compromise these extremes by transferring some extent of authority from the functional manager to the project manager; thus, there are both strong-form and weak-form matrix organizations.

The project manager should be a master of many skills. Organization, negotiation, and teambuilding are desirable, while technical expertise may be less important. An expert whose intense focus on technical detail excludes the broader aspects of the project can undermine projects. Communication skills are of prime importance, as written and oral reports are mandatory. In addition, clarity of the initial assignment can reduce the amount of conflict management required in later stages of the project.

Surrounding the project manager is a team with the goal of supporting the planning, directing, and controlling functions. Typically, a full-time (or nearly full-time) team member is assigned responsibility for traditional office functions, such as communication coordination. This member may also be in charge of fielding reports and recording the responses for comparison to the baseline schedule. Other members exercise delegated authority in project oversight, up to and including direct responsibility for sub-projects within the larger project context.

PROJECT INTEGRATION MANAGEMENT

Management of project integration includes the process of synthesis and response to change. The overall project employs five basic processes: *initiating, planning, executing, controlling, and closing.*

The initiating process incorporates development of the idea for the project and justification based on a feasibility study. It is at this stage that the boundaries of the project should be defined. To return to the earlier training example, the responsibility for identifying a specific training program should be determined.

Project planning addresses the specific timeframe and budget for the project. Activities are identified and assigned. Planning is considered a most important process because without excellent planning the ensuing activities are unlikely to succeed. Executing involves carrying out the assigned activities, while controlling monitors the activity for scope, time, and budget concerns.

Perhaps the most ignored process of projects in general is the closing process. Toward the end of a project, enthusiasm can wane, and it is the responsibility of the project manager to maintain active collaboration until the end of the project. Phased-out employees should be evaluated and returned to the pool/function from which they were recruited. A series of meetings should be held to review the degree to which the performance measures were met, from both the defined scope and the satisfaction of the customer. If these are not in agreement, then the reasons should be documented. Areas of success and failure are both important to note, as these can be the basis for company-wide learning. Even dissimilar projects can provide some learning opportunities, as the company understands, for instance, its tendency to underestimate costs or scheduling requirements.

While these processes, initiated through closing, appear to be linear in nature, they instead define a feedback system. The specifics of the planning process may indicate that the initiating idea was flawed. Execution may encounter problems with planning. Controlling may indicate a return to planning, or even to the earlier initiating idea process. And closing may determine that the entire project was doomed from the outset. Failure to recognize the iterative nature of these processes can be costly, as a project may be adjusted or abandoned at early stages to prevent loss.

Within the company, the project life-cycle stages of the project should be identified. Generically, these may be identified as definition, design, test, implementation, and retirement stages, or some variation on this theme. Interestingly, each of these stages employs each of the processes described above. For example, in the definition life-cycle stage, there is an initiation process, progressing to a feasibility study. As the definition stage reaches its conclusion, it "delivers" the project to the design stage, but only if the mini-project of definition has been successful. Many projects have lingered when a rational analysis would suggest that revision or abandonment would be less costly. The iterative nature of project management logic suggests a stringent review at frequent stages to ensure that both the project itself and the environment to which the project was to respond are in agreement. Management of the

integration of project stages is especially important in a rapidly changing environment.

RISK MANAGEMENT

One of the fundamental skills of project management is understanding, managing, and preparing for risk. Risk management may be the activity that best defines project management. This umbrella concept addresses the risks in all aspects of managing a project.

The four basic stages to risk-management planning are:

- Risk Identification
- Risks Quantification
- Risk Response
- Risk Monitoring and Control

To identify risks, managers must consider the traditional performance measures. Was the scope well defined? If the customer assumed that a specific aspect was included, then the contracting firm's reputation may be damaged when the aspect was not specified in the charter. Were the costs estimated correctly? Underestimating can undermine profits, while overestimating can lose an opportunity for business or in-house improvement. Were the time estimates reasonable? Past-due penalties can be significant. Other risks can include the insolvency of the customer and/or a subcontractor, or the lack of in-house expertise to accomplish the tasks involved in the project. Weather, economic changes, and governmental regulations can change the feasibility of any project. Above all is the risk that the project is not sufficient to respond to changes in the environmental circumstances that triggered the project's initiation, especially in a project of long duration.

To quantify risk, two dimensions need to be taken into account: (1) the potential impact of the risk; and (2) the probability of the risk occurring. The potential impact is a stronger factor. If the probability of a risk is high but the impact is low, then the risk is considered a medium one, while a high-impact risk with a low probability is a high priority. As project management expert Neville Turbit notes, "A remote chance of a catastrophe warrants more attention than a high chance of a hiccup."

There are several different strategies available for planning risk response. One is to avoid the risk by doing something to remove it or to mitigate the risk by taking actions to lessen the impact or the probability of the risk occurring. Another is to transfer the risk by making someone else—a vendor perhaps—responsible for a particularly risky part of the project. Finally, the project manager may decide to accept the risk based on a cost-benefit analysis of the potential impact and the costs associated with avoiding, mitigating, or transferring the risk.

The final step in risk management is to monitor risks continually throughout the project in order to note any change in the status or a potential risk. Risk managers accomplish this by holding regular risk reviews that identify changes in risk probability or impact, risks that have passed, and new risks that have arisen since the project began.

Managing a project, and its associated risks, requires a structured approach to solving a problem with a temporary, unique solution. Project planning is a most important stage, setting the stage on which the rest of the project must play out. The project manager should be heavily involved in this planning process to ensure his/her understanding of scope, time, and cost, the primary performance measures by which project success is measured. Monitoring of the activities enhances the probability that the project will stay on track for all of these measures. Each stage and process of project management should address the minimization of risk to the firm, in terms of both money and reputation.

PURCHASING AND PROCUREMENT

Purchasing and procurement is the term denoting the function of and the responsibility for procuring materials, supplies, and services. Recently, the term "supply management" has increasingly come to describe this process. Employees who serve in this function are known as

buyers, purchasing agents, or supply managers. Depending on the size of the organization, buyers may further be ranked as senior buyers or junior buyers. Once seen as a purely clerical function, purchasing and procurement is today a central managerial function and a key to the competitive success of any firm.

DEVELOPMENT

Prior to 1900, there were few separate and distinct purchasing departments in U.S. business. Most pre-twentieth-century purchasing departments existed in the railroad industry. Early in the twentieth century, several books on purchasing were published, while discussion of purchasing practices and concerns were tailored to specific industries in technical trade publications. Early buyers were responsible for ensuring a reasonable purchase price and maintaining operations (avoiding shutdowns due to stockouts).

The shortages of materials and alterations in global markets caused by both World War I and World War II brought more attention to the purchasing profession, but until the 1960s, purchasing agents were still seen as order-placing clerical personnel serving in a staff-support position.

In the late 1960s and early 1970s purchasing personnel became more integrated with a materials system. As materials became a part of strategic planning, the importance of the purchasing department increased. In the 1970s the oil embargo and the shortage of almost all basic raw materials brought much of business world's focus to the purchasing arena. In the 1980s, the advent of just-in-time production—with its emphasis on inventory control and supplier quality, quantity, timing, and dependability—made purchasing a cornerstone of competitive strategy.

By the 1990s the term "supply chain management" had replaced the terms "purchasing," "transportation," and "operations," and purchasing had assumed a position in organizational development and management. In other words, purchasing had become responsible for acquiring the right materials, services, and technology from the right source, at the right time, in the right quantity. Only in small firms is purchasing still viewed as a clerical position. When one notes that, on average, purchasing accounts for over half of most organizations' total monetary expenditures, it is no wonder that purchasing is marked as an increasingly pivotal position.

THE ROLE OF PURCHASING

There are two basic types of purchasing: purchasing for resale and purchasing for consumption or transformation. The former is generally associated with retailers and wholesalers. The latter is defined as industrial purchasing.

Purchasing can also be seen as either strategic or transactional—"direct" and "indirect" are terms that can also be used to distinguish the two types. Strategic (direct) buying involves the establishment of mutually beneficial long-term relationships between buyers and suppliers. Usually strategic buying involves purchase of materials that are crucial to the support of the firm's distinctive competence. This could include raw material and components normally used in the production process. Transactional (indirect) buying involves repetitive purchases, from the same vendor, probably through a blanket purchase order. These orders could include products and services not listed on the bill of materials, such as MRO goods (maintenance, repair, and operating supplies), but are used indirectly in producing the item.

The purchasing department is responsible for determining the organization's requirements, selecting an optimal source of supply, ensuring a fair and reasonable price (for both the purchasing organization and the supplier), and establishing and maintaining mutually beneficial relationships with the most desirable suppliers. In other words, purchasing departments determine what to buy, where to buy it, how much to pay, and ensure its availability by managing the contract and maintaining strong relationships with suppliers.

In more specific terms, today's purchasing departments are responsible for the following:

- Coordinating purchase needs with user departments
- Identifying potential suppliers
- Conducting market studies for material purchases
- Proposal analysis
- Supplier selection
- Issuing purchase orders
- Meeting with sales representatives
- Negotiating
- Contract administration
- Resolving purchasing-related problems
- Maintenance of purchasing records

IMPORTANCE OF PURCHASING

While purchasing is of some importance to nearly all firms, the relative importance of purchasing in a particular firm is determined by four factors:

1. Availability of materials
2. Absolute dollar volume of purchases
3. Percent of product cost represented by materials
4. Types of materials purchased

Purchasing must concern itself with whether or not the materials used by the firm are readily available in a competitive market or whether some are bought in volatile markets that are subject to shortages and price instability. If the latter condition prevails, creative analysis by top-level purchasing professionals is required.

If a firm spends a large percentage of its available capital on materials, the sheer magnitude of expense means that efficient purchasing can produce a significant savings. Even small unit savings add up quickly when purchased in large volumes. When a firm's materials costs are 40 percent or more of its product cost (or its total operating budget), small reductions in material costs can increase profit margins significantly. In this situation, efficient purchasing and purchasing management can make or break a business.

Perhaps the most important of the four factors is the amount of control purchasing and supply personnel actually have over materials availability, quality, costs, and services. Large companies tend to use a wide range of materials, yielding a greater chance that price and service arrangements can be influenced significantly by creative purchasing performance. Some firms, on the other hand, use a fairly small number of standard production and supply materials, from which even the most seasoned purchasing personnel produce little profit, despite creative management, pricing, and supplier selection activities.

SUPPLY MANAGERS

Even in firms where materials costs are not a large percentage of overall expenditures, purchasing functions entail a significant amount of responsibility. In recent decades, the role of purchasing has grown in importance, and purchasing departments are being charged with even more responsibilities. Newer responsibilities for purchasing personnel, in addition to all purchasing functions, include participation in the development of material and service requirements and related specifications, conducting material and value-analysis studies, inbound transportation, and even management of recovery activities such as surplus and scrap salvage, as well as its implications for environmental management.

In the 1970s and 1980s purchasing fell under the rubric of "materials management." Many corporations and individual facilities employed executives who held the title "materials manager," responsible for purchasing and supply management, inventory management, receiving, stores, warehousing, materials handling, production planning, scheduling and control, and traffic/transportation. Today, the term materials management has expanded to include all activities from raw material procurement to final delivery to the customer, to management of returns; hence, the newer title supply chain management.

As purchasing personnel became even more central to the firm's operations they became known as "supply managers." As supply managers, they are active in the strategic-planning process, including such activities as securing partnering arrangements and strategic alliances with suppliers; identification of threats and opportunities in the supply environment; strategic, long-term acquisition plans; and monitoring continuous improvement in the supply chain.

Strategic purchasing often enables firms to foster close working relationships with a limited number of suppliers, promotes open communication among supply chain partners, and develops a long-term strategic relationship orientation for achievement of mutual goals. This implies that strategic purchasing plays a synergistic role in fostering value-enhancing relationships and knowledge exchange between the firm and its suppliers, thereby creating value. In addition, supply managers are heavily involved in cross-functional teams charged with determining supplier qualification and selection, as well ensuring early supplier involvement in product design and specification development.

A comprehensive list of objectives for supply managers includes:

- To support the firm's operations with an uninterrupted flow of materials and services

- To buy competitively and wisely (achieve the best combination of price, quality, and service)

- To minimize inventory investment and loss

- To develop reliable and effective supply sources

- To develop and maintain healthy relations with active suppliers and the supplier community

- To achieve maximum integration with other departments, while achieving and maintaining effective working relationships with them

- To take advantage of standardization and simplification

- To keep up with market trends

- To train, develop, and motivate professionally competent personnel

- To avoid duplication, waste, and obsolescence

- To analyze and report on long-range availability and costs of major purchased items

- To continually search for new and alternative ideas, products, and materials to improve efficiency and profitability

- To administer the purchasing and supply management function proactively, ethically, and efficiently

DETERMINING REQUIREMENTS

In progressive firms, purchasing has a hand in new product development. As a part of a product development team, purchasing representatives have the opportunity to help determine the optimal materials to be used in a new product, propose alternative or substitute materials, and assist in making the final decision based on cost and material availability. Purchasing representatives may also participate in a make-or-buy analysis at this point. The design stage is the point at which the vast majority of the cost of making an item can be reduced or controlled.

Whether or not purchasing had an impact on a product's design, the purchasing agent's input may certainly be needed when defining the materials-purchase specifications. Specifications are detailed explanations of what the firm intends to buy in order to get its product to market.

Generally specified is the product itself, the material from which it is to be made, the process for making it, minimum levels of quality, tolerances (a range in which a specified characteristic is acceptable, e.g., an outer diameter must be a certain size ±25 millimeters), inspection and test standards, and a specific function the product must perform.

If the product requires a standardized component, the specifications are easily communicated by specifying a trade or brand name. However, a custom part can complicate the situation considerably; if incorrectly manufactured, such a product can severely damage a relationship, resulting in unnecessary costs and possible legal action. It is the buyer's responsibility to adequately communicate the specifications to the supplier so that there is no misunderstanding.

SUPPLY SOURCING

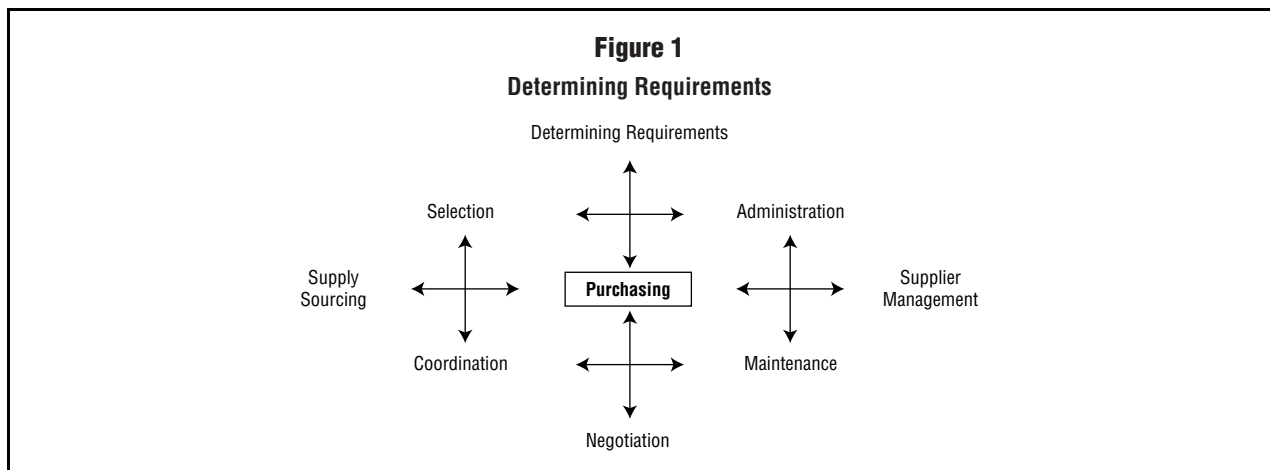
Part of the sourcing decision involves determining whether to purchase a part from an outside supplier or produce the part internally. This is typically known as a make-or-buy decision. If the buyer chooses to purchase the part externally, then he must find qualified suppliers who are willing to make and sell the product to his or her firm under the specified conditions.

Buyers have a number of places to go to locate sources of supply, some obvious and some indirect. The most obvious sources would include the Yellow Pages, other purchasing departments, and direct marketing. Purchasing departments typically have a number of trade publications to which they subscribe, such as *Purchasing, Iron Age,* and *Purchasing World,* which are filled with advertisements for a multitude of suppliers. Also, being a subscriber usually puts the buyer's name on a mailing list so that flyers, postcards, and other varieties of direct marketing find their way into the purchasing department's hands.

Other sources of supply include manufacturer directories and trade registers. The best known of these is *Thomas's Register of American Manufacturers,* frequently referred to simply as the *Thomas Register.* With 125,000 trade and brand names, 151,000 U.S. and Canadian company listings, and 6,000 catalogs, as well as online company listings, over 1 million downloadable CAD drawings of mechanical and electric parts, and over 500,000 downloadable CAD drawings of architectural and building parts, it is an invaluable tool for buyers. Practically every purchasing department has access to this source, either through the thirty-four-volume book series or CD-ROMs.

Suppliers also may be found at trade exhibits, in supplier catalogs, or via recommendations from other knowledgeable sources, such as salesmen and engineers. Probably the most important and frequently used source will soon be the World Wide Web; countless firms maintain Web pages and are listed in online catalogs and directories.

Many firms find themselves in a situation where a suitable supplier cannot be found. In this situation, the firm is forced to develop a supplier. Supplier development

Figure 1
Determining Requirements


is sometimes referred to as "reverse marketing," which entails finding the supplier with the most potential for success and providing the resources necessary for the supplier to manufacture the needed product. This could include training in production processes, quality, and management assistance, as well as providing temporary personnel, tooling, and even financing.

BIDDING AND NEGOTIATION

When the product being purchased is fairly standard and readily available, most firms choose to utilize the competitive bidding process of supplier selection. This involves little or no negotiation. A request for bids is sent to a limited number of qualified suppliers asking for a price quote for the product, given the terms and conditions of the contract. The contract generally goes to the lowest bidder. For government bid requests, the contract legally must go to the lowest bidder qualified to fulfill the contract.

When competitive bidding is not the appropriate mechanism for reaching the purchasing department's objectives, the buyer turns to the process of negotiation. This does not indicate a second-choice alternative, since the negotiation process is more likely to lead to a complete understanding of all issues involved between the supplier and the purchasing firm. This improved understanding can greatly reduce the number and impact of unseen problems that may arise later.

A number of circumstances dictate the use of negotiation. When a thorough analysis is required to solve a difficult make-or-buy decision, or when the risks and costs involved cannot be accurately predetermined, negotiation should be used. Also, when a buyer is contracting for a portion of the seller's production capacity rather than a product, negotiation is typically appropriate.

Other circumstances where negotiation is favored include: when early supplier involvement is employed, when tooling and setup costs represent a large percentage of the supplier's costs, when production is interrupted frequently for change orders, or when a long time is required to produce the purchased products.

If successful negotiation is to occur, the buyer must have a reasonable knowledge of what is being purchased, the process involved, and any factors that may affect cost, quality, delivery, and service. A thorough cost and/or price analysis is essential. The negotiating buyer must also know the strengths and weaknesses of the negotiating supplier, as well as his own. Also, in light of today's global marketplace, strong cultural awareness is a must. Through proper preparation and some negotiating skill, the purchasing agent should be able to secure a contract that fulfills his or her company's needs and is adequately beneficial to the supplier as well.

SUPPLIER MANAGEMENT

After locating proper suppliers and securing contracts, it then falls to the purchasing function to monitor and control the suppliers' performance until the contracts are fulfilled—and beyond, if further business is to be conducted. All purchasing organizations need some vehicle for assessing supplier performance. Many firms have formal supplier-evaluation programs that effectively monitor supplier performance in a number of areas, including quality, quantity delivery, on-time delivery, early delivery (just-in-time users do not like early deliveries), cost, and intangibles.

For some firms, consistent supplier performance results in certification. Supplier certification generally implies (or in some cases formally asserts) that the supplier has been a part of a formal education program, has demonstrated commitment to quality and delivery, and has proven consistency in his processes. Frequently, organizations are able to take delivery from certified suppliers and completely bypass the receiving inspection process.

The buyer is also responsible for maintaining a congenial relationship with the firm's suppliers. If the buyer is an unreasonable negotiator and does not allow the supplier to make an adequate profit, future dealings may be endangered. The supplier may refuse to deal with the buyer in the future, or the supplier may greatly increase the price of a product the buyer could not obtain elsewhere. Also, relations can become strained when the buyer consistently asks for favored treatment such as expediting or constantly changing a particular order's delivery schedule.

INTERNET DEVELOPMENTS

The rise of e-commerce brought on by the Internet has drastically changed the way purchasing is done, leading to the rapid rise of "e-purchasing," also known as "e-procurement." Rapid communication enhances both the competitive bidding process and negotiation, and the establishment of online systems improves purchase order placement, order tracking, and follow-up ordering. Recent developments in electronic data interchange (EDI), which allows firms to standardize electronic transmission of data between computers, have been a driving force in the rise of e-procurement, resulting in corporate extranets linking suppliers and customers. By the twenty-first century, EDIs had almost completely taken over business-to-business data transfers, greatly improving the purchasing process. The Internet has also facilitated reverse auctions, where buying firms specify a requirement and then receive bids from suppliers, with the lowest bid winning.

There are many advantages to e-procurement. These include getting the right product, from the right supplier, at the right time, for the right price, and in the right quantity. Perhaps the biggest advantage is that

e-procurement procedures can provide real-time information to vendors about the status of a customer's needs. Many firms have vendor agreements that include automatic shipping of materials when the customer's stock level reaches a certain point. One disadvantage of e-procurement for purchasers is that vendors have more information about the customer than they would normally have, potentially allowing them to take advantage of the customer's position in the marketplace.

The use of e-procurement is one of the characteristics of a world-class purchasing organization, and in the twenty-first century, it is becoming increasingly difficult for purchasers to remain competitive without using e-procurement practices. The use of e-procurement technologies in some firms has resulted in reduced prices for goods and services, shortened order-processing and fulfillment cycles, reduced administrative burdens and costs, improved control over off-contract spending, and better inventory control. Because of the widespread use of e-procurement, and the diffusion of its benefits throughout the global market, firms must use e-procurement to remain competitive. This has only further increased the importance of well-organized supply management, making purchasing an integral part of any firm's strategic operations.

Q

QUALITY GURUS

Quality management is the practice of managing the whole production process to produce an excellent (quality) product or service. Quality management focuses on the customer and meeting the customer's needs, and everyone in the firm is responsible for the quality of the product. The basic quality management principles are: quality, teamwork, and proactive management. Quality management is not a single doctrine derived from a particular individual or idea—it is a collection of ideas—but there is a core group of contributors known as the Quality Gurus. These are Dr. W. Edwards Deming, Dr. Joseph Juran, Philip Crosby, Shigeo Shingo, Dr. Genichi Taguchi, Dr. Kaoru Ishikawa, Armand V. Feigenbaum, and Dr. H. James Harrington. The Quality Gurus have all had a significant impact on the world through their contributions to improving not only businesses, but all organizations including state and national governments, military organizations, educational institutions, healthcare organizations, and many others.

DR. W. EDWARDS DEMING

Dr. W. Edwards Deming (1900–1993) is probably the most widely-recognized and influential of the Quality Gurus. Deming was trained as a mathematical physicist, and he utilized mathematical concepts and tools (statistical process control) to reduce variation and prevent defects. However, one of his greatest contributions might have been in recognizing the importance of organizational culture and employee attitudes in creating a successful organization. In many ways, his philosophies paralleled the development of the resource-based view of organizations that emphasized that employee knowledge and skills and organizational culture are very difficult to imitate or replicate, and they can serve as a basis of sustainable competitive advantage.

Deming is best known for reminding management that most problems are systemic and that it is management's responsibility to improve the systems so that workers (management and non-management) can do their jobs more effectively. Deming argued that higher quality leads to higher productivity, which, in turn, leads to long-term competitive strength. The theory is that improvements in quality lead to lower costs and higher productivity because they result in less rework, fewer mistakes, fewer delays, and better use of time and materials. With better quality and lower prices, a firm can achieve a greater market share and thus stay in business, providing more and more jobs.

In emphasizing management's responsibility, Deming noted that workers are responsible for 10 to 20 percent of the quality problems in a factory, and that the remaining 80 to 90 percent is under management's control. Workers are responsible for communicating to management the information they possess regarding the system. Deming's approach requires an organization-wide cultural transformation. He advocated a statistical analysis of the manufacturing process and emphasized cooperation of workers and management to achieve high-quality products. Deming's quality methods centered on systematically tallying product defects, analyzing their causes, correcting the causes, and recording the effects of the corrections on subsequent product quality as defects were prevented. He taught that it is less costly in the long run to get things done right the first time than to fix them later.

The Rise of Deming's Influence. Deming worked in the 1930s with Walter A. Shewhart at Bell Telephone Company. Shewhart was a statistician who developed the theory that product control could best be managed by statistics. He developed a statistical chart for the control of product variables. Deming developed a process, based on Shewhart's, using statistical control techniques that alerted managers of the need to intervene in the production process.

He then utilized these techniques during World War II while working on government war production. In 1947 Douglas MacArthur and the U.S. State Department sent Deming to Japan to help the war-devastated Japanese manufacturing plants. He introduced these "statistical process control" methods in a series of lectures on statistical methods to Japanese businessmen and engineers. The Japanese were an attentive audience and utilized Deming's ideas readily. They found him charming and considerate and listened to his ideas. His concept of employees working toward quality fit well into their personal ideas. His philosophy went beyond statistical quality control and encouraged building quality into the product at all stages.

Deming's System of Profound Knowledge. One of Deming's essential theories is his System of Profound Knowledge, which includes appreciation for a system, knowledge about variation (statistics), theory of knowledge, and psychology (of individuals, groups, society, and change). Although the Fourteen Points are probably the most widely known of Dr. Deming's theories, he actually taught them as a part of his System of Profound Knowledge. His knowledge system consists of four interrelated parts:

1. Theory of Optimization
2. Theory of Variation
3. Theory of Knowledge
4. Theory of Psychology

The objective of an organization is the optimization of the total system and not the optimization of the individual subsystems. The total system consists of all constituents—customers, employees, suppliers, shareholders, the community, and the environment. A company's long-term objective is to create a win-win situation for all of its constituents.

Subsystem optimization works against this objective and can lead to a suboptimal total system. According to Deming, it is poor management, for example, to purchase materials or service at the lowest price or to minimize the cost of manufacturing if it is at the expense of the system. Inexpensive materials may be of such inferior quality that they will cause excessive costs in adjustment and repair during manufacturing and assembly.

Deming's philosophy focuses on improving the product and service uncertainty and variability in design and manufacturing processes. Deming believed that variation is a major cause of poor quality. In mechanical assemblies, for example, variations from specifications for part dimensions lead to inconsistent performance and premature wear and failure. Likewise, inconsistencies in service frustrate customers and hurt companies' reputations. Deming taught Statistical Process Control and used control charts to demonstrate variation in processes and how to determine if a process is in statistical control.

There is a variation in every process. Even with the same inputs, a production process can produce different results because it contains many sources of variation; for example, the materials may not always be exactly the same; the tools wear out over time and they are subjected to vibration heat or cold; or the operators may make mistakes. Variation due to any of these individual sources appears at random; however, their combined effect is stable and usually can be predicted statistically. These factors that are present as a natural part of a process are referred to as common (or system) causes of variation.

Common causes are due to the inherent design and structure of the system. It is management's responsibility to reduce or eliminate common causes. Special causes are external to the system, and it is the responsibility of operating personnel to eliminate such causes. Common causes of variation generally account for about 80 to 90 percent of the observed variation in a production process. The remaining 10 to 20 percent are the result of special causes of variation, often called assignable causes. Factors such as bad material from a supplier, a poorly trained operator or excessive tool wear are examples of special causes. If no operators are trained, that is a system problem, not a special cause. The system has to be changed.

Deming emphasized that knowledge is not possible without theory, and experience alone does not establish a theory. Experience only describes—it cannot be tested or validated—and alone is no help for management. Theory, on the other hand, shows a cause-and-effect relationship that can be used for prediction. There is a lesson here for the widespread benchmarking practices: copying only an example of success, without understanding it in theory, may not lead to success, but could lead to disaster.

Psychology helps people better understand interactions between people and circumstances, interactions between leaders and employees, and any system of management. Consequently, managing people requires knowledge of psychology. Also required is knowledge of what motivates people. Job satisfaction and the motivation to excel are intrinsic. Reward and recognition are extrinsic.

Management needs to create the right mix of intrinsic and extrinsic factors to motivate employees.

Deming's Main Ideas. Deming is probably best known for his fourteen points for management, but he is also known for the *Seven Deadly Diseases* and the *Deming Cycle*.

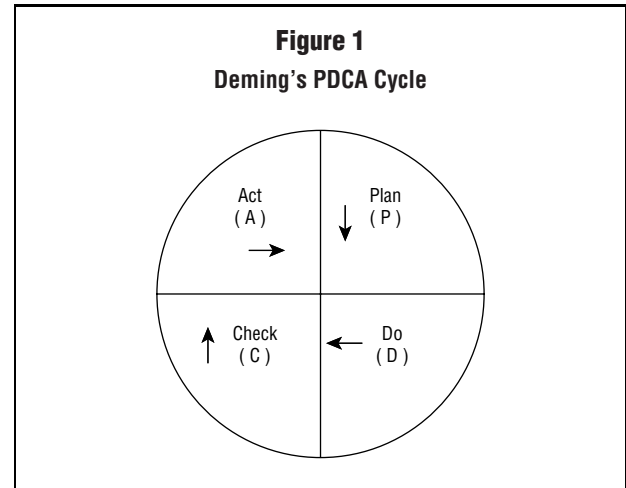
The fourteen points can be summarized as follows:

1. Create a plan; publish the aims and purposes of the organization.
2. Learn and adopt the new philosophy of quality.
3. Understand the purpose of inspection; stop depending on inspection.
4. Stop awarding business based on price alone.
5. Improve the system constantly.
6. Institute training.
7. Teach and institute leadership.
8. Drive out fear, create trust, and create a climate for innovation.
9. Optimize the efforts of teams, groups, and staff areas.
10. Eliminate exhortations and targets for the work force; provide methods of achievement.
11. Eliminate numerical quotas for the work force.
12. Remove barriers that rob people of pride for workmanship.
13. Encourage education and self improvement for everyone.
14. Take action to accomplish the transformation; make it everyone's job.

The Seven Deadly Diseases are:

1. Lack of constancy of purpose to plan products and services.
2. Emphasis on short-term profits.
3. Personal review systems for managers and management by objectives.
4. Job hopping by managers.
5. Using only visible data in decision making.
6. Excessive medial costs.
7. Excessive costs of liability driven up by lawyers that work on contingency.

The Deming Cycle, also known as the Deming Plan-Do-Check-Act (PDCA) Cycle, was originally invented by Shewhart and popularized by Deming. This approach is a cyclic process for planning and testing improvement activities prior to full-scale implementation and/or prior to

Figure 1
Deming's PDCA Cycle


formalizing the improvement. When an improvement idea is identified, it is often wise to test it on a small scale prior to full implementation to validate its benefit. Additionally, by introducing a change on a small scale, employees have time to accept it and are more likely to support it. The Deming PDCA Cycle provides opportunities for continuous evaluation and improvement.

The steps in the Deming PDCA or PDSA Cycle as shown in Figure 1 are as follows:

1. Plan a change or test (P).
2. Do it (D). Carry out the change or test, preferably on a small scale.
3. Check it (C). Observe the effects of the change or test. Study it (S).
4. Act on what was learned (A).
5. Repeat Step 1, with new knowledge.
6. Repeat Step 2, and onward. Continuously evaluate and improve.

DR. JOSEPH JURAN

Dr. Joseph Juran (1904–2008), whose teaching and consulting career spanned more than seventy years, was also one of the foremost experts on quality in the world. A quality professional from the beginning of his career, Juran joined the inspection branch of the Hawthorne Co. of Western Electric (a Bell manufacturing company) in 1924, after completing his B.S. in Electrical Engineering. In 1934, he became a quality manager. He worked with the U.S. government during World War II and afterward became a quality consultant. In 1952, Dr. Juran was invited to Japan. Dr. Deming helped arrange the meeting that led to this invitation and his many years of work with Japanese companies.

Juran founded the Juran Center for Quality Improvement at the University of Minnesota and the Juran Institute. His third book, *Juran's Quality Control Handbook,* published in 1951, was translated into Japanese. Other books include *Juran on Planning for Quality* (1988), *Juran on Leadership for Quality* (1989), *Juran on Quality by Design* (1992), *Quality Planning and Analysis* (1993), and *A History of Managing for Quality* (1995). *Architect of Quality* (2004) is his autobiography.

SELECTED JURAN QUALITY THEORIES

Juran's concepts can be used to establish a traditional quality system, as well as to support Strategic Quality Management. Among other things, Juran's philosophy includes the Quality Trilogy and the Quality Planning Roadmap.

Juran's Quality Trilogy. The Quality Trilogy emphasizes the roles of quality planning, quality control, and quality improvement. Quality planning's purpose is to provide operators with the ability to produce goods and services that can meet customers' needs. In the quality planning stage, an organization must determine who the customers are and what they need, develop the product or service features that meet customers' needs, develop processes that are able to deliver those products and services, and transfer the plans to the operating forces. If quality planning is deficient, then chronic waste occurs.

Quality control is used to prevent things from getting worse. Quality control is the inspection part of the Quality Trilogy where operators compare actual performance with plans and resolve the differences. Chronic waste should be considered an opportunity for quality improvement, the third element of the Trilogy. Quality improvement encompasses improvement of fitness-for-use and error reduction, seeks a new level of performance that is superior to any previous level, and is attained by applying breakthrough thinking.

While up-front quality planning is what organizations should be doing, it is normal for organizations to focus their first quality efforts on quality control. In this aspect of the Quality Trilogy, activities include inspection to determine percent defective (or first pass yield) and deviations from quality standards. Activities can then focus on another part of the trilogy, quality improvement, and make it an integral part of daily work for individuals and teams.

Quality planning must be integrated into every aspect of the organization's work, such as strategic plans; product, service and process designs; operations; and delivery to the customer. The Quality Trilogy is depicted below in Figure 2.

Juran's Quality Planning Road Map. Juran's Quality Planning Road Map can be used by individuals and teams throughout the world as a checklist for understanding customer requirements, establishing measurements based on customer needs, optimizing product design, and developing a process that is capable of meeting customer requirements.

Juran's Quality Trilogy and Quality Roadmap are not enough. An infrastructure for Quality must be developed, and teams must work on improvement projects. The infrastructure should include a quality steering team with top management leading the effort, quality should become an integral part of the strategic plan, and all people should be involved. As people identify areas with improvement potential, they should team together to improve processes and produce quality products and services.

Under the "Big Q" concept, all people and departments are responsible for quality. In the old era under the concept of "little q," the quality department was responsible for quality. Big "Q" allows workers to regain pride in workmanship by assuming responsibility for quality.

PHILIP CROSBY (1926–2001)

Philip Bayard Crosby (1926–2001) first began formulating his early concepts concerning quality after going to work for Crosley Corp. in Richmond, Indiana, as a junior electronic test technician. He joined the American Society for Quality, and then in 1955 went to work for Bendix Corp. as a reliability technician and quality engineer. He investigated defects found by the test people and inspectors. In 1957 he became a senior quality engineer with Martin Marietta Co. in Orlando, Florida. During his eight years with Martin Marietta, Crosby developed his "Zero Defects" concepts, began writing articles for various journals, and started his speaking career.

In 1965 International Telephone and Telegraph (ITT) hired Crosby as vice president in charge of corporate quality. During his fourteen years with ITT, Crosby worked with many of the world's largest industrial and service companies, implementing his pragmatic management philosophy, and found that it worked.

After a number of years in industry, Crosby established the Crosby Quality College in Winter Park, Florida. He is well known as an author and consultant and has written many articles and books. He is probably best known for his book *Quality is Free* (1979) and concepts such as his *Absolutes of Quality Management, Zero Defects, Quality Management Maturity Grid, 14 Quality Improvement Steps, Cost of Quality,* and *Cost of Nonconformance.*

Other books he has written include *Quality Without Tears* (1984) and *Completeness* (1994).

Attention to customer requirements and preventing defects is evident in Crosby's definitions of quality and "non-quality" as follows: "Quality is conformance to requirements; non-quality is nonconformance."

Crosby's Cost of Quality. In his book *Quality Is Free,* Crosby makes the point that it costs money to achieve quality, but it costs more money when quality is not achieved. When an organization designs and builds an item right the first time (or provides a service without errors), quality is free. It does not cost anything above what would have already been spent. When an organization has to rework or scrap an item because of poor quality, it costs more. Crosby discusses Cost of Quality and Cost of Nonconformance or Cost of Nonquality. The intention is to spend more money on preventing defects and less on inspection and rework.

Crosby's Four Absolutes of Quality. Crosby espoused his basic theories about quality in four Absolutes of Quality Management as follows:

1. Quality means conformance to requirements, not goodness.

2. The system for causing quality is prevention, not appraisal.

3. The performance standard must be zero defects, not "that's close enough."

4. The measurement of quality is the price of nonconformance, not indexes.

To support his Four Absolutes of Quality Management, Crosby developed the Quality Management Maturity Grid and Fourteen Steps of Quality Improvement. Crosby sees the Quality Management Maturity Grid as a first step in moving an organization towards quality management. After a company has located its position on the grid, it implements a quality improvement system based on Crosby's Fourteen Steps of Quality Improvement.

Crosby's Absolutes of Quality Management are further delineated in his Fourteen Steps of Quality Improvement as shown below:

Step 1. Management Commitment

Step 2. Quality Improvement Teams

Step 3. Quality Measurement

Step 4. Cost of Quality Evaluation

Step 5. Quality Awareness

Step 6. Corrective Action

Step 7. Zero-Defects Planning

Step 8. Supervisory Training

Step 9. Zero Defects

Step 10. Goal Setting

Step 11. Error Cause Removal

Step 12. Recognition

Step 13. Quality Councils

Step 14. Do It All Over Again

SHIGEO SHINGO

One of the world's leading experts on improving the manufacturing process, Shigeo Shingo (1919–1990) created, with Taiichi Ohno, many of the features of just-in-time (JIT) manufacturing methods, systems, and processes, which constitute the Toyota Production System. He has written many books including *A Study of the Toyota Production System From an Industrial Engineering Viewpoint* (1989), *Revolution in Manufacturing: The SMED (Single Minute Exchange of Die) System* (1985), and *Zero Quality Control: Source Inspection and the Poka Yoke System* (1986).

Shingo's greatness seems to be based on his ability to understand exactly why products are manufactured the way they are, and then transform that understanding into a workable system for low-cost, high quality production. Established in 1988, the Shingo Prize is the premier manufacturing award in the United States, Canada, and Mexico. In partnership with the National Association of Manufacturers, Utah State University administers the Shingo Prize for Excellence in Manufacturing, which promotes world class manufacturing and recognizes companies that excel in productivity and process improvement, quality enhancement, and customer satisfaction.

Rather than focusing on theory, Shingo focused on practical concepts that made an immediate difference. Specific concepts attributed to Shingo are:

- Poka Yoke requires stopping processes as soon as a defect occurs, identifying the source of the defect, and preventing it from happening again.

- Mistake Proofing is a component of Poka Yoke. Literally, this means making it impossible to make mistakes (i.e., preventing errors at the source).

- SMED (Single Minute Exchange of Die) is a system for quick changeovers between products. The intent is to simplify materials, machinery, processes and skills in order to dramatically reduce changeover times from hours to minutes. As a result products could be produced in small batches or even single units with minimal disruption.

- Just-in-Time (JIT) Production is about supplying customers with what they want when they want it. The aim of JIT is to minimize inventories by producing only what is required when it is required. Orders are "pulled" through the system when triggered by customer orders, not pushed through the system in order to achieve economies of scale with the production of larger batches.

DR. GENICHI TAGUCHI

Dr. Genichi Taguchi (b. 1924) is a Japanese engineer and statistician who defined what product specification means and how this can be translated into cost-effective production. He worked in the Japanese Ministry of Public Health and Welfare, Institute of Statistical Mathematics, Ministry of Education. He also worked with the Electrical Communications Laboratory of the Nippon Telephone and Telegraph Co. to increase the productivity of the R&D activities.

In the mid-1950s Taguchi was Indian Statistical Institute visiting professor, where he met Walter Shewhart. He was a visiting research associate at Princeton University in 1962, the same year he received his Ph.D. from Kyushu University. He was a professor at Tokyo's Aoyama Gakuin University and Director of the Japanese Academy of Quality.

Taguchi was awarded the Deming Application prize (1960), the Deming awards for literature on quality (1951, 1953, and 1984), and the Willard F. Rockwell Medal by the International Technologies Institute (1986).

Taguchi's contributions are in robust design in the area of product development. The Taguchi Loss Function, the Taguchi Method (Design of Experiments), and other methodologies have made major contributions in the reduction of variation and greatly improved engineering quality and productivity. By consciously considering the noise factors (environmental variation during the product's usage, manufacturing variation, and component deterioration) and the cost of failure in the field, Taguchi methodologies help ensure customer satisfaction.

Robust Design focuses on improving the fundamental function of the product or process, thus facilitating flexible designs and concurrent engineering. Taguchi product development includes three stages: (1) system design (the non-statistical stage for engineering, marketing, customer, and other knowledge); (2) parameter stage (determining how the product should perform against defined parameters; and (3) tolerance design (finding the balance between manufacturing cost and loss).

DR. KAORU ISHIKAWA

Dr. Kaoru Ishikawa (1915–1989) was a professor of engineering at the University of Tokyo and a student of

Dr. W. Edwards Deming. Ishikawa was active in the quality movement in Japan, and was a member of the Union of Japanese Scientists and Engineers. He was awarded the Deming Prize, the Nihon Keizai Press Prize, and the Industrial Standardization Prize for his writings on quality control, and the Grant Award from the American Society for Quality Control for his educational program on quality control.

Ishikawa's book, *Guide to Quality Control* (1982), is considered a classic because of its in-depth explanations of quality tools and related statistics. The tool for which he is best known is the cause and effect diagram. Ishikawa is considered the Father of the Quality Circle Movement. Letters of praise from representatives of companies for which he was a consultant were published in his book *What Is Total Quality Control?* (1985). Those companies include IBM, Ford, Bridgestone, Komatsu Manufacturing, and Cummins Engine Co.

Ishikawa believed that quality improvement initiatives must be organization-wide in order to be successful and sustainable over the long term. He promoted the use of Quality Circles to: (1) support improvement; (2) respect human relations in the workplace; (3) increase job satisfaction; and (4) more fully recognize employee capabilities and utilize their ideas. Quality Circles are effective when management understands statistical techniques and acts on recommendations from members of the Quality Circles.

FEIGENBAUM AND HARRINGTON

Armand Feigenbaum (b. 1922) was still a doctoral student at the Massachusetts Institute of Technology when he completed *Quality Control: Principles, Practice, and Administration* (1951), a work that led to the creation of Total Quality Management (TQM), one of the most influential management doctrines today. A revised and updated version of this classic work was issued in 1991 as *Total Quality Control*, at a time when the influence of TQM was spreading rapidly. He continues to be an influential management consultant.

Dr. H. James Harrington is an author and consultant in the area of process improvement. He has been a prolific author and major voice in the development of quality management practices. His books include *The Improvement Process, Business Process Improvement, Total Improvement Management, ISO 9000 and Beyond, Area Activity Analysis, The Creativity Toolkit, Statistical Analysis Simplified, The Quality/Profit Connection,* and *High Performance Benchmarking.*

QUALITY AND TOTAL QUALITY MANAGEMENT

Although quality and quality management does not have a formal definition, most agree that it is an integration of all functions of a business to achieve high quality of products through continuous improvement efforts of all employees. Quality revolves around the concept of meeting or exceeding customer expectation applied to the product and service. Achieving high quality is an ever changing, or continuous, process. As such, quality management emphasizes the ideas of working constantly toward improved quality. It involves every aspect of the company: processes, environment, and people. The whole workforce from the CEO to the line worker must be involved in a shared commitment to improving quality. Quality and total quality management (TQM for short) can be defined as directing (managing) the whole (total) production process to produce an excellent (quality) product or service.

Quality management differs from other management techniques in the attitude of management toward the product and toward the worker. Older management methods focused on the volume of production and the cost of the product. Quality was controlled by using a detection method (post production inspection), problems were solved by management and management's role was defined as planning, assigning work, controlling the production. In contrast, quality management is focused on the customer and meeting the customer's needs. Quality is controlled by prevention, i.e., quality is built in at every stage. Teams solve problems and everyone is responsible for the quality of the product. Management's role is to delegate, coach, facilitate, and mentor. The major quality management principles are: quality, teamwork, and proactive management philosophies for process improvement.

The U.S. Department of Defense's Definition of Total Quality

Total Quality (TQ) consists of continuous improvement activities involving everyone in the organization—managers and workers—in a totally integrated effort toward improving performance at every level. This improved performance is directed toward satisfying such cross-functional goals as quality, cost, schedule, missing, need, and suitability. TQ integrates fundamental management techniques, existing improvement efforts, and technical tools under a disciplined approach focused on continued process improvement. The activities are ultimately focused on increasing customer/user satisfaction.

ORIGINS AND CONTRIBUTIONS

Quality management is not derived from a single idea or person. It is a collection of ideas and has been called by various names and acronyms: TQM, total quality management; CQI, continuous quality improvement; SQC, statistical quality control; TQC, total quality control, etc. However each of these ideas encompasses the underlying idea of productivity initiatives that increase profit by improving the product.

Though most writers trace the quality movement's origins to W. Edwards Deming, Joseph M. Juran, and Philip B. Crosby, the roots of quality can be traced even further back, to Frederick Taylor in the 1920s. Taylor is the "father of scientific management." As manufacturing left the single craftsman's workshop, companies needed to develop a quality control department. As manufacturing moved into big plants, between the 1920s and the 1950s, the terms and processes of *quality engineering* and *reliability engineering* developed. During this time productivity was emphasized and quality was checked at the end of the line. As industrial plants became larger, post-production checks became more difficult and statistical methods began to be used to control quality. This was called *reliability engineering* because it moved quality control toward building quality into the design and production of the product. Taylor was the pioneer of these methods.

The ideas of W. Edwards Deming, Joseph M. Juran, and Philip B. Crosby had the biggest impact on the development of the quality management movement. The individual contributions of these and several other "quality gurus" are fully detailed in the article on "Quality Gurus." Therefore, only a brief outline will be provided here.

Deming relied heavily on "statistical process control" methods, though his philosophy went beyond statistical quality control and encouraged building quality into the product at all stages. He put forward the concept of the quality chain reaction: as quality improves, costs go down and productivity goes up; this leads to more jobs, greater market share, and long-term survival. He stressed worker pride and satisfaction and considered it management's job to improve the process, not the worker. Quality circles, a central Deming theme, are based on the importance of employees meeting regularly in groups to comprehensively discuss product quality.

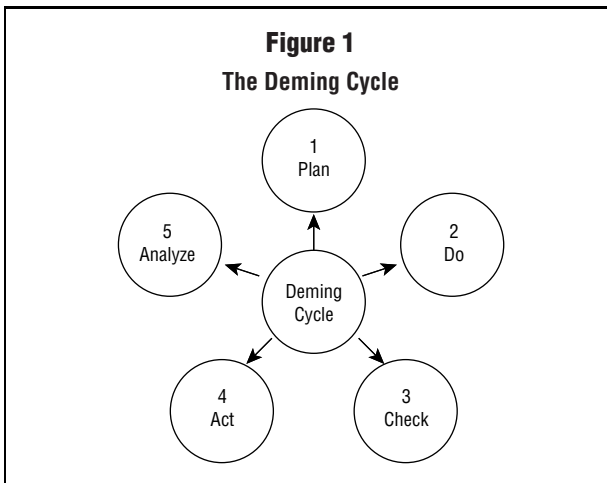
Deming's ideas were encapsulated in several important doctrines, including his fourteen points for management, the *Deming Cycle*, and the *Seven Deadly Diseases.* The Deming Cycle involves five steps: consumer research and planning of the product (plan), producing the product (do), checking the product (check), marketing the product (act), and analyzing how the product is received (analyze.) The Seven Deadly Diseases are:


Figure 1
The Deming Cycle

1. Lack of constancy of purpose to plan products and services

2. Emphasis on short-term profits

3. Personal review systems for managers and management by objectives

4. Job-hopping by managers

5. Using only visible data in decision making

6. Excessive medial costs

7. Excessive costs of liability driven up by lawyers who work on contingency

Joseph M. Juran was another influential quality guru. Like Deming, Juran emphasized planning, organizing, and controlling. However he emphasized customer satisfaction more than Deming did and focused on management and technical methods rather than worker satisfaction. Juran developed basic steps that companies must take, however he believed there was a point of diminishing return, a point at which quality goes beyond the consumer needs. For example, if the consumer trades his car in after 50,000 miles, the car need only be built to perform trouble-free for 60,000 miles. Building a better car would drive up costs without delivering the expected product. This is called the *Pareto Principle,* or the Juran 80/20 rule: 80 percent of the trouble comes from 20 percent of the problems. The rule is named for Vilfredo Pareto, an economist, but it was Juran that applied the idea to management. It can be expressed as: "concentrate on the 'vital few' sources of problems; don't be distracted by less important problems."

Like Deming, Juran developed a number of reinforcing doctrines, including Juran's trilogy—quality planning, quality control, and quality improvement—and his ten steps to quality improvement:

1. Build awareness of opportunities to improve.

2. Set goals.

3. Organize to reach goals.

4. Provide training.

5. Carry out projects to solve problems.

6. Report progress.

7. Give recognition.

8. Communicate results.

9. Keep score.

10. Maintain momentum by making annual improvement part of the systems and processes of the company.

Philip Crosby, author of *Quality Is Free*, was the third major quality guru. Crosby emphasized meeting customer requirements by focusing on prevention rather than correction. He claimed that poor quality costs about 20 percent of the revenue; a cost that could be avoided by using good quality practices. Crosby's method does not dwell on statistical process control and problem-solving techniques that the Deming method uses. He stated that quality is free because prevention will always be lower than the costs of detection, correction, and failure.

Looking at the history of quality management, we see several stages of development. The first was *quality control,* which involved setting up product specifications and then inspecting the product before it leaves the plant. The second state is *quality assurance,* which involved identifying the quality characteristics and procedures for quantitatively evaluating and controlling them. The next phase is the true *total quality control,* a term actually coined by Feingenbaum in 1983. At this stage the quality became a total organization effort. It effected production, profit, human interaction and customer satisfaction. The fourth stage is *total quality management.* In TQM the customer is the center and quality is an organization-wide effort.

QUALITY IN JAPAN AND THE UNITED STATES

Firms in the United States were slow to see the advantages of quality management. In the decades that followed World War II, demand was so high that U.S. manufacturers had no trouble selling everything they made. This situation drove U.S. industry to emphasize increasing production, which resulted in less quality control. U.S. manufacturers became complacent, thinking that they could sell any product and that the consumer did not want or demand quality. The situation in Japan after World War II was just the opposite. The war had left the country devastated, and it needed to rebuild its means of production. In addition, Japanese manufacturers needed to

Chronology

1931	Walter A. Shewhart of Bell Laboratories publishes Economic Control of Quality of Manufactured Products and introduces statistical quality control.
1950	W. Edwards Deming addressed Japanese scientists, engineers, and corporate executive on subject of quality.
1951	First Deming Prize awarded by the Union of Japanese Scientists and Engineers (JUSE).
1952	Joseph M. Juran publishes the Quality Control Handbook.
1970	Philip Crosby introduces the concept of zero defects.
1979	Crosby publishes Quality is Free.
1980	Ford Motor Company invites Deming to speak to executives.
1981	Bob Galvin, Motorola's chairman starts quality improvement, which leads to the six sigmas.
1982	Deming publishes Quality, Productivity, and Competitive Position.
1984	Crosby publishes Quality without Tears: The Art of Hassle-Free Management.
1987	Congress creates the Malcolm Baldrige National Quality Award.
1992	First European Quality Awards named, which is sponsored by the Foundation for Quality Management with support from the European Organization for Quality and the European Commission.

---

counteract the reputation they had that products "made in Japan" were of low quality.

Japan began focusing on serious quality efforts. Japanese teams went abroad to visit foreign countries to learn how other countries managed quality, and they invited foreign experts, including Deming and Juran, to lecture in Japan on quality management. It took twenty years of concerted effort to revamp Japan's industrial system. The strategies used involved high-level managers as leaders. All levels and functions were trained in managing for quality, continuous progress was undertaken, quality circles were used, and the entire workforce was enlisted. By the early 1980s Japanese products, particularly automobiles and electronic products, were superior in quality to U.S. products. U.S. companies lost markets in the United States and in the western world to the Japanese and went in search of the *Japanese secret.* They found the concept of quality management.

One of the first companies in the United States to grasp and utilize quality management was Motorola. In 1981 Bob Galvin, Motorola's chairman, called for an across-the-board improvement of 10:1 in five years. To accomplish this they needed a breakthrough technique. This breakthrough is detailed in the Six Sigma process:

• Faith that the improvement target could be achieved

• Total customer satisfaction

• Powerful new tools, especially design of experiments

- Cycle-time reduction

- Designing for ease of manufacturing

- Manufacturing innovations

- True partnerships with key suppliers

- Training for all employees

Within five years Motorola had achieved their goal. In 1988 they were awarded the Malcolm Baldridge National Quality Award for their impressive Six Sigma process. Keki R. Bhote nurtured the Six Sigma project for eleven years at Motorola and then went on to consult with other companies.

In the early 1980s when Donald Petersen was CEO of Ford, Ford executives were investigating the secret of the Japanese success. They discovered W. Edwards Deming's holistic blend of statistics and management. Deming's ideas came to Detroit. Ford was in serious trouble because of Japanese competition. Deming introduced the statistical methods needed to improve processes. These are the foundation of what became known as Six Sigma, a statistical measure that refers to 3.4 defects per million. Besides this scientific method of improving quality, Deming emphasized that all employees needed to work toward quality. He advocated teamwork and cross-department collaboration, close work with suppliers and employee training. Other companies that adopted the Deming quality methods were General Motors, Florida Power & Light, and Procter and Gamble.

IMPLEMENTING TQM

Although different authorities on total quality management emphasize different techniques and use different terminology, all share three common ideas: quality, teamwork and process improvement. Although many books have been written to guide U.S. companies through TQM, one of the major writers was Joseph Jablonski. In *Implementing TQM,* he identified three characteristics: (1) participative management; (2) continuous process improvement; and (3) utilization of teams.

Participative management is the opposite of the hierarchical management style of the early twentieth century businesses. It involves all employees in the management process and decision making by having managers set policies and make key decisions based upon the advice and ideas of subordinates. This method provides management with more information from the front line and motivates the workers as they have some control of the decisions. Continuous process improvement is one of Deming's major ideas and involves small steps toward the ultimate goal. This involves patience on the part of management. Teamwork refers to cross-functional teams of workers that share in problem solving.

In *Implementing TQM,* Jablonski lists six attributes necessary for success: (1) customer focus; (2) process focus; (3) prevention versus inspection; (4) employee empowerment and compensation; (5) fact-based decision making; and (6) receptiveness to feedback.

U.S. companies have long relied upon company organization by functions. TQM emphasizes a decentralized structure to encourage leadership and creativity. The purpose of this change in structure is to change the behavior of the employees. This is a major change for most U.S. companies. However, successful companies have more functional integration and fewer layers of hierarchy.

QUALITY FAILURES

Not all attempts at quality improvement have been successful. Frequently cited reasons for failure are poor leadership, team-mania (setting up teams before management or employees have been trained in team work), and lack of integration of quality efforts into the whole organization. Obstacles and barriers to success have been researched by Robert J. Masters. He lists eight common problems that lead to failure:

1. Lack of management commitment. Management must commit time and resources and clearly communicate the importance and goals to all personnel.

2. Inability to change the organizational culture. Change takes time and effort. In order for the culture to change, the employees need to want change and be willing to participate. This requires reasons that management must convey. The change will only occur if the employees trust the management. It cannot occur from a state of fear.

3. Improper planning. Planning must involve all parts of the organization and be communicated clearly to employees.

4. Lack of training. The most effective training comes from senior management. Informal training needs to occur on a continual basis.

5. Organizational structure problems and isolated individuals or departments. Multi-functional teams will help break down some of these barriers. Restructuring is another method.

6. Ineffective measurement and lack of data. Effective decisions require that the employees have access to the necessary data.

7. Inadequate attention to internal and external customers.

8. Inadequate empowerment, lack of teamwork. Teams require training. Their recommendations should be followed whenever possible. Individuals need to be empowered to make decisions.

QUALITY INTO THE 2000s

Since its initial introduction, TQM has gained wide acceptance in the United States. Quality management principles have had a remarkable influence on every sector of American business and are spreading to non-profit organizations and universities.

Beginning in the 1980s, many U.S. companies implemented total quality management systems in order to be competitive in the global market place. Successes lead them to be interested in hiring managers and engineers with some TQM training. This prompted universities to start teaching quality methods. To help universities in this, the University Challenge program was developed by a group of companies that had implemented TQM successfully. Their goal was to encourage universities to commit to integrating TQM in their own operations and courses. Initially eight universities with both business and engineering schools were chosen. Milliken worked with North Carolina State University and Georgia Institute of Technology. IBM worked with Massachusetts Institute of Technology and Rochester Institute of Technology. Motorola worked with Purdue University. Procter & Gamble Company worked with University of Wisconsin at Madison and Tuskegee University. Xerox worked with Carnegie Mellon.

Work on quality management concepts and tools has continued into the twenty-first century. Works such as *Process Improvement and Quality Management in the Retail Industry, Quality Management In Construction,* and *Quality Management in Health Care* have appeared in recent years to apply quality management techniques to areas such as retail, construction, healthcare, software development, and more. While quality may no longer be the hot new management idea that it was in the 1980s, the quality revolution has succeeded, making quality management techniques a permanent part of the global business world.

QUALITY OF WORK LIFE

In the fast-paced, high-technology world of the twenty-first century, the work environment is significantly different than it was a generation ago. Many employees these days feel they are working harder, faster, and longer hours than ever before, and work-related stress levels are notably higher than in past decades. Job-related employee stress can lead to lack of commitment to the corporation, poor productivity, and even leaving the company, all of which are of serious concern to management. Because of laptops, cell phones, and personal digital assistants (PDAs), employees bring work home with them on a regular basis and find it harder to escape from work concerns. It is also

Table 1

Work-Life Programs

1. Alternate Work Arrangements
   a. Telecommuting
   b. Flextime
   c. Alternate Work Scheules
2. On-site Childcare
3. Exercise Facilities
4. Relaxed Dress Codes
5. Mentoring Programs

now very rare for a person to stay with a single company his or her entire working life, and it is not uncommon for a person to change careers up to ten times in his or her lifetime. Because employees are often willing to leave a company for better opportunities, companies feel the pressure to find ways of luring and retaining qualified employees. These factors have all forced employers to pay more attention to the quality of work life.

More and more companies are starting to realize that a happy employee is a productive employee, and they have started to look for ways to improve the work environment. Many have implemented various work-life programs to help employees, including alternate work arrangements, on-site childcare, exercise facilities, relaxed dress codes, and more. Quality-of-work-life programs go beyond work/life programs by focusing attention less on employee needs outside of work and realizing that job stress and the quality of life at work bears more directly on worker satisfaction. Open communications, mentoring programs, and fostering more amicable relationships among workers are some of the ways employers are improving the quality of work life.

WORK-RELATED STRESS

As employers try to address employee turnover and job satisfaction issues, they must first determine what the issues are. Several companies have convened focus groups and conducted employee-satisfaction surveys to find out how their employees feel and to determine what they can do to make their employees happy.

Workplace stress has increased in intensity and societal concern over the past three decades. Beginning in the 1990s, mental health professionals began noting the disturbing rise of work-related stress. Even with the unprecedented prosperity of the late 1990s, work-related stress rose continuously during that decade and continued to increase in the twenty-first century. In 2007 the American Psychological Association (APA) reported that one-third of Americans are living with extreme stress, with work cited as the most common source of stress (74%).

Employees are also calling in "sick" in increasing numbers, largely because of stress.

The increasing incidence of work-related stress has wide-ranging effects, including absenteeism, impaired teamwork, workplace violence, decreased efficiency, and burnout. A 2005 survey (reported in the *Silicon Valley/ San Jose Business Journal*) found that only 38 percent of the employees who called in sick were actually suffering from a physical illness. The other 62 percent of these workers who failed to show up were dealing with stress, family issues, morale issues, and motivational issues.

One of the more stressful professions today is in the Information Technology (IT) field. Not long ago, IT professionals were extremely well respected and in demand. As technology advanced rapidly, there was a high demand for programmers and engineers. Most had their choice of high-paying jobs as technology companies competed to recruit the best of these employees. This is not the case today. In June 2004, Meta Group, Inc. surveyed 650 companies and found that nearly 75 percent of the companies acknowledged morale problems among their IT staffs. This number was up from the year before, which showed that two-thirds cited poor worker morale as an issue. Perhaps this is because the U.S. technology sector experienced widespread layoffs during the third quarter of 2004. In general, when layoffs happen the remaining employees are forced to pick up the workload of those who were laid off. This leads to added responsibility and longer work hours, often without additional compensation. This in turn leads to stress, burnout, and resentment. Other causes of employee dissatisfaction include low wages, lack of challenges, insufficient resources, unrealistic expectations, pressure to produce, willfully blind management, unreasonable policies and procedures, difficulty balancing family and work, and increased health benefit costs.

ADDRESSING QUALITY OF WORK LIFE ISSUES

There are a number of independent organizations that conduct employee surveys to gather this information and offer recommendations for reducing work-related stress and improving the quality of work life. One such organization is the Families and Work Institute (FWI; www.familiesandwork.org), a nonprofit research center "that provides data to inform decision-making on the changing workforce and workplace, changing family, and changing community." Founded in 1989, FWI is known for ahead-of-the-curve, non-partisan research into emerging work-life issues; for solutions-oriented studies addressing topics of vital importance to all sectors of society; and for fostering connections among workplaces, families, and communities.

The FWI's National Study of the Changing Workforce (NSCW) periodically surveys a nationally representative sample of employed workers; it is designed to collect and compile information on the work and personal/family lives of the U.S. workforce. The study is widely used by policymakers, employers, the media, and all those interested in the widespread impacts of the changing conditions of work and home life.

The 2002 NSCW showed a slight increase from 1992 in the number of companies that offer work-life supports on the job—both specific benefit entitlements and less formal policies and practices. Despite this, the survey showed a large increase in the number of employees with families who felt there was interference between their jobs and their family lives, than employees 25 years ago. The NSCW also found "the importance of supportive work-life policies and practices, such as flexible work arrangements, is clear—when they are available, employees exhibit more positive work outcomes, such as job satisfaction, commitment to employer, and retention, as well as more positive life outcomes, such as less interference between job and family life, less negative spillover from job to home, greater life satisfaction, and better mental health."

ALTERNATE WORK ARRANGEMENTS

Many employers have found it beneficial to allow alternate work arrangements for their employees. This is one way to improve employee productivity and morale. There are three alternate arrangements that are widely used today: telecommuting, flextime, and alternate work schedules.

Telecommuting describes the work situation in which the employee works outside of the office, usually at home or at a location closer to home. In general, when one telecommutes, he or she communicates with the office via telephone and e-mail, and may go into the office periodically to touch base with the employer and to attend meetings. Advancements in technology have made this possible for many people to telecommute. The telecommuting employee may be able to access files on the office's network from remote locations. And with conference call, videoconferencing, and WebEx capabilities, the employee can *attend* meetings from other locations. With WebEx technology, meeting attendees can sit at their own computers and view the meeting organizer's computer desktop via the Internet. As the meeting organizer opens applications and moves the mouse on his or her computer, the remote attendees can see those same applications and movements as if they were running them on their own computers.

Flextime is another name for flexible work hours. Although most employees with flextime do work a full eight-hour day, they can start and end the workday at a time agreeable both to the employer and to the employee, rather than the traditional 8:00 a.m. to 5:00 p.m. work day. Most employers require their employees to be in the office during "core hours," such as 10:00 a.m. to 2:00 p.m. but do not mandate the start and end times.

Alternate work schedules, like flexible schedules, involve working outside of the traditional 8 to 5 workday. However, alternate schedules have a fixed start and end time, whereas flextime allows the employee to vary the start and end as long as they are there during the core hours. An alternate schedule may be 6:00 a.m. to 3:00 p.m. or 11:00 a.m. to 8:00 p.m. five days a week, or it may be four ten-hour days, or any other *different* schedule.

The advantages of these alternate work arrangements to the employee include flexible work hours, shorter or no commute, and a comfortable working environment. The advantages to the employer include less need for office space, increased productivity, lower use of sick leave, and improved employee morale. The benefits of not commuting were dramatically demonstrated when gas prices began spiking into the $4 per gallon range in mid-2008, driving up commuting costs significantly without a corresponding increase in wages.

While there are many advantages to these alternatives, there are also several disadvantages that the employer must consider. These include problems maintaining adequate staffing coverage, difficulty scheduling meetings, lack of interpersonal dynamics, and concerns about safety and security (for flextime and alternate schedule employees who come in early or leave late). Whatever the disadvantages, alternate work arrangements are becoming more and more popular as companies realize that they can keep costs down—and employees happier—by offering options for telecommuting, flextime, and alternate work schedules. One study showed that the number of telecommuting jobs is rising sharply in the United States. In 2004, it was estimated that 44.4 million workers were telecommuting at least once a week; this is 7.5 percent higher than in 2003.

THE FUTURE OF QUALITY OF WORK LIFE

Although the difficult economic times of the mid-2000s often led employees to mute their concerns over quality of work life issues, employees in the future will likely be looking for corporations that have a new work environment, one that encourages each employee to work toward improvement in the product or service; gives employees the responsibility and authority to make decisions; provides timely feedback; and rewards employees based upon

the quality of the product and efforts. Team effort will assume central importance, especially for self-directed work teams. Employees will choose employers who have aims and values that match theirs and who value balance in their employees' lives. Employees want to learn and advance, so opportunities for professional growth will attract employees.

To improve the quality of work life and eliminate job stress, employers can also make efforts to be more aware of the workload and job demands. Employers need to examine employee training, communication, reward systems, coworker relationships, and work environment. Employees often are able to give employers the best advice on reducing work stress.

REINFORCEMENT THEORY

Reinforcement theory is the process of shaping behavior by controlling the consequences of the behavior. In reinforcement theory, a combination of rewards and/or punishments is used to reinforce desired behavior or extinguish unwanted behavior. Any behavior that elicits a consequence is called *operant behavior,* because the individual operates on his or her environment. Reinforcement theory concentrates on the relationship between the operant behavior and the associated consequences, and is sometimes referred to as operant conditioning.

BACKGROUND AND DEVELOPMENT OF REINFORCEMENT THEORY

Behavioral theories of learning and motivation focus on the effect that the consequences of past behavior have on future behavior. This is in contrast to classical conditioning, which focuses on responses that are triggered by stimuli in an almost automatic fashion. Reinforcement theory suggests that individuals can choose from several responses to a given stimulus, and that individuals will generally select the response that has been associated with positive outcomes in the past. E.L. Thorndike articulated this idea

in 1911, in what has come to be known as the *law of effect.* The law of effect basically states that, all other things being equal, responses to stimuli that are followed by satisfaction will be strengthened, but responses that are followed by discomfort will be weakened.

B.F. Skinner was a key contributor to the development of modern ideas about reinforcement theory. Skinner argued that the internal needs and drives of individuals can be ignored because people learn to exhibit certain behaviors based on what happens to them as a result of their behavior. This school of thought has been termed the behaviorist, or radical behaviorist, school.

REINFORCEMENT, PUNISHMENT, AND EXTINCTION

The most important principle of reinforcement theory is, of course, reinforcement. Generally speaking, there are two types of reinforcement: positive and negative. Positive reinforcement results when the occurrence of a valued behavioral consequence has the effect of strengthening the probability of the behavior being repeated. The specific behavioral consequence is called a reinforcer. An example of positive reinforcement might be a salesperson that exerts extra effort to meet a sales quota (behavior) and is then rewarded with a bonus (positive reinforcer). The administration of the positive reinforcer should make it more likely that the salesperson will continue to exert the necessary effort in the future.

Negative reinforcement results when an undesirable behavioral consequence is withheld, with the effect of strengthening the probability of the behavior being repeated. Negative reinforcement is often confused with punishment,

but they are not the same. Punishment attempts to decrease the probability of specific behaviors; negative reinforcement attempts to increase desired behavior. Thus, both positive and negative reinforcement have the effect of increasing the probability that a particular behavior will be learned and repeated. An example of negative reinforcement might be a salesperson that exerts effort to increase sales in his or her sales territory (behavior), which is followed by a decision not to reassign the salesperson to an undesirable sales route (negative reinforcer). The administration of the negative reinforcer should make it more likely that the salesperson will continue to exert the necessary effort in the future.

As mentioned above, punishment attempts to decrease the probability of specific behaviors being exhibited. Punishment is the administration of an undesirable behavioral consequence in order to reduce the occurrence of the unwanted behavior. Punishment is one of the more commonly used reinforcement-theory strategies, but many learning experts suggest that it should be used only if positive and negative reinforcement cannot be used or have previously failed, because of the potentially negative side effects of punishment. An example of punishment might be demoting an employee who does not meet performance goals or suspending an employee without pay for violating work rules.

Extinction is similar to punishment in that its purpose is to reduce unwanted behavior. The process of extinction begins when a valued behavioral consequence is withheld in order to decrease the probability that a learned behavior will continue. Over time, this is likely to result in the ceasing of that behavior. Extinction may alternately serve to reduce a wanted behavior, such as when a positive reinforcer is no longer offered when a desirable behavior occurs. For example, if employees are continually praised for the promptness in which they complete their work for several months, but receive no praise in subsequent months for such behavior, their desirable behaviors may diminish. Thus, to avoid unwanted extinction, managers may have to continue to offer positive behavioral consequences.

SCHEDULES OF REINFORCEMENT

The timing of the behavioral consequences that follow a given behavior is called the reinforcement schedule. Basically, there are two broad types of reinforcement schedules: continuous and intermittent. If a behavior is reinforced each time it occurs, it is called continuous reinforcement. Research suggests that continuous reinforcement is the fastest way to establish new behaviors or to eliminate undesired behaviors. However, this type of reinforcement is generally not practical in an organizational setting. Therefore, intermittent schedules are usually employed. Intermittent reinforcement means that each instance of a desired behavior is not reinforced.

There are at least four types of intermittent reinforcement schedules: fixed interval, fixed ratio, variable interval, and variable ratio.

Fixed interval schedules of reinforcement occur when desired behaviors are reinforced after set periods of time. The simplest example of a fixed interval schedule is a weekly paycheck. A fixed interval schedule of reinforcement does not appear to be a particularly strong way to elicit desired behavior, and behavior learned in this way may be subject to rapid extinction. The fixed ratio schedule of reinforcement applies the reinforcer after a set number of occurrences of the desired behaviors. One organizational example of this schedule is a sales commission based on number of units sold. Like the fixed interval schedule, the fixed ratio schedule may not produce consistent, long-lasting, behavioral change.

Variable interval reinforcement schedules are employed when desired behaviors are reinforced after varying periods of time. Examples of variable interval schedules would be special recognition for successful performance and promotions to higher-level positions. This reinforcement schedule appears to elicit desired behavioral change that is resistant to extinction.

Finally, the variable ratio reinforcement schedule applies the reinforcer after a number of desired behaviors have occurred, with the number changing from situation to situation. The most common example of this reinforcement schedule is the slot machine in a casino, in which a different and unknown number of desired behaviors (i.e., feeding a quarter into the machine) is required before the reward (i.e., a jackpot) is realized. Organizational examples of variable ratio schedules are bonuses or special awards that are applied after varying numbers of desired behaviors occur. Variable ratio schedules appear to produce desired behavioral change that is consistent and very resistant to extinction.

REINFORCEMENT THEORY APPLIED TO ORGANIZATIONAL SETTINGS

Probably the best-known application of the principles of reinforcement theory to organizational settings is called behavioral modification, or behavioral contingency management. Typically, a behavioral modification program consists of four steps:

1. Specifying the desired behavior as objectively as possible

2. Measuring the current incidence of desired behavior

3. Providing behavioral consequences that reinforce desired behavior

4. Determining the effectiveness of the program by systematically assessing behavioral change

Reinforcement theory is an important explanation of how people learn behavior. It is often applied to organizational settings in the context of a behavioral modification program. Although the assumptions of the theory are often criticized by academic psychologists, extended discussions of behavior modification theory in recent textbooks on organizational management—such as *Management of Organizational Behavior* (2007) and *Organizational Behavior and Management* (2007)—indicate that this theory continues to offer important insights to managers and organizational leaders.

However, Pinder's updated edition of *Work Motivation in Organizational Behavior* (2008) asserts that the recent scientific literature on behavior in the workplace shows that behavior is affected by many factors (such as frustration and violence, power, love, and sex, etc.) which are not typically treated in standard texts on work motivation and organizational management.

REQUEST FOR PROPOSAL (RFP)

A request for proposal (RFP) is a purchasing and procurement instrument that enables buying organizations to solicit high-quality products and services from the market at the most favorable prices; this is done by selecting potential suppliers through competitive bidding. Organizations issue RFPs with the ultimate objective of eliminating lengthy price negotiations for the supply of goods and services. RFPs are designed to achieve special partnerships or contractual relationships between buying parties and supplying agencies by spreading mutual benefits and the value addition of competitive advantage.

BENEFITS OF AN RFP

Typical RFPs have open specifications that leave the preference of response formats and structures to the absolute choice of suppliers, so that the stated requirements can be met by many suppliers. Indeed, open specifications provide suppliers with the opportunity to express their distinctive characteristics through their creative and innovative standards. Buying organizations can then use this information to gauge the individual capabilities of each supplier.

RFPs enable both small-scale and large-scale organizations to access markets and purchase products and services either directly or indirectly by utilizing the benefits of price transparency induced by competition among suppliers. Therefore, buying organizations can use RFPs as leverage for obtaining substantial price reductions and generous discount without having to participate in any negotiations with the suppliers. RFPs further portend the advantage of achieving significant market accessibility for small organizations when sourcing for products and services because RFPs enable organizations to discover opportunities for lower prices by initiating business-to-business relationships.

RFPs comprehensively summarize the preferential characteristics for products or services which buying organizations intend to achieve by spending on the acquisition of particular inputs. RFPs also indicate the long-term and short-term business objectives behind the acquisition of assets by organizations. Consequently, it is incumbent upon suppliers to base the perspectives of their offerings on the detailed insights of the buyers' specifications. An ideal RFP has the following key features:

- Price quotations
- Contract duration
- Performance limits
- Stipulated business requirements
- Item listings
- Guidelines for responding
- Submission deadlines
- Evaluation criteria
- Contacts for channeling inquiries
- Address of the company or organization

All these features are backed by stringent conditions through which organizations monitor the compliance of suppliers to the set guidelines for purchasing and procurement. For example, the U.S. military equipment acquisition system emphasizes innovation and reengineering as the prerequisite conditions for considering suppliers.

The use of RFPs by organizations to specify procurement requirements is viewed as a systematic and best

practices gesture that is closely linked to the transaction cost theory and resource-based theory.

TRANSACTION COST THEORY

Proposed by Ronald Coase (1910) and Oliver E. Williamson (1932), transaction cost theory (TCT) weighs the cost of acquiring goods or services from the market place against the cost of acquiring the same goods and services from within an organization. TCT focuses on the key aspects of transaction costs, asymmetrical information distribution, and asset specificity. Aspects of transaction costs include: costs for searching and bargaining, costs for bargaining and decision-making, and costs for policing and enforcing new structures vis-à-vis an organization's operational standards. The aspect of asymmetrical information distribution recognizes the fact that different parties involved in a transaction experience uneven access to information, a situation that may call for closer cooperation between or among the different parties for purposes of mutual benefits.

RESOURCE-BASED THEORY

Advanced by John Kay (1704–1780), resource-based theory (RBT) recognizes that each organization is characterized by unique sets of resources, opportunities, and core competencies. According to RBT, a firm can pursue competitive advantage by exploiting and combining its distinctive characteristics such as corporate architecture, innovation, and reputation, which are difficult to emulate. The idea of corporate architecture revolves around organizational characteristics such as the capacity to create, utilize, and store knowledge, as well as such characteristics as transparency, organizational flexibility, and employee cooperation. Innovation defines the capacity to reduce costs, improve service or product qualities, introduce new products and technologies, and emphasize best practices; this can often only be achieved through collaboration with other players external to the organization.

The arguments presented by the proponents of the two theories are in tandem with the primary purpose of RFPs, which is to contribute to the profitability of a firm by acquiring products and services of the highest qualities at the least possible total cost. Ultimately, the derivative satisfaction of the organization entirely depends on the acquisition of reliable supplies.

REQUEST FOR QUOTATION

Although an RFP is closely related to request for quotation (RFQ), the two forms of requests exhibit quite some considerable differences. In most cases, RFQ's serve as the preceding step to RFPs. Buying organizations use RFQs as tools for comparing quotes in situations where products or services are extremely commoditized or standardized.

For example, an organization seeking hotel accommodation services in a particular city can use an RFQ to source for the best prizes because of the standardized nature of accommodation rates of different hotels.

In addition to seeking specific price per unit for items, an ideal RFQ spells out the exact descriptive details for items such as quantity, quality, referees, skills, competencies, terms of service, transportation, shipping, tax settlement responsibilities, and terms and conditions. As such, price comparisons form the basis for choosing and engaging suppliers. Other forms of sourcing requests that can be used by buying organizations in procurement processes include request for tender (RFT) and request for information (RFI).

DESIGNING AN RFP

Many organizations have developed standardized RFP templates as a way of entrenching RFPs into the routine activities of the organizations. This is because standardized templates provide organizations with the advantage of accelerating the timeframe for procurement processes, especially in large firms which deal with high volumes of products and services. However, it must be noted that the use of standardized and automated RFPs does not guarantee a procurement process that is free of errors and administrative hitches.

The diversity of business requirements and customer demands can only be harnessed effectively if procurement processes are tailored to suit each and every need. Automated RFP software tools and standardized forms create uniformity of response that makes it difficult to ascertain differences in the qualities of products that different suppliers offer. Moreover, such a standardized approach makes it difficult for the buying organizations to base the vetting criteria on the creativity and innovative standards of the suppliers, especially in the outsourcing of large-scale services and transactions.

Therefore, the optimization of product and service qualities at the least possible cost should always be the overriding principle for composing and designing an RFP. This can only be achieved by designing an RFP that takes into account the diverse and competitive nature of the procurement environment. In this regard, an effective RFP should exhibit the following characteristics: define service boundaries; demonstrate flexibility; pronounce the criteria for evaluating performance; state discrete conditions; and establish contractual and binding relationships.

Defining Service Boundaries. An RFP must be as explicit and self-explanatory as possible, especially when sourcing for technological commodities or services that are complex in nature. An RFP must clearly state and define the scope of responsibilities, relationships, or partnerships

between the buying organizations and vendors. Buying organizations must never take the procurement process for granted by assuming that vendors are always ready to respond to any kind of an RFP without considering what the RFP offers. For example, an RFP that does not create a balance between possible risks and achievable benefits is unlikely to ignite much enthusiasm among suppliers, thus eliminating a competitive bidding environment.

Organizations can avoid such eventualities by designing RFPs that promote a competitive bidding environment with the potential to attract multiple suppliers who possess high qualifications for providing the best qualities of goods and services at favorable rates. Organizations can also achieve clarity on the nature of services being procured by preceding the issuance of RFPs with RFIs and RFQs. This will eliminate the likelihood of vendors misinterpreting the buyer's requirements because of ambiguity and uncertainty posed by buyer expectations.

Demonstrating Flexibility. RFPs that require lengthy and complicated selection processes may lock out potential suppliers. Similarly, RFPs with rigid response structures and overstated compliance conditions automatically disqualify many potential vendors from participating in procurement processes. These problems can be avoided through a comprehensive but balanced approach that ensures the organization is guarded from unqualified suppliers and at the same time leaves adequate room for suppliers to maneuver their aspirations. A flexible RFP also demonstrates the transition strategies for switching from an incumbent to a new supplier or for adopting new products or services from suppliers.

Pronouncing the criteria for evaluating performance. An ideal RFP should spell out clear guidelines for performance under specified conditions, either by means of a test or through the use of initial sample products and/or services. Other evaluation items—such as the criteria for passing tests as well as acceptable standards of performance—should be outlined with clarity and certainty.

Stating discrete conditions. In practice, RFPs should clearly indicate standards for passing or determining the fitness of required products or services. The specific requirements of the purchasers should always form the centerpiece of communications between the buyers and sellers of goods and services.

Establishing contractual and binding relationships. An RFP should have the capacity to bind a contractual relationship between a buyer and supplier. Consequently, an RFP should stand out as a reliable document against which comparisons between what a supplier finally delivers and specifications for orders can be based. In the event

of a dispute in a future date, an RFP can be referenced as a primary document through which a purchaser and a supplier established a framework for contractual relationship. However, due diligence must be observed to ensure that the legal implications of each and every specification contained in an RFP do not contradict limits set by the national and international standards of environmental, health, business, and/or safety regulations.

RESEARCH METHODS AND PROCESSES

In any organization, managers at all levels need accurate and timely information for managerial decision making. Whether the decisions made are at technical, tactical, or strategic levels, good, accurate, and timely information always leads to a better decision. Gathering of information is done through a sound and scientific research process. Each year organizations spend enormous amounts of money for research and development in order to maintain their competitive edge. Accurate information obtained through research leads to enormous benefits.

APPLIED VERSUS PURE RESEARCH

Research can be defined as scientifically and methodically delving into the unknown in order to provide information for solving problems. The heart of this definition is the concept of problem solving. Both applied and pure (also known as basic) research attempt to solve problems. In applied research, the researcher attempts to solve a known problem and find answers to specific questions. In other words, the emphasis of applied research is on practical

problem solving. For instance, when a paper recycling company wants to determine whether or not their recycled papers meet the required specification as to the thickness of the paper across the roll, they might design a systematic procedure for answering this specific question. The research in such a situation represents applied research. Applied research might also involve making predictions. For example, an online magazine might want to predict the number of click-throughs on its ads for the following quarter; in this case, the practical problem is predicting this number and determining which variables are good predictors.

Applied research can help make a decision about the following, including a variety of other business and management decisions:

- Pricing a new product

- Where to locate a new retail store

- How many employees to hire

- How many products to offer

- What to pay employees

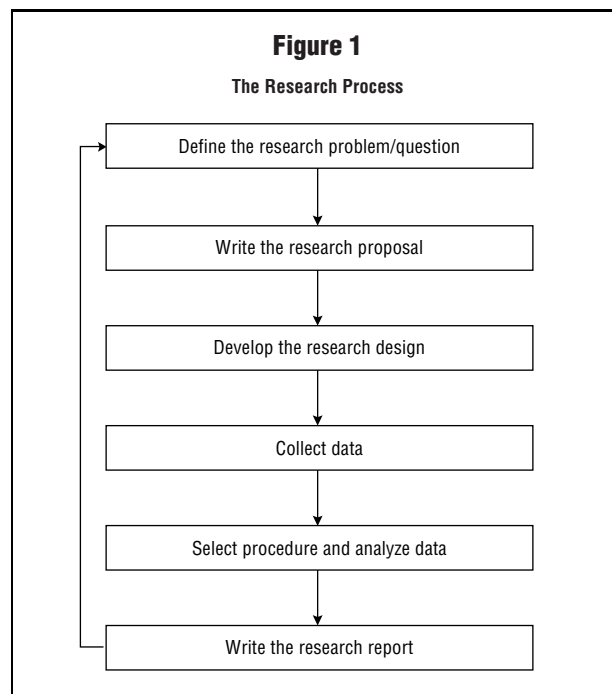
Applied research can be used to collect information about markets, competitors, and customers. For example, research can help pinpoint the optimal business location and the size of markets. It can also be used to monitor competitive actions. Customer research determines customer loyalty, customer satisfaction, and customer preferences.

On the other hand, pure, or basic, research does not necessarily try to answer specific questions or solve specific problems. Pure or basic research is done in order to expand knowledge and probe into the unknown. For example, when a researcher is interested in determining how employee demographics and tenure on the job relate to preference for flexible work schedules may represent pure research. Both pure and applied research deal with problem definition and problem solving. Most basic research is conducted by professors in academic institutions (i.e. colleges and universities), by the government, or by consulting firms. Few business organizations will engage in pure research related to business problems, although firms in certain industries—such as pharmaceuticals or defense—will engage in pure research in the hope of opening new markets. For all firms, it is important to understand the process and methods used for both applied and basic research in order to be able to interpret research results accurately and effectively.

RESEARCH PROCESS

All research involves several chronological steps, but that does not mean each step must be completed before the next step is undertaken. Furthermore, the process of research is dynamic and the process may change as the

Figure 1

The Research Process


research progresses. The steps involved in most research endeavors are shown in Figure 1.

THE RESEARCH QUESTION

Managers' needs for information are the primary source of problem definition and the research question. Managers need information to make educated decisions arising from unanticipated as well as planned changes. As such, managers must select between different alternatives and thus require information about the organization and its environment. The question to be answered or the problem to be solved must first be clearly defined. Questions to be answered could be very specific or extremely broad. The more specific the questions, the easier it will be to answer the research questions. There might be hypotheses that could be tested scientifically. Once the questions to be answered are clearly defined, then the value of the research must be assessed. Clearly, if the costs of performing the research project exceed the value that the research will provide, then the project should not be continued.

THE RESEARCH PROPOSAL

Research endeavors require a proposal that explains the problem to be addressed and the procedure by which the questions will be answered. The researcher's proposal tells the managers what they should expect from the research. It is a contract between the managers and the researcher. For instance, if a company wants to know the degree to which its new incentive program is effective in improving

employee performance, then the consultant or employee conducting the research will create a proposal that indicates to that company how the question will be addressed and what specific information the company will have at the end of the research process. The proposal may indicate, for example, that the research will indicate the level of satisfaction of employees with the new incentive plan, the increased firm performance with the plan, and the individual increases in performance (as measured by managers) with the incentive plan. The purpose of the research proposal is to effectively guide the researchers in their development of the research design and data collection to answer the specific research questions.

RESEARCH DESIGN

Once the proposal is approved, the researcher has a foundation for development of the research design. The plan for conducting the research is the research design. There are two general forms of research design, namely non-experimental (ex-post-facto) and experimental. In a non-experimental design, the researcher does not control or alter any of the independent variables. The researcher merely studies existing situations, variables, and the inter-relation among variables and reports the results of his or her findings. The two major non-experimental designs are field studies and surveys. Field studies combine literature review and possibly analysis of some case studies. For example, if one is interested in determining the effectiveness of total quality management (TQM), there will be a thorough literature search on the topic as well as a study of the firms that have applied TQM and have been successful. A literature review means that a researcher identifies previous writings and research on a topic, summarizes the current knowledge on the topic, and assesses the value of that prior research on the current problem. On the other hand, surveys deal with the formulation of a questionnaire (survey instrument) by which one can measure the magnitude of the desired variables as well as the interrelation among the variables. Non-experimental designs are primarily exploratory in nature and provide descriptive measures and can also be used for predictive purposes.

There are two broad categories of experimental designs: field and laboratory. In both field experiments and laboratory experiments, the researcher controls and may alter and introduce some variables in order to determine the effect of a given variable. Field experiments are done in a natural setting, whereas laboratory experiments are undertaken in a simulated setting. Studies on the effectiveness of different configurations of teams and their level of effectiveness can be undertaken in both field and office settings. In an office setting, a researcher might organize workplace teams, using different criteria to estab-

lish each, and then measure the success of their group interactions and their productivity on real work tasks. This would be a natural setting, except for the way in which teams were organized. Team composition could also be studied in a laboratory in which the researchers had complete control over more variables. To study team effectiveness in a laboratory setting, individuals would be placed in teams using different criteria, then asked to perform a series of tasks specially designed to measure team interactions and performance. This laboratory setting would allow the researcher more control, because the types of individuals involved could be chosen, rather than using only the employees available in a field setting; by designing tasks specific to the study, rather than using existing work tasks; and by having more ability to watch and measure team performance without hindering organizational performance.

DATA COLLECTION

Data collection is the process of gathering the specific information used to answer the research questions. There are a number of issues associated with data collection, including the use of primary or secondary data, survey design, sampling, survey administration, and increasing response rates.

Primary Data and Secondary Data. Data can be primary or secondary, and whether one or both are used, and which is used, depends largely on the research question and the availability of these data sources. Secondary data refer to data gathered by others. Secondary data is generally less costly and less time consuming than gathering primary data, typically is accumulated before primary data is gathered, and may even help determine the course by which primary data is pursued. When a company uses data from the U.S. Census Bureau, for example, the company is using secondary data. While secondary data can be used for background information about specific research, it may also answer some specific research questions. For instance, the 2007 Census Bureau report on building permits can indicate to researchers where construction activity is taking place most vigorously.

It should be noted that secondary data was usually collected for another purpose; therefore, it may not adequately address the new research question, or it may do so in a way, and using terms, that differ from the present purposes. In today's world of rapidly growing information technologies, secondary data are available from numerous sources. A researcher should explore the existing data before starting the research process, since there are datasets for many different types of information currently available. There are abundant data available in literature, company

records, government publications, trade associations, and through the Internet.

Primary data is that which is collected by the researcher to address the current research question. Types of primary data include subject demographics, lifestyle characteristics, attitudes, knowledge, intentions, motivations, and behavior. Demographic data includes statistics regarding populations, such as age, sex, income, level of education, and so forth. Lifestyle characteristics describe a respondent's activities, interests, and opinions. Attitudes refer to views and opinions about things, events, or ideas. Knowledge is the degree to which respondents are aware of these things, events, or ideas. Intentions generally refer to a respondent's planned future behavior. Motivations describe the reasons behind a respondent's behavior. Behavior is related to what respondents do.

Primary data can be collected in the field or the laboratory through communication and observation. Communication generally requires the direct questioning of respondents via a paper-and-pencil survey (i.e., questionnaire) or telephone survey. Observation involves the direct recording of respondent behavior. Surveys are probably the most common design in business research. For instance, if one is interested in determining the success of TQM, a survey can be designed that encompasses questions regarding elements of success, strengths, weaknesses, and other questions dealing with TQM. Then the survey can be sent to companies that have been successful in implementing TQM. The survey results could shed light on many aspects of TQM.

Survey Design. Survey design is of major importance, because if a survey is poorly designed, it will not provide the researchers with the data that addresses the research question. Survey questions, called items, must be properly chosen to elicit appropriate respondent answers. The steps involved include determining the information that will be sought, the type of questionnaire, the method of administration, the content of individual questions, the form of response to each question, the wording of each question, the sequence of questions, the physical characteristics of the questionnaire, and, finally, pretesting the questionnaire.

Some items for certain areas of interest already exist. For instance, there are existing surveys that measure employees' satisfaction with pay and benefits. If survey items do not already exist in the published literature, the researchers must create their own items, based on their review of the existing literature and their own expertise. Often, a focus group of experts can also help to create items. For example, if a company wants to assess its employees' attitudes towards an intended change in work rules, the researcher may lead a focus group of several experienced company managers to capture all of the rel-

evant ideas that need to be addressed by the survey. Before the survey instrument is sent out, it must be tested for reliability and validity. Reliability refers to how consistently the instrument measures, and validity refers to whether the instrument is measuring.

One concern when designing a survey is how to word the items. One of the most popular ways to measure attitudes on a survey is by using the Likert scale. This method presents a series of statements to respondents for which they are asked to indicate the degree to which they agree with the statements. An example of a statement might be "The sales people are helpful." Respondents are asked to indicate the degree to which they agree with the statements by checking either SA (strongly agree), A (agree), N (neither agree nor disagree), D (disagree), or SD (strongly disagree). Respondents' answers would then be scored where SA = 5, A = 4, N = 3, D = 2, and SD = 1. A total score would be computed by average or summing scores on related items.

Sampling. When administering a questionnaire there are two options as to who should complete the survey. Option one is to give the questionnaire to everyone in the targeted population. This is called a census. However, a census is usually not practical or cost effective. For instance, you may not be able to survey every one of your customers from last year to determine levels of customer satisfaction with your products. Consequently, in order to save time and money, only a sample or subset of the target population receives the questionnaire.

When selecting individuals for a sample, either a probability approach or a nonprobability approach can be used. Probability samples are those where each element of the population has a known probability of being selected. A random sample, for example, is the case where each element has the same probability of being selected. There are some specific types of nonprobability samples: convenience samples, judgment samples, and quota samples. Convenience samples are chosen at the convenience of the researcher. For example, a researcher might distribute a survey to all customers who enter one retail store in a one-week period to determine their level of customer satisfaction with the company's products. This sample is rather easy to select, but it may not represent the full range of customers who have used that product. In a judgment sample, individuals are selected by the researcher because they are believed to represent the population under study. Quota samples attempt to make the sample representative of the population under study where quotas are set for specific groups of people, which are generally selected on the basis of demographic characteristics.

The chief advantage of a probability sample over a nonprobability sample is the ability to assess the reliability and the amount of sampling error in the results. For

example, if the goal were to estimate the annual household income for a given county, probability sampling would allow an accuracy assessment of the estimate. This could not be accomplished with a nonprobability sample.

Survey Administration. After the survey has been designed and its reliability and validity assessed, the company must decide the administration method that it will use. Each administration method has its own advantages and disadvantages in terms of cost, information control, sampling control, and administrative control. Information control refers to the possible variation in responses to questions. Sampling control is the ability to select cooperative respondents. Administrative control refers to factors affecting the efficiency of the survey, including timing, quality control, and standardization.

Personal interviews are generally the most expensive means of data collection. In a company, this would mean having researchers meet with employees one-on-one to ask them the survey questions and record their responses. One of the main advantages of the personal interview is the ability to ask any type of question, including an open-ended question, and to adapt to the respondent's answers. However, in addition to being expensive and time consuming, this method is not anonymous, and therefore respondents may be reluctant to answer questions that they feel are sensitive or invasive.

The mail questionnaire is usually the least expensive method of data collection. Besides cost savings, another advantage of the mail questionnaire is its wide distribution potential. However, mail questionnaires cannot control the speed of responses, and the researcher cannot explain ambiguous questions. Mail questionnaires are probably best utilized when asking personal or sensitive questions, particularly if the survey can be made anonymous. Questionnaires can be circulated using various methods, such as post, electronic mail, and fax.

The telephone interview is associated with relatively low cost and higher response rates, and is one of the fastest methods of data collection. While there are methods to address the problem, unlisted numbers make it more difficult to obtain representative samples. Establishing rapport is also more difficult in telephone interviewing than in the personal interview.

One survey administration method that is growing in popularity is the Internet survey, in which respondents answer items on a survey that is located on a Web site. Newer, specialized software products are making it easier to conduct online surveys, even for those people with little to no computer programming skills. Studies indicate that Internet research can result in faster responses, lower costs, higher response rates, and better flexibility. Additionally, this method aids in data administration, since survey responses can be directly inserted into a data spreadsheet by the Web survey software.

Response Rates. One of the main concerns of survey research is the response rate, or the number of people who are asked to complete a survey who actually do. Nonresponse error is a source of bias because of the failure to get answers from some of the sample. "Not-at-homes" plague telephone surveyors. Recent laws have created a further difficulty with conducting telephone surveys. In 1999, Great Britain created a "no-call" list. The United States followed in 2003 and Canada in 2004. These lists block commercial telemarketers and surveyors from calling numbers registered by their owners. The widespread use of these lists by telephone customers has significantly limited the use of telephone interviewing for research purposes. At the same time, the Internet has opened other avenues of survey research, and traditional means such as mailings and personal interviews still remain viable.

While research results are mixed regarding effective means for increasing response rates, the following represent some ideas for increasing response rates:

- Give respondents advance notice of the survey.
- Guarantee confidentiality or anonymity.
- Provide monetary incentives.
- Provide a postage-paid return envelope for mail surveys.
- Personalize outgoing envelopes.

DATA ANALYSIS

Research provides data, and it is the task of the researcher to transform the collected data into useful information for management. The first step in data analysis is preparing the data by editing it for several factors, including:

- Completeness—checking for any omissions
- Legibility—making sure that handwriting is understandable so that answers will be coded correctly
- Comprehensibility—making sure the answer is understandable
- Consistency—checking for consistent answers from the respondent
- Uniformity—checking to see that responses are recorded in the same manner

Once the data is edited it is ready for coding, which is determining how survey responses will be transformed into numerical data. The first step in coding is the development of a codebook. The codebook formalizes the coding process by listing answers and their accompanying codes. After

Parts of a Complete Research Report

Research report parts

I. Prefatory section
   A. Title fly
   B. Title page
   C. Letter of authorization
   D. Letter of transmittal
   E. Table of contents
   F. Synopsis or executive summary

II. Introduction to the research
   A. Background comments
   B. Statement of the problem (research question)
   C. Objective of the research

III. Methodology
   A. Research design
   B. Instrument used and data collection
   C. Data analysis and statistical procedures used
   D. Limitations of the study

IV. Findings

V. Summary, conclusions and recommendations

VI. Appendices

VII. Bibliography

the data is coded and entered into a data spreadsheet, statistical analyses can be performed to create useful information for the researchers. If there are hypotheses to be tested, the researcher is in a position to use the gathered data to test the hypotheses. Data analysis could be as simple as reporting descriptive statistics such as averages, measures of variability, and percentages, or if needed, advance statistical techniques could be applied.

RESEARCH REPORT

The research report can be as simple as a short report of a few pages giving the overall findings of the research, or it can be a long report with numerous parts. The degree of formality required by management dictates the type of report to prepare. Figure 2 presents the order of inclusion of the various parts of a long formal report.

Prefatory Section. In this part of the report, first a title fly needs to be prepared. The title fly only includes the title of the report. The title should be carefully worded so it tells the reader exactly what the report is about. Following the title fly is the title page. The title page should include the title of the report, the name and the title of the recipient of the report, and the name and the title of the individual who prepared the report and the date. The letter that authorized the undertaking of the research project, followed by a letter of transmittal indicating the completion of the research report are the next items included in the report. Include a table of contents followed by an executive summary. The executive summary, summarizing the report's

major findings, should be brief and to the point. This summary should briefly explain the conclusions.

Introduction to the Research. This section of the report provides a clear background and statement of the research question and provides information about the objectives of the research. Included in this section would be a literature review about previous studies with the same or a similar problem. If there are hypotheses to be tested, population parameters to be estimated, theories to be considered, they will be incorporated into this section of the report

Research Method. This section will provide a detailed explanation of research design and will provide answers to many questions. What type of design was used? What instruments were used for the collection of data? Were there any subjects involved in the study? What did the subjects do? How was the sample selected? What kind of statistical or non-statistical techniques were used for data analysis? Finally, in this section of the report the limitations encountered in the study should be presented.

Findings. This section is one of the most important parts of the research report. Provided in this section would be the results of the data analyses and explanation of all the findings. At this point, all the raw data have been analyzed and converted to meaningful information for management's use. This is the section where the original research question is answered.

Summary, Conclusions, and Recommendations. A concise yet precise summary of major findings will be included in this section, followed by any recommendations that the researcher considers important and meaningful.

Appendices and Bibliography. Statistical tests, large tables of information, copies of measurement instruments, and supporting documents should be included in the appendices. Finally, the report should end by providing a bibliography of all sources of information.

RESULTS-ONLY WORK ENVIRONMENT

Results-Only Work Environment (ROWE) is a twenty-first century management concept that was invented at Best Buy company headquarters under the tutelage and guidance of Cali Ressier and Jodi Thompson. ROWE is simply a result-oriented work environment that attaches employee retention to output and performance. The distinctive nature of ROWE is defined by the following characteristics:

- No working schedules
- No fixed work stations
- No clocking in and out of work
- Greater performance accountability
- Increased staff morale
- Greater teamwork and cooperation
- Increased output
- No meetings
- Increased employee engagement
- Greater employee flexibility

Ressier and Thompson were serving as employees of Best Buy when they were tasked with the responsibilities of measuring human resource management practices at Best Buy against industry benchmarks, identifying problems and tracing roots of the problems, and suggesting the most appropriate solutions to eliminate the problems. Upon the completion of their research, Thompson and Ressier identified time wasting and lack of motivation among employees as being the biggest hurdles to the achievement of efficiency and increased productivity among employees. The two employees particularly identified the nine-to-five clocking system as being absolutely irrelevant to the prevailing company objectives. (Ressier and Thompson have since left Best Buy and are running a private human resource consultancy firm called CultureX, which guides different organizations in the process of adopting ROWE into their management practices.)

INITIAL IMPLEMENTATION OF ROWE
