Highlights

The 6th edition of the *Encyclopedia of Management (EoM)* presents a completely refreshed look at the vast and continually evolving field of management. Through 316 essays, readers will encounter thousands of terms, issues, and concepts such as:

- Angel Investors and Venture Capitalists
- Apprenticeship Programs
- Benchmarking
- Best Practices
- Coalition Building
- Consumer Behavior
- Corporate Social Responsibility
- Electronic Commerce
- Environmentalism and Sustainability
- Fuzzy Logic
- Globalization
- Hypothesis Testing
- Innovation
- Intellectual Property Rights
- International Management
- The Internet

- Lean Manufacturing and Just-in-Time Production
- Mission and Vision Statements
- Mobile Commerce
- New Product Development
- Organization Theory
- Outsourcing and Offshoring
- Pioneers of Management
- Privacy, Privacy Laws, and Workplace Privacy
- Project Management
- Quality of Work Life
- Social Networking
- Time-Based Competition
- Trends in Organizational Change
- Virtual Corporations
- Web 2.0
- Women and Minorities in Management

The *Encyclopedia of Management's* essays offer a unique starting point for individuals seeking comprehensive information that can't be adequately conveyed through brief dictionary-like definitions. Placed into context, and enhanced by background data as well as graphics and statistics, the topics covered in this volume are of both current and enduring interest.

ADDITIONAL FEATURES

- New to the 6th edition, a management glossary consisting of over 200 management terms
- Contents are arranged alphabetically from A to Z in one volume
- One comprehensive tiered index simplifies accessibility
- Cross-references abound to help readers locate information
- "Further Reading" sections provide source suggestions for further study
- Graphs, charts, and tables
- Math formulas illustrate concepts and models

Composed by business writers, *EoM* represents a substantial contribution to business and management reference. Students, scholars, and business practitioners alike will find a wealth of information in this fully revised source.

Contents

Preface and User's Guide

PREFACE

The *Encyclopedia of Management, 6th Edition* is an alphabetical reference book covering a comprehensive slate of management concepts. Last published in 2005, this fully revised work represents the latest management theories and practices. Each essay has been revised and new essays have been added to reflect the current state of management. The *Encyclopedia's* essays represent an authoritative treatment of the entire field of management, encompassing all the current theories and functional areas of this vast and growing discipline. For the management student, manager, business practitioner, reference librarian, or anyone interested in a better understanding of a business management term or concept, the *Encyclopedia* should be a first-stop for general information as well as a link to other management concepts, related terms, references, and electronic databases and information sources. It is designed to be a desk reference for everyday business management needs.

Still another use of the *Encyclopedia* is in a deeper understanding of one or more key functional areas of management. By using the book as a systematic or a programmed reading of entries in selected categories or cluster areas, the reader can obtain a more thorough, in-depth understanding of key functional areas of management. By reading all the essays for the terms under each heading in the "Guide to Functional Area Readings" (which is the entire list of essays in the volume), individuals with a limited business background, a specialty in another management functional area, or a liberal arts education background can have a broad, general familiarity with the entire scope of the management discipline today in one easy-to-use reference source.

The field of management is an extremely broad discipline that draws upon concepts and ideas from the physical and social sciences, particularly mathematics, philosophy, sociology, and psychology. Within business, the field of management includes terms and ideas also common to marketing, economics, finance, insurance, transportation, accounting, computer technologies, information systems, engineering, and business law.

Management has applications in a wide variety of settings and is not limited to business domains. Management tools, as well as the art and science of management, find applications wherever any effort must be planned, organized, or controlled on a significant scale. This includes applications in government, the cultural arts, sports, the military, medicine, education, scientific research, religion, not-for-profit agencies, and in the wide variety of

for-profit pursuits of service and manufacturing. Management takes appropriate advantage of technical developments in all the fields it serves.

The growth of the discipline of management has also led to specialization or compartmentalization of the field. These specialties of management make learning and study easier, but at the same time make broad understanding of management more difficult. It is particularly challenging to the entrepreneur and the small business owner to master the subject areas, yet this group is compelled to excel at all management functions to further their business's success. Management specialties have grown to such an extent it is difficult for any single manager to fully know what management is all about. So rapid have been the strides in recent years in such subjects as decision making, technology, the behavioral sciences, management information systems, and the like, to say nothing of proliferating legislative and governmental regulations affecting business, that constant study and education is required of all managers just to keep current on the latest trends and techniques. Thus, managers and executives need a comprehensive management desktop reference source to keep up-to-date. Having the management essays in one comprehensive encyclopedia saves valuable research time in locating the information.

In the growing age of specialists, there is a growing lack of generalists. Typically, a business manager spends a large percentage of their career developing a great familiarity and proficiency in a specialized field, such as sales, production, procurement, or accounting. The manager develops a very specialized knowledge in this area but may develop only a peripheral knowledge of advances in other areas of management. Yet as these individuals are promoted from a specialist-type position up the organizational chart to a more administrative or generalist supervisory or leadership position, the person with newly enlarged responsibilities suddenly finds that their horizon must extend beyond the given specialty. It must now include more than just a once-superficial understanding of all aspects of managing, including purchasing, manufacturing, advertising and selling, international management, quantitative techniques, human resources management, public relations, research and development, strategic planning, and management information systems. The need for broader management understanding and comprehension continues to increase as individuals are promoted.

The *Encyclopedia of Management* has had, as its goal, to bridge this gap in understanding and to offer every executive, executive-aspirant, management consultant, and educator and student of management, both comprehensive and authoritative information on all the theories, concepts, and techniques that directly impact the job of management. Building on the solid reputation established in prior editions, this thoroughly updated reference source strives to make specialists aware of the other functional areas of the management discipline and to give the top manager or administrator who occupies the general manager position new insights into the work of the specialists whom he or she must manage or draw upon in the successful management of others. In addition, the *Encyclopedia* proposes to make all practitioners aware of the advances in management science and in the behavioral sciences. These disciplines touch upon all areas of specialization because they concern the pervasive problems of decision-making and interpersonal relations.

USER'S GUIDE AND COMPILATION

Reference, Plus a Planned Reading Program. The information in the *Encyclopedia* is accessible in two forms. First, through the traditional A-to-Z compilation the reader readily has the quick answer to an immediate question or concise background information on any aspect of the field of management. As a handy desktop reference, the information is readily accessible. Second, and of more lasting importance, as a planned reading program for pursuit in depth of any of the functional areas of management—the reader's own M.B.A., if you will. This program is set forth in the **Guide to Functional-Area Readings** located at the end of the frontmatter.

Cross-referencing and Special Features. The arrangement of the essays on a strictly alphabetical basis, rather than by subject categories, makes for extremely rapid and convenient

information retrieval. At the same time, the extensive cross-referencing makes it easy to pursue a major area of interest in any depth of study desired. **"See-title"** cross-references serve to guide the reader directly toward the location of essays that may be recognized by more than one commonly used term. (For example, upon turning to "E-commerce" the see-title cross-reference would direct the reader to turn to "Electronic Commerce".)

Special features found within the essays include the following:

- **"See Also"** references, included at the end of many essays, refer the reader to further topics of closely related interest.

- **Charts, graphs, tables, and formulae** are included as illustrative examples whenever appropriate.

- **Further Reading** sections are included at the end of most entries. The bibliographic and URL citations point the reader toward a variety of suggested online and published sources for further study and research.

Glossary of Management Terms. This glossary defines over 200 management terms, including financial, governmental and general business terms. Cross-references and acronyms are also provided.

Index. Supporting the easy-to-use, extensive system of cross-references, is a comprehensive index at the back of the *Encyclopedia*. The **Index** contains alphabetical references to the following as mentioned in the essays: important or unusual terms; names of companies, institutions, organizations, and associations; key governmental agencies; specific legislation; relevant court cases; names of prominent or historical individuals; titles of groundbreaking literature; and significant studies.

Comprehensive Coverage and Compilation Method. Every effort has been made to achieve comprehensiveness in choice and coverage of subject matter. The 316 essays frequently go far beyond mere definitions and referrals to other sources. They are in-depth treatments, discussing background, subject areas, current applications, and schools of thought. In addition, information may be provided about the kinds of specialists who use the term in a given organization, the degree of current acceptance, and the possibilities for the future as the subject undergoes further development and refinement. Longer essays frequently provide charts, graphs, or examples to aid in understanding the topic.

The authors of all essays followed the editorial process specified for providing the reader an initial overview of the topic followed by information on the variety of management problems the information can be used to solve. Thus, if the reader has little knowledge of a term, after referring to the *Encyclopedia of Management, 6th Edition*, he or she will be in possession of the basics of the subject—objective, scope, implementation, current usage in practice, and expected future usage. With this information, the reader will then be in a position to ask the right kind of questions of specialists and technicians to make sure that the firm (or department, or unit, or agency, etc.) is taking full advantage of the opportunity the term presents.

Guide to Functional-Area Readings

XXIII

Glossary

Account statement: A record of transactions, including payments, new debt, and deposits, incurred during a defined period of time.

Accounting system: System capturing the costs of all employees and/or machinery included in business expenses.

Accounts payable: *See Trade credit*

Accounts receivable: Unpaid accounts which arise from unsettled claims and transactions from the sale of a company's products or services to its customers.

Advertising: A marketing tool used to capture public attention and influence purchasing decisions for a product or service. Utilizes various forms of media to generate consumer response, such as flyers, magazines, newspapers, radio, and television.

Age discrimination: The denial of the rights and privileges of employment based solely on the age of an individual.

Annual report: *(See also Securities and Exchange Commission)* Yearly financial report prepared by a business that adheres to the requirements set forth by the Securities and Exchange Commission (SEC).

Applied research: Scientific study targeted for use in a product or process.

Assets: Anything of value owned by a company.

Audit: The verification of accounting records and business procedures conducted by an outside accounting service.

Average cost: Total production costs divided by the quantity produced.

B2B: Business-to-business e-commerce.

B2C: Business-to-consumer e-commerce.

B2G: Business-to-government e-commerce.

Balance Sheet: A financial statement listing the total assets and liabilities of a company at a given time.

Bankruptcy: *(See also Chapter 7 of the 1978 Bankruptcy Act; Chapter 11 of the 1978 Bankruptcy Act)* The condition in which a business cannot meet its debt obligations and petitions a federal district court either for reorganization of its debts (Chapter 11) or for liquidation of its assets (Chapter 7).

Barriers to Entry: Obstacles that make it difficult for a new company to compete against companies already established in the industry. Examples of such obstatcles include patents, trademarks, copyrighted technology, and a dominant brand.

Basic research: Theoretical scientific exploration not targeted to application.

Benefit: Various services, such health care, flextime, day care, insurance, and vacation, offered to employees as part of a hiring package. Typically subsidized in whole or in part by the business.

Billing cycle: A system designed to evenly distribute customer billing throughout the month, preventing clerical backlogs.

Brainstorming: A group session where employees contribute their ideas for solving a problem or meeting a company objective without fear of retribution or ridicule.

Brand name: The part of a brand, trademark, or service mark that can be spoken. It can be a word, letter, or group of words or letters.

Budget: An estimate of the spending necessary to complete a project or offer a service in comparison to cash–on–

hand and expected earnings for the coming year, with an emphasis on cost control.

Business conditions: Outside factors that can affect the financial performance of a business.

Business cycle: A period of economic recession and recovery. These cycles vary in duration.

Business ethics: Moral values and principles espoused by members of the business community as a guide to fair and honest business practices.

Business license: A legal authorization issued by municipal and state governments and required for business operations.

Business name: *(See also Business license; Trademark)* Enterprises must register their business names with local governments usually on a "doing business as" (DBA) form. (This name is sometimes referred to as a "fictional name.") The procedure is part of the business licensing process and prevents any other business from using that same name for a similar business in the same locality.

Business plan: A document that spells out a company's expected course of action for a specified period, usually including a detailed listing and analysis of risks and uncertainties. For the small business, it should examine the proposed products, the market, the industry, the management policies, the marketing policies, production needs, and financial needs. Frequently, it is used as a prospectus for potential investors and lenders.

Capacity: Level of a firm's, industry's, or nation's output corresponding to full practical utilization of available resources.

Capital: Assets less liabilities, representing the ownership interest in a business. A stock of accumulated goods, especially at a specified time and in contrast to income received during a specified time period. Accumulated goods devoted to production. Accumulated possessions calculated to bring income.

Capital expenditure: Expenses incurred by a business for improvements that will depreciate over time.

Capital gain: The monetary difference between the purchase price and the selling price of capital.

Capital intensity: *(See also Debt capital; Equity midrisk venture capital; Informal capital; Internal capital; Owner's capital; Secondhand capital; Seed capital; Venture capital)* The relative importance of capital in the production process, usually expressed as the ratio of capital to labor but also sometimes as the ratio of capital to output.

Capital resource: The equipment, facilities and labor used to create products and services.

Cash flow: The movement of money into and out of a company. A positive cash flow is when more comes in than goes out. A negative cash flow is when more goes out than comes in.

Champion: An advocate for the development of an innovation.

Channel of distribution: The means used to transport merchandise from the manufacturer to the consumer.

Chapter 7 of the 1978 Bankruptcy Act: Provides for a court–appointed trustee who is responsible for liquidating a company's assets in order to settle outstanding debts.

Chapter 11 of the 1978 Bankruptcy Act: Allows the business owners to retain control of the company while working with their creditors to reorganize their finances and establish better business practices to prevent liquidation of assets.

Collateral: Securities, evidence of deposit, or other property pledged by a borrower to secure repayment of a loan.

Commercialization: The final stage of the innovation process, including production and distribution.

Common stock: The most frequently used instrument for purchasing ownership in private or public companies. Common stock generally carries the right to vote on certain corporate actions and may pay dividends, although it rarely does in venture investments. In liquidation, common stockholders are the last to share in the proceeds from the sale of a corporation's assets; bondholders and preferred shareholders have priority. Common stock is often used in first–round start–up financing.

Competitor: A business whose product or service is marketed for the same purpose/use and to the same consumer group as the product or service of another.

Continous Improvement Plan (CIP): A set of activities designed to bring gradual, but continual improvement to a process through constant review. One of the best known is The Shewhart Cycle.

Copyright: A legal form of protection available to creators and authors to safeguard their works from unlawful use or claim of ownership by others. Copyrights may be acquired for works of art, sculpture, music, and published or unpublished manuscripts. All copyrights should be registered at the Copyright Office of the Library of Congress.

Corporate financial ratios: *(See also Industry financial ratios).* The relationship between key figures found in a company's financial statement expressed as a numeric value. Used to evaluate risk and company performance. Also known as Financial averages, Operating ratios, and Business ratios.

Cost containment: Actions taken by employers and insurers to curtail rising health care costs; for example, increasing employee cost sharing, requiring second opinions, or preadmission screening.

Cross training: Training an employee in another activity that is related to their current work.

Customer service: Various techniques used to ensure the satisfaction of a customer.

Cyclical peak: The upper turning point in a business cycle.

Cyclical trough: The lower turning point in a business cycle.

Debt: *(See also Long–term debt; Mid–term debt; Securitized debt; Short–term debt)* Something owed by one person to another. Financing in which a company receives capital that must be repaid; no ownership is transferred.

Debt capital: Business financing that normally requires periodic interest payments and repayment of the principal within a specified time.

Deming Cycle: A set of activities (Plan, Do, Check, Act) designed to drive continuous improvement. Initially implemented in manufacturing, it also applies to business. It was first developed by Walter Shewhart, however is more commonly called the Deming Cycle in Japan where it was popularized by Edwards Deming.

Demographics: Statistics on various markets, including age, income, and education, used to target specific products or services to appropriate consumer groups.

Demonstration: Showing that a product or process has been modified sufficiently to meet the needs of users.

Deregulation: The lifting of government restrictions; for example, the lifting of government restrictions on the entry of new businesses, the expansion of services, and the setting of prices in particular industries.

Discrimination: The denial of the rights and privileges of employment based on factors such as age, race, religion, or gender.

Diseconomies of scale: The condition in which the costs of production increase faster than the volume of production.

Distribution: Delivering a product or process to the user.

Distributor: One who delivers merchandise to the user.

Diversified company: A company whose products and services are used by several different markets.

Dow Jones Industrial Average: An indicator of stock market performance.

Earnings Statement: A standard financial document that is a summary of a company's revenue and expenses for a specific period, usually one quarter of a fiscal year and the entire fiscal year.

EBITDA: Earnings before Interest, Tax, Depreciation and Amortization. It reports what the company would have earned during the period if it did not have to pay interest on its debt, didn't have to pay taxes, and had depreciated the full value of all assets at their acquisition. It is basically equivalent to the operating income line in the income statements.

Economic efficiency: The use of productive resources to the fullest practical extent in the provision of the set of goods and services that is most preferred by purchasers in the economy.

Economic indicators: Statistics used to express the state of the economy. These include the length of the average work week, the rate of unemployment, and stock prices.

Employer identification number: The business equivalent of a social security number. Assigned by the U.S. Internal Revenue Service.

Equal Employment Opportunity Commission (EEOC): A federal agency that ensures nondiscrimination in the hiring and firing practices of a business.

Equal opportunity employer: An employer who adheres to the standards set by the Equal Employment Opportunity Commission.

Equity: *(See also Common Stock; Equity midrisk venture capital)* The ownership interest. Financing in which partial or total ownership of a company is surrendered in exchange for capital. An investor's financial return comes from dividend payments and from growth in the net worth of the business.

Equity midrisk venture capital: An unsecured investment in a company. Usually a purchase of ownership interest in a company that occurs in the later stages of a company's development.

FASB: Financial Accounting Standards Board. The FASB was created in 1973, replacing the Accounting Principles Board and the Committee on Accounting Procedure of the American Institute of Certified Public Accountants.

Feasibility study: A study to determine the likelihood that a proposed product or development will fulfill the objectives of a particular investor.

Federal Trade Commission (FTC): Federal agency that promotes free enterprise and competition within the U.S.

Federal Trade Mark Act of 1946: *See Lanham Act.*

Financial analysis: The techniques used to determine money needs in a business. Techniques include ratio analysis, calculation of return on investment, guides for measuring profitability, and break–even analysis to determine ultimate success.

Financial statement: A written record of business finances, including balance sheets and profit and loss statements.

Fiscal year: Any twelve–month period used by businesses for accounting purposes.

Flexible benefit plan: A plan that offers a choice among cash and/or qualified benefits such as group term life

insurance, accident and health insurance, group legal services, dependent care assistance, and vacations.

Four Ps: Marketing terms: Product, Price, Place, and Promotion.

Free on board (FOB): A pricing term indicating that the quoted price includes the cost of loading goods into transport vessels at a specified place.

FTC: See Federal Trade Commission.

Fulfillment: The systems necessary for accurate delivery of an ordered item, including subscriptions and direct marketing.

Full–time workers: Generally, those who work a regular schedule of more than 35 hours per week.

GAAP: Generally Accepted Accounting Principles. A set of widely accepted accounting standards, set by the FASB, and used to standardize financial accounting of public companies.

Garment registration number: A number that must appear on every garment sold in the U.S. to indicate the manufacturer of the garment, which may or may not be the same as the label under which the garment is sold. The U.S. Federal Trade Commission assigns and regulates garment registration numbers.

GNP: *See Gross national product.*

Good Housekeeping Seal: Seal appearing on products that signifies the fulfillment of the standards set by the Good Housekeeping Institute to protect consumer interests.

Goods sector: All businesses producing tangible goods, including agriculture, mining, construction, and manufacturing businesses.

GPO: *See Gross product originating.*

Gross domestic product (GDP): The part of the nation's gross national product generated by private business using resources from within the country.

Gross national product (GNP): The most comprehensive single measure of aggregate economic output. Represents the market value of the total output of goods and services produced by a nation's economy.

Gross product originating (GPO): A measure of business output estimated from the income or production side using employee compensation, profit income, net interest, capital consumption, and indirect business taxes.

Health maintenance organization (HMO): Organization of physicians and other health care professionals that provides health services to subscribers and their dependents on a prepaid basis.

Health provider: An individual or institution that gives medical care. Under Medicare, an institutional provider is a hospital, skilled nursing facility, home health agency, or provider of certain physical therapy services.

Human Resources Management: A business program designed to oversee recruiting, pay, benefits, and other issues related to the company's work force, including planning to determine the optimal use of labor to increase production, thereby increasing profit.

Idea: An original concept for a new product or process.

Import: Products produced outside the country in which they are consumed.

Income: Money or its equivalent, earned or accrued, resulting from the sale of goods and services.

Income statement: A financial statement that lists the profits and losses of a company at a given time.

Industry financial ratios: *(See also Corporate financial ratios)* Corporate financial ratios averaged for a specified industry. These are used for comparison purposes and reveal industry trends and identify differences between the performance of a specific company and the performance of its industry. Also known as Industrial averages, Industry ratios, Financial averages, and Business or Industrial norms.

Inflation: Increases in volume of currency and credit, generally resulting in a sharp and continuing rise in price levels.

Informal capital: Financing from informal, unorganized sources; includes informal debt capital such as trade credit or loans from friends and relatives and equity capital from informal investors.

Initial public offering (IPO): A corporation's first offering of stock to the public.

Innovation: The introduction of a new idea into the marketplace in the form of a new product or service or an improvement in organization or process.

Intellectual property: Any idea/work that can be considered proprietary in nature and thus protected from infringement by others.

Internal capital: Debt or equity financing obtained from the owner or through retained business earnings.

Invention: The tangible form of a technological idea, which could include a laboratory prototype, drawings, formulas, etc.

Job description: The duties and responsibilities required in a particular position.

Job tenure: A period of time during which an individual is continuously employed in the same job.

Joint venture: Venture in which two or more people combine efforts in a particular business enterprise, usually a single transaction or a limited activity, and agree to share

the profits and losses jointly or in proportion to their contributions.

Keogh plan: Designed for self–employed persons and unincorporated businesses as a tax–deferred pension account.

Labor force: Civilians considered eligible for employment who are also willing and able to work.

Labor force participation rate: The civilian labor force as a percentage of the civilian population.

Labor intensity: *(See also Capital intensity)* The relative importance of labor in the production process, usually measured as the capital–labor ratio; i.e., the ratio of units of capital (typically, dollars of tangible assets) to the number of employees. The higher the capital–labor ratio exhibited by a firm or industry, the lower the capital intensity of that firm or industry is said to be.

Labor surplus area: An area in which there exists a high unemployment rate. In procurement, extra points are given to firms in counties that are designated a labor surplus area; this information is requested on procurement bid sheets.

Labor union: An organization of similarly–skilled workers who collectively bargain with management over the conditions of employment.

Lanham Act: Refers to the Federal Trade Mark Act of 1946. Protects registered trademarks, trade names, and other service marks used in commerce.

Large business–dominated industry: Industry in which a minimum of 60 percent of employment or sales is in firms with more than 500 workers.

Leader pricing: A reduction in the price of a good or service in order to generate more sales of that good or service.

Leveraged buy–out (LBO): The purchase of a business or a division of a corporation through a highly leveraged financing package.

License: A legal agreement granting to another the right to use a technological innovation.

Liability: An obligation or duty to perform a service or an act. Also defined as money owed.

Long–haul rates: Rates charged by a transporter in which the distance traveled is more than 800 miles.

Long–term debt: An obligation that matures in a period that exceeds five years.

Macro–efficiency: *(See also Economic efficiency)* Efficiency as it pertains to the operation of markets and market systems.

Market evaluation: The use of market information to determine the sales potential of a specific product or process.

Market failure: The situation in which the workings of a competitive market do not produce the best results from the point of view of the entire society.

Market information: Data of any type that can be used for market evaluation, which could include demographic data, technology forecasting, regulatory changes, etc.

Market research: A systematic collection, analysis, and reporting of data about the market and its preferences, opinions, trends, and plans; used for corporate decision–making.

Market share: In a particular market, the percentage of sales of a specific product.

Marketing: Promotion of goods or services through various media.

Matrix Management: A style of management where an employee has two reporting bosses – one functional and one operational.

Micro–efficiency: *(See also Economic efficiency)* Efficiency as it pertains to the operation of individual firms.

Mid–term debt: An obligation that matures within one to five years.

Minimum wage: The lowest hourly wage allowed by the federal government.

Multi–level marketing: A system of selling in which you sign up other people to assist you, and they, in turn, recruit others to help them. Some entrepreneurs have built successful companies on this concept because the main focus of their activities is their product and product sales.

NAFTA: *See North American Free Trade Agreement.*

NASDAQ: *See National Association of Securities Dealers Automated Quotations.*

National Association of Securities Dealers Automated Quotations: Provides price quotes on over–the–counter securities as well as securities listed on the New York Stock Exchange.

National income: Aggregate earnings of labor and property arising from the production of goods and services in a nation's economy.

Net assets: *See Net worth.*

Net income: The amount remaining from earnings and profits after all expenses and costs have been met or deducted. Also known as Net earnings.

Net profit: Money earned after production and overhead expenses have been deducted.

Net worth: *(See also Capital)* The difference between a company's total assets and its total liabilities.

New York Stock Exchange (NYSE): The oldest stock exchange in the U.S. Allows for trading in stocks, bonds, warrants, options, and rights that meet listing requirements.

Non-disclosure agreement: A legal contract that allows a company to share its intellectual property with others, whose input it needs, without jeopardizing that information.

North American Free Trade Agreement (NAFTA): Passed in 1993, NAFTA eliminates trade barriers among businesses in the U.S., Canada, and Mexico.

NYSE: *See New York Stock Exchange*

Occupational Safety & Health Administration (OSHA): Federal agency that regulates health and safety standards within the workplace.

Organizational chart: A hierarchical chart tracking the chain of command within an organization.

Overhead: Expenses, such as employee benefits and building utilities, incurred by a business that are unrelated to the actual product or service sold.

Owner's capital: Debt or equity funds provided by the owner(s) of a business; sources of owner's capital are personal savings, sales of assets, or loans from financial institutions.

Part–time workers: Normally, those who work less than 35 hours per week. The Tax Reform Act indicated that part–time workers who work less than 17.5 hours per week may be excluded from health plans for purposes of complying with federal nondiscrimination rules.

Part–year workers: Those who work less than 50 weeks per year.

Partnership: Two or more parties who enter into a legal relationship to conduct business for profit. Defined by the U.S. Internal Revenue Code as joint ventures, syndicates, groups, pools, and other associations of two or more persons organized for profit that are not specifically classified in the IRS code as corporations or proprietorships.

Patent: A grant by the government assuring an inventor the sole right to make, use, and sell an invention for a period of 17 years.

Pension: A series of payments made monthly, semiannually, annually, or at other specified intervals during the lifetime of the pensioner for distribution upon retirement. The term is sometimes used to denote the portion of the retirement allowance financed by the employer's contributions.

Pension fund: A fund established to provide for the payment of pension benefits; the collective contributions made by all of the parties to the pension plan.

Performance appraisal: An established set of objective criteria, based on job description and requirements, that is used to evaluate the performance of an employee in a specific job.

Private placement: A method of raising capital by offering for sale an investment or business to a small group of investors (generally avoiding registration with the Securities and Exchange Commission or state securities registration agencies). Also known as Private financing or Private offering.

Pro forma: The use of hypothetical figures in financial statements to represent future expenditures, debts, and other potential financial expenses.

Proactive: Taking the initiative to solve problems and anticipate future events before they happen, instead of reacting to an already existing problem or waiting for a difficult situation to occur.

Product development: The stage of the innovation process where research is translated into a product or process through evaluation, adaptation, and demonstration.

Production: The manufacture of a product.

Profit and loss statement (P & L): The summary of the incomes and costs of a company's operation during a specific period of time. Also known as Income and expense statement.

Prototype: A model that demonstrates the validity of the concept of an invention (laboratory prototype); a model that meets the needs of the manufacturing process and the user (production prototype).

Prudent investor rule or standard: A legal doctrine that requires fiduciaries to make investments using the prudence, diligence, and intelligence that would be used by a prudent person in making similar investments. Because fiduciaries make investments on behalf of third–party beneficiaries, the standard results in very conservative investments. Until recently, most state regulations required the fiduciary to apply this standard to each investment. Newer, more progressive regulations permit fiduciaries to apply this standard to the portfolio taken as a whole, thereby allowing a fiduciary to balance a portfolio with higher–yield, higher–risk investments. In states with more progressive regulations, practically every type of security is eligible for inclusion in the portfolio of investments made by a fiduciary, provided that the portfolio investments, in their totality, are those of a prudent person.

Public equity markets: Organized markets for trading in equity shares such as common stocks, preferred stocks, and warrants. Includes markets for both regularly traded and nonregularly traded securities.

Public offering: General solicitation for participation in an investment opportunity. Interstate public offerings are supervised by the U.S. Securities and Exchange Commission.

Quality control: The process by which a product is checked and tested to ensure consistent standards of high quality.

Rate of return: The yield obtained on a security or other investment based on its purchase price or its current market price.

Recession: Contraction of economic activity occurring between the peak and trough of a business cycle.

Regulated market: A market in which the government controls the forces of supply and demand, such as who may enter and what price may be charged.

Research: The initial stage of the innovation process, which includes idea generation and invention.

Research and development financing: A tax–advantaged partnership set up to finance product development for start–ups as well as more mature companies.

Resource realignment: The adjustment of productive resources to interindustry changes in demand.

Resources: The sources of support or help in the innovation process, including sources of financing, technical evaluation, market evaluation, management and business assistance, etc.

Retained business earnings: Business profits that are retained by the business rather than being distributed to the shareholders as dividends.

Revolving credit: An agreement with a lending institution for an amount of money, which cannot exceed a set maximum, over a specified period of time. Each time the borrower repays a portion of the loan, the amount of the repayment may be borrowed yet again.

Risk management: The act of identifying potential sources of financial loss and taking action to minimize their negative impact.

Routing: The sequence of steps necessary to complete a product during production.

Scale economies: The decline of the production cost per unit of output (average cost) as the volume of output increases.

Scale efficiency: The reduction in unit cost available to a firm when producing at a higher output volume.

Secondary market: A market established for the purchase and sale of outstanding securities following their initial distribution.

Secondhand capital: Previously used and subsequently resold capital equipment (e.g., buildings and machinery).

Securities and Exchange Commission (SEC): Federal agency charged with regulating the trade of securities to prevent unethical practices in the investor market.

Securitized debt: A marketing technique that converts long–term loans to marketable securities.

Seed capital: Venture financing provided in the early stages of the innovation process, usually during product development.

Service sector: Broadly defined, all U.S. industries that produce intangibles, including the five major industry divisions of transportation, communications, and utilities; wholesale trade; retail trade; finance, insurance, and real estate; and services.

Short–term debt: An obligation that matures in one year.

Standard Industrial Classification (SIC) codes: Four–digit codes established by the U.S. Federal Government to categorize businesses by type of economic activity; the first two digits correspond to major groups such as construction and manufacturing, while the last two digits correspond to subgroups such as home construction or highway construction.

SWOT: Strengths, Weaknesses, Opportunities, and Threats. These factors provide a reference which an organization can use to conduct an analysis of its operations.

Target market: The clients or customers sought for a business' product or service.

Tax number: *(See also Employer identification number)* A number assigned to a business by a state revenue department that enables the business to buy goods without paying sales tax.

Trade credit: Credit extended by suppliers of raw materials or finished products. In an accounting statement, trade credit is referred to as "accounts payable."

Trade secret: Competitive advantage gained by a business through the use of a unique manufacturing process or formula.

Trademark: A graphic symbol, device, or slogan that identifies a business. A business has property rights to its trademark from the inception of its use, but it is still prudent to register all trade marks with the Trademark Office of the U.S. Department of Commerce.

Trend: A statistical measurement used to track changes that occur over time.

Unfair competition: Refers to business practices, usually unethical, such as using unlicensed products, pirating merchandise, or misleading the public through false advertising, which give the offending business an unequitable advantage over others.

Uniform Commercial Code (UCC): A code of laws governing commercial transactions across the U.S., except Louisiana. Their purpose is to bring uniformity to financial transactions.

Uniform product code (UPC symbol): A computer–readable label comprised of ten digits and stripes that encodes what a product is and how much it costs. The first five

digits are assigned by the Uniform Produce Code Council, and the last five digits by the individual manufacturer.

Venture capital: *(See also Equity; Equity midrisk venture capital)* Money used to support new or unusual business ventures that exhibit above–average growth rates, significant potential for market expansion, and are in need of additional financing to sustain growth or further research and development; equity or equity–type financing traditionally provided at the commercialization stage, increasingly available prior to commercialization.

Withholding: Federal, state, social security, and unemployment taxes withheld by the employer from employees' wages; employers are liable for these taxes and the corporate umbrella and bankruptcy will not exonerate an employer from paying back payroll withholding. Employers should escrow these funds in a separate account and disperse them quarterly to withholding authorities.

Workers' compensation: A state–mandated form of insurance covering workers injured in job–related accidents. In some states, the state is the insurer; in other states, insurance must be acquired from commercial insurance firms. Insurance rates are based on a number of factors, including salaries, firm history, and risk of occupation.

Working capital: Refers to a firm's short–term investment of current assets, including cash, short–term securities, accounts receivable, and inventories.

Yield: *(See also Rate of return)* The rate of income returned on an investment, expressed as a percentage. Income yield is obtained by dividing the current dollar income by the current market price of the security. Net yield or yield to maturity is the current income yield minus any premium above par or plus any discount from par in purchase price, with the adjustment spread over the period from the date of purchase to the date of maturity.

ACTIVITY-BASED COSTING

To support compliance with financial reporting requirements, a company's traditional cost-accounting system is often articulated with its general ledger system. In essence, this linkage is grounded in cost allocation. Typically, costs are allocated for either valuation purposes (i.e., financial statements for external uses) or decision-making purposes (i.e., internal uses) or both. However, in certain instances, costs are also allocated for cost-reimbursement purposes (e.g., hospitals and defense contractors).

The traditional approach to cost-allocation consists of three basic steps: accumulate costs within a production or nonproduction department; allocate nonproduction department costs to production departments; and allocate the resulting (revised) production department costs to various products, services, or customers. Costs derived from this traditional allocation approach suffer from several defects that can result in distorted costs for decision-making purposes. For example, the traditional approach allocates the cost of idle capacity to products. Accordingly, such products are charged for resources that they did not use. Seeking to remedy such distortions, many companies have adopted a different cost-allocation approach called activity-based costing (ABC).

WHAT IS ACTIVITY-BASED COSTING?

In contrast to traditional cost-accounting systems, ABC systems first accumulate overhead costs for each organizational activity, and then assign the costs of the activities to the products, services, or customers (cost objects) causing that activity. As one might expect, the most critical aspect of ABC is activity analysis. Activity analysis is the processes of identifying appropriate output measures of activities and resources (cost drivers) and their effects on the costs of making a product or providing a service. Significantly, as discussed in the next section, activity analysis provides the foundation for remedying the distortions inherent in traditional cost-accounting systems.

TRADITIONAL COST-ACCOUNTING SYSTEMS VERSUS ABC

Geared toward compliance with financial reporting requirements, traditional cost-accounting systems often allocate costs based on single volume measures such as direct-labor hours, direct-labor costs, or machine hours. While using a single volume measure as an overall cost driver seldom meets the cause-and-effect criterion desired in cost allocation, it provides a relatively cheap and convenient means of complying with financial reporting requirements.

In contrast to traditional cost-accounting systems, ABC systems are not inherently constrained by the tenets of financial reporting requirements. Rather, ABC systems have the inherent flexibility to provide special reports to facilitate management decisions regarding the costs of activities undertaken to design, produce, sell, and deliver a company's products or services. At the heart of this

flexibility is the fact that ABC systems focus on accumulating costs via several key activities, whereas traditional cost allocation focuses on accumulating costs via organizational units. By focusing on specific activities, ABC systems provide superior cost allocation information—especially when costs are caused by non-volume-based cost drivers. Even so, traditional cost-accounting systems will continue to be used to satisfy conventional financial reporting requirements. ABC systems will continue to supplement, rather than replace, traditional cost-accounting systems.

IMPLEMENTATION

In most cases, a company's traditional cost-accounting system adequately measures the direct costs of products and services, such as material and labor. As a result, ABC implementation typically focuses on indirect costs, such as manufacturing overhead and selling, general, and administrative costs. Given this focus, the primary goal of ABC implementation is to reclassify most, if not all, indirect costs (as specified by the traditional cost-accounting system) as direct costs. As a result of these reclassifications, the accuracy of the costs is greatly increased.

According to Ray H. Garrison and Eric W. Noreen, there are six basic steps required to implement an ABC system:

1. Identify and define activities and activity pools

2. Trace costs directly to activities (to the extent feasible)

3. Assign costs to activity cost pools

4. Calculate activity rates

5. Assign costs to cost objects using the activity rates and activity measures previously determined

6. Prepare and distribute management reports

COSTS AND BENEFITS

While ABC systems are rather complex and costly to implement, Charles T. Horngren, Gary L. Sundem, and William O. Stratton suggest that many companies, in both manufacturing and nonmanufacturing industries, are adopting ABC systems for a variety of reasons:

1. Margin accuracy for individual products and services, as well as customer classifications, is becoming increasingly difficult to achieve given that direct labor is rapidly being replaced with automated equipment. Accordingly, a company's shared costs (i.e., indirect costs) are becoming the most significant portion of total cost.

2. Because the rapid pace of technological change continues to reduce product life cycles, companies do not have time to make price or cost adjustments once costing errors are detected.

3. Companies with inaccurate cost measurements tend to lose bids because of over-costed products, incur hidden losses because of under-costed products, and fail to detect activities that are not cost-effective.

4. Because computer technology costs are decreasing, the price of developing and operating ABC systems also has decreased.

In 2004 John Karolefski cited the following benefits realized by foodservice distributors and restaurants that have converted to activity-based costing practices:

1. Understanding the true costs and productivity of capital equipment

2. Understanding which products are most profitable and where to focus sales efforts

3. More accurate pricing and determination of minimum order size

4. Less time, money, and effort spent on the wrong products

Implementation costs are an obstacle to some, who feel that ABC is just a fad or will show little benefit. According to Karolefski, "ABC works better if it's kept simple" (2004, p. 18). Nevertheless, when implemented properly ABC yields benefits to the company, its business partners, and to consumers. Conversely, in 2007, a market review of ABC and other management systems found that it is poor implementation of the programs that often leads to failure. The report cites short cuts and mistakes as the reasons that ABC and related systems do not succeed.

ACTIVITY-BASED MANAGEMENT

To manage costs, a manager should focus on the activities that give rise to such costs. Accordingly, given the activity focus of ABC, managers should implement ABC systems to facilitate cost management. Using ABC systems to improve financial management is called activity-based management (ABM). The goal of ABM is to improve the value received by customers and, in doing so, to improve profits.

The key to ABM success is distinguishing between value-added costs and non-value-added costs. A value-added cost is the cost of an activity that cannot be eliminated without affecting a product's value to the customer. In contrast, a non-value-added cost is the cost of an activity that can be eliminated without diminishing value. Some value-added costs are always necessary, as long as the activity that drives such costs is performed efficiently. However, non-value-added costs should always be minimized because they are assumed to be unnecessary. Examples of non-valued-added activities include storing and handling inventories; transporting raw materials or partly finished products, such as work-in-process

inventory items, from one part of the plant to another; and redundancies in production-line configurations or other activities. Oftentimes, such non-value activities can be reduced or eliminated by careful redesign of the plant layout and the production process.

AFFIRMATIVE ACTION

Affirmative action is a descriptive phrase for policies and programs designed to correct the effects of past discrimination and increase the representation of historically disadvantaged groups, including women and African Americans. Affirmative action plans exist in the private and public sectors and involve the hiring of job applicants, the selection of contractors for government projects, and the admission of students to undergraduate and graduate educational institutions. Some employers, educational institutions, and government agencies are legally required by executive order to have affirmative action plans. Others may be ordered to develop affirmative action plans as part of a court finding that they have discriminated against individuals or groups. Still others voluntarily develop such plans because they believe it is good public policy, or that it provides them with a competitive advantage.

ORIGINS AND DEVELOPMENT OF AFFIRMATIVE ACTION

Although the roots of affirmative action in the United States go back to the nineteenth century, modern affirmative action plans originated with executive orders issued by Presidents John F. Kennedy, Lyndon B. Johnson, and Richard M. Nixon in the 1960s. Executive Order 11246, signed by President Johnson in 1965, required government agencies, contractors, and subcontractors to undertake affirmative action to remedy past discrimination in education, training, and employment. In 1969 President Nixon further strengthened affirmative action through Executive Order 11478, which required government contractors to develop goals for increasing the representation of historically disadvantaged groups and timetables for achieving them.

As amended in subsequent years, these executive orders eventually required all government agencies and contractors with annual contracts of $10,000 or more to undertake affirmative action. They also required agencies and contractors with 50 employees and government business of $50,000 or more to have written affirmative action plans. These written plans must include a utilization analysis, which compares the composition of the entity's workforce to the proportion of women and minorities in the available labor market. If underutilization is found, the agency or contractor must set specific goals and timetables for remedying the "imbalance" and develop specific plans for how this will be done. The use of affirmative action plans expanded greatly in the twenty years after the executive orders. Because most educational institutions and large organizations receive money and/or do business with the government, affirmative action plans are very common.

TYPES OF AFFIRMATIVE ACTION

In the employment context, affirmative action plans should be distinguished from equal employment opportunity (EEO) programs. EEO efforts focus on the process involved in hiring and promoting employees and attempt to ensure that there is a level playing field for all involved. Conversely, affirmative action programs focus on the outcomes of recruiting, hiring, and promotion processes, and involve additional efforts to increase the proportion of women and minorities that are hired and promoted.

There are various types of affirmative action plans. Some plans simply try to increase the number of applicants from underrepresented groups. Such plans, which are sometimes called "pure" plans or "opportunity enhancement" plans, involve proactive efforts to locate and recruit a larger number of individuals from the affected groups. Other affirmative action plans can be termed "limited preference" or "tiebreak" plans. They go a step further than pure affirmative action plans by considering race or

gender as a "plus" factor when evaluating the qualifications of applicants who essentially are equally qualified. Finally, the most aggressive affirmative action plans are "strong preferential treatment" or "quota" plans. In these plans, qualified members of a disadvantaged group may be preferred to more highly qualified individuals who are not in the affected group. Generally speaking, the more aggressive the affirmative action strategy employed, the more likely it is to generate challenges and the more difficult it is to defend legally.

Affirmative action plans are quite controversial and have been the subject of hundreds of lawsuits, several of which have gone to the U.S. Supreme Court. Lawsuits filed by those who believe they have been unfairly treated by affirmative action plans usually are called "reverse discrimination" lawsuits. Although the courts generally have agreed that affirmative action is legal if it meets certain criteria, court decisions in the 1990s and early 2000s seemed to reflect a trend toward restricting the more aggressive types of affirmative action programs, which may include preferences based on race or gender.

MOVEMENT AWAY FROM AFFIRMATIVE ACTION

In 1996, Proposition 209 was passed into California state law. The ballot proposition amended the state Constitution to prohibit public institutions from taking into consideration race, sex, or ethnicity. The ballot was spearheaded by the California Civil Rights Campaign and led by University of California Regent Ward Connerly. Two years later a Washington State Initiative was passed to bar any public institution from giving preferential treatment on the premise of race, sex, color, ethnicity, or national origin in the operation of employment, education, or contracting. The Michigan Civil Rights Initiative or Proposal 2 was a similar ballot initiative passed into Michigan Constitutional law in 2006.

In a landmark decision of the U.S. Supreme Court in 2007, *Parents Involved in Community Schools v. Seattle School District No. 1*—together with *Meredith v. Jefferson County Board of Education*—prohibited placing students in public schools for the purpose of racial integration. Furthermore, the court refused to recognize racial balancing as a compelling state interest.

AGGREGATE PLANNING

Aggregate planning is the process of developing, analyzing, and maintaining a preliminary, approximate schedule of the overall operations of an organization. The aggregate plan generally contains targeted sales forecasts, production levels, inventory levels, and customer backlogs. This schedule is intended to satisfy the demand forecast at a minimum cost. Properly done, aggregate planning should minimize the effects of shortsighted, day-to-day scheduling, in which an organization orders only small amounts of materials and must lay off workers one week, and the next week orders larger amounts and must rehire workers. This longer-term perspective on resource use can result in cost savings.

In simple terms, aggregate planning is an attempt to balance capacity and demand in such a way that costs are minimized. The term "aggregate" is used because planning at this level includes all resources "in the aggregate," for example, as a product line or family. Aggregate resources could be total number of workers, hours of machine time, or tons of raw materials. Aggregate units of output could include gallons, feet, pounds of output, as well as aggregate units appearing in service industries such as hours of service delivered, number of patients seen, etc.

Some contend that an aggregate process is superior in today's lean manufacturing and sales and operation (S&OP) environment, and that detailed long-term forecasts are no longer necessary. In 2007 Wallace and Stahl (of the firm Supply Chain Consultant) noted that detailed forecasts and plans are normally needed only within a specific time-frame, and beyond that, forecasting is a poor use of a company's resources.

Aggregate planning does not distinguish among sizes, colors, features, and so forth. For example, with automobile manufacturing, aggregate planning would consider

the total number of cars planned for, not the individual models, colors, or options. When units of aggregation are difficult to determine (for example, when the variation in output is extreme) equivalent units are usually determined. These equivalent units could be based on value, cost, worker hours, or some similar measure.

Aggregate planning is considered to be intermediate-term (as opposed to long- or short-term) in nature. Hence, most aggregate plans cover a period of three to eighteen months. Aggregate plans serve as a foundation for future short-range type planning, such as production scheduling, sequencing, and loading. The master production schedule (MPS) used in material requirements planning (MRP) has been described as the aggregate plan "disaggregated."

Steps taken to produce an aggregate plan begin with the determination of demand and the determination of current capacity. Capacity is expressed as total number of units per time period that can be produced (this requires that an average number of units be computed since the total may include a product mix utilizing distinctly different production times). Demand is expressed as total number of units needed. If the two are not in balance (equal), the firm must decide whether to increase or decrease capacity to meet demand, or increase or decrease demand to meet capacity. To accomplish this, a number of options are available.

Options for situations in which a firm needs to increase or decrease demand to match capacity include:

1. **Pricing.** To increase demand in periods when demand is less than peak, a firm can vary pricing, for example, by offering matinee prices for movie theaters, off-season rates for hotels, weekend rates for telephone service, and pricing for items that experience seasonal demand.

2. **Promotion.** Through advertising, direct marketing, and other forms of promotion, a firm can shift demand.

3. **Back-ordering.** By postponing delivery on current orders, demand is shifted to a period when capacity is not fully utilized. This is really just a form of smoothing demand. Service industries are able to smooth demand by taking reservations or by making appointments in an attempt to avoid walk-in customers. Some refer to this as "partitioning" demand.

4. **New demand creation.** A new, but complementary demand is created for a product or service. When restaurant customers have to wait, they are frequently diverted into a complementary (but not complimentary) service, the bar. Other examples include the addition of video arcades within movie theaters, and the expansion of services at convenience stores.

Options which can be used to increase or decrease capacity to match current demand include:

1. **Hire/lay off.** By hiring additional workers as needed or by laying off workers not currently required to meet demand, firms can maintain a balance between capacity and demand.

2. **Overtime.** By asking or requiring workers to work extra hours a day or an extra day per week, firms can create a temporary increase in capacity without the added expense of hiring additional workers.

3. **Part-time or casual labor.** By utilizing temporary workers or casual labor (workers who are considered permanent but only work when needed, on an on-call basis, and typically without the benefits given to full-time workers) firms can alter capacity to match fluctuations in demand.

4. **Inventory.** Finished-goods inventory can be built up in periods of slack demand and then used to fill demand during periods of high demand. In this way no new workers have to be hired, no temporary or casual labor is needed, and no overtime is incurred.

5. **Subcontracting.** Frequently firms choose to allow another manufacturer or service provider to provide the product or service to the subcontracting firm's customers. By subcontracting work to an alternative source, additional capacity is temporarily obtained.

6. **Cross-training.** Cross-trained employees may be able to perform tasks in several operations, creating some flexibility when scheduling capacity.

7. **Other methods.** While varying workforce size and utilization, inventory buildup/backlogging, and sub-contracting are well-known alternatives, there are other, more novel ways that find use in industry. Among these options are sharing employees with counter-cyclical companies and attempting to find interesting and meaningful projects for employees to do during slack times.

AGGREGATE PLANNING STRATEGIES

There are two pure planning strategies available to the aggregate planner: a level strategy and a chase strategy. Firms may choose to utilize one of the pure strategies in isolation, or they may opt for a strategy that combines the two.

Level Strategy. A level strategy seeks to produce an aggregate plan that maintains a steady production rate and/or a steady employment level. To satisfy changes in customer demand, the firm must raise or lower inventory levels in anticipation of increased or decreased levels of forecast demand. The firm maintains a level workforce and a steady rate of output when demand is somewhat low. This allows the firm to establish higher inventory levels than it currently needs. As demand increases, the firm is

able to continue a steady production rate/steady employment level, while allowing the inventory surplus to absorb the increased demand.

A second alternative would be to use a backlog or backorder. A backorder is simply a promise to deliver the product at a later date when it is more readily available, usually when capacity begins to catch up with diminishing demand. In essence, the backorder is a device for moving demand from one period to another, preferably one in which demand is lower, thereby smoothing demand requirements over time.

A level strategy allows a firm to maintain a constant level of output and still meet demand. This is desirable from an employee-relations standpoint. Negative results of the level strategy would include the cost of excess inventory, subcontracting or overtime costs, and back-order costs, which typically are the cost of expediting orders and the loss of customer goodwill.

Chase Strategy. A chase strategy implies matching demand and capacity period by period. This could result in a considerable amount of hiring, firing, or laying off of employees; insecure and unhappy employees; increased inventory carrying costs; problems with labor unions; and erratic utilization of plants and equipment. It also implies a great deal of flexibility on the firm's part. The major advantage of a chase strategy is that it allows inventory to be held to the lowest level possible, and for some firms this is a considerable savings. Most firms embracing the just-in-time production concept utilize a chase strategy approach to aggregate planning.

Most firms find it advantageous to utilize a combination of the level and chase strategies. A combination strategy (sometimes called a hybrid or mixed strategy) can be found to better meet organizational goals and policies and achieve lower costs than either of the pure strategies used independently.

TECHNIQUES FOR AGGREGATE PLANNING

Techniques for aggregate planning range from informal trial-and-error approaches, which usually utilize simple tables or graphs, to more formalized and advanced mathematical techniques. William Stevenson's textbook *Production/Operations Management* contains an informal but useful trial-and-error process for aggregate planning presented in outline form. This general procedure consists of the following steps:

1. Determine demand for each period.

2. Determine capacity for each period. This capacity should match demand, which means it may require the inclusion of overtime or subcontracting.

3. Identify company, departmental, or union policies that are pertinent, such as maintaining a certain safety stock level or maintaining a reasonably stable work-force. Other pertinent topics might include: backorder policies, overtime policies, inventory level policies, and other less explicit rules such as the nature of employment with the individual industry, the possibility of a bad image, and the loss of goodwill.

4. Determine unit costs for units produced. These costs typically include the basic production costs (fixed and variable costs as well as direct and indirect labor costs). Also included are the costs associated with making changes in capacity. Inventory holding costs must also be considered, as should storage, insurance, taxes, spoilage, and obsolescence costs. Finally, backorder costs must be computed. While difficult to measure, this generally includes expediting costs, loss of customer goodwill, and revenue loss from cancelled orders.

5. Develop alternative plans and compute the cost for each.

6. If satisfactory plans emerge, select the one that best satisfies objectives. Frequently, this is the plan with the least cost. Otherwise, return to step 5.

An example of a completed informal aggregate plan can be seen in Figure 1. It is an example of a plan determined by utilizing a level strategy. Notice that employment levels and output levels remain constant while inventory is allowed to build up in earlier periods only to be drawn back down in later periods as demand increases. Also, note that backorders are utilized in order to avoid overtime or subcontracting. The computed costs for the individual variables of the plan are as follows:

Output costs:
    Regular time = $5 per unit
    Overtime = $8 per unit
    Subcontracted = $12 per unit
Other costs:
    Inventory carrying cost = $3 per unit per period applied to average inventory
    Backorders = $10 per unit per period
Cost of aggregate plan utilizing a level strategy:
Output costs:
    Regular time = $5 × 1,500 = $7,500
    Overtime = $8 × 0 = 0
    Subcontracted = $10 × 0 = 0
Other costs:
    Inventory carrying cost = $3 × 850 = $2,400
    Backorders = $10 × 100 = $1,000
    Total Costs = $10,900

Figure 1

Period		1	2	3	4	5	6
Forecast		100	150	300	300	500	150
Output							
	Regular	250	250	250	250	250	250
	Overtime						
	Subcontract						
Output-forecast		150	100	-50	-50	-250	100
Inventory							
	Beginning	0	150	250	200	150	0
	Ending	150	250	200	150	0	100
	Average	75	200	225	175	75	50
Backlog	0	0	0	0	0	100	0

Cost of aggregate plan utilizing a level strategy:
Output:

Regular time	=	$5 X 1500	=	$7,500
Overtime	=	$8 X 0	=	0
Subcontracted	=	$10 X 0	=	0
Inventory carrying cost	=	$3 X 850	=	2,550
Backorders	=	$10 X 100	=	1000
Total Cost				$11,050

A second example, shown in Figure 2, presents the same scenario as in Figure 1 but demonstrates the use of a combination strategy (i.e., a combination of level and chase strategies) to meet demand and seek to minimize costs. For this example, let's assume that company policy prevents us from utilizing backorders and limits our plan to no more than 50 units of overtime per period. Notice that the regular output level is constant, implying a level workforce, while overtime and subcontracting are used to meet demand on a period-by-period basis (chase strategy). One will notice that the cost of the combination plan is slightly lower than the cost of the level plan.

Output costs:
Regular time = $5 × 1,200 = $6,000
Overtime = $8 × 100 = 800
Subcontracted = $12 × 250 = 3,000
Other costs:
Inventory carrying cost = $3 × 325 = 975
Backorders = $10 × 0 = 0
Total cost = $10,775

MATHEMATICAL APPROACHES TO AGGREGATE PLANNING

The following are some of the better known mathematical techniques that can be used in more complex aggregate planning applications.

Linear Programming. Linear programming is an optimization technique that allows the user to find a maximum profit or revenue or a minimum cost based on the availability of limited resources and certain limitations known as constraints. A special type of linear programming known as the Transportation Model can be used to obtain aggregate plans that would allow balanced capacity and demand and the minimization of costs. However, few real-world aggregate planning decisions are compatible with the linear assumptions of linear programming. *Supply Chain Management: Strategy, Planning and Operation*, by Sunil Chopra and Peter Meindl, provides an excellent example of the use of linear programming in aggregate planning.

Mixed-Integer Programming. For aggregate plans that are prepared on a product family basis, where the plan is essentially the summation of the plans for individual product lines, mixed-integer programming may prove to be useful. Mixed-integer programming can provide a method for determining the number of units to be produced in each product family.

Linear Decision Rule. Linear decision rule is another optimizing technique. It seeks to minimize total production costs (labor, overtime, hiring/lay off, inventory carrying cost) using a set of cost-approximating functions (three of which are quadratic) to obtain a single quadratic equation. Then, by using calculus, two linear equations

Figure 2

```
Output:
        Regular time     =   $5  X  1200  =   $6,000
        Overtime         =   $8  X   100  =      800
        Subcontracted    =  $12  X   250  =    3,000
Inventory carrying cost  =   $3  X   325  =      975
Backorders               =  $10  X     0  =        0
Total Cost                                 $10,775
```

can be derived from the quadratic equation, one to be used to plan the output for each period and the other for planning the workforce for each period.

Management Coefficients Model. The management coefficients model, formulated by E.H. Bowman, is based on the suggestion that the production rate for any period would be set by this general decision rule:

$$P_t = aW_{t-1} - bI_{t-1} + cF_{t+1} + K, \text{ where}$$

P_t = the production rate set for period t
W_{t-1} = the workforce in the previous period
I_{t-1} = the ending inventory for the previous period
F_{t+1} = the forecast of demand for the next period
$a, b, c,$ and K are constants

It then uses regression analysis to estimate the values of $a, b, c,$ and K. The end result is a decision rule based on past managerial behavior without any explicit cost functions, the assumption being that managers know what is important, even if they cannot readily state explicit costs. Essentially, this method supplements the application of experienced judgment.

Search Decision Rule. The search decision rule methodology overcomes some of the limitations of the linear cost assumptions of linear programming. The search decision rule allows the user to state cost data inputs in very general terms. It requires that a computer program be constructed that will unambiguously evaluate any production plan's cost. It then searches among alternative plans for the one with the minimum cost. However, unlike linear programming, there is no assurance of optimality.

Simulation. A number of simulation models can be used for aggregate planning. By developing an aggregate plan within the environment of a simulation model, it can be tested under a variety of conditions to find acceptable plans for consideration. These models can also be incorporated into a decision support system, which can aid in planning and evaluating alternative control policies. These models can integrate the multiple conflicting objectives inherent in manufacturing strategy by using different quantitative measures of productivity, customer service, and flexibility.

Functional Objective Search Approach. The functional objective search (FOS) system is a computerized aggregate planning system that incorporates a broad range of actual planning conditions. It is capable of realistic, low-cost operating schedules that provide options for attaining different planning goals. The system works by comparing the planning load with available capacity. After management has chosen its desired actions and associated planning objectives for specific load conditions, the system

weights each planning goal to reflect the functional emphasis behind its achievement at a certain load condition. The computer then uses a computer search to output a plan that minimizes costs and meets delivery deadlines.

Aggregate Planning in Services. For manufacturing firms the luxury of building up inventories during periods of slack demand allows coverage of an anticipated time when demand will exceed capacity. Services cannot be stockpiled or inventoried so they do not have this option. Also, since services are considered "perishable," any capacity that goes unused is essentially wasted. An empty hotel room or an empty seat on a flight cannot be held and sold later, as can a manufactured item held in inventory.

Service capacity can also be very difficult to measure. When capacity is dictated somewhat by machine capability, reasonably accurate measures of capacity are not extremely difficult to develop. However, services generally have variable processing requirements that make it difficult to establish a suitable measure of capacity.

Historically, services are much more labor intensive than manufacturing, where labor averages 10 percent (or less) of total cost. This labor intensity can actually be an advantage because of the variety of service requirements an individual can handle. This can provide quite a degree of flexibility that can make aggregate planning easier for services than manufacturing.

Other Ideas in Aggregate Planning. Rudy Hung, in his *Production and Inventory Management Journal* article titled "Annualized Hours and Aggregate Planning," presents a useful concept called Annualized Hours (AH). Under AH, employees are contracted to work for a certain number of hours (say 1,800 hours) per year, for a certain sum of money. Employees can be asked to put in more hours during busy periods and fewer hours in slow periods. Typically, employees receive equal monthly or weekly payments so that hourly workers in effect have gained salaried status. Overtime is paid only when employees have worked beyond their annual hours.

AH is also known as flexiyear, as it can be seen as an extension of flextime, in which employees can vary their work hours within limits. This concept is used almost exclusively in Europe, particularly in the United Kingdom. The Scandinavian pulp and paper industries pioneered AH in the mid-1970s. Around that time, some West German firms, particularly those in the retail industry, also used AH.

AH gives employers much flexibility. AH serves to cut labor costs by offering employees an annual sum less than their previous annual earnings with overtime. Even though their total earnings may fall, their average earnings per hour would remain the same or even rise. Effective earnings could rise even more if the employer is unable to consume all contracted hours. Employees have greater income security with no worries about layoffs. There is also increased morale because blue-collar workers are now salaried. In a 2007 publication, authors Lusa, Corominas and Pastor offer a practical approach to balancing AH workers' time, given their varied skill levels. Their publication, "An exact procedure for planning holidays and working time under annualized hours considering cross-trained workers with different efficiencies" attempts to bridge the gap between academic and realistic conversations about AH.

Another development affecting aggregate planning is postponement. This refers to delaying the "finish" of a product until the moment of sale. Firms that rely on the postponement strategy, such as PC-maker Dell, Inc., or clothing franchise Benetton Group Sp.A., depend upon the availability of aggregate inventories of components that can be assembled to order shortly after, or even immediately, as an order is taken. Dell's process also illustrates a subcategory of postponement known as tailored business streams, in which similar items are segregated into parallel tracks. In a tailored business stream, the manufacturer identifies common elements that unite a bulk of its output. The easier, more predictable processes can be managed with the least expensive management approach, while unpredictable elements are managed with a more structured—and thus more expensive—infrastructure. By keeping the processes separate, the company ensures that resources are used efficiently. This process also includes an element of monitoring so that as pricing or market conditions change, the company can ensure that the processes remain efficient.

ANGEL INVESTORS AND VENTURE CAPITALISTS

Angel investors and venture capitalists (VCs) are two sources of funding for businesses. Both angels and VCs invest in entrepreneurial firms in exchange for an equity share in the business. An angel is a high-net-worth individual who invests his or her own capital in a company, where a venture capitalist manages a fund of pooled money from other sources (such as pension funds and insurance companies). Angel investors tend to inject start-up capital into a company's seed round of investment, where VCs generally invest in later-stage companies. Typically, VCs invest $2,000,000 or more in a financing round and angels invest amounts in the $5,000 to $100,000 range. The Angel Capital Report by the Center for Venture Research found that venture capitalists invested $29.4 billion in 3,814 companies in 2007. By comparison, angels invested $26 billion in 57,120 companies.

ANGEL INVESTORS

Typically, angel investors are former entrepreneurs who have retired on profit they earned from starting up successful businesses. Angels tend to seek active involvement in the companies they fund. Angel investments are usually very high risk because many are lost when start-up companies fail—in 2007, 27 percent of angel investment exits were accounted for by bankruptcies. Thus, businesses funded by angels must have the potential to return ten or more times the original investment within five years through an exit strategy such as a sale or an initial public offering (IPO). In 2007, mergers and acquisitions accounted for 65 percent of angel exits and IPOs represented 4 percent.

Angel investment is the largest source of seed capital available in the United States. In 2007, 39 percent of investments made by angels were in the start-up stage.

According to the Center for Venture Research, market conditions and the capital gap between the upper range of angel investment and the lower end of VC financing have required angels to invest in later-stage businesses. In 2007, 35 percent of angel funding was given to businesses in the expansion stage.

ANGEL GROUPS

Angel Groups are formed when a number of private investors wish to pool their resources to invest collectively in companies. These groups meet to review proposals from businesses seeking funding and conduct "due diligence" to decide whether to invest in a firm. Angel groups are usually made up of 10 to 150 accredited investors. As of 2008, there are over 300 of these groups.

VENTURE CAPITALISTS

Venture capital is a form of private equity invested in companies in exchange for convertible debt of ownership equity with the intention of taking the business public. Venture capitalists are fund managers who invest capital pooled from third-party investors in high-risk companies with the potential for high returns. The third-party investors are made up of wealthy investors and financial institutions. VCs tend to fund enterprises that are too risky for bank loans or the standard capital markets. For this reason, many new companies with a limited operating history seek venture capital, because they cannot obtain funding through a debt issue. One disadvantage for entrepreneurs who are funded by venture capital is the VCs usually get a say in company decisions.

THE ART AND SCIENCE OF MANAGEMENT

One of the enduring questions in the field of management is whether management is an art or a science. Webster's College Dictionary defines an art as "skill in

conducting any human activity" and science as "any skill or technique that reflects a precise application of facts or a principle." Reflected in the differences in these definitions is the use of precision in science, in that there is a particular, prescribed way in which a manager should act. Thus, management as a science would indicate that in practice, managers use a specific body of information and facts to guide their behaviors, but that management as an art requires no specific body of knowledge, only skill.

Conversely, those who believe management is an art are likely to believe that there is no specific way to teach or understand management, and that it is a skill borne of personality and ability. Those who believe in management as an art are likely to believe that certain people are more predisposed to be effective managers than are others, and that some people cannot be taught to be effective managers. That is, even with an understanding of management research and an education in management, some people will not be capable of being effective practicing managers.

FOUNDATIONS OF THE MANAGEMENT AS A SCIENCE PERSPECTIVE

Practicing managers who believe in management as a science are likely to believe that there are ideal managerial practices for certain situations. That is, when faced with a managerial dilemma, the manager who believes in the scientific foundation of his or her craft will expect that there is a rational and objective way to determine the correct course of action.

This manager is likely to follow general principles and theories and also by creating and testing hypotheses. For instance, if a manager has a problem with an employee's poor work performance, the manager will look to specific means of performance improvement, expecting that certain principles will work in most situations. He or she may rely on concepts learned in business school or through a company training program when determining a course of action, perhaps paying less attention to political and social factors involved in the situation.

Many early management researchers subscribed to the vision of managers as scientists. The scientific management movement was the primary driver of this perspective. Scientific management, pioneered by Frederick W. Taylor, Frank and Lillian Gilbreth, and others, attempted to discover "the one best way" to perform jobs. They used scientific processes to evaluate and organize work so that it became more efficient and effective. Scientific management's emphasis on both reducing inefficiencies and on understanding the psychology of workers changed manager and employee attitudes towards the practice of management. See Exhibit 1 for a summary of the principles of scientific management.

Exhibit 1

Frederick W. Taylor's Principles of Scientific Management

1. Managers must study the way that workers perform their tasks and understand the job knowledge (formal and informal) that workers have, then find ways to improve how tasks are performed.

2. Managers must codify new methods of performing tasks into written work rules and standard operating procedures.

3. Managers should hire workers who have skills and abilities needed for the tasks to be completed, and should train them to perform the tasks according to the established procedures.

4. Managers must establish a level of performance for the task that is acceptable and fair and should link it to a pay system that rewards workers who perform above the acceptable level.

FOUNDATIONS OF MANAGEMENT AS AN ART PERSPECTIVE

Practicing managers who believe in management as an art are unlikely to believe that scientific principles and theories will be able to be implemented in actual managerial situations. Instead, these managers are likely to rely on the social and political environment surrounding the managerial issue, using their own knowledge of a situation rather than generic rules to determine a course of action.

For example, as a contrast to the example given previously, a manager who has a problem with an employee's poor work performance is likely to rely on his or her own experiences and judgment when addressing this issue. Rather than having a standard response to such a problem, this manager is likely to consider a broad range of social and political factors and is likely to take different actions depending on the context of the problem.

Henry Mintzberg is probably the most well-known and prominent advocate of the school of thought that management is an art. Mintzberg is an academic researcher whose work capturing the actual daily tasks of real managers was groundbreaking research for its time. Mintzberg, through his observation of actual managers in their daily work, determined that managers did not sit at their desks, thinking, evaluating, and deciding all day long, working for long, uninterrupted time periods. Rather, Mintzberg determined that managers engaged in very fragmented work, with constant interruptions and rare opportunities to quietly consider managerial issues. Thus, Mintzberg revolutionized thinking about managers at the time that his work was published, challenging the prior notion that managers behaved rationally and methodically. This was in line with the perspective of management as an art, because it indicated that managers did not necessarily have routine behaviors throughout their days, but instead used their own social and political skills to solve problems that arose throughout the course of work.

Another scholar that promoted the notion of management as an art was David E. Lilienthal, who in 1967 had his series of lectures titled *Management: A Humanist Art* published. In this set of published lectures, Lilienthal argues that management requires more than a mastery of techniques and skills; instead, it also requires that managers understand individuals and their motivations and help them achieve their goals. Lilienthal believed that combining management and leadership into practice not only by getting work done but by understanding the meaning behind the work, as effective managerial behavior. Thus, he promoted the idea of the manager as a motivator and facilitator of others. This manager as an artist was likely to respond differently to each employee and situation, rather than use a prescribed set of responses dictated by a set of known guidelines.

Another proponent of the management as art school of thought is Peter Drucker, famed management scholar who is best known for developing ideas related to total quality management. Drucker terms management "a liberal art," claiming that it is such because it deals with the fundamentals of knowledge, wisdom, and leadership, but because it is also concerned with practice and application. Drucker argues that the discipline (i.e., the science) of management attempts to create a paradigm for managers in which facts are established and exceptions to these facts are ignored as anomalies. He is critical of the assumptions that make up the management paradigm, because these assumptions change over time as society and the business environment change. Thus, management is more of an art, because scientific "facts" do not remain stable over time.

ART AND SCIENCE IN MANAGEMENT RESEARCH

Noted researcher Thomas Kuhn, in his book *The Structure of Scientific Revolutions,* addresses issues associated with the state of current scientific research and the opportunities for scientific discovery. Kuhn, in previous editions of this text, drew distinctions between mature and immature fields of study.

In mature fields of study, many of the central questions of that field have been answered, and strong consensus exists among researchers regarding the fundamental assumptions of that field. Conversely, in immature fields of study, there is still a great deal of debate on major questions in the field, and gains in knowledge come sporadically.

In many ways, management is an immature science. While its foundations in psychology, sociology, and other related areas give it a long and rich history, the nature of the areas of study renders it immature. That is, due to the difficulties of studying human behavior in a number of disparate settings, the study of management is still very young when compared to other fields of research (e.g., in the physical sciences). In fact, many scholars have argued that the social sciences (e.g., management research) suffer from envy of the physical sciences, in which "truths" are able to be determined through research. As such, social sciences researchers may strive to create a more "scientific" approach to their fields in order to grant them more legitimacy.

Despite its relative immaturity, some consistent answers have been developed in the field of management. In many ways this is due to the increased sophistication of management research. However, there are still a number of research gaps in management; despite our increased knowledge in some areas, there is still a great deal of disagreement and confusion in other areas. In these circumstances, the practice of management is likely to be dictated by the perspective of management as an art. Because there are no hard and fast rules in certain circumstances, individual managers' experiences and skills must guide them.

In the twenty-first century, much of the management research conducted in academic institutions blends the notion of management as an art and as a science. Some of these trends in management research that have pushed the field in either direction—namely increased statistical sophistication and the emphasis on contextual influences—are described below.

Increased Statistical Sophistication. As computer technology continues to improve, the ability of management researchers to conduct sophisticated statistical analyses has also been enhanced. Powerful statistical computing packages are now readily available for desktop computers, allowing for high-speed analysis of complex statistical models. Additionally, new statistical modeling techniques, such as structural equations modeling, have gained footing in management research. Thus, management researchers are now better able to empirically test more complex research hypotheses, and management as a science is perpetuated.

The improvement in researchers' ability to analyze statistics more quickly has resulted in an increase in information about theories of management. Practicing managers may now know of certain relationships that have received strong support through decades of empirical research. Such "truths" may become guiding principles that practicing managers see as ideal solutions to a variety of situations.

For instance, numerous empirical studies over several recent decades have supported the relationship between appropriate goal setting and higher work performance. This relationship has been tested in a variety of situations, with a number of contextual influences present, yet

the statistical relationship holds in nearly all of them. Thus, a practicing manager may see this body of empirical research and, in a work situation, see the benefits of goal setting on performance as a scientific ideal. He or she may then implement goal setting in a number of practical situations, bolstered by the confidence afforded by decades of research supporting such actions.

Meta-analysis, in particular, is a methodological procedure that has contributed significantly to the study of management. Meta-analysis is a statistical technique that allows a researcher to combine findings from multiple studies, correct for errors in study design, and determine an "average" statistical relationship among variables.

Meta-analysis first gained a foothold in management research in studies of the validity of selection techniques for different jobs in different organizations. Before the application of meta-analysis to research the validity of different selection techniques, there was a belief in the situational specificity of these selection methods. That is, studies of the accuracy of selection techniques in predicting subsequent job performance had such disparate results that academics concluded that validity of a standardized test, for example, would differ dramatically in each selection situation (e.g., with different job applicants, in different organizations, in different geographic regions). This myth was dispelled, however, with the application of meta-analysis to the results of the collected body of research on the validity of selection methods. The use of meta-analysis established that the differences in findings were due primarily to limitations of research design, such as small sample size, unreliability of measures, and other correctable problems. When meta-analysis was applied to this group of studies, they were combined to determine that validates of selection techniques were general across jobs and organizations. Thus, the use of meta-analysis helped to establish that cognitive ability tests and structured interviews were highly valid selection methods in nearly every job.

Meta-analysis has now been applied to many different areas of management research, including training, recruitment, fairness, and other topics. Additionally, there have been a number of refinements to the statistical corrections used in meta-analysis.

The increased acceptance and use of meta-analysis in management research supports the notion of management as a science. Meta-analysis provides for "truths" in management—relationships between variables that hold strong regardless of the people or situation involved.

For instance, one consistent finding is that structured selection interviews (ones in which applicants are asked the same set of predetermined questions, and in which responses are evaluated using the same criteria) are a more valid predictor of future job performance than are unstructured interviews (in which applicants are asked different questions and responses are evaluated using different criteria). Meta-analysis has been used to establish this finding, and thus a practicing manager may use this information as a scientific "fact" when conducting selection interviews.

Contextual Influences. While improvements in management researchers' ability to conduct statistical analysis in their studies has promoted the notion of management as a science, in some ways it has also promoted management as an art. Because of the capability to statistically analyze and interpret larger, more complex models of behavior, researchers are now testing models with this increased complexity.

In particular, there is an increased emphasis on contextual influences. That is, rather than focusing solely on how behaviors are linked to outcomes, many researchers now include individual, social, and political variables in research models to have a richer understanding of behavior. Thus, there are more complex recommendations that can be made from recent research, rather than basic truths.

For example, one of the most prominent areas of contextual research in recent years is in person-organization fit (p-o fit). The p-o fit model is a part of the attraction-selection-attrition model that suggests that certain types of individuals are attracted to particular organizations, selected by those organizations, and either adapt to become an effective part of the organization, or leave if they do not fit with the organization. The p-o fit model is the notion that the particular skills, attitudes, values, and preferences of an individual employee should fit with those of the organization in order for that employee to have high job satisfaction and performance. The model also indicates that this fit is likely to be as important as an assessment of applicants' abilities when hiring.

Previous models of selection emphasized a strict interpretation of applicant skills, with the use of valid selection tests as most important. However, the p-o fit model indicates that, even if skills and abilities have been appropriately measured, that hiring the applicant with the best skills is not always the best course of action, but that hiring an individual who fits into the culture of the organization could be more advantageous.

This move towards including contextual influences in management research models promotes the notion of management as an art. Rather than indicating that there are specific principles and guidelines that can guide management practice, it suggests that managerial behavior should change based on the social and political context of the situation.

ART AND SCIENCE IN MANAGEMENT EDUCATION AND DEVELOPMENT

Management education and development, which attempts to prepare today's managers for organizational challenges, are guided by both the notion of management as an art and as a science. The approach to management education and development is likely to differ dramatically depending on the belief one has as to the nature of the practice of management. The perspective of management as an art assumes to some extent that a manager has a disposition or experiences that guide him or her in managerial decisions and activities. Thus, with this perspective, many managers may be successful without any formal education or training in management. The perspective of management as a science, however, would indicate that management skills can be taught through an understanding of theory and principles of management. Many of today's educational institutions and workplaces blend the notion of management as a science and an art in their approach to preparing employees for management.

Management education in today's universities primarily emphasizes management as a science. Textbooks used in management courses emphasize many of the consistent findings of many decades of management research. And, as these degrees increase in popularity, it is likely that more practicing managers will have a set of established management ideals with which they operate.

While formal management education may promote management as a science, many development efforts support the notion of management as an art. To cultivate management talent, organizations offer mentoring, overseas experiences, and job rotation. These activities allow managers to gain greater social and political insight and thus rely on their own judgment and abilities to improve their management style. Much of mentoring involves behavior modeling, in which a protégé may learn nuances of managerial behavior rather than a set of specific guidelines for managing. Overseas experiences are likely to involve a great deal of manager adaptation, and the general rules by which a manager might operate in one culture are likely to change when managing workers in other countries. Finally, job rotation is a technique that requires a manager to work in a variety of settings. Again, this encourages a manager to be flexible and adaptive, and likely rely more on his or her personal skill in managing.

The foundations of management as an art and management as a science are evident in today's educational institutions and work organizations. Management as a science was primarily influenced by researchers in the area of scientific management, such as Frederick Taylor, and continues today in much of the empirical research on management issues. Management as an art has been influenced by scholars such as Henry Mintzberg and Peter Drucker, and is often evident in complex theories of management. Many scholars and practitioners blend art and science to more effectively cultivate managerial talent. This is evident in recent theories of management, research in workplaces, and education and development of managers.

Future Issues in Management Education. The Association to Advance Collegiate Schools of Business (AACSB) task force on management and education and other management theorists have identified challenges facing the future of the field of management. Among these challenges are making both the art and science of management accessible to students in the field. At the same time, managers must prepare to face the challenges of globalization. In meeting this challenge, management educators can bring a new focus to the managers who will lead in the next generation of businesses.

ARTIFICIAL INTELLIGENCE

Artificial intelligence (AI) refers to computer software that exhibits intelligent behavior. The term "intelligence" is difficult to define and has been the subject of heated debate by philosophers, educators, and psychologists for ages. Nevertheless, it is possible to enumerate many important characteristics of intelligent behavior. Intelligence includes the capacity to learn, maintain a large storehouse of knowledge, utilize commonsense reasoning, apply analytical abilities, discern relationships between facts, communicate ideas to others and understand communications from others, and perceive and make sense of the world around us. Thus, artificial intelligence systems are computer programs that exhibit one or more of these behaviors.

AI systems can be divided into two broad categories: knowledge representation systems and machine learning systems. Knowledge representation systems, also known as expert systems, provide a structure for capturing and encoding the knowledge of a human expert in a particular domain. For example, the knowledge of medical doctors might be captured in a computerized model that can be used to help diagnose patient illnesses.

MACHINE LEARNING SYSTEMS

The second category of AI, machine learning systems, creates new knowledge by finding previously unknown patterns in data. In contrast to knowledge representation approaches, which model the problem-solving structure of human experts, machine learning systems derive solutions by "learning" patterns in data, with little or no intervention by an expert. There are three main machine learning techniques: neural networks, induction algorithms, and genetic algorithms.

Neural Networks. Neural networks simulate the human nervous system. The concepts that guide neural network research and practice stem from studies of biological systems. These systems model the interaction between nerve cells. Components of a neural network include neurons (sometimes called "processing elements"), input lines to the neurons (called dendrites), and output lines from the neurons (called axons).

Neural networks are composed of richly connected sets of neurons forming layers. The neural network architecture consists of an input layer, which inputs data to the network; an output layer, which produces the resulting guess of the network; and a series of one or more hidden layers, which assist in propagating. This is illustrated in Figure 1.

During processing, each neuron performs a weighted sum of inputs from the neurons connecting to it; this is called activation. The neuron chooses to fire if the sum of inputs exceeds some previously set threshold value; this is called transfer.

Inputs with high weights tend to give greater activation to a neuron than inputs with low weights. The weight of an input is analogous to the strength of a synapse in a biological system. In biological systems, learning occurs by strengthening or weakening the synaptic connections between nerve cells. An artificial neural network simulates synaptic connection strength by increasing or decreasing the weight of input lines into neurons.

Neural networks are trained with a series of data points. The networks guess which response should be given, and the guess is compared against the correct answer for each data point. If errors occur, the weights into the neurons are adjusted and the process repeats itself. This learning approach is called backpropagation and is similar to statistical regression.

Neural networks are used in a wide variety of business problems, including optical character recognition, financial forecasting, market demographics trend assessment, and various robotics applications.

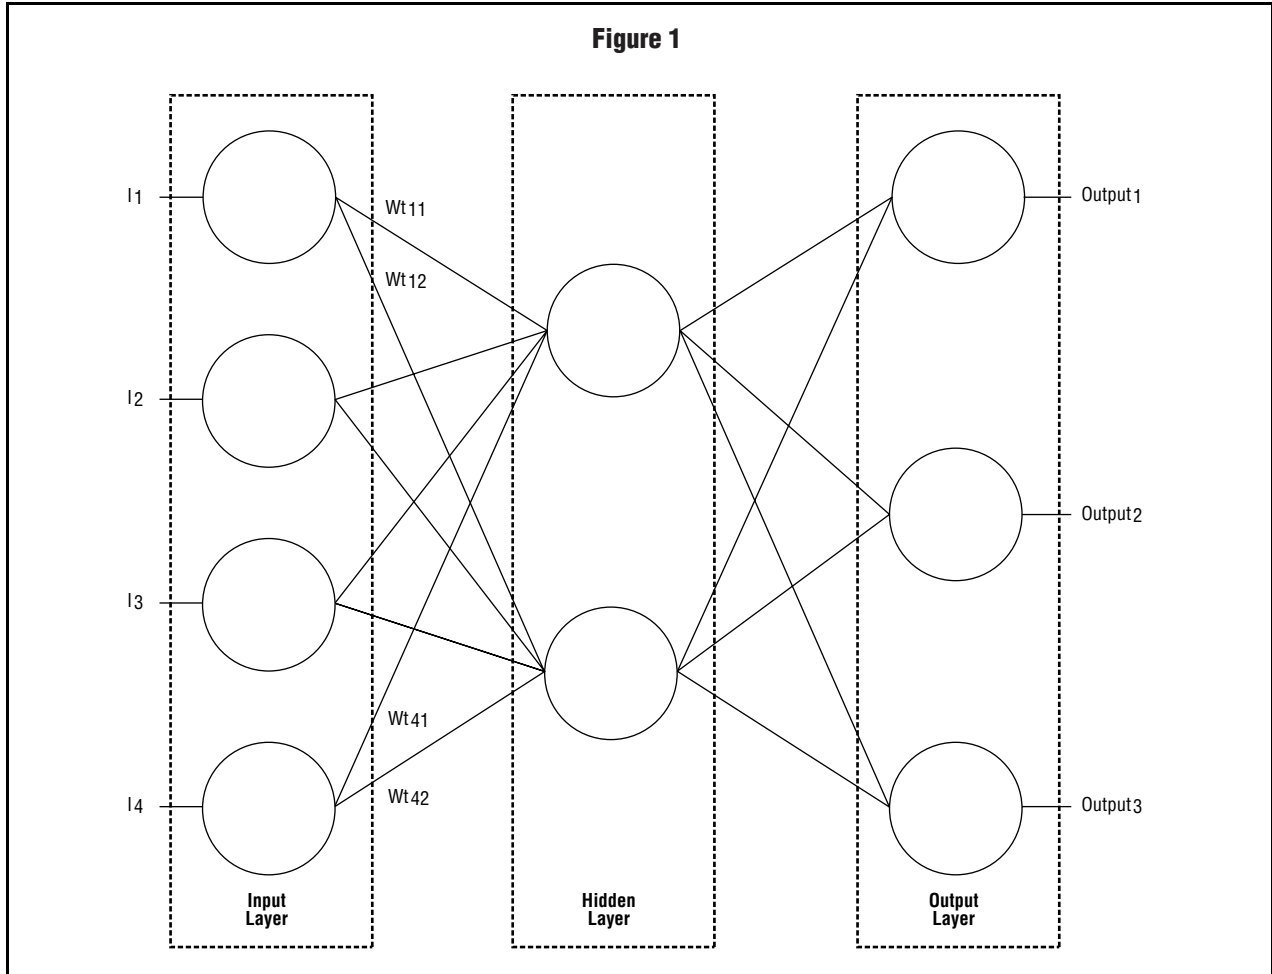
Induction Algorithms. Induction algorithms form another approach to machine learning. In contrast to neural networks (which are highly mathematical in nature), induction approaches tend to involve symbolic data. As the name implies, these algorithms work by implementing inductive reasoning approaches. Induction is a reasoning method that can be characterized as "learning by example." Unlike rule-based deduction, induction begins with a set of observations and constructs rules to account for these observations. Inductive reasoning attempts to find general patterns that can fully explain the observations. The system is presented with a large set of data consisting of several input variables and one decision variable. The system constructs a decision tree by recursively partitioning data sets based on the variables that best distinguish between the data elements. That is, it attempts to partition the data so that each partition contains data with the same value for a decision variable. It does this by selecting the input variables that do the best job of dividing the data set into homogeneous partitions. For example, consider Figure 2, which contains the data set pertaining to decisions that were made on credit loan applications.

An induction algorithm would infer the rules in Figure 3 to explain this data.

As this example illustrates, an induction algorithm is able to induce rules that identify the general patterns in data. In doing so, these algorithms can prune out irrelevant or unnecessary attributes. In the example above, salary was irrelevant in terms of explaining the loan decision of the data set.

Figure 1

Figure 1

and return to the origin. For such a problem there are $(n - 1)!$ possible solutions, or $(n - 1)$ factorial. For six cities, this would mean $5 \times 4 \times 3 \times 2 \times 1 = 120$ possible solutions. Suppose that the salesman must travel to 100 cities. This would involve $99!$ possible solutions, an astronomically high number.


Induction algorithms are often used for data mining applications, such as marketing problems that help companies decide on the best market strategies for new product lines. Data mining is a common service included in data warehouses, which are frequently used as decision support tools.

Genetic Algorithms. Genetic algorithms use an evolutionary approach to solve optimization problems. These are based on Darwin's theory of evolution, and in particular the notion of survival of the fittest. Concepts such as reproduction, natural selection, mutation, chromosome, and gene are all included in the genetic algorithm approach.

Genetic algorithms are useful in optimization problems that must select from a very large number of possible solutions to a problem. A classic example of this is the traveling salesperson problem. Consider a salesman who must visit n cities. The salesperson's problem is to find the shortest route by which to visit each of these n cities exactly once, so that the salesman will tour all the cities

Figure 2
Artificial Intelligence & Expert Systems

	Salary	Credit History	Current Assets	Loan Decision
a)	High	Poor	High	Accept
b)	High	Poor	Low	Reject
c)	Low	Poor	Low	Reject
d)	Low	Good	Low	Accept
e)	Low	Good	High	Accept
f)	High	Good	Low	Accept

Obviously, for this type of problem, a brute strength method of exhaustively comparing all possible solutions

---

Figure 3

If the credit history is good, then accept the loan application

If the credit history is poor and current assets are high, then accept the loan application

If the credit history is poor and current assets are low, then reject the loan application

---

will not work. This requires the use of heuristic methods, of which the genetic algorithm is a prime example. For the traveling salesperson problem, a chromosome would be one possible route through the cities, and a gene would be a city in a particular sequence on the chromosome. The genetic algorithm would start with an initial population of chromosomes (routes) and measure each according to a fitness function (the total distance traveled in the route). Those with the best fitness functions would be selected and those with the worst would be discarded. Then random pairs of surviving chromosomes would mate, a process called crossover. This involves swapping city positions between the pair of chromosomes, resulting in a pair of child chromosomes. In addition, some random subset of the population would be mutated, such that some portion of the sequence of cities would be altered. The process of selection, crossover, and mutation results in a new population for the next generation. This procedure is repeated through as many generations as necessary in order to obtain an optimal solution.

Genetic algorithms are very effective at finding good solutions to optimization problems. Scheduling, configuration, and routing problems are good candidates for a genetic algorithm approach. Although genetic algorithms do not guarantee the absolute best solution, they do consistently arrive at very good solutions in a relatively short period of time.

AI IN THE TWENTY-FIRST CENTURY

Artificial intelligence systems provide a key component in many computer applications that serve the world of business. In fact, AI is so prevalent that many people encounter such applications on a daily basis without even being aware of it.

One of the most ubiquitous uses of AI can be found in network servers that route electronic mail and in email spam-filtering devices. Expert systems are routinely utilized in the medical field, where they take the place of doctors to assess the results of tests like mammograms or electrocardiograms; credit card companies, banks, and insurance firms commonly use neural networks to help detect fraud. These AI systems can, for example, monitor consumer-spending habits, detect patterns in the data, and alert the company when uncharacteristic patterns

arise. Genetic algorithms serve logistics planning functions in airports, factories, and even military operations, where they are used to help solve incredibly complex resource-allocation problems. And perhaps most familiar, many companies employ AI systems to help monitor calls in their customer service call centers. These systems can analyze the emotional tones of callers' voices or listen for specific words, and route those calls to human supervisors for follow-up attention.

Artificial Intelligence is routinely used by enterprises in supply chain management through the use of a set of intelligent software agents that are responsible for one or more aspects of the supply chain. These agents interact with one another in the planning and execution of their tasks. For instance, a logistics agent is responsible for coordinating the factories, suppliers, and distribution centers. This agent provides inputs to the transportation agent, which is responsible for assignment and scheduling transportation resources. The agents coordinate their activities with the optimization of the supply chain as the common goal.

Customer Relationship Management uses artificial intelligence to connect product offers and promotions with consumer desires. AI software profiles customer behavior by finding patterns in transaction data. The software generates algorithms for evaluating different data characteristics, such as what products are frequently bought together or the time of year a product sells the most. Thus, the software is able to use historical data to predict customer behavior in the future.

Artificial intelligence is also used on Wall Street in the selection of stocks. Analysts use AI software to discover trading patterns. For instance, an algorithm could find that the price movements of two stocks are similar; when the stocks diverge a trader might buy one stock and sell the other on the assumption that their prices will return to the historical norm. As the use of trading algorithms becomes more commonplace, there is less potential for profit.

Although computer scientists have thus far failed to create machines that can function with the complex intelligence of human beings, they have succeeded in creating a wide range of AI applications that make people's lives simpler and more convenient.

ASSESSMENT CENTERS

An assessment center is a process used to make personnel decisions in which participants engage in a variety of exercises and have their performance evaluated by multiple assessors. The goal of an assessment center is to simulate job tasks so that an applicant can demonstrate skills or characteristics that would be effective on the job.

According to the International Task Force on Assessment Center Guidelines, assessment centers:

- Conduct job analyses of relevant behaviors

- Classify participants' behaviors into meaningful and relevant categories

- Use techniques that are designed to provide information for evaluating the dimensions previously determined by the job analysis

- Involve multiple assessment techniques, such as tests, interviews, questionnaires, sociometric devices, and simulations

- Include a sufficient number of job-related simulations, allowing opportunities to observe the candidate's behavior related to each competency/dimension being assessed

- Utilize several assessors to evaluate each participant

- Employ thoroughly trained assessors

- Provide a means for assessors to record their observations of participants' behavior as it occurs

- Involve the preparation of an assessor's report

- Base the integration of behaviors on the pooling of assessors' information, or upon a statistical integration process validated in accordance with professionally accepted standards

Behavioral dimensions that are frequently measured in assessment centers include planning and organizing, leadership, oral communication, tolerance for stress, and initiative. Participants have their performance on these and similar dimensions evaluated while engaging in two or more of the following activities over a one- or two-day period:

- In-basket exercises, in which participants respond to a series of administrative problems that simulate typical managerial tasks

- Leaderless group discussions, in which a group of participants without an assigned leader must arrive at a group solution to a specified problem within a given time period

- Role-plays, in which participants are involved in a simulation of a situation that could occur on the job

- Interviews, in which participants typically are questioned about how they have handled particular work situations in the past and how they would respond to specific work situations in the future

- Management games, in which participants must work cooperatively to meet mental or physical challenges

Evaluations of assessment center participants can be used for employee selection decisions (hiring and promotion) and to help identify training and development needs. The most common use of assessment centers is to evaluate participants' management potential. When used for selection or promotion decisions, the emphasis is on identifying participants who do well on essential job performance dimensions. When used for training and development purposes, the focus is on identifying participant deficiencies on critical job dimensions. The feedback and employee-development suggestions that result from an assessment form the basis for training programs that are designed to correct performance problems. For organizations, assessment centers can serve as needs assessment programs that identify employee development and hiring needs.

Early versions of assessment centers were used by the military in the 1940s. The first use of an assessment center in an industrial setting was in the 1950s, when AT&T used the process in an attempt to evaluate participants' potential for managerial success. The results of this early assessment center application were encouraging, and assessment center use increased following AT&T's apparent success. According to one study by Gaugler, Rosenthal, Thornton, and Bentson, by 1987 more than 2,000

organizations, including Pepsico, IBM, Rubbermaid, and the FBI, used assessment centers to select and promote managers.

As the use of assessment centers increased during the 1960s and 1970s, researchers identified several ways in which their utility as a personnel selection tool could be improved. In 1973, Bender suggested that companies should undertake validation studies to ensure that assessment centers actually predicted managerial success. He also pointed out that assessors should be more thoroughly trained before they evaluated assessment center participants.

In an attempt to encourage uniformity and professionalism in assessment center practices, the Task Force on Assessment Center Guidelines published *Guidelines and Ethical Considerations for Assessment Center Operations* in 1989. These guidelines were updated in 2000 and endorsed by the International Congress on Assessment Center Methods. They spell out the essential elements of assessment centers and provide recommendations regarding the content of assessor training, information participants should receive before beginning the assessment center, data usage, and validation methods. In addition, these guidelines provide a standard for judging assessment center practices employed by organizations. In 2004, the International Congress on Assessment Center Methods formed a task force to address the growing trend towards globalization. A draft of the guidelines was presented at the organization's annual conference in 2006. The document still exists in draft form at time of this writing.

The preponderance of research evidence indicates that, when designed and conducted in a manner consistent with professional guidelines, assessment centers are valid predictors of future promotions and job performance. Additional research suggests that assessment centers have less adverse impact on women and minorities than many other commonly used selection tools, and courts generally have upheld the use of properly designed assessment centers. Again, there are factors that must be considered as companies become increasingly multinational.

The primary criticism of assessment centers is that they are very expensive in terms of both development and implementation, which makes their use infeasible for many small organizations. Other researchers question the convergent and discriminant validity of the measurement of behavioral dimensions in assessment centers. One method used to overcome the expense problem is to videotape the candidates' performance and have the assessors evaluate them later. This avoids costs and problems related to the logistics of assembling candidates and assessors. Another technique is to use "situational judgment tests" or written simulation tests. Candidates either choose the best course of action from a selection of choices or provide a written course of action. Research indicates that situational judgment tests are good predictors of job performance.

AUTONOMY

Autonomy is the degree to which a job provides an employee with the discretion and independence to schedule his or her work and determine how it is to be done. Higher levels of autonomy on the job have been shown to increase job satisfaction, and in some cases, motivation to

perform the job. In traditional organizations, only those employees at higher levels had autonomy. However, new organizational structures, such as flatter organizations, have resulted in increased autonomy at lower levels. Additionally, many companies now make use of autonomous work teams. Autonomy in the workplace can have benefits for employees, teams, managers, and the company as a whole, but it also may have drawbacks. Information regarding both the pros and cons of autonomy for these groups is discussed below.

EMPLOYEE AUTONOMY

According to job design theories, increased autonomy should make employees feel a greater responsibility for the outcomes of their work, and therefore have increased work motivation. Research indicates that when employees have greater levels of autonomy, their personality traits (specifically conscientiousness and extroversion) have a stronger impact on job performance. Thus, by giving employees more autonomy, they are better able to use their personal attributes to contribute to job performance. Additionally, human resource research has shown that greater autonomy in the workplace leads to a broader self-definition held by workers. The same study found that this broader definition of role makes it more likely that workers will integrate more tasks into their role.

Unfortunately, too much autonomy can lead to employee dissatisfaction. Each individual has a different level of need for autonomy in his or her job. Some workers prefer more direction from a manager and feel uncomfortable with autonomy; they may not want to exert effort or take the responsibility of having their name solely associated with a task, project, or product. Additionally, if employees are not well-equipped—either in training or in personality—to exercise autonomy, it may result in workplace tension and poor performance. Finally, when given autonomy, workers may believe that they have authority somewhat equal to that of their direct supervisor. This may cause them to resent the extra responsibility or feel that their pay should be increased. A related concern is that managers may feel marginalized when employee autonomy increases, particularly when there is a change to a traditional work environment. Managers may feel that by giving employees autonomy, they no longer contribute as much to the organization or that their jobs may be at stake.

MANAGERIAL AUTONOMY

Managers tend to have increased autonomy in organizations that are more decentralized. In such organizations, managers have more latitude to make decisions regarding the work of employees and even personnel decisions. For example, managers with increased autonomy may be able to assign merit raises to the employees in their unit at their discretion. As with employee autonomy, this freedom can result in feelings of motivation and satisfaction for the manager, who may be in a better position to reward and motivate employees. However, as with employee autonomy, managers who have autonomy may not be equipped to handle it. If managers make poor decisions, this may be harmful to employees and the organization as a whole. Using the example of autonomy in deciding pay raises, a manager may give merit pay increases that are significantly higher than those in other work units, which may cause problems across the organization.

TEAM AUTONOMY

In recent years, many organizations have made use of teams in the workplace, many of which operate autonomously. Self-managed work teams are those in which a supervisor gives little direction to the team, and the team members manage themselves. The success of such teams depends greatly on the team members, including their professional capabilities and their ability to work together. Oftentimes, such autonomous teams can greatly enhance an organization's ability to be creative, flexible, and innovative. However, as with individuals, too much autonomy in a team can reduce productivity. When individuals work too independently, their lack of communication and monitoring of one another may result in poor team performance. Additionally, without supervision the team may pursue goals that are different from those of the organization. Thus, periodic meetings and supervision from a manager may be necessary to avoid problems associated with too much autonomy.

AUTONOMY AND THE ORGANIZATION

The autonomy of employees and managers is often dictated by an organization's structure and culture; traditional, bureaucratic organizations often have little autonomy, but newer, more organic structures rely on autonomy, empowerment, and participation to succeed. Employee autonomy is believed to have minimized some of the relational barriers between superiors and subordinates. Therefore, autonomy may improve workplace functions through the ideas and suggestions of employees, and foster relationships with a greater degree of trust between management and employees. However, increased autonomy in the organization also may create disparity among units through different work practices and rules. In the worst case, increased autonomy may allow some employees to engage in unethical behavior. Thus, a certain amount of oversight is necessary in

organizations to prevent wrongdoing that may go unnoticed when there are high levels of autonomy.

Autonomy generally is a positive attribute for employees, managers, teams, and organizations as a whole. Employees typically desire autonomy, and its introduction can increase motivation, overall job performance, and satisfaction. However, organizations should be careful when increasing autonomy, because too much autonomy can have organizational drawbacks.

B

B2B

B2B (business to business) companies make their primary profits by selling products or services to other businesses. Such companies often have an important place in the supply chain, channeling resources to manufacturing companies or handling distribution needs for retailers. The communication abilities that have arisen with widespread Internet service and Web-based applications have encouraged the growth of many different kinds of B2B companies that trade and market online.

Since B2B markets concern only businesses, product sales and contracts can often be streamlined, including much larger amounts and longer terms of service than result from selling only to consumers. Certain kinds of markets can be designed specifically for this type of transaction. Online B2B businesses typically use several different Web applications to reach other companies and establish relationships with them, including:

1. **Company Web sites.** Large B2B firms can set up their own Web sites to market services and promote their products. Interested companies can visit the Web site at any time to inspect the available good or service. The Web site can offer either a connection to a more private online structure available to contracted businesses, or can sell products directly from the site.

2. **Supply and procurement exchanges.** These are online markets designed specifically so that company agents can view available goods and services, and in many cases make bids for B2B contracts. This can include auctions, in which buyers vie to purchase from one

seller, and reverse auctions, in which many sellers lower their prices until a buyer accepts a contract. Some procurement sites focus on particular industries and the businesses exchanging services within them.

3. **Brokering sites.** These sites are a type of B2B company themselves, acting as a go-between for companies searching for a particular good or service and other companies that are able to offer those goods and services.

4. **Information sites, or Infomediary.** These Web sites offer a collection of information concerning specific industries. This information can include required legal standards, available businesses that provide needed products and services, and advice concerning purchasing prices and markets. Many information sites function as elaborate search engines on particular topics.

COMMON B2B COMPANY STRUCTURES

There are many types of B2B structures and marketing methods. Many strategies focus on relationship marketing—building a strong, long-lasting connection with a certain number of businesses based on high quality service and trust. Others work with complementary partners that can refer each other to buyers, thereby expanding the customer base via the partnership. Online marketing methods include mass e-mails, selective and effective telemarketing, and search engine optimization (SEO) techniques that create a significant Internet presence to buyers searching online for B2B supply and service solutions.

The type of products B2B businesses offer usually fall into three categories, based on the buyer's needs and expectations:

- **Commodities.** These types of products are readily available and can be immediately shipped to the businesses upon sales conclusion. These are usually simple goods that can be readily packaged and include few features. If the commodity is a service, then it is usually a standardized, simple process.

- **Customized goods.** These products are changed in some way to meet the buyer's specifications. These customizations are usually standard and often included in the marketing information advertised by the seller. Changes in color or style are types of customization common in B2B goods. This can slow down delivery, but such a delay is usually considered acceptable by the buyer.

- **Designed goods.** These products are built or engineered directly to buyer specifications, requiring a great deal of independent work to tailor them to company needs. Machine parts that need to work for a particular production system is one example. Designed services include advertising services applied to a specific good.

B2E MANAGEMENT (BUSINESS TO EMPLOYEE)

Many businesses exert effort to sell outside of the company, whether to other businesses, individual consumers, public organizations, or governments. However, there is another type of selling that companies are beginning to find more attractive, especially large companies, and this is B2E, or business-to-employee selling. This involves selling products and services within the company, advertising to employees through such in-company applications as intranets and e-mail. Often, special discounts or deals are extended to employees to encourage them to buy from the company. B2E enterprise can also refer to the spread of information and helpful services among employees to encourage overall company growth.

COMMON FORMS OF B2E

In the nonprofit services category, B2E initiatives usually fall into two groups that function as online applications over the company's intranet or Internet interface. The first group is mostly concerned with human resource (HR) functions, offering employees many types of opportunities and information. Updates concerning health care possibilities, payroll, and other types of compensation are included in this group, along with all types of online corporate training. The spread of company-wide messages or announcements also belong to the first set. The second group includes more extended types of employee benefits, such as travel reservations, compensation for certain types of employee expenses, credit services, and insurance management.

A separate type of nonprofit B2E services allows employees to access specialized portals containing necessary information for them and their tasks. This can include data, data mining operations, and certain searches that are available only to specific employees. There can also be meta-services that allow analysts to collect data on which employees use B2E services, which opportunities are most selected by the employees, and which services are the most successful.

ADVANTAGES TO B2E

There are many benefits for employees and organizations resulting from B2E practices. Employees—through participation and awareness—often increase their efficiency and overall ability to collaborate; they prove more willing to invest in the company and offer creative solutions for problems their business may encounter. B2E initiatives often lead to a logical increase in loyalty and satisfaction among the workforce, a movement directly related to awareness and availability of company services. The companies will benefit from B2E actions by saving on costs associated with interruption of data and a paper-oriented communication structure. Since B2E depends on online interaction, copying and distributing flyers, updates, or files is rarely necessary. B2E is also associated with a number of intranet networking applications, such as virtual teams and company wikis.

B2E portals and applications offer employees many of the same advantages online customers have, but are applied to their benefits at work. For instance, an important B2E tool can be a home page designed specifically for an employee. The employee can use their homepage to: access sites, files, and resources meant specifically for them; manage their health care options; explore other types of insurance the company offers; apply for expense

compensation; and review other features tailored to fit their needs. Such sites and applications may also include products or services of the company, made available at reduced cost for the employee. Any other data can be included in the employee portal to aid employees in collaboration and decisions.

BALANCE SHEETS

The balance sheet, also known as the statement of financial position, is a snapshot of a company's financial condition at a single point in time. It presents a summary listing of a company's assets, liabilities, and owners' equity. The balance sheet is prepared as of the last day of the business year. Therefore, it corresponds to the end of the time period covered by the income statement.

One must examine several accounting concepts to understand the balance sheet, its purpose, and its contents. First of all, the balance sheet represents the *accounting equation* for a company. The accounting equation is a mathematical expression that states the following:

<p align="center">Assets = Liabilities + Owners' Equity</p>

Stated more fully, this means that the dollar total of the assets equals the dollar total of the liabilities plus the dollar total of the owners' equity. The balance sheet presents a company's resources (e.g., assets, or anything the company owns that has monetary value) and the origin or source of these resources (i.e., through borrowing or through the contributions of the owners). Expressing the same dollar amount twice (once as the dollar total of the assets, then as the dollar total of where the assets came from or who has an equity interest in them) shows that the two amounts must be equal or balance at any given point in time.

An interesting observation about the balance sheet is the valuation at which assets are presented. The average

Table 1
Sample Balance Sheet

Assets		Liabilities and Owners' Equity	
Current assets	600,000	Current liabilities	280,000
Fixed assets	90,000	Long-term debt	500,000
Property	800,000	Owners' equity	900,000
Intangible assets	50,000		
Other assets	140,000		
Total Assets	**1,680,000**	**Total Liabilities and Owners' Equity**	**1,680,000**

person would assume that the assets listed on the balance sheet would be shown at their current market values. In actuality, generally accepted accounting principles require that most assets be recorded and disclosed at their historical cost, or the original amount that the company paid to obtain ownership or control of the assets. As time passes, however, the current value of certain assets will drift further and further away from their historical cost. In an attempt to present useful information, financial statements show some assets (for which there is a definite market value) at their current market value. When there is no specific market value, historical values are used.

A simple example of a balance sheet appears in Table 1.

ASSETS

As a category, assets include current assets, fixed or long-term assets, property, intangible assets, and other assets.

Current Assets. Assets can be viewed as company-owned or controlled resources from which the organization expects to gain a future benefit. Examples of assets for a typical company include cash, receivables from customers, inventory to be sold, land, and buildings. To make the balance sheet more readable, assets are grouped together based on similar characteristics and presented in totals, rather than as a long list of minor component parts.

The first grouping of assets is current assets. *Current assets* consist of cash, as well as other assets that will probably be converted to cash or used up within one year. The one-year horizon is the crucial issue in classifying assets as current. The concern is to present assets that will provide liquidity in the near future. Current assets should be listed on the balance sheet in the order of most liquid to least liquid. Therefore, the list of current assets begins with cash. Cash includes monies available in checking accounts and any cash on-hand at the business that can be used immediately as needed. Any cash funds or temporary investments that have restrictions on their

withdrawals, or that have been set up to be spent beyond one year, should not be included in current assets.

Temporary investments known as trading securities are short-term investments that a company intends to trade actively for profit. These types of investments—common to the financial statements of insurance companies and banks—are shown on the balance sheet at their current market value as of the date of the balance sheet. Any increase or decrease in market value since the previous balance sheet is included in the calculation of net income on the income statement.

The next category on the list of current assets is *accounts receivable,* which includes funds that are to be collected within one year from the balance sheet date. Accounts receivable represents the historical amounts owed to the company by customers as a result of regular business operations. Many companies are unable to collect all of the receivables due from customers. In order to disclose the amount of the total receivables estimated to be collectible, companies deduct what is known as a *contra account.* A contra account has the opposite balance of the account from which it is subtracted. The specific account title might be "allowance for uncollectible accounts" or "allowance for bad debts", and its balance represents the portion of the total receivables that will probably not be collected. The expense related to this is shown on the income statement as *bad debt expense.* The net amount of accounts receivable shown is referred to as the *book value.* Other receivables commonly included on the balance sheet are notes receivable (due within one year) and interest receivable.

Inventory is shown next in the current asset section of the balance sheet. If the company is a retailer or wholesaler, this asset represents goods that a company has purchased for resale to its customers. If the company is a manufacturer, it will have as many as three different inventory accounts depending on the extent to which the goods have been completed.

Inventory classified as *raw materials* represents the basic components that enter into the manufacture of the finished product. For a tractor manufacturer, raw materials would include the engine, frame, tires, and other major parts that are directly traceable to the finished product. The second type of inventory for a manufacturer would be *goods in process.* This category represents products that have been started but are not fully completed.

After the goods are completed, they are included in the final inventory classification known as *finished goods.* The value assigned to inventory is either its current market price or its cost to the manufacturer, whichever is lower. This is a conservative attempt to show inventory at its original cost, or at its lower market value if it has declined in value since it was purchased or manufactured.

The final group in the current assets section of the balance sheet is *prepaid expenses.* This group includes prepayments for such items as office supplies, postage, and insurance for the upcoming year. The total for these items is shown at historical cost.

Fixed or Long-Term Assets. These assets differ from those listed under current assets because they are not intended for sale during the year following the balance sheet date; that is, they will be held for more than one year into the future. Such asset investments are classified under the headings of *held to maturity* for investments in debt instruments such as corporate or government bonds, and *available for sale* for investments in equity (stock) instruments of other companies or debt securities that will not be held to maturity.

Held-to-maturity investments are disclosed in the balance sheet at their *carrying value.* The carrying value is initially equal to the historical cost of the investment; this amount is adjusted each accounting period so that, when the investment matures, its carrying value will then be equal to its maturity value. These adjustments are included in the calculation of income for each accounting period.

Available-for-sale investments are adjusted to market value at the end of each accounting period, and these adjustments are included in the calculation of owners' equity.

Property. Sometimes listed under the expanded heading "property, plant, and equipment," this section of the balance sheet includes long-term, tangible assets that are used in the operation of the business. These assets have a long-term life and include such things as land, buildings, factory and office equipment, and computers. Land is listed first because it has an unlimited life and is shown at its historical cost. The other assets, such as buildings and equipment, are shown at book value. Book value is the original cost of the asset reduced by its total depreciation since being placed into service by a company. This net amount is frequently called net book value, and it represents the remaining cost of the asset to be depreciated over the remaining useful life of the asset.

Several methods are used to calculate depreciation (e.g., straight-line and accelerated), and each uses a mathematical formula to determine the portion of the original cost of the asset that is associated with the current year's operations. Note that depreciation is not an attempt to reduce a long-lived asset to its market value. Accountants use market value on the balance sheet when it is readily available and required for use by generally accepted accounting principles. However, in the case of many property items an unbiased estimate of market value

may not be available. As a result, accountants use the asset's historical cost reduced by the depreciation taken to date to indicate its remaining useful service potential.

Intangible Assets. Some long-lived assets of a company represent legal rights or intellectual property protections that are intangible by nature. Examples of this type of asset include a company's patents, copyrights, and trademarks. Each of these assets has a legally specified life and expires at the end of that period, although a few can be renewed. Accountants attempt to measure this decline in usefulness by amortizing the historical costs of these assets. This concept is the same as recording depreciation for items of tangible property discussed above.

One special type of intangible asset is known as *goodwill*. Goodwill is acquired when one company purchases another company and pays more than the estimated market value of the net assets held by the purchased company. The buying company might do this for a number of reasons, but it is often necessary in order to encourage the previous owners to sell and to guarantee that the acquisition is successful. The difference between the purchase price and the market value of the assets also can be attributed to intangible factors in the purchased company's success, such as proprietary processes or customer relationships. Like other intangible assets, the historical cost of goodwill is amortized over its future years. Historically, accounting rules set a maximum life of forty years for goodwill, but in the twenty-first century twenty years is often used as the maximum amount of time.

Other Assets. This final section covering the disclosure of assets on the balance sheet is a miscellaneous category that includes any long-lived asset that does not fit in any of the categories defined above. This category might include such assets as long-lived receivables (from customers or related companies) and long-lived prepaid insurance premiums (those paid for coverage beyond the next year from the balance sheet date). Another example is a deferred charge (such as a deferred tax asset), or an amount that has been prepaid based on generally accepted accounting principles and holds future benefit for the company.

LIABILITIES
Liabilities include current liabilities and long-term debt.

Current Liabilities. Current liabilities are debts that come due within one year following the balance sheet date. These debts usually require cash payments to another entity. They often have the word "payable" as part of their name. *Accounts payable* are amounts owed to suppliers by a company that has purchased inventory or supplies on a credit basis. *Interest payable* represents interest that has accrued on notes payable or other interest-bearing payables since the last payment was made by a company; this type of payable might be included in a general group known as accrued expenses. Other current liabilities include estimated warranty payments, taxes payable, and the current year's portion of long-term debt that is coming due within one year from the balance sheet date.

Long-Term Debt. Long-term debts are those that come due more than one year following the balance sheet date. They include bonds payable, mortgage payable, and long-term notes payable, all of which have a specific maturity date. *Deferred income taxes payable* might also be disclosed in this category. The latter item is rather technical and controversial; it arises when accounting rules used in preparing the financial statements for reporting to owners differ from rules used on income tax returns for income tax authorities. Deferred income taxes payable typically result from an item being deducted on the income tax return (as allowed by tax rules) before it is reported as an expense on the income statement (as allowed by generally accepted accounting principles). When these timing differences reverse in future years, the deferred income taxes payable category is removed as the actual payment to tax authorities is made.

OWNERS' EQUITY
This final section of the balance sheet is one of the most difficult to comprehend. It is known as stockholders' equity for a corporation and consists of several possible subdivisions: paid-in capital, adjustments for changes in value of certain investments in stocks of other companies, and retained earnings.

Paid-in capital discloses the investment made in the corporation by the stockholder-owners. It will include the amount paid into the corporation by the stockholders for different types of equity instruments that have been issued by the corporation, such as preferred stock equity and common stock equity. Paid-in capital usually is separated into two parts—the par value of the stock and the amount paid in excess of the par value—as required by generally accepted accounting principles.

The *adjustments for market value changes in available-for-sale investments in other companies* section is shown as a component of owners' equity. These adjustments also are reported in comprehensive income because they reflect a change in owners' equity that is not a part of net income. Changes in the value of trading securities, which are short-term investments, are included in the calculation of net income, whereas changes in value of available-for-sale securities are reported only in owners' equity and the statement of comprehensive income.

The last category usually found under the heading of owners' equity is *retained earnings.* This amount represents any earnings (or the difference between total net income and net loss) since the inception of the business that have not been paid out to stockholders as dividends.

Returning to the aforementioned accounting equation, a user of financial statements can better understand that owners' equity is the balancing amount. If assets are considered a company's resources, they must equal the "sources" from which they came. The sources for assets are a company's creditors (as seen in the total of the liabilities) and its owners (as seen in the total for owners' equity). As such, the retained earnings section does not represent a fund of cash; instead it represents the portion of each asset that is owned by the stockholders. The remaining portion of each asset is owed to creditors in the form of liabilities.

BALANCE SHEET SUMMARY

It is important to keep in mind that the balance sheet does not present a company's market value. Whereas some assets are presented at market value, others cannot be disclosed at market value because no such specific market value exists. The changes in the value of the assets that are required to be adjusted to market value for each balance sheet are included in either net income or comprehensive income, depending on the nature of the asset and the purpose for which management chose to acquire it.

Another important consideration about the balance sheet is the manner in which both assets and liabilities are separated into current and noncurrent groups. Not all companies will have all of the classifications discussed above, but all will have both current and noncurrent items. The user of the balance sheet studies this separation to compare a company's current liquidity needs and resources to its long-term solvency status.

In the early 2000s Enron and a number of other companies took advantage of *off-balance-sheet accounting* to appear stronger financially. Using off-balance-sheet accounting, a company does not have to include certain assets and liabilities in its balance sheet. These assets were "off-sheet" and thus, not considered part of the financial statements. In some types of off-balance-sheet accounting, companies move debt to a company called a special purpose entity (SPE)—as was the case with Enron—or a variable interest entity (VIE). Companies rarely use this practice anymore due to a requirement from the Financial Accounting Standards Board stipulating that companies must list SPEs on their balance sheets. This law as spelled out in Section 401(a) of the Sarbanes-Oxley Act (2002), which states that annual and quarterly financial reports must disclose all material off-balance-sheet transactions, arrangements, and obligations. While Sarbanes-Oxley has led to greater transparency in balance sheets, it is not a panacea; during the subprime mortgage crisis of 2007-2008, many banks interpreted the rules in such a way that risky loans were kept off their balance sheets.

Balance sheets are an important tool to help managers, lenders, and investors analyze a company's financial status and capabilities. They are particularly useful in helping to identify trends in the areas of payables and receivables. However, it is vital to remember that the document only presents a company's financial situation at a given point in time. It does not provide any information about the past decisions that helped the company to arrive at that point, or about the company's future direction or potential for success. For this reason, the balance sheet should be considered along with other required financial statements, as well as historical data, when evaluating a company's performance.

BALANCED SCORECARD

The balanced scorecard is a performance measurement tool developed in 1992 by Harvard Business School professor Robert S. Kaplan and management consultant David P. Norton. Kaplan and Norton's research led them to believe that traditional financial measures, like return on investment, could not provide an accurate picture of a company's performance in the innovative business

environment of the 1990s. Rather than forcing managers to choose between "hard" financial measures and "soft" operational measures—such as customer retention, product development cycle times, or employee satisfaction—they developed a method that would allow managers to consider both types of measures in a balanced way. "The balanced scorecard includes financial measures that tell the results of actions already taken," Kaplan and Norton explained in the seminal 1992 *Harvard Business Review* article that launched the balanced scorecard methodology. "And it complements the financial measures with operational measures on customer satisfaction, internal processes, and the organization's innovation and improvement activities—operational measures that are the drivers of future financial performance."

The balanced scorecard provides a framework for managers to use in linking the different types of measurements together. Kaplan and Norton recommend looking at the business from four perspectives: the customer's perspective, an internal business perspective, an innovation and learning perspective, and the financial (or shareholder's) perspective. Using the overall corporate strategy as a guide, managers derive three to five goals related to each perspective, and then develop specific measures to support each goal. Ideally, the scorecard helps managers to clarify their vision for the organization and translate that vision into measurable actions that employees can understand. It also enables managers to balance the concerns of various stakeholders in order to improve the company's overall performance. "The balanced scorecard is a powerful concept based on a simple principle: managers need a balanced set of performance indicators to run an organization well," Paul McCunn wrote in *Management Accounting*. "The indicators should measure performance against the critical success factors of the business, and the "balance" is the balancing tension between the traditional financial and nonfinancial operational, leading and lagging, and action-oriented and monitoring measures."

The popularity of the balanced scorecard has declined over the past few years. According to the *Financial Times*, it was adopted by 80 percent of large U.S. companies as of 2004, making it the nation's most popular management tool for increasing performance. However, the 2007 Management Tools and Trends survey by Bain & Company found that only 66 percent of executives used a balanced scorecard, and its satisfaction rating was significantly below average.

Even so, some companies have enjoyed considerable success using the balanced scorecard. Since Minneapolis-based electronics retailer Best Buy Co., Inc. implemented the balanced scorecard in 2003, its revenue, stock price, and dividends have risen dramatically. CFO Darren Jackson found that the company's performance culture has improved since they began linking their strategy with metrics, publishing the information and rewarding progress. Even CEO Brad Anderson's bonus is tied to customer-loyalty scores, employee-turnover improvement, and a metric called "customer centricity store revenue." According to Jackson, the balanced scorecard approach reinforces positive strategic outcomes.

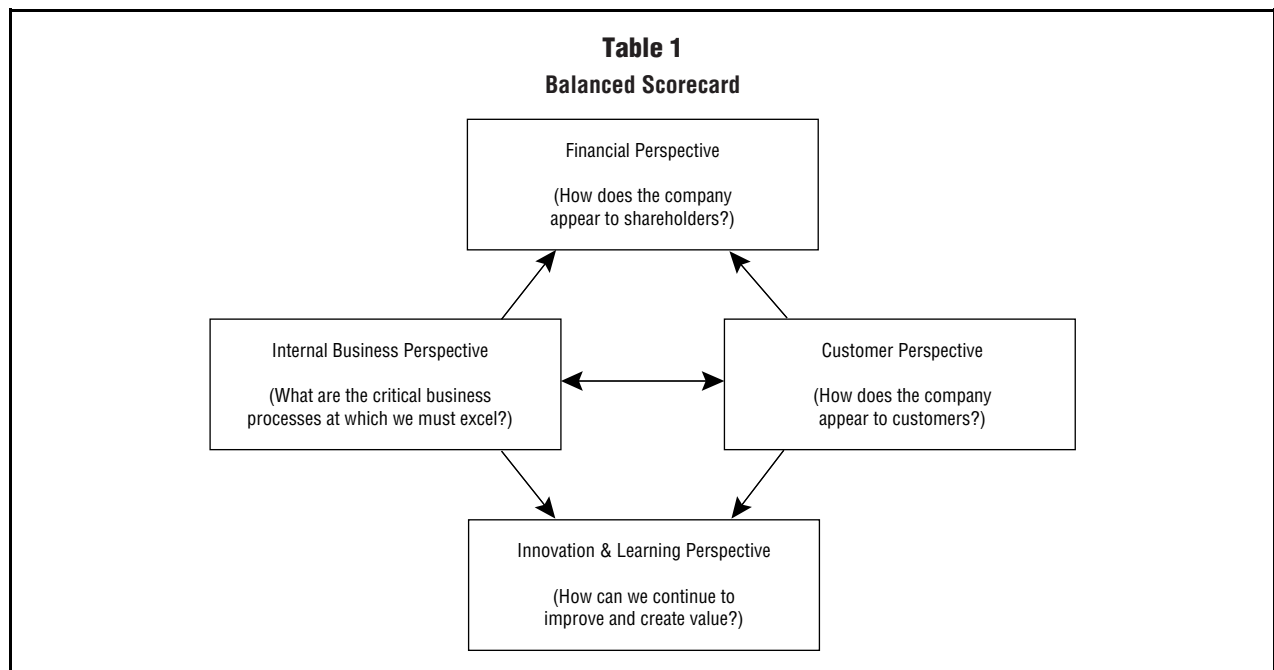
(What are the critical business processes at which we must excel?)

Customer Perspective

(How does the company appear to customers?)

Innovation & Learning Perspective

(How can we continue to improve and create value?)


HISTORY OF THE BALANCED SCORECARD APPROACH

In 1990 Robert S. Kaplan, a professor of accounting at the Harvard Business School, and David P. Norton, co-founder of a Massachusetts-based strategy consulting firm called Renaissance Worldwide Inc., conducted a year-long research project involving twelve large companies. The original idea behind the study, as Anita van de Vliet explained in her 1997 article in *Management Today*, was that "relying primarily on financial accounting measures was leading to short-term decision-making, over-investment in easily valued assets (through mergers and acquisitions) with readily measurable returns, and under-investment in intangible assets, such as product and process innovation, employee skills, or customer satisfaction, whose short-term returns are more difficult to measure."

Kaplan and Norton looked at the way these companies used performance measurements to control the behavior of managers and employees. They used their findings to devise a new performance measurement system that would provide businesses with a balanced view of financial and operational measures. Kaplan and Norton laid out their balanced scorecard approach to performance measurement in three *Harvard Business Review* articles beginning in 1992. Before long, the balanced scorecard had become one of the hottest topics at management conferences around the world. In fact, the *Harvard Business Review* called it one of the most important and influential management ideas of the past 75 years. In 1996 Kaplan and Norton expanded upon their original concept in a book titled *The Balanced Scorecard: Translating Strategy into Action.* They followed up with two other books that further developed the approach: *The Strategy-Focused Organization: How Balanced Scorecard Companies Thrive in the New Business Environment* (2001) and *Strategy Maps: Converting Intangible Assets into Tangible Outcomes* (2004).

THE FOUR PERSPECTIVES

Kaplan and Norton's basic balanced scorecard asks managers to view their business from four different perspectives: the customer perspective, an internal business perspective, an innovation and learning perspective, and the financial or shareholder perspective. These perspectives are relevant to all types of businesses. However, additional perspectives also may be important in certain types of businesses. For example, a company in the oil industry might wish to incorporate an environmental regulation perspective. In this way, the balanced scorecard maintains some flexibility for companies with special needs to add other perspectives.

Customer Perspective. According to Kaplan and Norton, viewing a business from the customer perspective involves asking the question: "How do customers see us?" They contend that many companies in a wide range of industries have made customer service a priority. The balanced scorecard allows managers to translate this broad goal into specific measures that reflect the issues that are most important to customers. For example, Kaplan and Norton mention four main areas of customer concern: time, quality, cost, and performance. They recommend that companies establish a goal for each of these areas and then translate each goal into one or more specific measurements. Kaplan and Norton note that some possible measures, like percent of sales from new products, can be determined from inside the company. Other measures, like on-time delivery, will depend on the requirements of each customer. To incorporate such measures into the balanced scorecard, managers will need to obtain outside information through customer evaluations or benchmarking. Collecting data from outside the company is a valuable exercise because it forces managers to view their company from the customers' perspective.

Internal Business Perspective. The internal business perspective is closely related to the customer perspective. "After all, excellent customer performance derives from processes, decisions, and actions occurring throughout an organization," Kaplan and Norton wrote. "Managers need to focus on those critical internal operations that enable them to satisfy customer needs." Viewing a company from the internal business perspective involves asking the question, "What must we excel at?" Kaplan and Norton recommend focusing first on the internal processes that impact customer satisfaction, such as quality, productivity, cycle time, and employee skills. Using these critical processes as a base, managers should develop goals that will help the company to meet its customers' expectations. These goals should then be translated into measures that can be influenced by employee actions. It is important that internal goals and measures are broken down at the local level in order to provide a link between top management goals and individual employee actions. "This linkage ensures that employees at lower levels in the organization have clear targets for actions, decisions, and improvement activities that will contribute to the company's overall mission," the authors explained.

Innovation and Learning Perspective. In including the innovation and learning perspective in their balanced scorecard, Kaplan and Norton recognized that modern companies must make continual improvements in order to succeed in an intensely competitive global business environment. "A company's ability to innovate, improve, and learn ties directly to the company's value," they noted. That is, only through the ability to launch new products, create more value for customers, and improve operating

efficiencies continually can a company penetrate new markets and increase revenues and margins—in short, grow and thereby increase shareholder value. Accordingly, viewing a business from the innovation and learning perspective involves asking the question, "How can we continue to improve and create value?" Managers should establish goals related to innovation and learning, and then translate the goals into specific measures—such as increasing the percentage of the company's sales derived from new products.

Financial Perspective. Kaplan and Norton developed the balanced scorecard at a time when financial measures were increasingly coming under attack from management experts. Critics claimed that judging performance by financial measures encouraged companies to focus on short-term results and avoid taking actions that would create value over the long term. They also argued that financial measures looked backward at past actions rather than forward at future possibilities. Some experts told managers to focus solely on operational improvements and allow the financial performance to improve on its own.

Although these arguments convinced Kaplan and Norton to conduct their study of performance measurement, they found that financial controls are an important part of the puzzle. They claim that managers need to know whether or not their operational improvements are reflected in the bottom line. If not, it may mean that management needs to reevaluate its strategy for the business. "Measures of customer satisfaction, internal business performance, and innovation and improvement are derived from the company's particular view of the world and its perspective on key success factors. But that view is not necessarily correct," Kaplan and Norton wrote. "Periodic financial statements remind executives that improved quality, response time, productivity, or new products benefit the company only when they are translated into improved sales and market share, reduced operating expenses, or higher asset turnover."

Thus, the fourth perspective in the balanced scorecard asks the question: "How do we look to shareholders?" Some of the goals a company might set in this area involve profitability, growth, and shareholder value. The measures attached to these goals might include traditional financial performance measures, such as return on assets or earnings per share. Although these measures can prove misleading when taken alone, when incorporated into a balanced scorecard they can provide managers with valuable information about whether the strategy has contributed to bottom-line improvement. According to Kaplan and Norton, a common mistake for managers making large-scale operational improvements is failing to follow up with additional actions. For example, a company might undertake a quality improvement initiative which, when implemented successfully, creates excess capacity or makes certain employees redundant. Financial measurements will point out the need to make further changes.

DEVELOPING A BALANCED SCORECARD

Development of a balanced scorecard begins with the company's overall strategy or vision. It is important to consult with top management, rather than line managers, to obtain a clear picture of where the company wants to be in three to five years. The next step is to appoint a "scorecard architect" to establish the framework and methodology for designing the scorecard. With this framework in mind, the organization must define a linked set of strategic objectives that will lead the company toward top management's vision. These objectives should be true drivers of performance for the business as a whole, rather than a list of separate goals for business units or departments. It may be helpful to begin with the four perspectives included in the balanced scorecard model and then add more if needed, depending on the industry.

At this point, most companies will begin to involve line managers and staff members—and perhaps even customers—in establishing goals or objectives. The involvement might take the form of an executive workshop at which participants review and discuss the goals and appropriate measures. This approach builds consensus around the balanced scorecard and reduces the potential for unrealistic goals to be handed down from the top.

The strategic objectives provide a framework for managers to use in developing specific performance measures. "Most of the measures we use are not new, but they had been held in different silos, different boxes, in the organization," Rick Anderson, a performance analyst at BP Chemicals, told van de Vliet. "The [balanced scorecard] approach has brought existing measures onto one piece of paper, so everybody can relate to one area." The goals and measures in an organization's balanced scorecard can be broken down to provide custom scorecards for all business levels, even down to individual employees. These custom scorecards show how an employee's work activities link to the business's overall strategy. For incentive and compensation purposes, it is possible to assign weights to each measure based on its importance to the company and the individual's ability to affect it.

Once the balanced scorecard is in place, the next step is to collect and analyze the data for performance measurements. This data will enable the organization to see its strong performance areas, as well as areas for potential improvement. It is important to supply the performance data to employees, and to empower employees to find ways to sustain high performance and improve poor performance. Managers also must realize that the balanced scorecard is not set in stone. Experience in using the scorecard

may point out areas that should be modified or adapted. In addition, managers may find ways to tie the scorecard into other areas, such as budgets, resource allocation, compensation, succession planning, and employee development.

AVOIDING POTENTIAL PITFALLS

Numerous organizations have implemented some version of the balanced scorecard since its introduction in 1992. However, professor Claude Lewy of the Free University of Amsterdam found that 70 percent of scorecard implementations failed. Many companies are attracted by the power and simplicity of the balanced scorecard concept, but then find implementation to be extremely time-consuming and expensive. Lewy admits that the balanced scorecard can be an effective way of translating an overall strategy to the many parts of an organization. However, he stresses that organizations must have a clear idea of what they want to accomplish, and be willing to commit the necessary resources in order to successfully implement the balanced scorecard. Along with Lex Du Mee of KPMG Management Consulting, Lewy conducted a study of seven European companies and came up with what he called the Ten Commandments of Balanced Scorecard Implementation.

To ensure an effective balanced scorecard implementation, Lewy and Du Mee recommended that organizations obtain the commitment of a top-level sponsor, as well as relevant line managers. The balanced scorecard initiative must be the organization's top priority if implementation is to succeed. They also emphasized the importance of putting strategic goals in place before implementing the scorecard. Otherwise, the goals and measures included in the scorecard are likely to drive the wrong behavior. Lewy and Du Mee also suggested that organizations try a pilot program before moving on to full-scale implementation. Testing the balanced scorecard in a few key business areas enables managers to make necessary changes and increase support for the initiative before involving the entire company. It also is important to provide information and training to employees prior to an organization-wide rollout.

Lewy and Du Mee also warn managers against using the balanced scorecard as a way to achieve extra top-down control. Employees are unlikely to support the goals and measures if the scorecard is used as a "gotcha" by management. Another potential pitfall, according to the researchers, is trying to use a standardized scorecard. Instead, they stress that each organization must devote the time and resources to develop its own customized program. Lewy and Du Mee found that balanced scorecard implementation was more likely to fail when companies underestimated the amount of training and communication required during the introductory phase, or the extra workload and costs involved with periodic reporting later on. Even though the balanced scorecard appears to be a simple idea, implementing it is likely to mean huge changes in an organization.

SOFTWARE AND SUPPORT

Once the balanced scorecard has been implemented successfully, the next significant task involves collecting and analyzing measurement data. A "dashboard" is an executive information system user interface that collects data from numerous different computer systems throughout the organization and presents it in an easily readable format. A dashboard can obtain information from the local operating system in a computer, from one or more applications, and from one or more sites on the Web. Business dashboards are used to track corporate functions such as recruiting, human resource, sales, operations, and security. The content of a digital dashboard project might include key performance indicators and sales performance figures.

BANDWIDTH

Bandwidth deals with how information passes through electronic systems. Since today's business world relies heavily on online communication, Internet research, and intranet resources, bandwidth is a primary concern in emerging technologies. When technicians speak of gaining or needing bandwidth, they are referring to the ability to transmit more information through the online connections. Many measurements involving bandwidth are also important to companies, such as how much data is transmitted in a continuous flow and how much data can be transmitted over a particular time.

FACTORS AFFECTING BANDWIDTH

Bandwidth can be used in a very broad definition; in this manner, it often refers to any need for more time, information, and space. In a connotative sense, bandwidth can mean the number of employees in a given department or the time constraints on a particular project. The narrow meaning of the word bandwidth is the electrical capacity, either analog or digital. In analog channels the rate is defined in hertz, the difference between higher and lower frequencies. In digital channels, the rate is defined by bits per second.

Company bandwidth, no matter how it is received, can be limited by several different factors, most notably the relationship between what online applications the company is using and the services and technology cable and DSL (digital subscriber line) providers offer. There are several important terms used in describing bandwidth space and a company's use of it:

- *Bottleneck link bandwidth*. This is the maximum rate data can travel in a given online system, from the source to the end receiver. This definition assumes that the data is traveling on the slowest possible path between its destinations.

- *Surplus available bandwidth*. This is the amount of bandwidth left over after the company has used all of its available bandwidth in the bottleneck link scenario. Businesses often deal with this concept since they have multiple applications and have usually purchased a large amount of bandwidth from their provider.

- *Fair-share available bandwidth*. A company rarely reaches and surpasses this level of use, unless it is pursuing aggressive or inappropriate bandwidth usage that drowns out other users and creates a state of congestion along the provider's line. Fair-share bandwidth is the maximum amount any business should plan on using, an amount that neither interferes with online communication traffic nor consumes too much space for company usage.

- *Protocol-dependent available bandwidth*. Based on what applications it is using, this is the amount of bandwidth a company should expect to take. This number may be produced by an agreement with the server or as a natural result of business expectations. The protocol-dependent bandwidth is how much bandwidth the company needs to run, and it lies somewhere between surplus bandwidth and fair-share bandwidth.

GENERAL GUIDELINES ABOUT BANDWIDTH USAGE

Despite the increasing availability of high-speed Internet connections and new ways of transferring data, bandwidth consumption remains a concern for many Internet providers, and businesses should be careful when purchasing and using their bandwidth so that they are not subject to penalties or sudden price adjustments. Consumption should be carefully monitored; this can be done with a simple program that can be bought or downloaded for free from certain Web sites. Bandwidth use should also be plotted over time so that companies can see if there are any sudden changes and where those changes may have come from. It is possible that employees, attracted by the high-speed connection offered by their company, will use company bandwidth for personal downloads, which can use a large amount of available space. There are bandwidth-management systems that can be put into place to automatically regulate Internet usage and help undo such problems.

Some business analysts have concerns, which are summed up by Tim Wu in a 2008 article, "OPEC 2.0." In this piece, Wu theorizes that bandwidth may become another scarce, necessary commodity, in the same way that oil is today. Wu points to the control of bandwidth in the hands of only a few companies, and the growing need for bandwidth to run information-driven societies, as signs of this trend. However, current bandwidth rates are neither high enough or consequential enough to prove this theory, and although most businesses depend on online interaction of some type, restrictions regarding the flow of information have not yet hampered overall productivity.

BAR CODING AND RADIO FREQUENCY IDENTIFICATION

A bar code is a series of parallel black bars and white spaces, both of varying widths. Bars and spaces together are called *elements.* Different combinations of the bars and spaces represent different characters, such as numbers or letters. Each combination or sequence of bars and spaces is a code that can be translated into information such as price, product type, place of manufacture, or origin of shipment.

Bar codes are simple to use, accurate, and quick. Almost everyone is familiar with their use in retail establishments. They also often are used in warehouses and manufacturing for selecting items from storage, receiving goods, and shipping.

In the 1950s, two men, Bernard Silver and Norman Woodland, took out a patent on the bar-code concept. In the 1960s Kroger attempted the use of bar codes in its retail stores. Though they first envisioned a classification system based on a mark of concentric circles, the standard bar code system—developed in 1970—used the lines and spaces people are most familiar with today. This system was known as UGPIC, the Universal Grocery Products Identification Code. Through the 1970s and 1980s, bar codes became more and more common, adopted by both industries and government.

Few bar-code uses are regulated. However, according to requirements established by the FDA in 2004, "certain human drug and biological product labels" must include a specific amount of information, often placed on the container but at times micro-stamped onto the medication itself. This code must include the drug's National Drug Code (NDC). This is mostly to prevent theft and mistake at hospitals. Such bar-code requirements issued by government departments are currently established for the safety of the public.

HOW BAR CODING WORKS

The bar code itself does not actually contain detailed information. The bar code simply provides a reference number that cues a computer to access information. A bar-code reader is required to read a bar code. Bar-code readers may be fixed, portable batch, or portable RF. Fixed readers are attached to a host computer and terminal, and transmit one item at a time as the data is scanned. Battery-powered portable batch readers store data into memory for batch transfer into a host computer at a later time. The portable RF reader can transmit data in real-time, online.

Scanners and Decoders. The basic reader consists of a scanner and a decoder. Scanners capture the image of the bar code, and the decoder takes the digitized bar space patterns, decodes them, and transmits the decoded data to the computer.

There are several types of scanners. Laser scanners use a single spot of light to sweep across the bar code in a linear fashion. CCD scanners use an LED array with thousands of light detectors; the entire bar-code image is captured and then transmitted. Automatic scanners are in a fixed position and read bar codes as they go by on a conveyor. Handheld scanners, such as wands, are portable and may be carried from place to place, as in a warehouse.

When a scanner is passed over the bar code, the dark bars absorb the scanner's light while the light spaces reflect it. A photocell detector receives the reflected light and converts it into an electrical signal. A low electrical signal is created for the reflected light and a high electrical signal is created for the dark bars. The width of the element determines the duration of the electrical signal. The decoder then decodes the signal into the characters represented by the bar code and passes it to a computer in traditional data format.

TYPES OF BAR CODES

There are different types of bar codes. Some bar codes are entirely numeric, whereas others have numeric and alphabetic characters. The type used is dependent upon the implementation, the data that needs to be encoded, and how the bar code is to be printed. There are several bar code standards, called symbologies, each serving a different purpose. Each standard defines the printed symbol and how the scanner reads and decodes the printed symbol.

While America used the Uniform Product Code (UPC) during most of its bar-code history, this code has been replaced in recent years by the EAN/UCC-13 code, which is becoming the international standard for bar coding. The EAN/UCC-13 code is comprised of three different parts: a company prefix, a supplier number, and a check digit. Together, these equal thirteen numbers, although when transferred to older formats such as GTIN (Global Trade Item Number), a zero is presumed at the beginning of the code. This standardized code has been an important step in business globalization.

In certain industries dominated by their own classification systems, the use of EAN/UCC-13 has lead to some internal modifications. An excellent example of this

would be the publishing industry, which uses ISBN codes that can be scanned as bar codes. At the beginning of 2007, ISBN codes began to be transferred over to ISBN-13s. If UPC codes are still active in such industries, they are treated as the new 13-series code.

RFID

Radio frequency identification (RFID) could become the most far-reaching wireless technology since the cell phone. RFID is a method of remotely storing and retrieving data using a small object attached to or incorporated into a product. Its purpose is to enable data to be transmitted via a portable device called a tag, read by a reader, and processed according to the needs of the particular application.

Transmitted data may provide information about product location, or specifics such as color, price, or purchase date. In some systems, a return receipt can be generated. RFID tags contain far more detailed information than can be placed on a bar code. Some tags hold enough information to provide routing information for shipping containers, as well as a detailed inventory of what is inside the container.

It is said the origins of RFID technology began with the use of radar in World War II, when armies began searching for ways to identify incoming vessels as friend or enemy. According to the 2008 RFID Journal, the first patents for true RFID technology were taken out in the 1970s, most notably by Mario Cardullo. At the same time, the government was working on radio identification technology to guard high-level security sites and to mark livestock for the agriculture department. In the 1990s, RFID systems developed by IBM and Intermec began to be used commercially, though the expense kept many companies from entering the field.

An RFID system consists of tags, tag readers, tag programming stations, circulation readers, sorting equipment, and tag inventory wands. The tag is the key component. Data can be printed or etched on an electronic substrate and then embedded in a plastic or laminated paper tag.

Tags are classified according to their radio frequency: low-frequency, high-frequency, UHF, and microwave. Low-frequency tags are commonly used in automobile antitheft systems and animal identification. High-frequency tags are used in library books, pallet tracking, building access, airline baggage tracking, and apparel tracking. Low- and high-frequency tags can be used without a license. UHF tags are used to track pallets, containers, trucks, and trailers. UHF cannot be used globally as there is no one global standard. Microwave tags are used in long-range access, such as General Motors' OnStar system.

While most RFID tags are write-once/read-only, there are some that offer read/write capability. These tags would allow tag data to be rewritten if need be.

Tags may either be passive or active. Passive tags do not have their own power supply; their power comes from a minute electrical current induced by an incoming radio-frequency scan. In contrast, active tags have their own power source. The lack of a power source makes the passive tag much less expensive to manufacture and much smaller (thinner than a sheet of paper) than an active tag. As a result, the vast majority of RFID tags are passive. However, the response of a passive tag is typically just an ID number. Active tags have longer ranges, the ability to store more information, and they are more accurate and reliable.

The tag contains a transponder with a digital memory chip with a unique electronic product code. A stationary or handheld device called an interrogator, consisting of an antenna, transceiver, and decoder, emits a signal creating an electromagnetic zone. When a tag comes within the range of a reader, it detects an activation signal that causes the tag to "wake up" and start sending data. The reader captures the data encoded in the tag's integrated circuit, decodes it, and sends it over a network to a host computer for processing.

THE ADVANTAGES OF RFID OVER BARCODING

RFID tags can contain far more detailed information than bar codes. Bar codes require a clear line of sight between the scanner and the bar code, a need that is absent from the RFID. Also, it is possible to scan only one bar code at a time. Within the field of a reader, hundreds of RFID tags can be read within seconds. RFID codes are long enough that every RFID tag may have a unique code, allowing an individual item to be tracked as it changes location. Bar codes are limited to a single code for all stages of movement of a particular product.

The foremost problem with widespread RFID use is cost. Many companies cannot afford the expenses associated with RFID technology, and would not see a large enough gain in efficiency to implement the system. According to David Gulbransen at *InformIT*, a single RFID scanner costs anywhere from several hundred to several thousand dollars, and multiple scanners would be needed for many companies. The tags themselves range in usability. As of 2008, active ID tags cost anywhere from $0.75 to $3.00, and the cheaper, more common, passive tags can cost $0.25 to $0.50, though the technology is improving. Some experts contend that costs for the tags will need to reach an estimated $0.10 per tag before RFID use can spread much further.

Some companies hope to achieve greater profits and a better return on investment (ROI) immediately after switching from bar-coding to RFID technology. However, a 2006 study by RFID Solutions and Strategy of the Manhattan Associates showed that this is not necessarily the case. Organizations that already have an efficient system of bar codes may actually lose some of their efficiency when

transferring to the new protocols required by RFID systems. Only in companies where manual scanning takes time and manpower would RFID systems make a noticeable difference. As Greg Gilbert, Director of RFID Solutions and Strategy, points out, merely analyzing the possible savings of RFID technology allows companies to find alternative methods to save time and increase ROI, such as the elimination of costly paper trails or the conservation of manufacturing space.

RFID USES

Once established, RFID technology began to be picked up by a myriad of different industries. According to Das and Harrop, in their 2008 analysis and forecast of RFID technology, 2008 should see some 325 million RFID tags in use. Das and Harrop divide the uses of RFID into the two separate tags, passive and active.

The uses for passive tags include:

- Drugs
- Other healthcare
- Retail apparel
- Consumer goods
- Tires
- Postal
- Books
- Manufacturing parts, tools
- Archiving
- Military
- Retail CPG pallet/cases
- Smart cards, smart tickets, etc.
- Air baggage
- Animals
- Vehicles
- People

The uses for active RFID Tags include:

- Pharmacy
- Cold retail supply Chain
- Consumer goods
- Postal
- Shelf edge labels
- Conveyances/rollcages
- Vehicles
- People
- Car clickers

More specific examples include using RFID tags at toll booths for electronic toll collection, using cash cards imbedded with RFID technology, putting RFID tags on prisoners (as is done in the Ohio Dept. of Rehabilitation and Correction), using RFID to monitor expirable foods, and using RFID technology to create paper money to stop counterfeiting, as is done in some parts of Europe.

The *RFID Journal* gives examples of several companies that have used RFID systems to transform they way they do business. The BHP Billiton Mitsubishi Alliance, for instance, uses radio tags to track miners and mining equipment during work hours, to better ensure the safety of their employees. A Seattle sushi chain, Blue C, is using RFID technology to ensure the constant freshness of their sushi dishes. Nordam, which creates airplane parts, uses RFID tags to track its precision molds during the manufacturing process. Stafford Tower Crane tags all of its cranes to make sure the right equipment is at the right job site The list grows each day as more and more companies find new and cost-saving ways to use RFID technology.

CONTROVERSY OVER RFID USE

The use of RFID has caused some concern for privacy advocates. They feel that it may be a privacy violation for a consumer unaware of the presence of an RFID tracking tag, or if they are unable to remove or deactivate it. Other concerns revolve around the ability to fraudulently or surreptitiously read a tag from a distance, and the ability to identify a purchaser through the use of a credit card or a loyalty card.

In Seattle, a University of Washington team is carrying out an experiment designed to analyze the possible negative effects of RFID use. Begun in 2008, the project involves various students and faculty wearing radio tags that can be monitored to see where they go, who they meet with, and how long they stay in particular areas. The idea is to see where RFID technology proves useful in tracking social interaction, and where the system breaks down in dangerous ways. While such technology can be used to monitor employee performance, it can also be unnecessarily invasive and—according to *Seattle Times* reporter Kristi Helm—"a bit like Big Brother."

RFID advocates, however, feel that opposition will lessen as RFID use becomes more widespread and its use across a wide range of industries becomes apparent.

A more active field of concern for RFID technology is patent infringement. As more industries attempt to create or use radio tagging, more targets are created for lawsuits. In 2004 a lawsuit battle began between Intermec, one of the first RFID suppliers, and Matrics, another RFID company. After a series of counter lawsuits these two companies eventually settled. In 2005 Intermec sued another company, Alien Technology, for multiple patent

infringements, which again led to prolonged litigation involving more than one company. Many suppliers of RFID technology wait for a series of standards and trends to be set regarding RFID distribution and application that will bring an end to such problems.

BARRIERS TO ENTRY

Barriers to entry are any hindrance (market, technological, legislative, or competitive) that can block an entrepreneurial business from entering the business world and finding customers. Some barriers to entry are natural to their markets, while others can develop in certain economies or business environments.

BARRIERS AND E-COMMERCE

Many barriers to entry have changed in the current business world, where electronic communication has altered the way companies can reach customers and each other. This makes online business a very important part of the market, as e-commerce can eliminate many barriers to entry and let even small companies enter markets that would not be available to them otherwise. However, some markets—especially those not connected to Internet applications—are still traditionally difficult to enter. A small company, for instance, cannot establish a brick-and-mortar financial company at an elite city block; such a company would still be hampered by availability, cost, and materials. Even if they were able to establish such an office, they might have trouble finding customers with a new business that has no prestige. Online, however, such a business would be able to establish the same sort of financial services by creating a professional Web site offering tailored assistance, and they could potentially perform successfully at far less cost.

However, the rise of online business has raised other barriers to entry even as it brings down older ones. As social networking and other Web 2.0 applications become increasingly important to successful e-retailing, e-marketing, and online services, new barriers are being set into place. Internet businesses must have an understanding of online applications to become successful, and these applications are growing in number and complexity. The concept of relational businesses applies to the online world as well, and the more companies that enter into e-commerce,

the more necessary it becomes to develop relationships with other online companies.

TYPES OF BARRIERS TO ENTRY

Barriers to entry can be divided into different categories based on their source and effects. These categories include:

- **Economies of scale**. The larger a company becomes, the more easily it can produce and manufacture while saving costs. Large businesses can buy in bulk and receive discounts, produce in bulk at less cost, and access suppliers or distributors that smaller businesses would not be able to reach.

- **Capital requirements**. A new business will probably be low on funding, and capitalists will be less willing to invest in entrepreneurial endeavors than in established and successful companies. Raising enough capital to properly start a business is one of the first and most daunting barriers to entry.

- **Access to suppliers**. Relationships with suppliers are usually set up via contract, which is preceded by negotiations. Large and reliable suppliers are more likely to sign with dependable businesses that have proven their stability, rather than starting companies. Finding a supplier may cost extra time and money, and many suppliers will not be able to offer their discounts and deals to smaller organizations.

- **Access to customers**. Customers, like suppliers, prefer to use a business that has been around for a while and can prove its success and stability. In a well-established market, customers need good reasons to switch from current companies to someone new.

- **Product perception**. Brand loyalty will keep some customers depending on the old suppliers. New companies must market their products and create their own brand loyalty in order to succeed in competitive markets.

- **Government legislation**. Official regulation and requirements can make it difficult to enter some markets, especially those in which there is little competition or those that have strict standards, such as health industries.

- **Asset specificity**. This refers to special skills or technology that is needed to succeed in a particular market. A business must learn these skills and buy this technology in order to enter the market.

- **Patents**. Some markets are dependent on patents to secure technology and protect privacy. If a new business does not have any innovative procedures or products, they may struggle.

Despite such difficulties, there are always entrepreneurs and start-up companies that are able to harness new technologies or invent innovative business practices as a way to circumvent the barriers to entry that exist in a particular market.

BASES OF POWER

SEE *Leadership Styles and Bases of Power*

BENCHMARKING

Benchmarking is the process through which a company measures its products, services, and practices against its competitors, or those companies recognized as leaders in its industry. Benchmarking is a management tool for determining whether the company is performing particular functions and activities efficiently, whether its costs are in line with those of competitors, and whether its internal activities and business processes need improvement. The objective of benchmarking is for management to identify the practices that are most successful in the marketplace and to incorporate those techniques into the operation of their business.

Benchmarking focuses on company-to-company comparisons of how well basic functions and processes are performed. Among many possibilities, it may look at how materials are purchased, suppliers are paid, inventories are managed, employees are trained, or payrolls are processed; at how fast the company can get new products to market; at how the quality control function is performed; at how customer orders are filled and shipped; and at how maintenance is performed.

Benchmarking enables managers to determine what the best practice is, to prioritize opportunities for improvement, to enhance performance relative to customer expectations, and to leapfrog the traditional cycle of change. It also helps managers to understand the most accurate and efficient means of performing an activity, to learn how lower costs are achieved, and to take action to improve a company's cost competitiveness.

Companies usually undertake benchmarking to obtain a competitive advantage by reducing labor cost, streamlining the work flow through reengineered business processes and common administrative systems, improving data center operations through consolidation and downsizing, implementing new technology, outsourcing some assignments and functions and redesigning the development and support processes.

BENCHMARKING BASICS

The goal of benchmarking is to identify the weaknesses within an organization and improve upon them, with the idea of becoming the "best-in-class." The benchmarking process helps managers to find gaps in performance and turn them into opportunities for improvement. Benchmarking enables companies to identify the most successful strategies used by other companies of comparable size, type, or regional location, and then adopt relevant measures to make their own programs more efficient. Most companies apply benchmarking as part of a broad strategic process. For example, companies use benchmarking in order to find breakthrough ideas for improving processes, to support quality improvement programs, to motivate staffs to improve performance, and to satisfy management's need for competitive assessments.

Benchmarking targets roles, processes, and critical success factors. Roles are what define the job or function that a person fulfills. Processes are what consume a company's resources. Critical success factors are issues that a company must address for success over the long-term in order to gain a competitive advantage. Benchmarking focuses on these things in order to point out inefficiencies and potential areas for improvement.

There are many motivators that drive the different types of benchmarking. Application benchmarking and infrastructure benchmarking, for example, use such motivators as cost, quality, competition, and goal setting. An advantage of benchmarking is that it facilitates the process of change, clearly laying out the types of solutions external organizations have used and providing a global perspective on how part of the company affects the whole. It further helps focus improvement in the areas where actual gains can be made, which translate into value added to the company as well as its employees.

Benchmarking can be used at any time, but is usually performed in response to needs that arise within a company. According to C.J. McNair and Kathleen H.J. Leibfried in their book *Benchmarking: A Tool for Continuous Improvement*, some potential "triggers" for the benchmarking process include:

- Quality programs
- Cost reduction/budget process
- Operations improvement efforts

- Management change
- New operations/new ventures
- Rethinking existing strategies
- Competitive assaults/crises

Methodology. Benchmarking involves selecting a product, process, or service to benchmark, and then identifying the key performance metrics for that particular function. A metric is a quantitative measure that is used as a reference point for comparisons. The analysis can take the form of vertical or horizontal benchmarking. Vertical benchmarking is where the focus is placed on specific departments or functions, while horizontal benchmarking is where the focus is placed on a specific process or activity.

There are four main approaches to benchmarking, including strategic benchmarking, functional benchmarking, best practices benchmarking, and product benchmarking. Strategic benchmarking compares different companies' strategies with particular reference to process capability, technology portfolio, and product line. Functional benchmarking analyzes the performance of core business functions, whereas best practices benchmarking breaks the function down into discrete targets for comparison with the industry leaders. It is a more focused study than functional benchmarking in that it assesses business processes and the management techniques behind them. Finally, product benchmarking, also known as reverse engineering or competitive product analysis, assesses competitor costs, product concepts, and alternative designs by dissecting competitors' products.

After isolating the aspect of the company to be benchmarked, the managers choose what they will measure the function against. Internal benchmarking is the analysis of existing practices within various departments or divisions of the organization, looking for best performance as well as identifying baseline activities and drivers. Competitive benchmarking looks at a company's direct competitors and evaluates how the company is doing in comparison. Knowing the strengths and weaknesses of the competition is not only important in plotting a successful strategy, but it can also help prioritize areas of improvement as specific customer expectations are identified. Industry benchmarking is a more trend-based approach. Because of its broad scope, it is primarily used by companies to establish performance baselines.

Once an internal department or another company has been selected to benchmark against, management collects data about its practices and performance. Benchmarking uses different sources of information, including published material, trade meetings, and conversations with industry experts, consultants, customers, and marketing

representatives. Databases such as APQC.org from the non-profit American Productivity and Quality Center contain performance indicators for thousands of different companies. Management analyzes the data and identifies the best practices. Once the opportunity for improvement has been observed, the managers must implement the necessary changes and monitor subsequent performance.

SUCCESSFUL BENCHMARKING

According to a 2007 Bain and Company survey, benchmarking received the fourth-highest usage score (81%) among more than two dozen management tools used by senior executives around the world. The survey also reported that users tend to be highly satisfied (rated 3.8 on a 5-point scale) with the results benchmarking provides to their companies.

There are several keys to successful benchmarking. Management commitment is one that companies frequently name. Since management from top to bottom is responsible for the continued operation and evaluation of the company, it is imperative that management be committed as a team to using and implementing benchmarking strategies. A strong network of personal contacts and an open mind to new ideas are other keys. In order to implement benchmarking at all stages, there must be a well-trained team of people in order for the process to work accurately and efficiently. Based on the information gathered by a well-trained team, there must also be an effort toward continuous improvement. Other keys include a benchmarking process that has historical success, sufficient time and staff, and complete understanding of the processes to be benchmarked.

In almost any type of program that a company researches or intends to implement, there must be goals and objectives set for that specific program. Benchmarking is no different. Successful companies determine goals and objectives, focus on them, keep them simple, and follow through on them. As in any program, it is always imperative to gather accurate and consistent information. The data should be understood and should be able to be defined as well as measured. The data must be able to be interpreted in order to make comparisons with other organizations. Lastly, keys to successful benchmarking include a thorough follow-through process and assistance from consultants with experience in designing and establishing such programs.

BEST PRACTICES

In a general sense, the term best practice refers to the most efficient way of doing something. The fastest method that uses the least resources (including labor and parts) to create the highest quality output is the "best practice." Almost every thinkable industry has adopted best practices in some aspect of its processes, but those that have made use of it successfully and publicly have typically done so in the fields of technology development, quality control, project management, teaching (on the college and secondary circuits), manufacturing, healthcare, and sales.

What was once considered plain "good sense" in many corporate spheres can now often be referred to as best practice, making the phrase seem inconsequential or part of corporate pop culture to opponents who would rather stick to common sense approaches and hard work. Best practice, therefore, can be seen as still in its infancy in terms of truly determining what it defines and for whom. For now, best practice is a way to describe the best ideas for the successful completion of specific jobs during actual application. It would be hard to oppose this kind of simple sense in any industry, but opponents of the term "best practice" oppose it on the basis that for some it has become an umbrella under which what is best for a particular agenda is the objective, not what is best overall. For example, a construction company that subcontracts a friend's bulldozer company for a kickback may be seen as best practice for both friends, but it would not be considered a best practice for those paying for the construction.

Best practice is also the outgrowth of the standard of good practice (SoGP) and benchmarking, both of which are highly organized methodologies. As it applies to business in general, best practice itself is optimally executed

using the tenets established by Robert Camp in his 1989 text "Benchmarking: The Search for Industry Best Practices that Lead to Superior Performance."

PHASES OF IMPLEMENTATION

Planning. Some consider the planning phase of benchmarking or best practice to be the step in which a firm decides what, exactly, it would like to improve within its process. Where does the problem begin? Where does it end? What are the frequent complaints among workers and managers? Once these questions are answered, a more concrete plan of what needs to be done to have the best practice possible for the particular phase of production or creation can be conceived.

In this initial phase of creating a best practice for any aspect of a firm's process, it is extremely important to remember the stakeholders, customers, and employees; what will they think of changing the practice in question? If there is any doubt as to whether any party will object to changes in the process, sidestepping the forward movement of best practice implementation may be best until alternative approaches or unanimous opinions on the change can be reached.

Analysis. Once a consensus has been reached about where the problem exists, and there are no challenging opinions or opponents of changing the existing format of a firm's process, analysis of the problem can begin. Fundamental aspects of the analysis phase of best practice implementation include answering important questions about: why the current system is not working; what goals are not being met due to an outdated method; where is production slowed and why; what are the aspects of the existing process that contribute to a negative public image for the firm; and what resources are being used inefficiently to achieve too little. Analysis of these questions will establish whether there is in fact a great enough need to constitute the implementation of a new, better practice.

During the analysis phase of best practice conception, it is crucial to ensure that all data used in the analysis and decision-making process is true, accurate, from a reliable source, and timely. Additionally, those who gather data must be careful and considerate of sources and should never misrepresent why and how the information may be used. Proprietary information should never be shared with anyone outside of the benchmarking, analysis, or best practice implementation process.

Integration. The integration phase of best practice implementation is the creation of a measurable plan based on information gathered during analysis. The plan will allow action to be taken so that the best practice can be created and initialized. Integration will begin the process of solving the problem and lay the groundwork for the action that must be taken to bring the best practice to fruition. Looking to how other firms have successfully integrated their analysis into a workable plan is a good way to ensure a positive outcome.

Action. The action part of implementing best practice will need to follow the measurable plan created during the integration process. The plan has to be measurable in terms of resources and hours used, monies budgeted, and any other quantitative aspects of the new practice. This will enable managers to determine whether the new practice is actually the best practice in regards to time, money, and resources.

Another part of taking action is monitoring the effectiveness of the plan and how well the action is working. Are workers and managers following the new plan or is there resistance to the change? Monitoring the effectiveness of the new action plan allows managers to establish whether real change is taking place. The action should be taken for at least one fiscal quarter to determine its efficacy within the firm's processes.

It is important to remember how to determine when and how a best practice should be implemented. Changing the old model for reasons other than what is best for the firm at large should always be avoided, and implementing a plan of action must always be a measurable process; otherwise, determining the results it has created is nearly impossible. The best practice will always be the one that creates the best results in the least amount of time while using the fewest resources.

BLACK FRIDAY

Black Friday is the term used for the day after Thanksgiving in the United States. This day is often considered the start of the holiday shopping season and is often marked by major sales, loss leaders, and early opening hours at retailers.

BACKGROUND

The practice of referring to especially difficult days with the word "Black" stems from early financial panics, dating as far back as 1869. According to several sources, the term Black Friday was first used to refer to the day after Thanksgiving in 1975, because of horrendous traffic and badly behaved shoppers. The name Black Friday stuck, and over time it has become accepted that the name refers to the accounting practice of recording profits in black ink and losses in red ink. In other words, Black Friday is the day that retailers get out of the red and into the black. Statistically, Black Friday is not actually the day with the highest sales of the year. It is important, however, as a predictor or indicator of consumer attitudes for the season at hand.

BLACK FRIDAY IN CONTEXT

The holiday shopping season is the most important one for most retailers, but the season's duration has increased in recent years. According to retail tracking organizations, most malls were decorated for Christmas by November 1 during 2006. Retail managers begin the holiday season preparation long before the decorations go up; planning for staffing and advertising is usually completed by October. Training for holiday staff can then take place in November, before the rush hits. On average, most retailers extend their hours for the season beginning on the day after Thanksgiving, or Black Friday. These extended hours generally last through Christmas Eve.

RECENT DEVELOPMENTS

Some recent developments in holiday retailing have changed the status of Black Friday and the time frame connected to the holiday season as a whole. First, the immense popularity of prepaid giftcards changes preconceived ideas about the parameters of the holiday buying season. The season has traditionally begun after Thanksgiving and ended on Christmas Eve. Because of the cards, however, holiday sales continue to be made in January, when recipients of the giftcards redeem them. This, coupled with the tendency to start the holiday shopping season earlier and earlier each year, has led to an ever-expanding holiday season.

The widespread popularity of online shopping is the second development that has affected the status of Black Friday and the entire holiday shopping season. According to a survey conducted by a leading consulting agency, chief marketing officers consider the first Monday after Thanksgiving, called Cyber Monday because of online shopping, as important as Black Friday.

Despite changes in the holiday retailing landscape, Black Friday traffic has increased slightly in recent years. While overall sales vary based on economic factors, in most years Black Friday ranks about fifth for total sales, with the Saturday before Christmas dependably being the number one sales day of the year.

BRAINSTORMING

Brainstorming was developed by Alex F. Osborn in 1939 to enhance the ability of work groups to solve problems creatively. The participants in his early groups called his process "brainstorming" because it seemed to them that they were using their brains "to storm a creative problem and to do so in commando fashion, with each stormer audaciously attacking the same objective." According to David Whetten and Kim Cameron, there are four cardinal principles that govern effective brainstorming processes:

1. No evaluation of the effectiveness of any given alternative is to be undertaken while the group is generating alternatives. Evaluation of alternatives must come at a later stage in the problem-solving process.

2. The leader of the group must place no parameters upon the group regarding what kinds of alternatives or solutions should be suggested; in fact, the team leader should encourage the group to come up with novel ideas that normally would not receive consideration in the organization.

3. The quantity of ideas should initially take precedence over the quality of ideas; that is, the leader should push the group to produce a large number of ideas irrespective of their quality.

4. Participants should feel free to add to or modify previous ideas proposed by others; it is often the case that marginal ideas that are added upon or altered in some fashion become transformed into powerful solutions. It should be emphasized that ideas do not belong to the individual who presents them, but to the group.

BRAINSTORMING CATEGORIES

In Hossenlopp and Hass's 2007 book *Unearthing Business Requirements*, several types of brainstorming sessions are listed, separating the different ways innovation is encouraged. When planning a brainstorming session, it is wise to first decide what type of session to have, how many people to invite, and what the parameters of the session will be—the decisions to be made or problems to solve.

The first type of brainstorming is the *Individual* session. In this structure, the team leader of the session listens to the input of all members as the problem is explored, and creates a single list of ideas based on the conversations. This adds focus to the brainstorming, and it is often helpful to have a person designated to listen to the others and record the suggestions in a cohesive, clear manner.

The second type of brainstorming is the *Open* meeting. In an open session, participants call out thoughts and suggestions as inclined, and these thoughts are collected into a list of ideas. Many types of brainstorming go through open phases, and though they can often be confusing, such free-for-all sessions work particularly well for skilled, strong-willed individuals. A listener or designated note-taker is usually required for open sessions as well, although they will not generally have as much authority as in an individual meeting.

The last type of brainstorming is the *Structured* meeting. Structured sessions are planned and carried out carefully, avoiding any confusion. Usually, this means group participants write down their ideas silently, and then meet for a short time to select the best ideas of the pool to examine. Using these ideas, the group then returns to silent cogitation, refining their thoughts into a second series of ideas, which are again taken and improved. By the end of such a session, the goal is to have several ideas already subject to extensive analysis and ready to be accepted or rejected. Although this type of brainstorming has excellent clarity, it can be stifling for the more creative or strong-willed participants.

No matter what type of brainstorming is planned, having some sort of focus for the meeting is highly advised. Hossenlopp and Hass suggest writing down the goals or purpose of the session somewhere where everyone can see it, whether on a PowerPoint or a whiteboard. This gives a visual center for the participants to gather around.

FACILITATING BRAINSTORMING

When generating ideas, it is best to have the members of a group first generate ideas individually and silently rather than shouting out ideas as an entire group. Research indicates that by having people work individually, they generate a greater number of unique ideas than when brainstorming as a group. After individual brainstorming, all ideas can be shared, and further brainstorming as a group can be used.

What topics should be addressed in brainstorming sessions? While theoretically it is possible to brainstorm around any topic, Osborn believed that the problem or topic should be specific rather than general; that is, it should be narrow enough so that the participants can easily comprehend its nature and target their responses to its solution. Also, multiple problems, such as brainstorming about what a new product should be named, how it should be packaged, and how it should be advertised, should not be set before a brainstorming group. The problems should be separated, and brainstormed in separate meetings that are devoted to one of the aforementioned topics.

Osborn believed the ideal size for a brainstorming group was between five and ten people; however, he also contended that with the right kind of leader, large numbers of people of up to one hundred could successfully participate in brainstorming sessions. However, research indicates that larger groups generally do not generate more ideas than small groups.

In order to facilitate success, leaders of brainstorming sessions should do the following:

1. Facilitators should teach the principles and objectives of brainstorming to the group before beginning the brainstorming session. Unless all group members understand these rules, the brainstorming effort will fail.

2. Facilitators must enforce the rules during the brainstorming session. Inevitably, people will begin evaluating suggestions during the "generation" phase of brainstorming or violate one of the other principles. When such violations occur, the leader must re-teach the principle in question that has been violated, and relaunch the brainstorming process in the group.

3. Facilitators must ensure that the ideas are listed so that they can be referred to later when the group analyzes the ideas that it has generated. Idea records are often kept on flip charts, but an individual can record the information and the results can be photocopied and distributed to the participants as well.

4. Facilitators should try to encourage all group members to get involved in the session and contribute ideas. Some group members may be reluctant to share their thoughts, which could lead to one or

two participants dominating the session. A good facilitator finds ways to draw out ideas from all group members.

5. Facilitators need to keep the group focused and prevent participants from getting discouraged. Typically, participants offer several ideas at the beginning of a session; often these are the more obvious alternative solutions to the problem at hand. After these initial ideas are offered, the session might get bogged down as the quantity of ideas subsides. Facilitators should assist the group to push past this initial stage and continue working to come up with other alternatives, because it is at this point where truly creative solutions to problems may be offered.

6. Facilitators need to be able to restate and distill poorly articulated ideas in a way that clarifies without altering their meaning.

After a large set of ideas has been generated, they must then be evaluated and culled according to their efficacy. At this point, a large number of options are open to the leader in terms of how the ideas should be evaluated. However, generally it is advisable that the group who generated the ideas be accountable for evaluating them as well. During the analysis stage the leader must facilitate an evaluation of the ideas that the group generated. As the listed ideas are subtracted, merged, and refined in group discussion, it is common for a more comprehensive solution to the problem to be produced than what could have been generated individually or in other group problem-solving processes.

AVOIDING GROUPTHINK

Certain problems plague group synergy when people gather to make decisions. Irving Janis coined the term "groupthink" in the 1970s to describe these pitfalls, and today organizations should be wary of groupthink, especially when creating new ideas or seeking inspiration. Most groups are not aware of the mistakes they make under groupthink, and so require some kind of outside check or review of their decisions. Daniel Levi, in his 2007 book *Group Dynamics for Teams*, gives eight commonly recognized signs of groupthink—"symptoms" that can show up in meetings and lead to poor decisions. These signs should be known and watched for by the members of the brainstorming session:

1. *Illusion of invulnerability.* The group believes its decisions are without fault, and that they will work no matter what.

2. *Collective rationalization.* Ideas are supported throughout the group, so that poor ideas are often encouraged on the basis of the group's high opinion of each other.

3. *Belief in the group's morality.* The group considers itself to be always in the right and is never ethically questionable or capable of doing wrong.

4. *Pressure on dissenters.* Those who disagree with the majority of the group are immediately silenced or belittled, pressured into joining the majority or leaving the group.

5. *Stereotypes of outside groups.* The group believes it is superior to other tools and organizational structures, exaggerating its own importance and forgetting the necessity of other groups or processes.

6. *Self-censorship.* Group members who disagree keep their opinions to themselves. They are afraid to question the others and are convinced it is easier to just agree with everyone rather than bring up negative aspects to ideas.

7. *Illusion of unanimity.* The group believes that all its members agree with all decisions.

8. *Self-appointed mind guards.* The group has members who downplay all negative results and block criticism from reaching the group.

POTENTIAL PROBLEMS

Certain studies have shown that brainstorming may have some inherent flaws when trying to produce new ideas and processes. According to Levi, brainstorming may not be an improvement over the talented efforts of individuals. A study by Mullen, Johnson, and Salas conducted in 1991 showed that the total of individual work—people creating solutions on their own—usually equaled the number of useful ideas produced in brainstorming sessions. Levi also points out that during brainstorming, a great deal of time is wasted in the speaking queue that develops. People who are participating listen to the speaker while waiting to speak their own ideas, and while waiting do not contribute any thought-value to the group. This often creates a series of mental log jams in which people are waiting to say ideas without coming up with any more themselves.

If groupthink and negative employee impressions take over, the brainstorming session can degenerate to a "blamestorming" session. The change occurs when participants begin to blame their managers, restrictions, and organization for personal grievances. At this point, little creativity is possible, and unhealthy grumbling is more likely. Despite some of these faults, organizations believe that brainstorming fosters creativity and encourages its members, and the track record of success for brainstorming has sustained its popularity.

Face-to-face brainstorming sessions may not always generate a large number of creative ideas for a variety of reasons. One problem with face-to-face sessions is called production blocking, which is basically anything that

prevents a group member from verbalizing his or her ideas as they occur. Common production blocks are forgetting and distractions. Another problem with face-to-face sessions is evaluation apprehension, which simply means that individuals are afraid to vocalize their ideas. Evaluation apprehension might be caused because individuals are reluctant to share novel, but incompletely developed, ideas. Group members might also be afraid of how others will react if they suggest unpopular or politically sensitive alternatives. Another potential problem with face-to-face brainstorming is social loafing, which occurs when individuals put forth less effort on a group project than they do working alone.

Electronic brainstorming sessions may reduce some of these problems. In online or network settings, participants can simultaneously contribute ideas, and can usually do so anonymously. Anonymity may make it more likely that individuals will contribute a larger number of creative alternatives. In fact, empirical research suggests that electronic sessions are generally more effective than face-to-face sessions in terms of the number of alternative ideas generated.

Although the anonymity offered by electronic brainstorming sessions may reduce the negative impact of some of the problems associated with face-to-face sessions, other research suggests that social loafing might still be a problem. One study published in the *Journal of Management Information Systems* found that allowing participants in electronic sessions to view and compare their participation rates against those of others in the group (e.g., a tally of how many ideas were suggested by each person) increased individuals' contributions of ideas, as everyone could readily see who was not participating much. In this study, electronic idea forums that allowed social comparison were the most productive, followed by anonymous electronic forums. Face-to-face sessions were the least productive in terms of the quantity of alternative solutions generated.

BRAINSTORMING AS CREATIVE DECISION MAKING

Because of its emphasis on group participation and creativity, brainstorming may also be seen as a tool for creative decision making. Creative decision making is a group decision-making technique in which group members attempt to generate as many alternative solutions as possible for a given problem. It is one of a number of decision-making tools that are used to ensure consideration of a diverse set of alternative solutions. Other common decision-making techniques include the nominal group technique and the Delphi technique.

Businesses can approach brainstorming in a variety of ways. The online options are useful for a company that wishes to bring together far-flung departments, or talents that cannot easily meet face to face. In Andrew Griffiths' 2007 book *101 Ways to Market Your Business*, the author suggests having scheduled meetings for brainstorming. One possible schedule is a monthly meeting, giving all the members of the group time to plan or travel if needed. Griffiths also encourages making the sessions casual. Inviting a smaller group to lunch each month is one possibility—a small expenditure to put the group at ease and allow ideas to flow more easily.

BREAK-EVEN POINT

A company's break-even point is the amount of sales or revenues that it must generate in order to equal its expenses. In other words, it is the point at which the company neither makes a profit nor suffers a loss.

Calculating the break-even point (through break-even analysis) can provide a simple, yet powerful quantitative tool for managers. In its simplest form, break-even analysis provides insight into whether revenue from a product or service has the ability to cover the relevant costs of production of that product or service. Managers can use this information in making a wide range of business decisions, including setting prices, preparing competitive bids, and applying for loans.

BACKGROUND

The break-even point has its origins in the economic concept of the *point of indifference.* From an economic perspective, this point indicates the quantity of some good at which the decision maker would be indifferent (i.e., would be satisfied without reason to celebrate or to opine). At this quantity, the costs and benefits are precisely balanced.

Similarly, the managerial concept of break-even analysis seeks to find the quantity of output that just covers all costs so that no loss is generated. Managers can determine the minimum quantity of sales at which the company would avoid a loss in the production of a given good. If a product cannot cover its own costs, it inherently reduces the profitability of the firm.

MANAGERIAL ANALYSIS

Typically the break-even scenario is developed and graphed in linear terms. Revenue is assumed to be equal for each unit sold, without the complication of quantity discounts. If no units are sold, there is no total revenue ($0). However, total costs are considered from two perspectives. Variable costs are those that increase with the quantity produced; for example, more materials will be required as more units are produced. Fixed costs, however, are those that will be incurred by the company even if no units are produced. In a company that produces a single good or service, this would include all costs necessary to provide the production environment, such as administrative costs, depreciation of equipment, and regulatory fees. In a multi-product company, fixed costs are usually allocations of such costs to a particular product, although some fixed costs (such as a specific supervisor's salary) may be totally attributable to the product.

Figure 1 displays the standard break-even analysis framework. Units of output are measured on the horizontal axis, whereas total dollars (both revenues and costs) are the vertical units of measure. Total revenues are nonexistent

($0) if no units are sold. However, the fixed costs provide a floor for total costs; above this floor, variable costs are tracked on a per-unit basis. Without the inclusion of fixed costs, all products for which marginal revenue exceeds marginal costs would appear to be profitable.

In Figure 1, the break-even point illustrates the quantity at which total revenues and total costs are equal; it is the point of intersection for these two totals. Above this quantity, total revenues will be greater than total costs, generating a profit for the company. Below this quantity, total costs will exceed total revenues, creating a loss.

To find this break-even quantity, the manager uses the standard profit equation, where profit is the difference between total revenues and total costs. Predetermining the profit to be $0, he or she then solves for the quantity that makes this equation true, as follows:

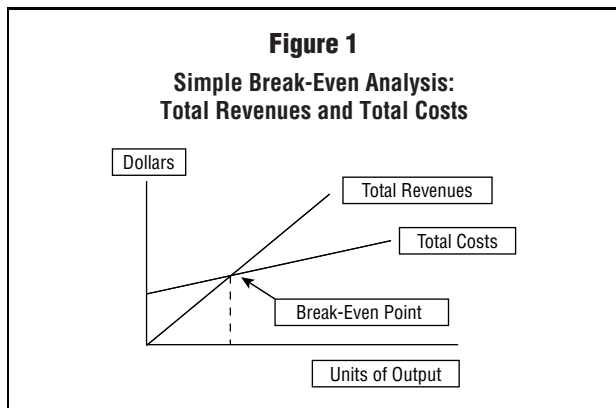
$$\text{Let } TR = \text{Total revenues}$$
$$TC = \text{Total costs}$$
$$P = \text{Selling price}$$
$$F = \text{Fixed costs}$$
$$V = \text{Variable costs}$$
$$Q = \text{Quantity of output}$$
$$TR = P \times Q$$
$$TC = F + V \times Q$$
$$TR - TC = \text{profit}$$

Because there is no profit ($0) at the break-even point, $TR - TC = 0$, and then $P \times Q - (F + V \times Q) = 0$. Finally, $Q = F(P - V)$.

This is typically known as the contribution margin model, as it defines the break-even quantity (Q) {note: Q is previously defined as "quantity of output"} as the number of times the company must generate the unit contribution margin ($P - V$), or selling price minus variable costs, to cover the fixed costs. It is particularly interesting to note that the higher the fixed costs, the higher the break-even point. Thus, companies with large investments in equipment and/or high administrative-line ratios may require greater sales to break even.

As an example, if fixed costs are $100, price per unit is $10, and variable costs per unit are $6, then the break-even quantity is 25 ($100 ÷ [$10 − $6] = $100 ÷ $4). When 25 units are produced and sold, each of these units will not only have covered its own marginal (variable) costs, but will also have contributed enough in total to have covered all associated fixed costs. Beyond these 25 units, all fixed costs have been paid and each unit contributes to profits by the excess of price over variable costs, or the contribution margin. If demand is estimated to be at least 25 units, then the company will not experience a loss. Profits will grow with each unit demanded above this 25-unit break-even level.

Figure 1

**Simple Break-Even Analysis:
Total Revenues and Total Costs**


While it is useful to know the quantity of sales at which a product will cease to generate losses, it may be even more useful to know the quantity necessary to generate a desired level of profit. (Let D = desired level of profit.)

$$TR - TC = D$$
$$P \times Q - (F + V \times Q) = D$$
$$\text{Then } Q = (F + D) \div (P - V)$$

Here, the desired profit is regarded as an increase in the fixed costs to be covered by sales of the product. As the decision-making process often requires profits for payback period, internal rate of return, or net present value analysis, this form may be more useful than the basic break-even model.

BASIC ASSUMPTIONS

Several assumptions affect the applicability of break-even analysis. If these assumptions are violated, the analysis may lead to erroneous conclusions.

It is tempting to set the contribution margin (and thus the price) by using the sales goal (or certain demand) as the quantity. However, sales goals and market demand are not necessarily equivalent, especially if the customer is price-sensitive.

Price-elasticity exists when customers will respond positively to lower prices and negatively to higher prices, and is particularly applicable to nonessential products. A small change in price may affect the sale of skis more than the sale of insulin, an inelastic-demand item due to its inherently essential nature. Therefore, using this method to set a prospective price for a product may be more appropriate for products with inelastic demand. For products with elastic demand, it is wiser to estimate demand based on an established, acceptable market price.

Typically, total revenues and total costs are modeled as linear values, implying that each unit of output incurs the same per-unit revenue and per-unit variable costs. Volume sales or bulk purchasing may incorporate quantity discounts, but the linear model appears to ignore these options.

A primary key to detecting the applicability of linearity is determining the relevant range of output. If the forecast of demand suggests that 100 units will be demanded, but quantity discounts on materials are applicable for purchases over 500 units from a single supplier, then linearity is appropriate in the anticipated range of demand (100 units plus or minus some forecast error). If, instead, quantity discounts begin at 50 units of materials, then the average cost of materials may be used in the model.

A more difficult issue is that of volume sales, when such sales are frequently dependent on the ordering patterns of numerous customers. In this case, historical records of the proportionate quantity-discount sales may be useful in determining average revenues.

Linearity may not be appropriate due to quantity sales/purchases, as noted, or to the step-function nature of fixed costs. For example, if demand surpasses the capacity of a one-shift production line, a second shift may be added. The second-shift supervisor's salary is a fixed-cost addition, but only at a sufficient level of output. Modeling the added complexity of nonlinear or step-function costs requires more sophistication, but may be avoided if the manager is willing to accept average costs to use the simpler linear model.

One obviously important measure in the break-even model is that of fixed costs. In the traditional cost-accounting world, fixed costs may be determined by full costing or by variable costing. Full costing assigns a portion of fixed production overhead charges to each unit of production, treating these as a variable cost. Variable costing, by contrast, treats these fixed production overhead charges as period charges; a portion of these costs may be included in the fixed costs allocated to the product. Thus, full costing reduces the denominator in the break-even model, whereas the variable costing alternative increases the denominator. While both of these methods increase the break-even point, they may not lend themselves to the same conclusion.

Recognizing the appropriate time horizon may also affect the usefulness of break-even analysis, as prices and costs tend to change over time. For a prospective outlook incorporating generalized inflation, the linear model may perform adequately. Using the earlier example, if all prices and costs double, then the break-even point $Q = 200 \div (20 - 12) = 200 \div 8 = 25$ units, as determined with current costs. However, weakened market demand for the product may occur, even as materials costs are rising. In this case, the price may shift downward to \$18 to bolster price-elastic demand, while materials costs may rise to \$14. In this case, the break-even quantity is 50 ($200 \div [18 - 14]$), rather than 25. Managers should project break-even quantities based on reasonably predictable prices and costs.

It may defy traditional thinking to determine which costs are variable and which are fixed. Typically, variable costs have been defined primarily as "labor and materials." However, labor may be effectively salaried by contract or by managerial policy that supports a full workweek for employees. In this case, labor should be included in the fixed costs in the model.

Complicating the analysis further is the concept that all costs are variable in the long run, so that fixed costs and the time horizon are interdependent. Using a make-or-buy analysis, managers may decide to change from in-house production to subcontracting production; in this

case, fixed costs are minimal and almost 100 percent of the costs are variable. Alternatively, they may choose to purchase cutting-edge technology, in which case much of the variable labor cost is eliminated; the bulk of the costs then involve the (fixed) depreciation of the new equipment. Managers should project break-even quantities based on the choice of capital-labor mix to be used in the relevant time horizon.

Traditionally, fixed costs have been allocated to products based on estimates of production for the fiscal year and on direct labor hours required for production. Technological advances have significantly reduced the proportion of direct labor costs and have increased the indirect costs through computerization and the requisite skilled, salaried staff to support company-wide computer systems.

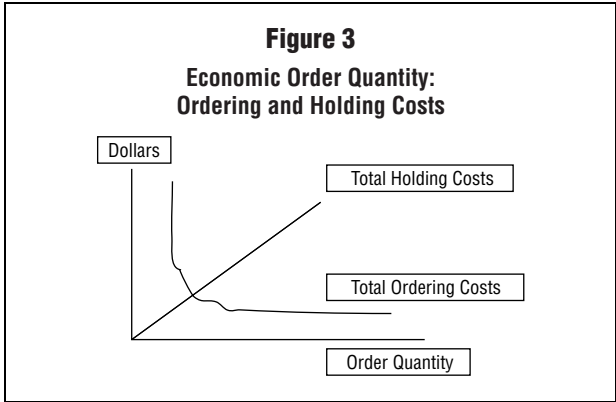
Activity-based costing (ABC) is an allocation system in which managers attempt to identify "cost drivers" which accurately reflect the appropriate usage of fixed costs attributable to production of specific products in a multi-product firm. This ABC system tends to allocate, for example, the CEO's salary to a product based on his or her specific time and attention required by this product, rather than on its proportion of direct labor hours to total direct labor hours.

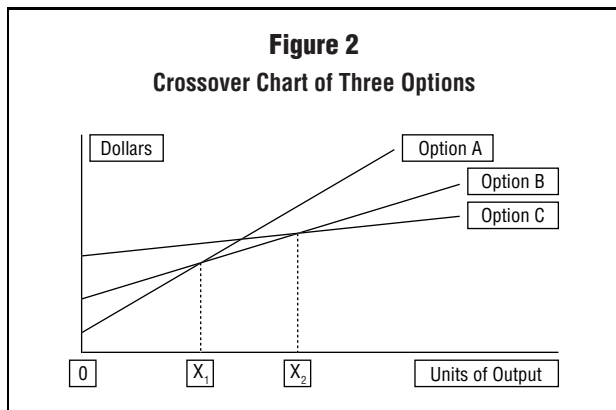
EXTENSIONS OF BREAK-EVEN ANALYSIS

Break-even analysis typically compares revenues to costs. However, other models employ similar analysis.

In the crossover chart, the analyst graphs total-cost lines from two or more options. These choices may include alternative equipment choices or location choices. The only data needed are fixed and variable costs of each option. In Figure 2, the total costs (variable and fixed costs) for three options are graphed. Option A has the low-cost advantage when output ranges between zero and X units, whereas Option B is the least-cost alternative between X and X units of output. Above X units, Option

Figure 2
Crossover Chart of Three Options

Figure 3
Economic Order Quantity:
Ordering and Holding Costs




C will cost less than either A or B. This analysis forces the manager to focus on the relevant range of demand for the product, while allowing for sensitivity analysis. If current demand is slightly less than X, Option B would appear to be the best choice. However, if medium-term forecasts indicate that demand will continue to grow, Option C might be the least-cost choice for equipment expected to last several years. To determine the quantity at which Option B wrests the advantage from Option A, the manager sets the total cost of A equal to the total cost of B ($F_A + V_A \times Q = F_B + V_B \times Q$) and solves for the sole quantity of output (Q) that will make this equation true. Finding the break-even point between Options B and C follows similar logic.

The Economic Order Quantity (EOQ) model attempts to determine the least-total-cost quantity in the purchase of goods or materials. In this model, the total of ordering and holding costs is minimized at the quantity where the total ordering cost and total holding cost are equal (i.e., the break-even point between these two costs).

As companies merge, layoffs are common. The newly formed company typically enjoys a stock-price surge, anticipating the leaner and meaner operations of the firm. Obviously, investors are aware that the layoffs reduce the duplication of fixed-cost personnel, leading to a smaller break-even point and thus profits that begin at a lower level of output.

APPLICATIONS IN SERVICE INDUSTRIES

While many of the examples used have assumed that the producer was a manufacturer (i.e., labor and materials), break-even analysis may be even more important for service industries. The reason for this lies in the basic difference in goods and services: Services cannot be placed in inventory for later sale. What is a variable cost in manufacturing may necessarily be a fixed cost in services. For example, in the restaurant industry, unknown demand requires that cooks

and table-service personnel be on duty even when customers are few. In retail sales, clerical and cash register workers must be scheduled. If a barber shop is open, at least one barber must be present. Emergency rooms require round-the-clock staffing. The absence of sufficient service personnel frustrates the customer, who may balk at this visit to the service firm and may find competitors that fulfill their needs.

The wages for this basic level of personnel must be counted as fixed costs. They are necessary for the potential production of services, despite the actual demand. However, the wages for on-call workers might be better classified as variable costs. These wages will vary with units of production. Services, therefore, may be burdened with an extremely large ratio of fixed-to-variable costs.

Service industries, without the luxury of inventoriable products, have developed a number of ways to provide flexibility in fixed costs. Professionals require appointments, and restaurants take reservations; when the customer flow pattern can be predetermined, excess personnel can be scheduled only when needed, reducing fixed costs. Airlines may shift low-demand flight legs to smaller aircraft, using less fuel and fewer attendants. Hotel and telecommunication managers advertise lower rates on weekends to smooth demand through slow business periods and avoid times when the high-fixed-cost equipment is underutilized. Retailers and banks track customer flow patterns by day and by hour to enhance their short-term scheduling efficiencies. Whatever method is used, the goal of these service industries is the same as that in manufacturing: Reduce fixed costs to lower the break-even point.

The fixed costs of many of these examples are further decreased by taking advantage of the Internet. No longer are employees needed onsite for a specific number of hours. Instead, business owners can use the Web to offer shopping and banking experiences and to schedule appointments, among other things. In fact, in the first decade of the twenty-first century nearly three-quarters of small businesses report that the Internet has helped increase their revenues and sales, and has decreased their administrative costs. One online research group estimates that Web-based retailing comprised one-tenth of all total U.S. retail sales in 2008, and this percentage should continue to increase as more and more people shop online.

Shared services offers another way to reduce fixed costs. Using this strategy, companies centralize administrative tasks, such as finance and document copying, that several different divisions of a company often perform. By sharing services, companies are able to justify larger investments in technology by creating a critical mass; they create economies of scale by standardizing procedures that are often repeated, such as hiring.

Break-even analysis is a simple tool that defines the minimum quantity of sales that will cover both variable and fixed costs. Such analysis gives managers a quantity to compare to the forecast of demand. If the break-even point lies above anticipated demand, implying a loss on the product, the manager can use this information to make a variety of decisions. The product may be discontinued or, by contrast, may receive additional advertising and/or be re-priced to enhance demand. One of the most effective uses of break-even analysis lies in the recognition of the relevant fixed and variable costs. The more flexible the equipment and personnel, the lower the fixed costs and the lower the break-even point.

BUDGETING

Organizations develop specific plans for saving and spending income. These plans, or budgets, are essential for developing spending and saving priorities. A properly prepared budget also serves as a reference to check how well money is being managed, by allowing managers to see actual revenues and expenses compared to budgeted revenues and expenses during a period. Managers can identify revenue shortfalls or expense excesses and take corrective action earlier.

The term "budget" can be dated back to medieval England, where it meant leather purse or wallet. A budget allows businesses to meet specific goals by creating a system of saving and spending money efficiently. Simply defined, a budget is a plan for using corporate funds in a way that best meets the firm's wants and needs. The plan

includes a recorded entry of expected income, expenses, and savings over a defined period of time.

A wide range of budgeting techniques exist and although the fundamental purposes are similar, the specifics among various organizations are often different. One important aspect of budgeting is how organizations increase cash to finance ongoing operations and new opportunities. Large corporations, for example, may have the option of increasing cash by selling *treasury stock*, previously authorized shares of ownership that have never been offered for sale on the stock market. The liquidity of equity (stock) markets allows managers to implement these equity decisions fairly quickly to budget for projected needs.

Several independent organizations rate the debt-paying ability of large corporations. This creates a market for corporate debt, more commonly referred to as bonds. Corporations with favorable debt ratings have the ability to borrow money, that is, issue bonds, at lower interest rates than those with unfavorable debt ratings.

Small businesses, in contrast, often do not have publicly traded shares of stock. Although these businesses can sell stock to investors, the process is more uncertain because the market for this type of stock is less liquid. Venture capital is also an option, but the number of small businesses seeking venture capital nearly always exceeds the amount of venture capital available. Also, debt-rating agencies do not rate the debt-paying ability of many small businesses, limiting the extent to which these businesses can raise cash through bond issues. Without a ready market for debt, small businesses must often turn to the less liquid forms of debt financing such as bank loans, in some cases at higher interest rates than would be available from established credit markets available to larger corporations.

Budgets allow businesses to better utilize the financial resources available to them. To begin with, budgets help businesses operate within their means. Over the long term, budgets assist businesses in spending less money than they earn. Next, budgets help businesses achieve their financial goals by planning for the future and organizing money into categories such as income, expenses, and savings. In short, budgets help a business avoid credit problems, better prepare for financial emergencies, and build better money management skills by creating a structured plan.

Businesses should follow several steps to successfully implement a budget. These include setting financial goals, planning budget categories, maintaining financial records, and balancing and adjusting the budget. Setting financial goals is the starting point in the budgeting process. Questions managers should ask include:

- "What do we want accomplished within one month, one year, or ten years?"
- "What new products or services do we want to offer in the short- and long-term, and how can we finance these?"
- "Will my operating expenses increase with inflation, and how will we increase revenue to meet these additional expenses?"

These questions provide a starting point to spur additional questions. The answers to these questions should help determine how income should be spent and saved. Managers should ask dozens of additional questions to cover all the categories of revenue, expense, and debt and equity financing.

In general, budgeting questions should revolve around estimates of income and expenses. Categories include fixed expenses such as rent, insurance premiums, and taxes; estimates of variable expenses such as utilities and wages; and estimates that allow for uncertainties.

One way to budget is by comparing estimated financial figures created before a budgeting period with actual experience at the end of the budgeting period. The initial estimates are called pro forma financial statements. The three primary types of financial statements are a balance sheet, income statement, and statement of cash flows. The balance sheet shows assets owned, liabilities owed, and owners' equity (owners' financial stake in the businesses). The income statement details profit and loss for a given period. The statement of cash flows helps managers see where cash came from and where it went. By comparing pro forma financial statements to end-of-period financial statements, managers can judge whether or not their budgets are in line with estimates. Adjustments can then be made for future budgeting periods.

Companies often experience a budget variance, the difference between a budgeted figure and an actual figure. There are two kinds of budget variance. A quantity variance is due to an increase or decrease in the quantity of the resource used. A cost variance is due to a difference in the cost of a resource. For example, a company may have a fuel budget based on an estimated consumption of 100 gallons at $3 per gallon. If the company uses more than 100 gallons of fuel, a quantity budget variance has occurred. Likewise, if the cost of the fuel increases to $3.50, the company is facing a cost variance. The variance tells companies that something is out of line.

A budget must meet certain characteristics to help businesses successfully manage money. The budget should be realistic as well as flexible. When a budget variance occurs, the budget should be specific enough to provide information that shows what costs are out of budget. When unexpected expenses arise, the spending plan should be able

to handle these costs. A budget is not a permanent plan and should be realigned when circumstances occur that alter budget categories. The budget should be carefully planned and organized, yet clear enough to be communicated to organizational stakeholders such as lenders and owners.

Companies create budgets for a mixture of reasons. They can serve a variety of functions, and many techniques can be implemented to develop them. Budgets can be used as a means of forecasting and planning for the future. Their creation can also be used as a motivational tool. The plan can be used as a means of evaluation and control as well as a resource for information and decision-making.

In addition to preparation or pro forma financial statements and comparison to actual financial statements, many different approaches to the budgeting process can be used depending on the desired function of the company. Breakeven analysis, for instance, estimates the amount of sales required to cover the expenses of a new product or service. Payback periods are similar, but increase the focus of breakeven analysis on needed sales by adding the length of time needed to achieve those sales. This tells managers how long it will take to recoup initial expenses. Another type of budgeting is capital budgeting, in which the estimated revenue from capital projects such as purchase of property, plants, and equipment is projected. Additional techniques include parametric, partial, zero-based, and equity budgeting. Each of these may be applied to organizations' financial situations depending on the needs of the individual businesses.

Each department within a corporation plays a key role in the overall budget process. Regardless of the approach, those working on the budget must know the corporation's goals and initiatives for the coming year. By considering corporate strategy, all departments within the corporation create their budget in a way that helps enable the company to hit its key initiatives for the coming fiscal year, and to meet short- and long-term corporate goals.

Budgeting is essential. Businesses without budgets can quickly find themselves short of cash not only for new products and services, growth and expansion, and improvements in capital projects, but also in simply meeting short-term needs such as payroll, insurance, and tax expenses. Budgeting is thus a key element in all business planning.

BUSINESS PLAN

A business plan is a written document used to describe a proposed venture or idea. It typically includes the current state of a business, future vision for the business, target market analysis and challenges, sales and marketing strategies, and funding requirements to reach stated goals. Many business plans are designed with the intention of securing funding and investors to support a proposed idea; others are designed to assist with reorganization, takeovers, or to serve as an internal planning document. On its Web site, the U.S. Small Business Administration (SBA) describes it this way:

> A business plan precisely defines your business, identifies your goals, and serves as your firm's resume. It helps you allocate resources properly, handle unforeseen complications, and make good business decisions. Because it provides specific and organized information about your company and how you will repay borrowed money, a good business plan is a crucial part of any loan application. Additionally, it informs sales personnel, suppliers, and others about your operations and goals.

In addition to these continuing benefits, a business plan can also offer clear, immediate advantages to struggling companies, or to those intending to sell their business concepts. Mike McKeever gives several of these advantages in his book, *How to Write a Business Plan* (2007):

1. *A business plan will help the business find financial backers.* Since investors require a business plan before giving a company any significant backing, it is a good idea to plan and write one before looking for aid. After creating a plan, leaders of the business will understand more clearly where their money goes and what it is spent on—information the investors will want to know.

2. *A business plan will help a starting company decide whether to proceed or stop.* Creating a plan for a new business allows leaders to examine potential strengths and weaknesses of the business, giving them the confidence to move forward or possibly the knowledge to reassess the functionality of their ideas.

3. *A business plan allows leaders to improve the business concept.* In making the plan, leaders may realize parts of the organization they need to change or reevaluate. Writing the plan gives a chance to change the goals of the business for the better.

4. *A business plan helps keep the business on track.* With the straightforward rules, goals, and parameters of the plan written down, a business has more focus.

GETTING STARTED

The article "Write the Right Business Plan" lists ten things to consider before tackling the document:

1. Decide why you're writing your plan—what is your motivation?

2. Do your homework—read some books, explore web resources.

3. Compile your information—locate articles and financial statements.

4. Start typing—write down all your ideas, notes, and questions in outline form.

5. Write a rough draft—flesh out the outline with full sentences and paragraphs.

6. Do more research—support your case with data via small business association contacts, annual reports, and competitors in the chosen industry.

7. Think about the numbers—develop pro forma financial statements.

8. Write a final draft—demonstrate attention to detail with accuracy and clarity.

9. Get feedback—have someone else read over your plan and offer advice.

10. Polish your plan to perfection—include a cover page, table of contents, nondisclosure form, and an executive summary containing highlights.

Employees with the right skill set and expertise can collaborate to create the business plan. Alternatively, a consultant can be hired to assist with the process. A consultant can bring expertise and professionalism to the appearance and tone of your business plan, provide informed market analysis and research assistance, and supply educated projections for a market that the entrepreneur might be unfamiliar with or have little experience analyzing.

After determining who will be working on the plan, it is useful to decide on the scope of the plan and timeframe for completion of the plan. Once the team or consultant is in place, research and analysis can begin. Internal and external assessments should be conducted and then examined. The interpretations of these assessments will be the framework of the plan and will guide goal setting and strategies for the company. Once goals and strategies are determined, a solid business plan can be formed toward fulfilling these goals.

From a management perspective, a business plan allows managers to set priorities and allocate resources effectively. It brings order and direction to an organization and provides a vision of the future that employees throughout the company can put energy into and get excited about. This shared vision and focus will benefit the company at every level and ensure that all constituents are working cooperatively and cohesively. Ideally, all employees will utilize the information from the business plan to assist in goal setting, and guide in decision making and performance assessments.

A 2005 guide by Covello and Hazegren on beginning business plans reports that a strong plan will take approximately fifty to one hundred hours to complete. From an entrepreneur's stand, that is about six months of review, study, analysis, and research. This time devoted to making the business plan is useful, since by the end, the entrepreneur is aware of most of the positive and negative aspects of the business, and has a clear idea how to market it to outsiders.

ELEMENTS OF A BUSINESS PLAN

The U.S. Small Business Administration recommends that a business plan describe four main elements of the proposed venture: an overview of the business, a marketing analysis, a financial plan, and a management plan. An executive summary and other supporting documents should also accompany the plan. These elements provide a solid starting point for a general plan, but there is no single formula to a business plan and a multitude of factors will impact the amount of content needed in a good business plan.

The executive summary is a synopsis of the entire business plan. It is critical that this summary be carefully crafted and compelling. This is the first and possibly the only information that a potential investor will read; if it is not informative enough or if it is lacking crucial data, the investor might not read beyond this summary component.

The business overview segment is a profile of the company and its primary industry. Projections, trends, and industry outlooks should be included. In this section the company describes the unique elements that make it a prime candidate for its proposed venture.

A market analysis details how the company will handle its sales and marketing strategies. This analysis includes information on the company's products or services and intended customers, and how customers will be made aware of the product or service. This section should also include a competitive analysis with a breakdown identifying Strengths, Weaknesses, Opportunities, and Threats

(SWOT) to the company and the business proposed. A plan of action should explain how the company will address, exploit, or withstand each of these eventualities.

The financial section discusses the current financial state of the company and what types of financing will be required for the proposed venture. In this area, it is appropriate to discuss the specific dollar amounts required for the business venture, the cost to maintain and sustain the venture, and projections of income, balance sheets, and cash flow. Statistics, facts, and research should support any financial projections listed. In a 2008 article, "Successful Business Plan," Amy Tailor details the SMART model of financial analysis, which many experts watch for. According to the SMART system, the business should be able to list and explain how its goals are Specific, Measurable, Achievable, Realistic, and Timed. Specific goals should be natural to a strong business plan. Measurable goals should include current and expected data, along with systems of analysis to track changes. Achievable and realistic goals can be met within the framework of the business's assets and skills, and timed

goals are set forth at the proper moment in the organization's evolution.

The management plan section should discuss the strengths, experience, achievements, and expertise of the person or team undertaking the business venture. Investors want to know that they are offering their support to a person or team qualified and capable of handling the business proposed and the funds loaned.

A complete business plan will provide evidence to the lender that the entrepreneur has performed a thorough investigation of this new business venture, because it details how the business will generate cash flow, pay for operating expenses, and service debt repayment.

The accompanying table offers several elements for inclusion in designing a business plan.

In addition to these structures, Edward Rogoff gives six main strengths every business plan should convey in his 2007 book *Bankable Business Plans: Second Edition*. These strengths Rogoff calls the six immutable points, the goal being to prove these points to any reader of the business plan.

Elements of a Business Plan

1. Cover sheet
2. Statement of purpose
3. Table of contents

I. The Business
A. Description of business
B. Marketing
C. Competition
D. Operating procedures
E. Personnel
F. Business insurance

II. Financial Data
A. Loan applications
B. Capital equipment and supply list
C. Balance sheet
D. Breakeven analysis
E. Pro-forma income projections (profit & loss statements)
    1. Three-year summary
    2. Detail by month, first year
    3. Detail by quarters, second and third years
    4. Assumptions upon which projections were based
F. Pro-forma cash flow

III. Supporting Documents
A. Tax returns of principals for the last three years
B. Personal financial statement (all banks have these forms)
C. For franchised businesses, a copy of franchise contract and all supporting documents provided by the franchisor
D. Copy of proposed lease or purchase agreement for building space
E. Copy of licenses and other legal documents
F. Copy of resumes of all principals
G. Copies of letters of intent from suppliers, etc.

---

1. You are profit-oriented.

2. You are honest.

3. You are qualified.

4. You are thorough.

5. You are committed to meeting everyone's needs.

6. You are flexible.

CUSTOMIZING FOR INVESTOR TYPE

Bankers, venture capital fund managers, and business angels each look at different features of a business plan when assessing it for investment. Bankers tend to focus on the financial aspects of the plan and give little emphasis to marketing and management issues. Venture capital fund managers are typically most interested in both the marketing and the financial aspects of the plan. Business angels focus on entrepreneurial elements and "investor fit" considerations. Thus business plan writers should customize their proposals based on the audience they are trying to reach.

Bankers are interested in businesses that will be successful over the long term and entrepreneurs who will remain committed to the project as described in the business plan. When making their lending decisions, they are interested in collateral as security for the loan, and tend to support projects that are less risky. A banker's main interest is the repayment of the loan.

Venture capital fund managers invest for capital gain, and when a venture is successful, they also benefit. Likewise, if a business fails, venture capital fund managers stand to lose significantly and at much cost to the outside investors whose funds they are managing. Therefore, venture capital fund managers focus on the uniqueness of the product or service, the status of the market, and the management team's potential for success. Venture capital fund managers' main interest is growth potential and potential returns.

Business angels' interests align more closely with venture capital fund managers than with bankers. Business angels focus on how their interests match up with the entrepreneur's and how well they are able to work with the entrepreneur over the length of the project. They seek out entrepreneurs who have strong, positive qualities, such as integrity and responsibility, and with whom they feel a connection. Because the investment is personal for the business angel, he or she is interested in financial gains, but also enjoys the opportunity to participate in the venture itself. A business angel's main interest is potential returns, camaraderie with the entrepreneur(s), and personal involvement.

Steingold, in his 2007 *Complete Guide to Selling a Business*, says that a good business plan will aid investors in several other, more intangible ways. The strength of a strong vision for business direction can inspire interested buyers, communicating the power of the idea as well as the financial prospects. Investors who believe in the organization's goals will be much more likely to understand business models and provide financial support for endeavors. Also, Steingold believes a strong business plan gives buyers a cushion, something to rely on when they get cold feet. Negotiations can go on for weeks, and when the time lends uncertainty to the buyer's decision, they can rely on the business plan as proof the sellers know what they are doing.

RECENT TRENDS

An article by A. Gome investigates a growing trend among certain entrepreneurs to move away from the old-style business plan that contains an extended, long-term outlook. They are opting instead to use an abbreviated, shorter-term document that better fits their business strategy.

Long-range planning documents don't work as well for some entrepreneurs because of the fast-changing markets they are entering into, which renders the business plan irrelevant within months. And, the short-term nature of some ventures precludes the need for a long-term plan. It is unnecessary to have a five-year plan if the entrepreneur expects to conclude his venture within a shorter time frame.

LIVING DOCUMENTS

Replacing the traditional business plan is what is called a "living document," typically one page in length and with a forward-looking range of one year. Goal-setting may be projected on three- to six-month timeframes, which are more easily monitored and attainable. The living document contains similar elements of a typical business plan—vision, values, objectives, methods toward reaching objectives—but abbreviated to fit on a single page. This document needs constant updating and adjusting, with ample flexibility to respond to customer and market fluctuations. Highly-tailored documents may also need to be prepared for each type of stakeholder, whether bankers, venture capital fund managers, or business angels.

RESOURCES

There are many resources for the entrepreneur looking to write a business plan. Local business organizations, public libraries, colleges and universities may offer useful workshops, seminars, or courses.

Local SBA offices or Web sites (<http://www.sba.gov>) also offer resources. The SBA has sponsored more than 200,000 loans worth more than $45 billion, making it the largest single financial backer of U.S. businesses in the country. The SBA provides free online courses, e-mail guidance, print materials, and face-to-face consultations to small business owners.

The SBA also administers the Small Business Development Center Program to provide management assistance to current and prospective small business owners. This program provides a broad-based system of assistance for the small business community by linking the resources of federal, state and local governments with the resources of the educational community and the private sector.

There are also several books and software programs that assist with creating a business plan.

BUSINESS PROCESS REENGINEERING

Process reengineering is redesigning or reinventing how people perform their daily work, and it is a concept that is applicable to all industries regardless of size, type, and location.

While selected elements of process reengineering are well documented in the late nineteenth and early twentieth centuries, process reengineering as a body of knowledge (or as an improvement initiative) takes the best of the historical management and improvement principles and combines them with more recent philosophies and principles; in theory, this makes all people in an organization function as process owners and reinvent processes. It is this combination of the old and the new as well as the emphasis on dramatic, rapid reinvention that makes process reengineering an exciting concept.

The beginning of business process reengineering is often cited as an MIT research project conducted from 1984 to 1989, showing that managers were beginning to recreate their businesses using new technology and ideas. The concept traveled quickly through the business world, jumpstarted by a 1990 article by Michael Hammer called "Re-engineering Work: Don't Automate, Obliterate." Neil Botten and Adrian Sims explain Hammer's idea in their 2007 CIMA textbook, *Management Accounting–Business Strategy* and use as an example the reengineering of credit sales at IBM. The IBM sales force processed certain sales in a series of steps, each step requiring separate authorization: authorization of the sale, approval by the legal department, allocation of funds from the financial, and so on. This process took weeks, and was often too long to make a sale. Realizing the entire process needed only a few minutes to complete, IBM used technology to reinvent the steps, and today the IBM sales force uses laptops to carry out all authorizations on a demand basis.

BPR (business process reengineering) is often compared to TQM (total quality management), and the rise in one has corresponded to the rise in the other in recent years. In Malhotra's 1998 article "Business Process Redesign: An Overview," he cites clear differentiation between the two regarding how they are carried out. TQM is seen as being composed of small, incremental steps, all aimed at improving the company's efficiency over time. In contrast, BPR is composed of much larger steps; it is an overhaul, a radical redesigning of the business's plans and ways of reaching goals.

The process of BPR can begin in many different ways and on many different levels within an organization. Peter Carter, in his Introductory Guide to BPR (2005), suggests that BPR can start with an organization's mission or vision statement. Profound changes in a mission statement can give a company new direction, serving as a base for reengineering across company levels. Since mission and vision statements often include goals and areas of focus for organizations, any change in them trickles down to change the entire organization. (Other principle ways to implement business process reengineering are covered later in the article.)

In today's technological business world, many tools for BPR can be found in software or in a company's online

structures. Carter gives several examples, such as easy and instant electronic documentation of processes, simulation analysis, and "object oriented technology," allowing decisions made in the network to affect all parts of that network. The advent of ERP (enterprise resource planning) systems helped organizations unite many departments into integrated online resources, making BRP much easier.

BASICS OF PROCESS REENGINEERING

The first question in process reengineering is: "Why are we doing this at all?" Answering this question is the beginning of the immediate, dramatic change and the application of supporting technical and behavioral concepts and tools that are necessary to implement process reengineering. To accomplish this, organizations must foster an environment that encourages quantum leaps in improvement by throwing out existing systems and processes and inventing new ones.

The intent of process reengineering is to make organizations significantly more flexible, responsive, efficient, and effective for their customers, employees, and other stakeholders. According to field experts Hammer and James Champy, process reengineering requires the "fundamental rethinking and radical redesign of business processes to achieve dramatic improvements in critical, contemporary measures of performance, such as cost, quality, service, and speed."

If process reengineering is to work, a business's priorities must change in the following ways: (1) from boss to customer focus; (2) from controlled workers to empowered, involved process owners and decision makers; (3) from activity-based work to a results orientation; (4) from scorekeeping to leading and teaching so that people measure their own results; (5) from functional (vertical) to process (horizontal or cross functional) orientation; (6) from serial to concurrent operations; (7) from complex to simple, streamlined processes; (8) from empire building and guarding the status quo to inventing new systems and processes and looking toward the future (i.e., from the caretaker mentality to visionary leadership).

As organizational priorities change, the culture will change as well. As people understand the vision for a better culture with better capabilities and results, they will be able—individually and as members of teams—to contribute positively to make the organizational vision a reality.

REASONS FOR PROCESS REENGINEERING

There are several reasons for organizations to reengineer their business processes: (1) to re-invent the way they do work to satisfy their customers; (2) to be competitive;

(3) to cure systemic process and behavioral problems; (4) to enhance their capability to expand to other industries; (5) to accommodate an era of change; (6) to satisfy their customers, employees, and other stakeholders who want them to be dramatically different and/or to produce different results; (7) to survive and be successful in the long term; and (8) to invent the "rules of the game."

Whatever the reason for reengineering, managers should ask themselves: What do our customers and other stakeholders want/require? How must we change the processes to meet customer and other stakeholder requirements and be more efficient and effective? Once streamlined, should the processes be computerized (i.e., how can information technology be used to improve quality, cycle time, and other critical baselines)? Processes must be streamlined (i.e., re-invented) before they are computerized. Otherwise, the processes may produce results faster, but those results may not be the ones needed.

REQUIREMENTS FOR SUCCESSFUL PROCESS REENGINEERING

Many experts indicate that there are essential elements of process reengineering, including:

- Initiation from the top by someone with a vision for the whole process and relentless deployment of the vision throughout the organization.

- Leadership that drives rapid, dramatic process redesign.

- A new value system which includes a greater emphasis on satisfying customers and other stakeholders.

- A fundamental re-thinking of the way people perform their daily work, with an emphasis on improving results (quality, cycle time, cost, and other baselines).

- An emphasis on the use of cross-functional work teams, which may result in structural redesign as well as process redesign.

- Enhanced information dissemination (including computerization after process redesign) in order to enable process owners to make better decisions.

- Training and involvement of individuals and teams as process owners who have the knowledge and power to re-invent their processes.

- A focus on total redesign of processes with non-voluntary involvement of all internal constituents (management and non-management employees).

- Rewards based on results and a disciplined approach.

POTENTIAL PROBLEMS

In Robert Plant and Stephen Murrell's book *An Executive's Guide to Business Technology* (2007), several negative issues of BRP are examined. The authors note that, because BRP is such an intense, company-wide overhaul, it has the potential to break an organization as much as make it. If the workforce is angry or is against the change, BRP can fail, despite careful planning. Plant and Murrell give the example of the drug company Foxmeyer, which attempted a massive reengineering strategy based on BRP systems but was driven to bankruptcy in 1996. Since BRP can be so greatly affected by employee attitude, Plant and Murrell advise careful expectation management of the reinvention. However, experts state there are many other reasons that process reengineering fails, including:

- Not focusing on critical processes first.

- Trying to gradually "fix" a process instead of dramatically re-inventing it.

- Making process reengineering the priority and ignoring everything else (e.g., strategy development and deployment, re-structuring based on new strategies, etc.).

- Neglecting values and culture needed to support process reengineering and allowing existing culture, attitudes, and behavior to hinder reengineering efforts (e.g., short-term thinking, bias against conflict, consensus decision making, and so forth).

- "Settling" for small successes instead of requiring dramatic results.

- Stopping the process reengineering effort too early, before results can be achieved.

- Placing prior constraints on the definition of the problem and the scope for the reengineering effort.

- Trying to implement reengineering from the bottom up instead of top down.

- Assigning someone who doesn't understand reengineering to lead the effort.

- Skimping on reengineering resources.

- Dissipating energy across too many reengineering projects at once.

- Attempting to reengineer when the CEO is near retirement.

- Failing to distinguish reengineering from, or align it with, other improvement initiatives (e.g., quality improvement, strategic alignment, right-sizing, customer-supplier partnerships, innovation, empowerment, etc.).

- Concentrating primarily on design and neglecting implementation.

- Pulling back when people resist making reengineering changes (not understanding that resistance to change is normal).

RELATED STRATEGIES

Strategic approaches that are process-focused and that are extensions of process reengineering include the following:

- Intensification—improving/re-inventing processes to better serve customers

- Extension—using strong processes to enter new markets

- Augmentation—expanding processes to provide additional services to existing customers

- Conversion—using a process that you perform well and performing that process as a service for other companies

- Innovation—applying processes that you perform well to create and deliver different goods and services

- Diversification—creating new processes to deliver new goods or services

Bjorn Anderson gives some guidelines for businesses seeking BRP in his 2007 book *Business Process Improvement Toolbox*. Businesses that are looking for an increase in profits or a certain percentage gain in certain areas should not attempt BRP. Although process reengineering does increase profits and growth if it is a success, it should not be attempted simply to bolster a company's income. Neither should it be attempted by organizations that are looking to solely streamline business and combine operations. Instead, process reengineering is a valuable concept for organizations that are willing to undergo dramatic change and radical process redesign. It can co-exist with ongoing gradual process improvement efforts because not all processes can be radically redesigned at once.

In process reengineering, as in all improvement initiatives, assessments should be made in terms of cost/benefit analysis, and risk analysis. However, even the assessments should be done with a sense of urgency since process reengineering requires speed as well as radical redesign. Documentation of results will serve as the baseline for future improvements.

The various improvement methodologies (i.e., continuous improvement and process reengineering) should not be used as separate efforts but rather as two approaches within a single improvement initiative. In fact, a single flowchart can be used to make choices regarding both continuous process improvement and process reengineering. Both gradual continuous improvement and process reengineering should be an integral part of process management.

BUSINESS STRUCTURE

One of the first critical decisions to be made when forming a new company is the formal structure that the business will take. The formal structure of the business impacts issues such as liability, ownership, operating strategy, and taxation. Four different business structures are discussed below: partnership, corporation, subchapter S, and limited liability corporation (LLC).

PARTNERSHIPS

A partnership is a business association where two or more individuals (or partners) share equally in profits and losses. As is the case with a sole proprietorship, partners have full legal responsibility for the business (including debts against the business). Persons entering into this type of business need a partnership agreement detailing how much each partner owns of the business, how much capital each person will contribute, and the percentage of profits to which they are entitled; how company decisions will be made; if the company is open to new/additional partners, and how they can join; and in what cases and how the company would be dissolved.

In a general partnership, all partners are liable for actions made on the company's behalf, including decisions made and actions taken by other partners. Profits (and loss) are shared by all partners, as are company assets and authority.

A limited partnership is a similar business arrangement with one significant difference. In a limited partnership, one or more partners are not involved in the management of the business and are not personally liable for the partnership's obligations. The extent to which the limited partner is liable is thus "limited" to his or her capital investment in the partnership.

In a limited partnership agreement, several conditions must be met, the most important of which is that a limited partner or partners have no control or management over the daily operations of the organization. At least two partners, and one or more of the general partners, must manage the business and are liable for firm debts and financial responsibilities. If a limited partner becomes involved in the operation of the partnership, he or she stands to lose protection against liability. In addition, a limited partnership agreement, certificate, or registration has to be filed, usually with the secretary of state, but this varies by state. Such an agreement generally

includes the names of general and limited partners, the nature of the business, and the term of the limited partnership or the date of dissolution. Since limited partnerships are often used to raise capital, the agreement has a set term of duration. Individual states may also have additional limited partnership requirements.

The most frequent use of the limited partnership agreement has been as an investment, removing the limited partner from financial liability but raising capital through his or her investments or contributions. Limited partnerships are common in real estate investments and, more recently, in entertainment business ventures.

Partnerships are not required to file tax returns for the company, but individual partners do have to claim their share of the company's income or loss on personal tax returns. The Internal Revenue Service (IRS) governs limited partnerships for tax purposes. IRS guidelines restrict limited partnership investments to 80 percent of the total partnership interests. (See IRS Revenue Procedure 92-88 for information governing limited partnerships.) Limited partnerships are also taxable under state revenue regulations.

CORPORATIONS

The major difference between a partnership and a corporation is that the corporation exists as a unique and separate entity from its owners, or shareholders. A corporation must be chartered by the state in which it is headquartered. It can be taxed, sued, or entered into contractual agreements, and it is responsible for its own debts. The shareholders own the corporation, and they elect a board of directors to make major decisions and oversee corporate policy. The corporation files its own tax return and pays taxes on its income from operations. Unlike partnerships, which often dissolve when a partner leaves, a corporation can continue despite turnover in shareholders/ownership. For this reason, a corporate structure is more stable and reliable than a partnership.

Incorporating offers several major advantages over partnership. Sale of stock can help raise large amounts of capital significantly faster and shareholders are only responsible for their personal financial investment in the company. Shareholders have only limited liability for debts and judgments made against the company. And the corporation can deduct the cost of benefits paid to employees from corporate tax returns.

Forming a corporation costs more money than forming a partnership, including legal and regulatory fees, which vary depending on the state in which the business is incorporated. Corporations are subject to monitoring by federal and state agencies, and some local agencies. More paperwork related to taxes and regulatory compliance is required. Taxes are higher for corporations, partic-

ularly if it pays dividends, which are taxed twice (once as corporation income, then again as shareholder income).

SUBCHAPTER S

Some small businesses are able to take advantage of the corporate structure and avoid double taxation. These companies must be small, domestic firms with seventy-five shareholders or less and only one class of stock, and all shareholders must meet eligibility requirements. If a company meets these requirements, they can treat company profits as distributions through shareholders' personal tax returns. This way the income is taxed to shareholders instead of the corporation, and income taxes are only paid once. Subchapter S corporations are also known as small business corporations, S-corps, S corporations, or tax-option corporations.

LIMITED LIABILITY CORPORATION

The limited liability corporation (LLC) structure combines the benefits of ownership with the personal protection a corporation offers against debts and judgments. One or more people can form an LLC, and business owner(s) can either choose to file taxes as a sole proprietorship/partnership or as a corporation. The process of forming an LLC is more extensive than a partnership agreement but still involves less regulatory paperwork than incorporation.

Major advantages offered by the LLC structure are:

- The business does not have to incorporate (or pay corporate taxes).
- One person alone can create an LLC.
- Owners can be compensated through company profits.
- Business losses can be reported against personal income.

Still, some may choose to file taxes as a corporate entity, particularly if owners want to keep corporate income within the business to aid its growth. According to the Small Business Administration, an LLC cannot file partnership tax forms if it meets more than two of the following four qualifications that would classify it as a corporation: (1) limited liability to the extent of assets; (2) continuity of life; (3) centralization of management; and (4) free transferability of ownership to interests. If more than two of these apply, the LLC must file corporation tax forms.

An LLC that chooses to be taxed as an S corporation can also do the following, which the traditional S corporation cannot:

- Have more than seventy-five business owners
- Include a nonresident alien as an owner

- Have either a corporation or a partnership as an owner

- Have more than 80 percent ownership in a separate corporate entity

- Have disproportionate ownership—ownership percentages that are different from each respective owner's investment in the business

- Have flow-through business loss deductions in excess of each respective owner's investment in the business

- Have owners/members who are active in the management of the business without losing limited personal liability exposure

Companies can change their business structure. Tax filing—and the subsequent tax payment—prompts many businesses to make decisions about restructuring their business. Owners may opt for a new structure due to changes to tax laws or in the business itself. In order to anticipate what changes in structure might be beneficial, companies should schedule an annual discussion about long-term business plans with an accountant and/or tax advisor.

C

CAFETERIA PLAN— FLEXIBLE BENEFITS

A cafeteria plan, also called a flexible benefit plan, allows employees to choose from a menu of optional benefits the ones that best fit their individual needs. Cafeteria plans earn their nickname from the flexibility they give employees in customizing their benefits from this menu. In a cafeteria plan, benefits required by law (e.g., Social Security, unemployment compensation, workers' compensation) and those mandated by company policies or labor agreements are supplemented by a list of other benefits to which employees can subscribe.

Employees' choices of optional benefits are limited only by the total benefit dollars available and the variety of benefits offered by the employer. Optional benefits that are often part of cafeteria plans include dental insurance, vision care, group-term life insurance, child care, and disability insurance. Many companies offer some form of cafeteria benefit plan to their employees, although smaller companies are less likely than larger companies to offer flexible benefits.

Most cafeteria plans are compliant with Section 125 of the Internal Revenue Code. This means that they meet specific requirements set out by the Internal Revenue Service (IRS). Such plans offer the potential of cost savings both to employers and employees, particularly because amounts spent by either the employer or the employee are spent out of pre-tax earnings. Thus, both employers and employees may save on Federal Insurance Contributions Act payroll taxes. The employee also may save on state and federal income taxes.

TYPES OF CAFETERIA PLANS

Employers offer several variations of cafeteria plans, including core-plus plans and modular plans. Core-plus plans provide a set of mandatory benefits that are usually designed to meet the basic needs of all employees. In addition to legally-required benefits, medical insurance, long-term disability insurance, and retirement benefits are often included in the core. Optional benefits are offered to employees who spend benefit credits to select other benefits that best fit their needs.

Modular plans usually package several different bundles of benefits that offer increasingly extensive arrays of benefits. The basic module might include only the legally-required benefits, basic health insurance, and life insurance. A second module might include everything in the basic module plus additional benefits. A third module might include everything in modules one and two, and additional benefits. Employees would choose the module that best fits their needs and life situation.

Two specific benefits are often part of the cafeteria plan: pre-tax health insurance premium deductions, known as a Premium Only Plan (POP), and flexible spending accounts (FSAs) for dependent care and out-of-pocket unreimbursed medical expenses. Under POP plans, employees may elect to withhold a portion of their pre-tax salary to pay for their premium contribution for most employer-sponsored health and welfare benefit plans. The POP plan is the simplest type of Section 125 plan. It requires little maintenance after it is set up through a company's payroll.

FSAs are reimbursement accounts that employees fund based on those qualified expenses that they expect

to incur during the year. As mentioned previously, the two main types of reimbursement accounts are dependent care and health care reimbursement accounts. While there are no federal limits on how much employees may set aside, there are employer-mandated limits. Employers set an annual maximum on FSAs, which are subject to an annual "use-or-lose" rule. An FSA cannot provide a cumulative benefit to the employee beyond the plan year.

PROBLEMS WITH CAFETERIA PLANS

Perhaps the largest problem with cafeteria plans, as opposed to one-size-fits-all benefit plans, is that cafeteria plans are more complicated to administer. Since employees choose individualized benefit packages, the company must take care to record and maintain each employee's benefit package accurately. The company must maintain adequate communication with employees about changes in the cost of benefits, their coverage, and their use of benefits. Employees must also be offered the opportunity to revisit their benefit choices and make new selections as their needs and life situations change. Additionally, employers must comply with IRS rules and regulations regarding cafeteria plans so that the plans retain their tax-favored status.

Another issue that arises with cafeteria plans is the adverse selection problem. This problem occurs because employees are likely to choose the optional benefits they are most likely to use. If enough employees do this, the cost of the benefit will eventually be driven up, as the premiums received must cover the expenditures of the benefit. For example, suppose a company allows employees to change their cafeteria plan selections once each year. During this "free enrollment" period, an employee who knows (or suspects) that he or she faces extensive dental work in the coming year would be more likely to sign up for dental insurance than the employee who expects only routine dental care. Likewise, an employee who has begun having vision problems would probably be more likely to sign up for vision coverage than an employee with perfect eyesight.

Sometimes employers will place restrictions on certain benefits to try to alleviate the adverse selection problem. Modular plans may reduce the adverse selection problem, as the employer can package benefits in a way that limits employees' opportunity to choose individual benefits by requiring them to choose a broad package of benefits.

In addition to cafeteria plans, companies are adopting benefit programs that offer financial incentives as a reward for employees who adopt healthy lifestyles. A 2007/2008 Watson Wyatt and National Business Group on Health survey found that nearly half of employers surveyed offer financial incentives to encourage workers to improve their health. An additional 26 percent of employers reported that they will offer similar financial incentives before 2010.

Regardless of trends in health care, the increasing diversity of the labor force means that the demand for benefit packages tailored to individual needs and circumstances is likely to remain strong. Thus, the number of companies offering flexible benefit plans and the rate of employee participation in such plans should continue to increase.

CAPACITY PLANNING

Capacity planning has seen an increased emphasis due to the financial benefits of the efficient use of capacity plans within material requirements planning systems and other information systems. Insufficient capacity can cause deteriorating delivery performance, unnecessarily increase work-in-process, and frustrate sales and manufacturing personnel. However, excess capacity can be costly and unnecessary. The inability to properly manage capacity can be a barrier to the achievement of maximum firm performance. In addition, capacity is an important factor in the organization's choice of technology.

Capacity is usually assumed to mean the maximum rate at which a transformation system produces or processes inputs. Sometimes, this rate may actually be "all at once"—as with the capacity of an airplane. A more usable definition of capacity would be the volume of output per elapsed time and the production capability of a facility.

Capacity planning is the process used to determine how much capacity is needed (and when) in order to

manufacture greater product or begin production of a new product. A number of factors can affect capacity—number of workers, ability of workers, number of machines, waste, scrap, defects, errors, productivity, suppliers, government regulations, and preventive maintenance. Capacity planning is relevant in both the long term and the short term. However, there are different issues at stake for each.

LONG-TERM CAPACITY PLANNING

Over the long term, capacity planning relates primarily to strategic issues involving the firm's major production facilities. In addition, long-term capacity issues are interrelated with location decisions. Technology and transferability of the process to other products is also intertwined with long-term capacity planning. Long-term capacity planning may evolve when short-term changes in capacity are insufficient. For example, if the firm's addition of a third shift to its current two-shift plan still does not produce enough output, and subcontracting arrangements cannot be made, one feasible alternative is to add capital equipment and modify the layout of the plant (long-term actions). It may even be desirable to add additional plant space or to construct a new facility (long-term alternatives).

SHORT-TERM CAPACITY PLANNING

In the short term, capacity planning concerns issues of scheduling, labor shifts, and balancing resource capacities. The goal of short-term capacity planning is to handle unexpected shifts in demand in an efficient, economic manner. The time frame for short-term planning is frequently only a few days but may run as long as six months.

Alternatives for making short-term changes in capacity are fairly numerous and can even include the decision to not meet demand at all. The easiest and most commonly used method to increase capacity in the short term is working overtime. This is a flexible and inexpensive alternative. While the firm has to pay one and one half times the normal labor rate, it foregoes the expense of hiring, training, and paying additional benefits. When not used abusively, most workers appreciate the opportunity to earn extra wages. If overtime does not provide enough short-term capacity, other resource-increasing alternatives are available. These include adding shifts, employing casual or part-time workers, the use of floating workers, leasing workers, and facilities subcontracting.

Firms may also increase capacity by improving the use of their resources. The most common alternatives in this category are worker cross-training, and overlapping or staggering shifts. Most manufacturing firms inventory some output ahead of demand so that any need for a capacity change is absorbed by the inventory buffer. From a technical perspective, firms may initiate a process design

intended to increase productivity at work stations. Manufacturers can also shift demand to avoid capacity requirement fluctuation by backlogging, queuing demand, or lengthening the firm's lead times. Service firms accomplish the same results through scheduling appointments and reservations.

A more creative approach is to modify the output. Standardizing the output or offering complimentary services are examples. In services, one might allow customers to do some of the process work themselves (e.g., self-service gas stations and fast-food restaurants). Another alternative—reducing quality—is an undesirable yet viable tactic.

Finally, the firm may attempt to modify demand. Changing the price and promoting the product are common examples. Another alternative is to partition demand by initiating a yield or revenue management system. Utilities also report success in shifting demand by the use of "off-peak" pricing.

CAPACITY-PLANNING TECHNIQUES

There are four procedures for capacity planning; capacity planning using overall factors (CPOF), capacity bills, resource profiles, and capacity requirements planning (CRP). The first three are rough-cut approaches (involving analysis to identify potential bottlenecks) that can be used with or without manufacturing resource planning (MRP) systems. CRP is used in conjunction with MRP systems.

Capacity using overall factors is a simple, manual approach to capacity planning that is based on the master production schedule and production standards that convert required units of finished goods into historical loads on each work center. Bills of capacity is a procedure based on the manufacturing production schedule (MPS). Instead of using historical ratios, however, it utilizes the bills of material and routing sheet (which shows the sequence or work centers required to manufacture the part, as well as the setup and run time). Capacity requirements can then be determined by multiplying the number of units required by the MPS by the time needed to produce each. Resource profiles are the same as bills of capacity, except lead times are included so that workloads fall into the correct periods.

Capacity requirements planning is only applicable in firms using MRP or MRP II. CRP uses the information from one of the previous rough-cut methods, plus MRP outputs on existing inventories and lot sizing. The result is a tabular load report for each work center or a graphical load profile for helping plan-production requirements. This will indicate where capacity is inadequate or idle, allowing for imbalances to be corrected by shifts in personnel or equipment or the use of overtime or added shifts. Finite capacity scheduling is an extension of CRP

that simulates job order stopping and starting to produce a detailed schedule that provides a set of start and finish dates for each operation at each work center.

Technology plays an essential role in capacity planning. Many companies rely on software to provide real-time inventory data, a task especially important in an increasingly globalized economy dependent on outsourcing. Furthermore, the technology sector itself requires extensive capacity planning in order to optimize network traffic. According to a Microsoft capacity-planning white paper, "Network planning can be compared to designing a town's road system. In both tasks, you need to understand who is using which routes, how large batches of traffic are (and can be), where journeys start, where they stop, and how all of these things vary over time."

A failure to understand the critical nature of managing capacity can lead to chaos and serious customer service problems. If there is a mismatch between available and required capacity, adjustments should be made. However, it should be noted that firms cannot have perfectly-balanced material and capacity plans that easily accommodate emergency orders. If flexibility is the firm's competitive priority, excess capacity would be appropriate.

CASE METHOD OF ANALYSIS

The case method of analysis involves studying actual business situations—written as an in-depth presentation of a company, its market, and its strategic decisions—in order to improve a manager's or a student's problem-solving ability. Cases typically investigate a contemporary issue in a real-life context. There are multiple issues to consider, and many "correct" or viable alternatives for solving the case issues are presented. Case studies provide students with a "note of reality" that makes learning more relevant and enjoyable.

Cases are written and published in textbooks by students, faculty, or consultants. Cases may be based on actual company experiences, like a consulting project, or may be developed from articles and events in business periodicals and newspapers. Cases include actual information of a company's decisions and may include interviews, observations, or data from firm and industry records, as well as database records and published historical facts on the company and the industry. Barbazette identified five types of case studies:

1. Identification case studies help learners identify positive and negative characteristics of the situation.

2. Problem-solving case studies use systematic and creative problem-solving techniques.

3. Practice case studies require students to use a new idea or try a new skill.

4. Application case studies are used at the end of a training program to summarize and review.

5. Serial case studies progressively add new elements.

HISTORY OF CASES

The case method was invented by the Harvard Business School in the 1920s, where it still remains the foundation for teaching and research. By studying and examining actual cases, professors believed students could develop better insight as to how organizations reach conclusions. This method of study and analysis is seen as an effective way to train young business leaders to consider facts and present them more efficiently.

POPULARITY OF CASES TODAY

Today, cases remain a popular method of study in educational institutions across the country, particularly in Master of Business Administration (MBA) programs. While technology, computer simulations, and other learning methods continue to grow, cases fill a much-needed function in the educational process of students, future managers, and leaders. Cases are used in a wide variety of disciplines and areas of study. They are also popular for executive training and are used in weekend-format continuing education and professional development programs.

In their study of the skills of technologists, Birchall and Smith found that technologists are often seen as not having sufficient input into the strategic decision-making

processes of organizations. Thus, many turn to MBA programs to develop their knowledge, understanding, and personal competencies. The case method has traditionally been used to aid in this educational process. They also stress the use of multimedia tools and groupware to create enhanced learning opportunities based on a dynamic case analysis.

Many groups and organizations also publish cases for educational use. Sources for cases for business schools include:

- The Aspen Institute Business and Society Program

- The Batten Institute, Darden Graduate School of Business, University of Virginia

- Harvard Business School

- Richard Ivey School of Business, University of Western Ontario

- South-Western Publishing Company's CaseNet

- Stanford Graduate School of Business

The American Association for Business Communication, for example, included the best cases for teaching communications in a special issue of *Business Communication Quarterly*. Rogers and Rymer report that their reviewer panel of experienced instructors agreed that the best cases include the following attributes:

- Focus on the discipline

- Require decision making

- Furnish a business context

- Present an engaging story or scenario

- Provide sufficiently-realistic detail for analysis and response

- Function readily in a classroom setting

- Apply to a wide range of teaching philosophies and educational settings

- Relate to contemporary issues and problems

In recent years, the use of case studies in job interviews has become increasingly popular, particularly in the consulting and investment banking industries. Typically, an interviewer will present a business situation similar to those handled by the company. The interviewee is then asked to work through the case and eventually arrive at a feasible conclusion in a short period of time. According to the McKinsey & Company Web site, "Since no particular background or set of qualifications necessarily prepares [an individual to be a successful consultant], we've come to rely upon the case study as an integral part of our interview process...It gives us an opportunity to gauge

[the interviewee's] sense of prioritization and judgment within a business context."

TEACHING WITH CASES

Cases rely almost exclusively upon discussion to elicit diverse ideas, experiences, and views about case material. Cases allow students to explore actual decisions made by companies. The case presents an account of what happened to a business or industry over a period of time, for example. It includes the events with which managers had to deal and charts various responses to these decisions. According to Hill and Jones, cases provide students with the experience of organizational problems they have not yet had the opportunity to experience first-hand. In a relatively short period of time, students have the chance to appreciate and analyze problems faced by many different companies and to understand how managers attempted to resolve them. Cases also illustrate underlying business theories.

To prepare a case analysis, students typically read the case several times before a classroom discussion. They first read for a general idea about the problem, the players in the case, the level of the decision, and the type of company or industry presented. On second and subsequent readings, students look for deeper problems and issues and try to differentiate symptoms from real case problems.

Some schools encourage students to research the company by locating articles on the company at the time the case situation occurred. Another research technique is to have students conduct a financial analysis of the company that might include ratio analysis or industry/competitor research. Many schools encourage students to discuss assigned cases in small groups or study teams before class. These teams may develop potential alternatives to solve the problems and ensure each member has considered the relevant facts in the case.

Class discussion occurs in either one large group or several smaller groups. In these groups, participants decide on the solution(s) and the proper course of implementation. They must also consider the time frame for implementation as well as evaluation and success measures. Class members or participants critique the various viable alternatives that are presented. The class is then presented with what the company under study actually did to solve the problem. Some cases are used as quizzes or exams.

For the most part, teaching with cases has changed relatively little over the years. An exception to this is the "real-time case method" developed by Theroux in 2001. In this method, a semester-long case is delivered in weekly installments and focuses on one company and the current events it faces. This method differs from the traditional case-study method by its extended coverage and real-time

interactivity. In some iterations of this method, students participate in online forums in which they can ask the managers questions about the company.

STUDENTS' PERCEPTIONS OF CASES

Although case method teaching has been used extensively in virtually all business schools for years, little research has been conducted to investigate the effectiveness and usefulness of the method. Among the few studies available is Weil's, which measures students' perceptions. Weil's study confirmed the usefulness of the case method.

Many students favor the case method because there are no "right" or "wrong" answers to the cases. Unlike solving a math or finance problem, there may be multiple ways to reach a successful solution for the case. Diversity of opinion and diversity of group make-up often bring unique solutions to cases. Students learn to respond quickly, formulate answers, speak up, and participate in class discussion. They learn to separate background information from the real problem. They learn to succinctly state problems, to recommend potential alternative solutions, and to explore the pros and cons of each solution. They learn to find hidden information in charts, graphs, tables, and financial data often included in cases.

Some students are discouraged by cases because they do not yield only one clear answer. Students are forced to develop skills of critical thinking, and these skills, while important to today's managers, take time to perfect. Students may also fear presenting their ideas to a large group. They may fear public speaking or presentation in general or they may fear their particular thoughts will be ridiculed by others. Some with limited work or life experience may not feel capable of critiquing a top-level manager's past decisions. However, these unique and fresh ideas often present interesting alternatives.

CASH FLOW ANALYSIS AND STATEMENT

Cash flow analysis is a method of analyzing the financing, investing, and operating activities of a company. The primary goal of cash flow analysis is to identify, in a timely manner, cash flow problems as well as cash flow opportunities. The primary document used in cash flow analysis is the cash flow statement. Since 1988, the Securities and Exchange Commission (SEC) has required every company that files reports to include a cash flow statement with its quarterly and annual reports. The cash flow statement is useful to managers, lenders, and investors because it translates the earnings reported on the income statement—which are subject to reporting regulations and accounting decisions—into a simple summary of how much cash the company has generated during the period in question. "Cash flow measures real money flowing into, or out of, a company's bank account," Harry Domash notes on MSN Money. "Unlike reported earnings, there is little a company can do to overstate its bank balance."

THE CASH FLOW STATEMENT

A typical cash flow statement is divided into three parts: cash from operations (from daily business activities like collecting payments from customers or making payments

to suppliers and employees); cash from investment activities (the purchase or sale of assets); and cash from financing activities (the issuing of stock or borrowing of funds). The final total shows the net increase or decrease in cash for the period.

Cash flow statements facilitate decision making by providing a basis for judgments concerning the profitability, financial condition, and financial management of a company. While historical cash flow statements facilitate the systematic evaluation of past cash flows, projected (or pro forma) cash flow statements provide insights regarding future cash flows. Projected cash flow statements are typically developed using historical cash flow data modified for anticipated changes in price, volume, interest rates, and so on.

To enhance evaluation, a properly-prepared cash flow statement distinguishes between recurring and nonrecurring cash flows. For example, collection of cash from customers is a recurring activity in the normal course of operations, whereas collections of cash proceeds from secured bank loans (or issuances of stock, or transfers of personal assets to the company) is typically not considered a recurring activity. Similarly, cash payments to vendors is a recurring activity, whereas repayments of secured bank loans (or the purchase of certain investments or capital assets) is typically not considered a recurring activity in the normal course of operations.

In contrast to nonrecurring cash inflows or outflows, most recurring cash inflows or outflows occur (often frequently) within each cash cycle (i.e., within the average time horizon of the cash cycle). The cash cycle (also known as the operating cycle or the earnings cycle) is the series of transactions or economic events in a given company whereby:

1. Cash is converted into goods and services.
2. Goods and services are sold to customers.
3. Cash is collected from customers.

To a large degree, the volatility of the individual cash inflows and outflows within the cash cycle will dictate the working-capital requirements of a company. Working capital generally refers to the average level of unrestricted cash required by a company to ensure that all stakeholders are paid on a timely basis. In most cases, working capital can be monitored through the use of a cash budget.

THE CASH BUDGET

In contrast to cash flow statements, cash budgets provide much more timely information regarding cash inflows and outflows. For example, whereas cash flow statements are often prepared on a monthly, quarterly, or annual basis, cash budgets are often prepared on a daily, weekly,

or monthly basis. Thus, cash budgets may be said to be prepared on a continuous rolling basis (e.g., are updated every month for the next twelve months). Additionally, cash budgets provide much more detailed information than cash flow statements. For example, cash budgets will typically distinguish between cash collections from credit customers and cash collections from cash customers.

A thorough understanding of company operations is necessary to reasonably assure that the nature and timing of cash inflows and outflows is properly reflected in the cash budget. Such an understanding becomes increasingly important as the precision of the cash budget increases. For example, a 360-day rolling budget requires a greater knowledge of a company than a two-month rolling budget.

While cash budgets are primarily concerned with operational issues, there may be strategic issues that need to be considered before preparing the cash budget. For example, predetermined cash amounts may be earmarked for the acquisition of certain investments or capital assets, or for the liquidation of certain indebtedness. Further, there may be policy issues that need to be considered prior to preparing a cash budget. For example, should excess cash, if any, be invested in certificates of deposit or in some form of short-term marketable securities (e.g., commercial paper or U.S. Treasury bills)?

Generally speaking, the cash budget is grounded in the overall projected cash requirements of a company for a given period. In turn, the overall projected cash requirements are grounded in the overall projected free cash flow. Free cash flow is defined as net cash flow from operations less the following three items:

1. Cash used by essential investing activities (e.g., replacements of critical capital assets)
2. Scheduled repayments of debt
3. Normal dividend payments

If the calculated amount of free cash flow is positive, this amount represents the cash available to invest in new lines of business, retire additional debt, and/or increase dividends. If the calculated amount of free cash flow is negative, this amount represents the amount of cash that must be borrowed (and/or obtained through sales of nonessential assets, etc.) in order to support the strategic goals of the company. To a large degree, the free cash flow paradigm parallels the cash flow statement.

Using the overall projected cash flow requirements of a company (in conjunction with the free cash flow paradigm), detailed budgets are developed for the selected time interval within the overall time horizon of the budget (i.e., the annual budget could be developed on a daily, weekly, or monthly basis). Typically, the complexity of the company's operations will dictate the level of detail required for the

cash budget. Similarly, the complexity of the corporate operations will drive the number of assumptions and estimation algorithms required to properly prepare a budget (e.g., credit customers are assumed to remit cash as follows: 50 percent in the month of sale; 30 percent in the month after sale; and so on). Several basic concepts germane to all cash budgets are:

1. Current period beginning cash balances plus current period cash inflows less current period cash outflows equals current period ending cash balances.

2. The current period ending cash balance equals the new (or next) period's beginning cash balance.

3. The current period ending cash balance signals either a cash flow opportunity (e.g., possible investment of idle cash) or a cash flow problem (e.g., the need to borrow cash or adjust one or more of the cash budget items giving rise to the borrow signal).

RATIO ANALYSIS

In addition to cash flow statements and cash budgets, ratio analysis can also be employed as an effective cash flow analysis technique. Ratios often provide insights regarding the relationship of two numbers (e.g., net cash provided from operations versus capital expenditures) that would not be readily apparent from the mere inspection of the individual numerator or denominator. Additionally, ratios facilitate comparisons with similar ratios of prior years of the same company (i.e., intracompany comparisons) as well as comparisons of other companies (i.e., intercompany or industry comparisons). While ratio analysis may be used in conjunction with the cash flow statement and/or the cash budget, ratio analysis is often used as a stand-alone, attention-directing, or monitoring technique.

TRANSACTION VALUATION

The cash flow statement is an essential part of cash flow valuation techniques. In recent years, cash flow has become an increasingly common method of valuating both public and private companies, especially for industries where large up-front capital expenditures can result in negative earnings. For example, *The Motley Fool* reports that "cable TV companies . . . have reported negative earnings for years due to the huge capital expense of building their cable networks, even though their cash flow has actually grown." Investors use cash flow analysis to unmask this type of growth, typically using a definition of cash flow called amortization.

ADDITIONAL BENEFITS

In his book, *Buy Low, Sell High, Collect Early, and Pay Late: The Manager's Guide to Financial Survival,* Dick Levin suggests the following benefits that stem from cash

forecasting (i.e., preparing a projected cash flow statement or cash budget):

1. Knowing what the cash position of the company is and what it is likely to be avoids embarrassment. For example, it helps avoid having to lie that the check is in the mail.

2. A firm that understands its cash position can borrow exactly what it needs and no more, thereby minimizing interest or, if applicable, the firm can invest its idle cash.

3. Walking into the bank with a cash flow analysis impresses loan officers.

4. Cash flow analyses deter surprises by enabling proactive cash flow strategies.

5. Cash flow analysis ensures that a company does not have to bounce a check before it realizes that it needs to borrow money to cover expenses. In contrast, if the cash flow analysis indicates that a loan will be needed several months from now, the firm can turn down the first two offers of terms and have time for further negotiations.

LOAN APPLICATIONS

Potential borrowers should be prepared to answer the following questions when applying for loans:

1. How much cash is needed?

2. How will this cash help the business (i.e., how does the loan help the business accomplish its business objectives as documented in the business plan)?

3. How will the company pay back the cash?

4. How will the company pay back the cash if the company goes bankrupt?

5. How much do the major stakeholders have invested in the company?

Admittedly, it is in the best interest of the potential borrower to address these questions prior to requesting a loan. Accordingly, in addition to having a well-prepared cash flow analysis, the potential borrower should prepare a separate document addressing the following information:

1. Details of the assumptions underpinning the specific amount needed should be prepared with cross-references to relevant information included in the cash flow analysis.

2. The logic underlying the business need for the amount of cash requested should be clearly stated and cross-referenced to the relevant objectives stated in the business plan or some other strategic planning document.

3. The company should clearly state what potential assets would be available to satisfy the claims of the lender in case of default (i.e., the company should indicate the assets available for the collateralization of the loan).

4. Details of the equity interests of major stakeholders should be stated.

In some cases, the lender may also request personal guarantees of loan repayment. If this is necessary, the document will need to include relevant information regarding the personal assets of the major stakeholders available to satisfy the claims of the lender in case of default.

INADEQUATE CAPITALIZATION

Many businesses fail due to inadequate capitalization. Inadequate capitalization basically implies that there were not enough cash and/or credit arrangements secured prior to initiating operations to ensure that the company could pay its debts during the early stages of operations (when cash inflows are nominal, if any, and cash outflows are very high). Admittedly, it is extremely difficult to perform a cash flow analysis when the company does not have a cash flow history. Accordingly, alternative sources of information should be obtained from trade journals, government agencies, and potential lenders. Additional information can be solicited from potential customers, vendors, and competitors, allowing the firm to learn from others' mistakes and successes.

UNCONSTRAINED GROWTH

While inadequate capitalization represents a front-end problem, unconstrained growth represents a potential back-end problem. Often, unconstrained growth provokes business failure because the company is growing faster than its cash flow. While many cash flow problems are operational in nature, unconstrained growth is a symptom of a much larger strategic problem. Accordingly, even to the extent that cash flow analyses are performed on a timely basis, such analyses will never overcome a flawed strategy underpinning the unconstrained growth.

BANKRUPTCY

A company is said to be bankrupt when it experiences financial distress to the extent that the protection of the bankruptcy laws is employed for the orderly disposition of assets and settlement of creditors' claims. Significantly, not all bankruptcies are fatal. In some circumstances, creditors may allow the bankrupt company to reorganize its financial affairs, allowing the company to continue or reopen. Such a reorganization might include relieving the company from further liability on the unsatisfied portion of the company's obligations. Admittedly, such reorganizations are performed in vain if the reasons underlying the financial distress have not been properly resolved. Unfortunately, properly-prepared and timely cash flow analyses cannot compensate for poor management, poor products, or weak internal controls.

CELLULAR MANUFACTURING

Cellular manufacturing is a manufacturing process that produces families of parts within a single line or cell of machines operated by machinists who work only within the line or cell. A cell is a small scale, clearly-defined production unit within a larger factory. This unit has complete responsibility for producing a family of like parts or a product. All necessary machines and manpower are contained within this cell, thus giving it a degree of operational autonomy. Each worker is expected to have mastered a full range of operating skills required by his or her cell. Therefore, systematic job rotation and training are necessary conditions for effective cell development.

Complete worker training is needed to ensure that flexible worker assignments can be fulfilled.

Cellular manufacturing, which is actually an application of group technology, has been described as a stepping stone to achieving world class manufacturing status. The objective of cellular manufacturing is to design cells in such a way that some measure of performance is optimized. This measure of performance could be productivity, cycle time, or some other logistics measure. Measures seen in practice include pieces per man hour, unit cost, on-time delivery, lead time, defect rates, and percentage of parts made cell-complete.

Since many manufacturing tasks are in fact not perfectly defined and not necessarily easy to represent graphically or with data, the use of "fuzzy set theory" is common when designing cellular manufacturing systems. Huang, Heutte, and Loog's 2007 book, *Advanced Intelligent Computing Theories and Applications*, suggests practicing "fuzzy algorithms" when designing a factory for cells or other types of lean manufacturing. The parameters of a particular part of the factory, or a particular task the workers carry out, may not be clear. There may be overlap, or constant human decision involved. This makes creating mathematic models of possible cells difficult, so fuzzy clustering and fuzzy mathematical programming are used in the equations. These tools enable the creators of cell structures to allow some uncertainty in what the machine and workers do, when assigning productions to various cells. They provide, essentially, room for error in the equations pertaining to cellular manufacturing.

The basic cell-creating process involves placing a cluster of carefully selected sets of functionally dissimilar machines in close proximity to each other. The result is small, stand-alone manufacturing units dedicated to the production of a set or family of parts—or essentially, a miniature version of a plant layout.

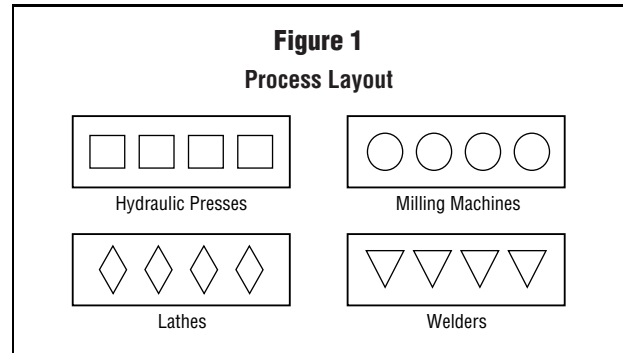
While the machinery may be functionally dissimilar, the family of parts produced contains similar processing requirements or has geometric similarities. Thus, all parts basically follow the same routing with some minor variations (e.g., skipping an operation). The cells may have no conveyorized movement of parts between machines, or they may have a flow line connected by a conveyor that can provide automatic transfer.

Cellular manufacturing is a hybrid system that links the advantages of a job shop with the product layout of the continuous flow line. The cell design provides for quick and efficient flow, as well as the high productivity associated with assembly lines. However, it also provides the flexibility of the job shop, allowing both similar and diverse products to be added to the line without slowing the process. Figures 1 and 2 compare a cellular layout to that of the typical job shop (process layout).

Figure 1
Process Layout

Hydraulic Presses Milling Machines
Lathes Welders

Figure 2
Cellular Layout

Cell #1 Cell #2
Cell #3 Cell #4


BENEFITS OF CELLULAR MANUFACTURING

Many firms utilizing cellular manufacturing have reported near immediate improvements in performance, with only relatively minor adverse effects. Cited improvements which seem to have occurred fairly quickly include reductions in work-in-process, finished goods, lead time, late orders, scrap, direct labor, and workspace.

In particular, production and quality control is enhanced. By breaking the factory into small, homogeneous and cohesive productive units, production and quality control is made easier. Cells that are not performing according to volume and quality targets can be easily isolated, since the parts/products affected can be traced to a single cell. Also, because the productive units are small, the search for the root of problems is made easier.

Quality parameters and control procedures can be dovetailed to the particular requirements of the parts or workpieces specific to a certain cell. By focusing quality control activity on a particular production unit or part type, the cell can quickly master the necessary quality requirements. Control is always enhanced when productive units are kept at a minimum operating scale, which is what cellular manufacturing provides.

When production is structured using cellular manufacturing logic, flow systematization is possible. Grouping of parts or products into sets or families reveals which ones are more or less amenable to continuous, coupled flow. Parts that are standardized and common to many products will have very low changeover times, and thus, are quickly convertible to continuous, line-flow production. Products that are low-volume, high-variety and require longer set-up times can be managed so that they evolve toward a line flow.

Cells can be designed to exploit the characteristics peculiar to each part family so as to optimize the flow for each cell and for groups of cells as a whole. Flow systematization can be done one cell at a time so as to avoid large disruptions in operations. Then the cells that were easy to systemize can provide experience that can be exploited when the more difficult systematization projects occur later. Cells that have been changed to a line flow will invariably show superior performance in the areas of quality, throughput time, and cost, which can lead to eventual plant-wide benefit.

LIMITATIONS

While its benefits have been well documented, it should also be noted that some have argued that implementing cellular manufacturing could lead to a decrease in manufacturing flexibility. It is felt that conversion to cells may cause some loss in routing flexibility, which could then impact the viability of cell use. Obtaining balance among cells is also more difficult than for flow or job shops. Flow shops have relatively fixed capacity, and job shops can draw from a pool of skilled labor, so balance isn't that much of a problem. By contrast, with cells, if demand diminishes greatly, it may be necessary to break up that cell and redistribute the equipment or reform the families.

Also, some researchers have warned that the benefits of cellular manufacturing could deteriorate over time due to ongoing changes in the production environment. Finally, it must be noted that conversion to cellular manufacturing can involve the costly realignment of equipment. The burden lies with the manager to determine if the costs of switching from a process layout to a cellular one outweigh the costs of the inefficiencies and inflexibility of conventional plant layouts.

THE IMPLEMENTATION PROCESS

A wide variety of methods for the implementation of cellular manufacturing have been proposed. These range from complex computer and mathematical models to straightforward applications, such as production flow analysis. A pattern for implementation is now presented.

The first step in implementing cellular manufacturing is to break down the various items produced by the company into a number of part sets or families. The grouping process (group technology) involves identifying items with similarities in design characteristics or manufacturing characteristics, and grouping them into part families. Design characteristics include size, shape, and function; manufacturing characteristics or process characteristics are based on the type and sequence of operations required. In many cases, though not always, the two kinds of characteristics are correlated. Therefore design families may be distinctly different from processing families.

Once identified, similar items can be classified into families. Then a system is developed that facilitates retrieval from a design and manufacturing database. For example, the system can be used to determine if an identical or similar part exists before a completely new part is designed. If a similar part is found, it may be that a simple modification would produce satisfactory results without the expense of new part design. Similarly, planning the manufacturing of a new part after matching it with an existing part family can eliminate new and costly processing requirements.

This grouping of part or product families requires a systematic analysis that often proves to be a major undertaking. Usually there is a considerable amount of data to analyze, and this in turn can be quite time-consuming and costly. Three primary methods exist for accomplishing the grouping process: visual inspection, examination of design and production data, and production flow analysis. Visual inspection is the least accurate of the three but nonetheless the simplest and the least costly. The most commonly used method of analysis is the examination of design and production data. This method is more accurate but is also more time-consuming. Production flow analysis examines operation sequences and machine routing to uncover similarities (therefore, it has a manufacturing perspective rather than a design perspective). However, unless the operation sequencing and routings are verified, this method could be far from optimal.

The resulting number of families determines the number of cells required, as well as what machines are required within each cell. The cell usually includes all the processing operations needed to complete a part or subassembly. However, it is possible for a product to go from raw materials to packaging and be ready for shipment by the time it reaches the end of the cell.

The families will also help determine where within the cell each machine will be located for the most efficient flow, and how many employees are needed within each cell. After the product families are determined, the machines needed for the production process of a specific family are organized into cells according to processing requirements (e.g., the order of processing). Frequently, machines are grouped in an efficient U-shaped configuration. Since each

machine operates on its own for much of the cycle, few workers may be needed, and even then only for a limited number of steps.

The optimal layout is one that minimizes the distance between cells, or the distance to the next production point. The resulting reduction in time and handling ultimately provides a reduction in processing costs. Some firms utilize "linked-cell manufacturing," which is the concept of arranging the manufacturing cells near the assembly cells. Again, this decreases travel distances while reducing materials handling. Hopefully, the floor layout will also provide for the easy flow of a product to shipping, if shipping is located close to the cells in a streamlined flow.

Some plants in advanced stages of cellular manufacturing utilize what is known as a "mini-plant." The cell not only does the manufacturing, but also has its own support services, including its own industrial engineer, quality manager, accountant, and marketing representative and/or salesperson. Only research and development and human resource management are not dedicated to the mini-plant.

An entire facility can be broken down into a number of mini-plants, each of which operates as an independent profit center.

KAIZEN EVENTS

Michel Baudin's book, *Working with Machines* (2007), discusses several different approaches to implementing cellular manufacturing; one of the most common is the *kaizen* event. The goal of a *kaizen* event is to analyze the organization's production capabilities, find a usable cell model that can be applied to the factory, then buy the necessary equipment and convert the production process to cellular manufacturing, all within a very short amount of time (the goal is often one week). While *kaizen* refers to the Japanese notion of constant improvement and has many business applications, *kaizen* events are short bursts of intense, permanent change. These are popular in America when adopting such processes as cellular conversion.

In a *kaizen* event, several different factors must be present. On a purely practical level, it must be possible to move the old equipment, ship the new machinery, and then install it, all within several days. The team designated to carry out the *kaizen* event must be skilled enough to handle such high-speed decisions and action, hopefully having previous experience in swift conversions. Baudin also suggests that the manager in charge of the *kaizen* project must be motivated to succeed in a very short time. If the manager has a deadline of six months, he will not aim for finishing in a week. An energetic, motivated

supervisor and a very strict timetable are both necessary to pull off a successful *kaizen* switchover.

There are, of course, dangers in completely converting to cellular manufacturing within one week. Analysis is often rushed and can be open to errors. Mistakes can be made in ordering and installing machinery. Workers may not have enough time to be properly trained in the new system or the new layout of the factory. An organization should only attempt a *kaizen* event if it is confident in its skilled team.

COMMON CELLULAR MANUFACTURING TECHNIQUES

Certain techniques are used in cellular manufacturing to ease the process, or to make transitions more simple. These are integrated into the new layout designs to help production. The EPA gives several examples for 2008:

SMED, or single-minute exchange of die, is used by organizations that have only a limited number of machines but several different products to create. To enable cellular manufacturing, organizations become practiced at switching out machine parts to produce different products on demand. The goal is to reach the ability to switch the machines to different procedures in under a minute, hence the "single-minute" part of SMED.

The process of *Autonomation* is used by organizations that have production lines that can be switched to automatic assembly. Computers and robotic systems are set up to take control of certain parts of the cells, and they are often capable of following very detailed instructions. Once automated, systems can be programmed to double check themselves, detect recurring flaws, cease production when necessary, and run through halting routines if the machinery needs to be reset. Employees are free to focus on other aspects of production while also being available to fix any occurring assembly problems.

Organizations moving to cellular manufacturing often install *right-sized equipment*, or equipment that meets the required models for the tight cells of production. Usually, this means that large machinery will be replaced with smaller machinery that performs the same task in order to save room and to allow the production lines room to set up the cells. Right-sized equipment is often movable and can be switched around at convenience.

THE IMPACT OF CELLULAR MANUFACTURING ON WORKERS

Nancy Hyer and Urban Wemmerlov noted in *Mechanical Engineering* that while technology and processes represent the "hard side" of cells, people represent the "soft side." They state that the soft side factors are far more difficult to change than are the hard side factors. Most implementing

firms spend most of their time struggling with soft issues. Cellular manufacturing calls for radical changes in the way industrial work is designed, structured, planned, controlled, and supervised. It makes worker self-management a reality, so management must be convinced that the workers can master all the required aspects of the work.

The decision to implement cellular manufacturing requires a deep commitment to excellence and a desire to permanently change the way factories are viewed and managed. Cellular manufacturing affects workers in a number of ways. Among the factors now discussed are issues of self-management, motivation, employee input, supervision, and group cohesiveness.

Examples of successful cellular manufacturing are common, especially in technology and parts production. Viking Plastics, in a 2001 drive to expand their cellular manufacturing capabilities, switched their injection molding press assembly to an all-electric model which allowed employees to focus on quality control in other areas. Other companies such as DMP (Defiance Metal Products) work with cellular manufacturing when making products of similar natures. DMP divided their process in cells, such as the Punch and Brake Cell and the Weld Assembly Cell.

Self-Management. Cell workers are encouraged to think creatively about production problems and are expected to arrive at pragmatic solutions to them. While they are free to seek advice from plant management and staff, the identified problems and subsequent analysis, and usually the solutions, are entirely their own. Workers have the authority and are encouraged to implement and follow up on action plans to improve their work. Some managers ask cells to set improvement targets for themselves and measure their performance in comparison to these targets. In addition, workers are given the freedom to plan, coordinate, and control their work within their cell as long as they meet company standards of quality, volume, time, and cost.

In the Productivity Development Team's 1999 book *Cellular Manufacturing: One-piece Flow for Workteams*, the aspect of worker independence is referred to as "autonomous maintenance." Autonomous maintenance involves teaching different tasks to the same employees, thereby making the factory team more versatile. Operator groups and maintenance groups can be combined into one unit of skilled employees that have the ability to deal with a multitude of problems on the factory floor. Operators are taught to clean equipment, notice signs of wear and damage, and deal with breakdowns themselves, making the cell even stronger as a whole.

Motivation. Behavioral psychology proposes that challenging work assignments keep employees motivated, sat-

isfied, and productive. Flexible work assignments within the cells ensure that employees are constantly learning new tasks and constantly being challenged. Job rotation within the cell introduces variety in work patterns, thereby breaking the monotony (which has been known to cause absenteeism and problems in quality and productivity). Industrial work is productively accomplished in a group work setting. Cellular manufacturing can energize the group, attacking the lethargy found in many industrial situations.

Employee Input. With the cell work group energized and motivated, the employees are more likely to actively and continually bring their mental capabilities to bear on job-related problems. Cell workers are the closest ones to the production process, so practical ideas are likely to instigate other ideas, which could then give rise to a continuous, almost self-sustaining chain reaction of improvement. As the workers see their own creative output being implemented, they begin to develop self-esteem and a stronger desire to succeed. They even begin to challenge each other to improve on their prior accomplishments.

The drive toward excellence is fueled by the human need to achieve until the desire to excel and continuously improve becomes part of the factory culture. Then as workers learn by doing more, they become more proficient at generating ideas, which perpetuates the cycle of improvement. Cellular manufacturing can be the structural catalyst that starts, contains, and sustains the improvement process.

Supervision. The intense use of manufacturing cells tends to flatten the factory management structure and reduce overhead costs. When work group autonomy, worker versatility, and small group improvement activities converge, the need for supervision is drastically reduced, if not eliminated altogether. Cell manufacturing perpetuates the idea that the work group should supervise itself. A workforce that is motivated, trained, and assigned specific clear responsibility for a product or part, coupled with simplified production planning and control, does not need to be minutely controlled or supervised in order to do a good job.

Group Cohesiveness. The creation of small-scale productions dedicated to production of a few similar parts increases work group cohesiveness. Since each cell has few employees, typically less than fourteen, extensive interpersonal contact is unavoidable. The workers are now part of a single, identifiable unit with operating autonomy and responsibility for a specific product, linked by the common purpose of continually improving the productive unit for which they are responsible. The cell structure keeps problems at a level where they are manageable and gives employees the opportunity to exercise

their creative potential in a pragmatic way. When problems that call for technical expertise beyond that of the workers arise, managers and production staff can be called on to provide assistance. Cell manufacturing builds a cohesive subculture within the wider social environment of the plant.

The use of flexible work assignments contributes even more to the group's cohesiveness and loyalty. Employees who regularly perform the work also done by coworkers are more likely to demonstrate empathy and support when dealing with each other on the job. If each worker has experienced each job firsthand, they are more able to offer encouragement and advice on how the work can be improved and each worker is more receptive to the input of his or her coworkers. Each worker can view and understand completely the task, responsibilities, and mission that top management has dedicated to the cell. The cross-fertilization process that emerges can generate some truly creative ideas for process improvement. As the expression goes, "as iron sharpens iron, so shall one man sharpen another."

Finally, work-group cohesiveness, reinforced by the cell structure, facilitates total people management. Due to its small scale and mission focus, the cell can be easily mobilized. Top management is too far removed, spatially and socially, from the workers to be able to interact with them extensively enough to significantly control the socialization process. Management can shape corporate values and create a nurturing social environment, but it cannot instill these values into the minds of the lower-level employees. Hence, corporate values are better communicated and instilled into daily work habits by small group processes.

The cell is better able to exercise social control over deviant workers, since it can directly and immediately manipulate social rewards and punishment. Any worker who fails to conform may find his deviant behavior quickly detected and reacted to by the withdrawal of the social support of the cell. Deviant behavior that is hidden from management for long periods of time is very visible to the small group and can be dealt with quickly.

Conversely, high-performing group members are also quickly visible but are rewarded with esteem and respect from the other cell workers. Consequently, management can work through the cell to instill the corporation's values, attitudes, and philosophies. Once these are internalized by the group's key members, the group itself will take over the socialization process of indoctrinating these values into the mindset of each worker.

FOCUSED CELLULAR MANUFACTURING

In a 2003 article in the *International Journal of Operations and Production Management*, Fahad Al-Mubarak and

Basheer M. Khumawala discuss a similar alternative to cellular manufacturing, focused cellular manufacturing (FCM). They define focused cellular manufacturing as a layout scheme that groups components by end-items and forms the cell of the machine for fabrication and assembly of the end-items. It differs from cellular manufacturing in that it does not attempt to take advantage of process similarities so as to reduce setup times.

The major advantage of FCM is the reduction of completion times for assembled end-items and work-in-process inventories while maintaining some degree of flexibility. In addition, it should be easy to install in a firm producing a few end-items in large volume or many end-items produced in small volume. Apparently, installing a single, focused cell for a few end-items is more practical than installation of many cells as required for a cellular layout.

The flow systematization and physical process integration of cellular manufacturing reinforce each other in potent ways. The underlying mechanisms can be collectively used to push manufacturing to higher performance levels. The result is an effectively designed cellular manufacturing structure, a production operation that integrates many concepts of superior manufacturing performance into a single small-scale production unit whose place in the large manufacturing system is clearly visible.

PROBLEMS AND DIFFERENTIATION

Since cellular manufacturing can be easily disrupted by machine breakdown (or the time it takes to repair broken machinery), it is always wise to have replacements on hand and the capability to substitute the broken parts quickly. This extra machinery and the space it occupies will be a significant cost, and it should therefore always be counted in the cost when considering a switch to lean manufacturing. When production includes duplicate machinery, multi-period production planning, or dynamic system reconfiguration, careful planning is required, since cellular manufacturing can be difficult to change once put into place. Production that requires seasonal shifts—or that may be subject to technological changes—also presents difficulties when switching to cellular manufacturing.

One final note is to distinguish cellular manufacturing from flexible manufacturing. A flexible manufacturing system is a more fully automated version of cellular manufacturing. A flexible manufacturing system utilizes a computer to control the start of work at each machine and to control the transfer of parts from machine to machine. While quite expensive, flexible manufacturing systems enable manufacturers to achieve some of the benefits of product layouts because the system can operate with little or no human intervention.

CHANGE—TRENDS IN ORGANIZATIONS

SEE *Trends in Organizational Change*

CHAOS THEORY

Chaos theory is a scientific principle describing the unpredictability of systems. Heavily explored and recognized during the mid-to-late 1980s, its premise is that systems sometimes reside in chaos, generating energy but without any predictability or direction. These complex systems may be weather patterns, ecosystems, water flows, anatomical functions, or organizations. While these systems' chaotic behavior may appear random at first, chaotic systems can be defined by a mathematical formula, and

they are not without order or finite boundaries. This theory, in relation to organizational behavior, was somewhat discounted during the 1990s, giving way to the very similar complexity theory. Complexity theory differs primarily in that it tries to find simple ways to explain and control multifaceted business systems, while chaos theory is more concerned with predicting changes and understanding the random parts of systems.

Organizations respond to the ideas of chaos theory in a number of different ways, from eagerness to skepticism. As Lyndon Pugh's 2007 *Change Management in Information Services* says, "The key points about chaos theory are that it affirms the need for environmental sensitivity, and that uncertainty represents opportunities."

ORIGINS OF CHAOS THEORY

One of the first scientists to comment on chaos was Henri Poincaré (1854–1912), a late-nineteenth-century French mathematician who extensively studied topology and dynamic systems. He left writings hinting at the same unpredictability in systems that Edward Lorenz (b. 1917) would study more than half a century later. Poincaré explained, "It may happen that small differences in the initial conditions produce very great ones in the final phenomena. A small error in the former will produce an enormous error in the latter. Prediction becomes impossible." Unfortunately, the study of dynamic systems was largely ignored long after Poincaré's death.

During the early 1960s, a few scientists from various disciplines were again taking note of "odd behavior" in complex systems such as the earth's atmosphere and the human brain. One of these scientists was Edward Lorenz, a meteorologist from the Massachusetts Institute of Technology (MIT), who was experimenting with computational models of the atmosphere. In the process of his experimentation he discovered one of chaos theory's fundamental principles—the Butterfly Effect. The idea is named for its assertion that a butterfly flapping its wings in Tokyo can impact weather patterns in Chicago. More scientifically, the Butterfly Effect proves that forces governing weather formation are unstable. These unstable forces allow minuscule changes in the atmosphere to have major impact elsewhere. More broadly applied, the Butterfly Effect means that what may appear to be insignificant changes to small parts of a system can have exponentially larger effects on that system. It also helps to dispel the notion that random system activity and disturbances must be due to external influences, and not the result of minor fluctuations within the system itself.

Another major contributor to chaos theory is Mitchell Feigenbaum (b. 1944). A physicist at the theoretical division of the Los Alamos National Laboratory starting in 1974, Feigenbaum dedicated much of his time

researching chaos and trying to build mathematical formulas that might be used to explain the phenomenon. Others working on related ideas (though in different disciplines) included a Berkeley, California mathematician who formed a group to study "dynamical systems," and a population biologist pushing to study strangely-complex behavior in simple biological models. During the 1970s, these scientists and others in the United States and Europe began to see beyond what appeared to be random disorder in nature (the atmosphere, wildlife populations, etc.), finding connections in erratic behavior. As recounted by James Gleick (b.1954) in *Chaos*, a French mathematical physicist had just made the disputable claim that turbulence in fluids might have something to do with a bizarre, infinitely tangled abstraction he termed a "strange attractor." Stephen Smale (b. 1930), at the University of California, Berkeley, was involved in the study of "dynamical systems." He proposed a physical law that systems can behave erratically, but the erratic behavior cannot be stable. At this point, however, mainstream science was not sure what to make of these theories, and some universities and research centers deliberately avoided association with proponents of chaos theory.

By the mid-1980s, chaos was a buzzword for the fast-growing movement reshaping scientific establishments, and conferences and journals on the subject were on the rise. Universities sought chaos "specialists" for high-level positions. A Center for Nonlinear Studies was established at Los Alamos, as were other institutes devoted to the study of nonlinear dynamics and complex systems. A new language consisting of terms such as *fractals*, *bifurcations*, and *smooth noodle maps* was born. In 1987, James Gleick published his landmark work, *Chaos: Making a New Science*, chronicling the development of chaos theory, as well as the science and scientists fueling its progress.

There are many possible applications for chaos theory, in and out of the business world, and many are still being studied. In Amita Paul's 2008 article on chaos theory and business practices, Paul gives several examples of data that can be predicted by studying complexity models, such as epileptic seizures, financial markets, manufacturing systems, and weather systems. In order to capitalize on chaos theory, Paul suggests a three-tiered approach:

1. A goal should be created, a particular state to be aimed at by the business. This could be the solving of a problem or reaching a certain state of productivity.

2. The organization and its structure should be capable of reaching its goal—it should be achievable.

3. The means to influence the systems should be known by the organization, and the leaders should be willing to put the plans into motion.

Paul admits the many applications possible for chaos theory, but questions its usefulness in the business world. Complexity analysis is always very complicated, requiring a large amount of data and intense mathematics, which can be open to error. A business must have talent, time, and funds to began a chaos analysis on any of its systems.

THE SCIENCE OF CHAOS THEORY

As stated by James Gleick, chaos is a science of the "global nature of systems," and so it crosses many disciplinary lines—from ecology to medicine, electronics, and the economy. It is a theory, method, set of beliefs, and way of conducting scientific research. Technically, chaos models are based on "state space," improved versions of the Cartesian graphs used in calculus. In calculus, speed and distance can be represented on a Cartesian graph as x and y. Chaos models allow the plotting of many more variables in an imaginary space, producing more complex imaginary shapes. Even this model assumes, however, that all variables can be graphed, and may not be able to account for situations in the real world where the number of variables changes from moment to moment.

The primary tool for understanding chaos theory (and complexity theory as well) is dynamic systems theory, which is used to describe processes that constantly change over time (e.g., the ups and downs of the stock market). When systems become dislodged from a stable state, they go through a period of oscillation, swinging back and forth between order and chaos. According to Margaret J. Wheatley in *Leadership and the New Science*, "Chaos is the final state in a system's movement away from order." When a system does reach that point, the parts of a system are manifest as turbulence, totally lacking in direction or meaning. Wheatley quotes researchers John Briggs and F. David Peat explaining the process of oscillation:

> Evidently familiar order and chaotic order are laminated like bands of intermittency. Wandering into certain bands, a system is extruded and bent back on itself as it iterates, dragged toward disintegration, transformation, and chaos. Inside other bands, systems cycle dynamically, maintaining their shapes for long periods of time. But eventually all orderly systems will feel the wild, seductive pull of the strange chaotic attractor.

In simpler terms, every system has the potential to fall into chaos.

The above "strange attractor" is the very same that a French mathematical physicist identified in the early 1960s. In complex systems, where all should fall apart, the attractor comes in, magnetically pulling system variables into an area and creating a visible shape. Because previous efforts to graph such phenomena could only be

completed in two dimensions, this effect could not be visualized. However, computers now allow the phenomena of "strange attractors" to become visible, as images of multiple dimensions representing multiple variables can finally be created.

Part of the difficulty in studying chaos theory arises because complex systems are difficult to study in pieces. Scientists' efforts to separate pieces of dynamical systems often fall apart. The system depends on each minute part of that system and the way it interacts with all other components. As Briggs and Peat state, "The whole shape of things depends upon the minutest part. The part is the whole in this respect, for through the action of any part, the whole in the form of chaos or transformative change may manifest."

In the same breath, it is important to establish the importance of the autonomy the smallest parts of a system possess. Each component of a complex system has the ability to fluctuate, randomly and unpredictably, within the context of the system itself. The system's guiding principles (the attractors) allow these parts to cohere over time into definite and predictable form. This runs contrary to the impression many have of chaos theory, believing there is no order to be had in such a system. However, chaotic movement does possess finite boundaries, within which is the capacity for infinite possibility. Even lacking direction, parts of a system can combine so that the system generates multiple configurations of itself, displaying "order without predictability." These systems never land in the same place twice, but they also never exceed certain boundaries.

PRACTICAL APPLICATION OF CHAOS THEORY

By the early 1980s, evidence accumulated that chaos theory was a real phenomenon. One of the first frequently-cited examples is a dripping water faucet. At times, water drops from a leaky faucet exhibit chaotic behavior (the water does not drip at a constant or orderly rate), eliminating the possibility of accurately predicting the timing of those drops. Scientists took advantage of applications using chaos to their benefit; chaos-aware control techniques could be used to stabilize lasers and heart rhythms, among multiple other uses.

As Kolb and Overdahl point out in their 2007 *Futures, Options, and Swaps*, chaos theory was also considered to have great potential in predicting the future changes of stocks and bonds. Although no set analysis has been able to use chaos theory infallibly to find patterns in the futures market, much work in chaos mathematics is focused on finding ways to predict stock prices. The idea is that the fluctuations of the trading market resemble the drip of a faucet or the fractals of tree branches; this

implies they are similar enough that someone could conceivably find the proper mathematical points and predict changes correctly.

Another arena within which chaos theory is useful is that of organizations. Applying chaos theory to organizational behavior allows theorists to take a step back from the management of day-to-day activities and see how organizations function as unified systems. An organization is a classic example of a nonlinear system (i.e., a system in which minor events have the potential to set off grave consequences or chain reactions, and major changes may have little or no effect on the system whatsoever). In order to exploit the chaotic quality of an organization, one needs to try to see the organizational shape that emerges from a distance. Instead of pinpointing causes in the organization for organizational problems, the company is better served, according to chaos theory, by looking for organizational patterns that lead to certain types of behavior within the organization.

Organizational expectations for acceptable behavior, and the degree of freedom with which individuals are allowed to work, shape the way a company's problems and challenges are handled by its members. By allowing people and groups within an organization some autonomy, businesses encourage the organization to organize itself, enacting multiple iterations of its own functioning until the various pieces of the organization can work together most effectively. An organization that encourages this type of management has been termed a *fractal organization*, one that trusts in natural organizational phenomena to order itself.

In the guide *CIMA Learning System* (2007), Botten and Sims discuss what this means for organizations trying to apply complexity theories in a useful manner. How does a business know when chaos theory applications have not done enough or have done too much? After taking a practical look at the results of chaos research, Botten and Sims created a concept of three separate states an organization can find itself in.

Chaos can either: (1) not affect a simple system at all, leading to consistent and accurate results without change; or (2) it can affect a system with a slight amount of error, so that some calculations will always be wrong and some results unexpected; or (3) chaos can reign uncontrolled on a complex system without predictability or order. These three possibilities apply to everything chaos theory deals with, from weather to business planning. Botten and Sims define the first state as *stable equilibrium*, the second as *bounded instability* (chaos under control), and the third as *explosive instability* (uncontrolled chaos).

While explosive instability can be very dangerous for a company, leading to loss of profit and the implosion of its systems, stable equilibrium can also pose a threat to

organizations. Business tends to suffer without change and without at least a little chaos to produce the unexpected, thereby forcing the adaptation and innovation that make organizations successful. In a static environment, organizations lose the ability to react well. Therefore, Botten and Sims suggest that the best state for business systems is the middle state, bounded instability, where an amount of controlled chaos is making the system unpredictable enough to be valuable, but not so unpredictable that it falls apart. In bounded instability, the system is not so repetitive that employees grow bored and lose the ability to function, but instead change occurs based on understood phenomena—the different seasons, for instance, or popular opinion, or the advances of technology. When a business reaches the third stage, explosive instability, it has gone too far; from a chaos theory perspective, it resembles a wildfire or war more than a functioning part of an organization. The middle road should be aimed for when applying chaos theory—not complete predictability and not utter confusion.

However, applying chaos theory to organizational practice tends to go against the grain of most formal management patterns. Order can be confused with the more popular notion of control. Defined by organization charts and job descriptions, traditional management does not generally seek to add disorder to its strategic plan. As Wheatley states, "It is hard to open ourselves up to a world of inherent orderliness." Organizations are focused on structure and design. Charts are drawn to illustrate who is accountable to whom or who plays what role and when. Business experts break down organizations into the smallest of parts. They build models of organizational practice and policy with hope that this atomizing yields better information on how to improve the organization's functioning. However, chaos theory implies that this is unnecessary, even harmful.

Self-organizing systems are those enabled to grow and evolve with free will. As long as each part of the system remains consistent with itself and the systems's past; these systems can harness the power of creativity, evolution, and free will—all within the boundaries of the organization's overall vision and culture. In this respect, chaos theory shows the need for effective leadership, a guiding vision, strong values, organizational beliefs, and open communication.

WRITING ON CHAOS THEORY

During the 1980s, chaos theory did begin to change decision-making processes in business. A good example is the evolution of high-functioning teams. Members of effective teams frequently recreate the role each member plays, depending on the needs of the team at a given point. Though not always the formally-designated manager, informal leaders emerge in an organization not because they have been given control, but because they have a strong sense of how to address the needs of the group and its members. The most successful leaders understand that it is not the organization or the individual who is most important, but the relationship between the two. And that relationship is in constant change.

One of the most influential business writers of the 1980s and 1990s, Tom Peters (b. 1942), wrote, *Thriving on Chaos: Handbook for a Management Revolution* in 1987. Peters offers a strategy to help corporations deal with the uncertainty of competitive markets through customer responsiveness, fast-paced innovation, empowering personnel, and most importantly, learning to work within an environment of change. In fact, Peters asserts that we live in "a world turned upside down," and survival depends on embracing "revolution." While not explicitly concerned with chaos theory, Peters's focus on letting an organization (and its people) drive itself is quite compatible with the central tenets of chaos theory.

As the global economy and technology continue to change the way business is conducted on a daily basis, evidence of chaos is clearly visible. While businesses could once succeed as "non-adaptive," controlling institutions with permanently-installed hierarchical structures, modern corporations must be able to restructure as markets expand and technology evolves. According to Peters, "To meet the demands of the fast-changing competitive scene, we must simply learn to love change as much as we have hated it in the past."

Organizational theorist Karl Weick (b. 1936) offers a similar theory to that of Peters, believing that business strategies should be "just in time...supported by more investment in general knowledge, a large skill repertoire, the ability to do a quick study, trust in intuitions, and sophistication in cutting losses." Though he did not articulate his theories in terms of the explicit ideas offered by quantum physics and chaos theory, his statements support the general idea that the creation and health of an organization (or a system) depends on the interaction of various people and parts within that system. However, as Wheatley states in her book:

> Organizations lack this kind of faith, faith that they can accomplish their purposes in various ways and that they do best when they focus on direction and vision, letting transient forms emerge and disappear. We seem fixated on structures...and organizations, or we who create them, survive only because we build crafty and smart—smart enough to defend ourselves from the natural forces of destruction.

As Botten and Sims theorized with their ideas on bounded instability, some chaos is considered good for an organization. Anthony Walker calls this the "edge of

chaos" in his 2007 book, *Project Management in Construction*. While the edge of chaos is far from a stable environment, it is also very exciting—a place where the organization's predictable "legitimate system" tries to keep structures unchanged, and its dangerous "shadow system" attempts to undermine and challenge the status quo. When both are in healthy competition with each other, at the edge of chaos, they provide the power for change and required innovation.

COALITION BUILDING

Coalitions refer to the temporary formation of persons, groups, or even nations for some type of joint or common action. It is most often used in relation to political or national issues, such as in the Coalition to Protect Senior Care. In business, coalitions have been present for many years as a means of bringing together people, departments within an organization, entire companies, or industries with some common purpose. Examples of such purposes might include achieving a common corporate goal, lowering insurance rates, regulating an industry action, or strategic planning. Coalitions are an exercise in power, whether in politics or business.

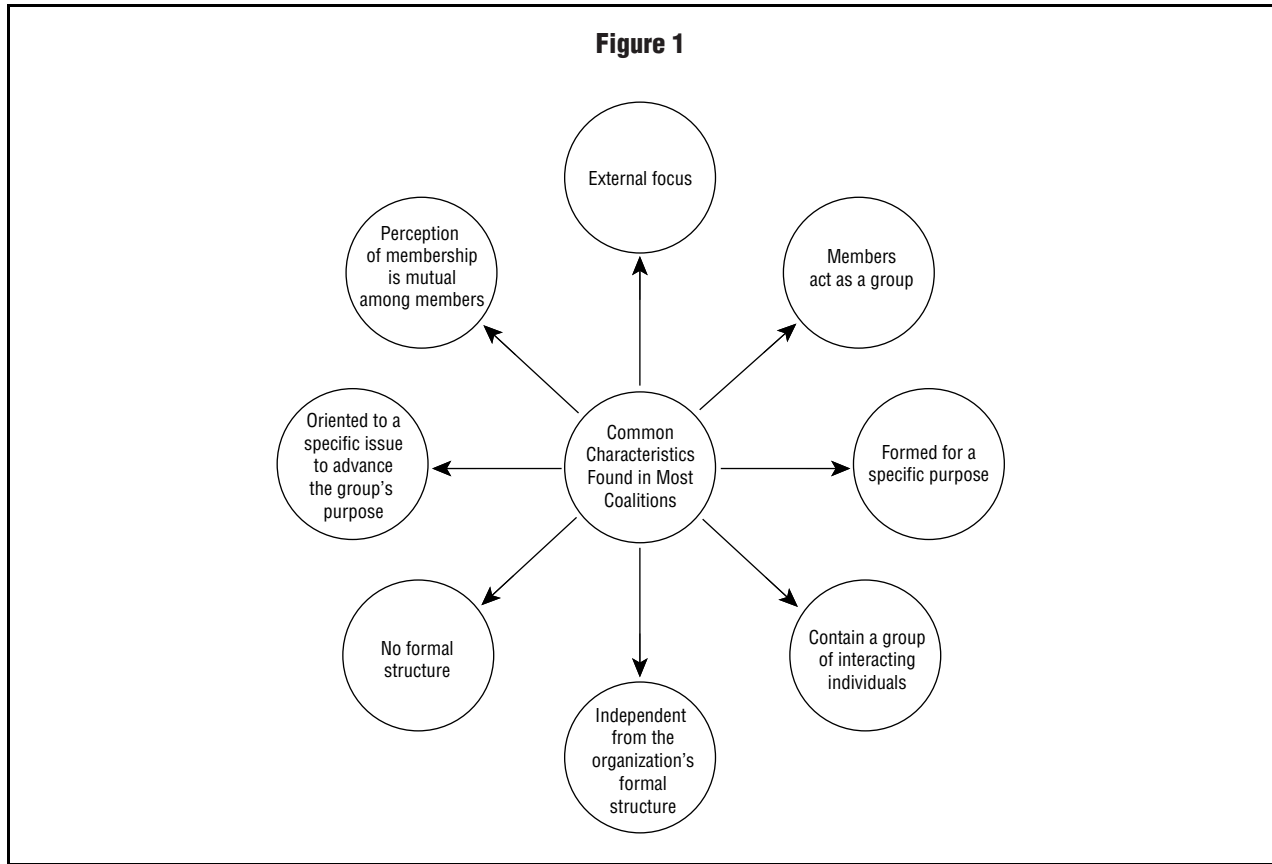
HISTORY OF COALITIONS

The concept of coalition building has too often been confused with interest groups and lobbying. The term refers to the formation of different interests, but not necessarily with the same intent as an interest group. From the French *coalascere*, the word is generally defined in political terms. Most early coalitions were temporary alliances formed among nontraditional allies to combat a common foe. An example of this type of usage is the coalition between the United States and Afghanistan (as well as other countries), in which a multi-national force comes together to fight militants in Afghanistan. Coalitions are also formed for election purposes. A historical example of this is the Republican Party, formed in the mid-nineteenth century from representatives from virtually all parties then existing on the American political scene—Whigs, Democrats, Free-Soilers, Abolitionists, Know-Nothings, members of the temperance movement, and others without a party allegiance. All of these elements did not survive the formation of the Republican Party as we know it today.

COALITIONS DEFINED

There are various definitions of a coalition that fit an organizational behavior setting. One simply states that a coalition occurs when members of a group organize to support their side of a particular issue. Another definition refers to a coalition as a relationship over a specific issue. Coalitions exist to preserve and even enhance self-interests, whether those of an individual or group, and achieve an adequate balance of power favorable to the coalition members' advantage. A more complete definition is a group formed to pursue a strategy that will be to the advantage of those most directly affected.

Another example of a coalition is one that forms over the issue of funding for management information systems within a single organization. Individuals express initial concern about a lack of resources to fully develop an integrated information system, yet have no formal way to share concerns with management. These individuals represent several units within the organization, including accounting, research, marketing, and distribution—few of whom commonly interact with the others. The issue focuses on management's budget control. But, as a group, membership serves on the overall organizational budget planning committee. At the point of decision making, the

Figure 1


coalition acts in accord with common interests to recommend a comprehensive information system mutual to the needs of all units. Once this recommendation is forwarded to the organization's executive, the coalition disbands or continues, depending on the final decision on how the resources are to be used for information management.

Whatever definition of coalitions is accepted, understanding organizational coalitions enhances understanding of behavior in complex organizational structures. Coalitions are a potent force in organizations. Organizational behavior literature is largely independent of the social psychology literature on coalitions, yet a closer tie between the two fields is building. Likewise, business and organization literature has not utilized the vast literature of political science that examines the unique formation of coalitions for mutual goals. The merging of these three independent disciplines into a body of coalition literature can only enhance our understanding of the formation of groups for common purposes.

COALITION BUILDING

A review of the business and behavioral science literature on coalitions suggests the following are common characteristics found in most coalitions:

1. Members act as a group.

2. They are formed for a specific purpose.

3. They contain a group of interacting individuals.

4. They are independent from the organization's formal structure.

5. They have no formal structure.

6. They are oriented to a specific issue to advance the group's purpose.

7. Perception of membership is mutual among members.

8. They have an external focus.

These characteristics may be common with other types of groups within organizations, but coalitions are separate and quite often powerful. As a part of an organizational power structure, coalitions are frequently seen as a manager's legitimate search for power, and as such, are used to increase personal power or to achieve organizational goals. When building a coalition, potential members will identify those individuals or groups who have a common interest or goal and who are most likely to join. Generally, coalitions take time to form as participants

identify the common goal, the best manner to approach that goal, and the individuals or groups most likely to share the preferred strategy of goal-seeking. Borrowing from social psychology literature, "Coalitions form, one person (or group) at a time."

Coalitions are used to increase a power base. Therefore, an understanding of coalition building is integral to a comprehensive knowledge of organizational behavior. In politics, the word "temporary" is closely associated with coalitions, but this is not necessarily the rule in corporate life. Social psychologists Keith Murnigham and Danny Brass conclude that successful coalitions are fluid, form rather quickly, expand, burst at the moment of decision, and then rapidly disappear. Other types of relationships within the organization can include alliances, networks, cliques, a supportive managerial relationship, and other forms. Networks are a broad-based cooperative pursuit of general self-interests, while alliances involve individuals or groups supporting each other. A clique is a group of individuals held together by a common interest. Cliques often form coalitions. Research indicates that some surreptitiousness (e.g., mobilizing quietly) may be essential to building a coalition. There is also research concluding that resistance, fear of retaliation, and insults often create ripe conditions for coalition building.

Several conditions have to be present for the formation of a coalition. First, there has to be an issue that requires addressing or interest in an issue that coalition members find they have in common. Second, potential members have to share a belief that they can achieve success through building a coalition. Third, there must be an understanding that the action taken has to be jointly performed. Once these criteria are met, the building of the coalition begins. Generally, coalition members form from a weakness—that is, individually they are not strong enough in the organization to achieve their goal.

When this collective action leads to a response, coalitions can take one of several directions. If initially successful, the coalition may grow. But the same is true if the coalition first encounters failure yet persists in reaching a collective goal. Disbanding the coalition is also a possibility in either scenario, resulting in the dormancy of the coalition. Coalitions may well be strengthened by success and continue to grow in power and influence. A dormant coalition may also be able to exercise power at a later time, but this is unlikely in most organizations. Coalitions may prevail and coalition goals may become the dominant organizational goal, although this alternative course of coalition action lacks adequate research findings from which to derive any solid conclusions. The stability of coalitions thus depends on goals, course of action, outcomes, and continued common interest.

COALITION GOALS

Coalition goals generally focus on the distribution of resources, usually a source of contention in organizations. The lack of adequate resources, changes in the resource base, perceived inequitable resource distribution, and lack of a comprehensive understanding of resource allocation frequently result in the development of coalitions. Research also indicates that those with broader discretion and influence in job responsibilities and work activities are more likely to participate in coalition building. When the work environment is more rigidly controlled, coalitions are not as likely to be pursued as a strategy for addressing collective goals.

An example of a coalition and its effectiveness can be found in Belarus's 2007 bid for a seat on the UN Human Rights Council. Objecting to the country's record of human rights violations, more than 40 nongovernmental organizations from around the world came together to condemn Belarus's bid. As a result of these efforts as well as campaigns by the United States and parts of Europe, Belarus was defeated and did not win a seat on the Council. Although an example of a very powerful coalition, it includes most of the common characteristics of the coalition—an interacting group (the nongovernmental organizations), a specific purpose (blocking Belarus's bid), a concentrated act (petitioning the UN), no formal internal structure (a group of organizations), external focus (the leadership of an intergovernmental human rights body), and orientation to advance the members' purpose (human rights advocacy).

COALITION LITERATURE

The concept of coalitions has undergone differing applications and meanings within organizational theory. The earliest uses focus on conflicts within organizations and the presence of multiple goals within the same organization. Herbert Simon, former professor at Carnegie Mellon University and 1978 recipient of the Nobel Prize in economics, was one of the first researchers to identify the issue of conflict over goals in an organization. Simon, however, failed to mention coalitions arising within the organizations over this conflict. Simon's 1958 book, *Organizations*, which he co-authored with James G. March, mentioned coalitions between but not within organizations. March, also at Carnegie Mellon and later at Stanford, did draw a relationship between coalitions and organizations in a 1962 article in the *Journal of Politics*. March continued his work with Richard Cyert (also at Carnegie Mellon at that time and later president of the institution from 1972 to 1990) in works like the 1963, *A Behavioral Theory of the Firm*.

The second significant period of coalition research centered on James Thompson, who adopted the work of

March and Cyert in his 1967 book, *Organizations in Action*, where he coined the term, "dominant coalition." Thompson (who was teaching business at Indiana University in 1967) concluded there were certain constraints on coalition building, mainly the organization's technology and environment. Thompson theorized that the more uncertainty in organizations due to technology and environment, the more power bases that exist. The coalition grows as the uncertainty increases.

Thompson also used the term, "inner circle" to describe the select few within an organization whose connections provide them with influence. Their role in coalition building is often one of leadership, but they seldom act alone in achieving goals. Their power is enhanced as the coalition strives to achieve a group goal; thus, the individual and coalition feed off each other. Carrying Thompson's point one step further, interdependency in an organization creates a greater likelihood for the formation of a coalition or coalitions.

A third phase of coalition scholarship was generated with the introduction of political science and social psychology methods and studies to organizational behavior. This led to the current divergent use of the term, and research from several disciplines points to how individual efforts at influence become the basis for coalition building. The application of different schools of research on coalitions led to more thorough study into the formation and operation of coalitions in the organization. In addition, game theory proponents contribute to understanding of the role of coalitions and their formation.

More recently, research into coalitions has moved away from the organizational environment to the political arena where coalitions have an impact on business. Periodical literature is highlighted with articles on how coalitions influence international business and economics, the health care industry, diversity and integration issues, foreign trade, the insurance market, and community activism. In the area of organizational behavior, research centers on the role of coalitions in organizational change, or how groups with seemingly dichotomous interests merge to exercise power on business strategy and decision making within an organization undergoing significant administrative and structural change.

In their seminal article on coalition research, William Stephenson, Jone Pearce, and Lyman Porter (of the University of California at Irvine) state that the study of coalitions has yet to produce any new way of understanding organizational processes. Considering the wide array of research from psychology, political science, game theory, sociology, and organizational behavior, their conclusion still begs an adequate answer. We can come to an understanding of the conditions necessary for the formation of a coalition, how they are built, how they exercise power and influence, and how they survive or disband, yet the question of the role of the coalition in organizational behavior remains unanswered and fertile for the researcher so inclined to look further for questions and answers.

COMMUNICATION

Communication is the sharing or exchange of thought by oral, written, or nonverbal means. To function effectively, managers need to know, and be able to apply strategically, a variety of communication skills that match varying managerial tasks. These tasks might call for nonverbal, presentational, or written skills as the manager meets others, speaks at meetings, or prepares reports to be read by clients or those higher on the organizational ladder. To work effectively, managers also need to know sources of information. Finally, managers need to understand the different communication channels available.

UPWARD AND DOWNWARD COMMUNICATION

Information, the lifeblood of any organization, needs to flow freely to be effective. Successful management requires downward communication to subordinates, upward communication to superiors, and horizontal communication to peers in other divisions. Getting a task done, perhaps through delegation, is just one aspect of the manager's job. Obtaining the resources to do that job, letting others know what is going on, and coordinating with others are also crucial skills. These skills keep the organization working and enhance the visibility of the manager and her division, thus ensuring continued support and promotion.

Downward communication is more than passing on information to subordinates. It may involve effectively managing the tone of the message, as well as showing skill in delegation to ensure the job is done effectively by the right person. In upward communication, tone is even more crucial, as are timing, strategy, and audience adaptation. In neither case can the manager operate on automatic as the messages are sent out.

THE COMMUNICATION PROCESS

At first glance the communication process, or the steps taken to get a message from one mind to another, seems simple enough. As the definition at the opening suggested, the sender has an idea, which he transmits to the receiver through signs—physical sensations capable of being perceived by another. These signs might be a printed or spoken word, a gesture, a handshake, or a stern look, to name just a few. The receiver takes those signs, interprets them and then reacts with feedback.

The process is more complex, though. When communicating, the sender encodes the message. That is, she chooses some tangible sign (something which can be seen, heard, felt, tasted, or smelled) to carry the message to the receiver. The receiver, in turn, decodes that message; that is, he finds meaning in it. Yet the signs used in messages have no inherent meaning; the only meaning in the message is what the sender or receiver attributes to it.

To make sense out of a message, to determine the meaning to attribute to it, the receiver uses perception. With perception, the receiver interprets the signs in a communication interaction in light of his past experience. That is, he makes sense out of the message based on what those signs meant when he encountered them in the past. A firm, quick handshake, for example, may signal "businesslike" to someone because in the past he found people who shook hands that way were businesslike.

PERCEPTION

No person sees things exactly the same way as another; each has a unique set of experiences, a unique perceptual "filter," through which he or she compares and interprets messages. Making up this filter is the unique blend of education, upbringing, and all of the life experiences of the perceiver. Even in the case of twins, the perceptual filter will vary between them. When communicating, each receiver uses that filter to give meaning to or make sense out of the experience.

Herein lies the challenge in communication, particularly for managers who need to be understood in order to get things done: getting the receiver to comprehend the message in a way similar to what was intended. While the word "communication" implies that a common meaning is shared between sender and receiver, this is not always the case. Under optimum circumstances, the meaning attributed to the message by the receiver will be close to what was intended by the sender. In most situations, however, the meaning is only an approximation, and may even be contrary to what was intended. The challenge of communication lies in limiting this divergence of meanings between sender and receiver.

While the wide range of potential experiences makes communicating with someone from within the same culture a challenge, across cultures the possibilities are even wider and the challenges even greater. What one sign means in one culture might be taken in an entirely different way in another. The friendly Tunisian businessman who holds another man's hand as they walk down the street may be misunderstood in the North American culture, for example. Similarly, an intended signal may mean nothing to someone from another culture, while an unintended one may trigger an unexpected response.

Understanding the dynamics that underlie perception is crucial to effective and successful communication. Because people make sense out of present messages based on past experiences, if those past experiences differ, the interpretations assigned may differ slightly or even radically depending on the situation. In business communication, differences in education, roles in the organization, age, or gender may lead to radical differences in the meaning attributed to a sign.

AUDIENCE ADAPTATION

The effective communicator learns early the value of audience adaptation and that many elements of the message can be shaped to suit the receiver's unique perceptual filter. Without this adaptation, the success of the message is uncertain. The language used is probably the most obvious area. If the receiver does not understand the technical vocabulary of the sender, then the latter needs to use terms common to both sender and receiver.

On the other hand, if the receiver has less education than the sender, then word choice and sentence length may need to be adapted to reflect the receiver's needs. For

example, if the receiver is skeptical of technology, then someone sending a message supporting the purchase of new data processing equipment needs to shape it in a way that will overcome the perceptual blinders the receiver has to the subject. If the receiver is a superior, then the format of the message might need to be more formal.

COMMUNICATION BARRIERS

Communication barriers (often also called noise or static) complicate the communication process. A communication barrier is anything that impedes the communication process. These barriers are inevitable. While they cannot be avoided, both the sender and receiver can work to minimize them.

Interpersonal communication barriers arise within the sender or receiver. For example, if one person has biases against the topic under discussion, anything said in the conversation will be affected by that perceptual factor. Interpersonal barriers can also arise between sender and receiver. One example would be a strong emotion like anger during the interaction, which would impair both the sending and receiving of the message in a number of ways. A subtler interpersonal barrier is bypassing, in which the sender has one meaning for a term, while the receiver has another (for example, "hardware" could be taken to mean different things in an interchange).

Organizational barriers arise as a result of the interaction taking place within the larger work unit. The classic example is the serial transmission effect. As a message passes along the chain of command from one level to the next, it changes to reflect the person passing it along. By the time a message goes from bottom to top, it is not likely to be recognized by the person who initiated it.

Although communication barriers are inevitable, effective managers learn to adapt messages to counteract their impact. The seasoned manager, especially when in the role of sender, learns where they occur and how to deal with them. As receiver, she has a similar and often more challenging duty. The effort is repaid by the clearer and more effective messages that result.

COMMUNICATION REDUNDANCY

While audience adaptation is an important tool in dealing with communication barriers, it alone is not enough to minimize their impact. As a result, communication long ago evolved to develop an additional means to combat communication barriers: redundancy, the predictability built into a message that helps ensure comprehension. Every message is, to a degree, predictable or redundant, and that predictability helps overcome the uncertainty introduced by communication barriers. Effective communicators learn to build in redundancy where needed.

Communication redundancy occurs in several ways. One of the most obvious of these is through simple repetition of the message, perhaps by making a point early and again later into the same message. A long report, by contrast, might have its main points repeated in a variety of places, including the executive summary, the body, and the conclusion.

Another source of redundancy lies in the use of multiple media. Much spoken communication is repeated in the nonverbal elements of the message. A formal oral presentation is usually accompanied with slides, product samples, or videotaped segments to support the spoken word. A person interviewing for a job stresses his seriousness and sincerity with a new suit, a warm handshake, consistent eye contact, and an earnest tone in his voice.

NONVERBAL COMMUNICATION

Nonverbal communication occurs when there is an exchange of information through nonlinguistic signs. In a spoken (and to some extent written) message, it consists of everything except the words. Nonverbal communication is a valid and rich source of information and merits close study. As with other elements of communication, the meaning of nonverbal signals depends upon perception. It does not have to be intentional in order to carry meaning to another person.

Nonverbal communication serves a variety of purposes, including sending first impressions such as a warm handshake. It also signals emotions (through tears or smiles), status (through clothing and jewelry), and when one wants to either take or relinquish a turn in conversation (using gestures or drawing a breath). Nonverbal signals can also signal when someone is lying; for example when being deceptive, vocal pitch often rises.

Many think of "body language" as synonymous with nonverbal communication. Body language is a rich source of information in interpersonal communication. The gestures that an interviewee uses can emphasize or contradict what he is saying. Similarly, his posture and eye contact can indicate respect and careful attention. Far subtler, but equally important, are the physical elements over which he has little control, but which still impact the impression he is making on the interviewer. His height, weight, physical attractiveness, and even his race are all sources of potential signals that may affect the impression he is making.

But nonverbal signals come from many other sources, one of which is time. If the interviewee in the previous example arrived ten minutes late, he may have made such a poor impression that his chances for hire are jeopardized. A second interviewee who arrives ten minutes early signals eagerness and promptness.

Haptics is a source of nonverbal communication that deals with touch. An interviewee with a weak handshake

may leave a poor impression. The pat on the back that accompanies a verbal "well done" and a written commendation may strongly reinforce the verbal and written statements. Subconsciously, most managers realize that when the permissible level of haptic communication is exceeded, it is done to communicate a message about the state of the parties' relationship. It is either warmer than it had been, or one of the parties wishes it so. Unfortunately, explain Borisoff and Victor, conflict can arise when the two parties involved do not agree on an acceptable haptic level for the relationship.

Nonverbal communication also includes proxemics, a person's relationship to others in physical space. Most are familiar with the idea of a personal space "bubble" that we like to keep around ourselves. In the North American culture, this intimate space may be an 18-inch circle around the person, which only those closest are allowed to invade. Just beyond this space close friends may be tolerated, and acquaintances even farther out. Other cultures may have wider or narrower circles. Table 1 sets out the meanings typically attributed to personal spaces in the North American culture.

Managers also send nonverbal signals through their work environment. These signals can affect the communication process in obvious or subtle ways. For example, a manager may arrange the office so that she speaks to subordinates across a broad expanse of desk. Or, she may choose to be less intimidating and use a round table for conferences. The artifacts she uses in the office may say something about who the manager is, or how she wishes to be seen. The organization also speaks through the space it allots to employees. For example, the perception that a large, windowed, corner office may signal prestige while a tiny, sterile cubicle may convey (intentionally or unintentionally) low status.

THE GRAPEVINE

The grapevine is the informal, confidential communication network that quickly develops within any organiza-

tion to supplement the formal channels. The structure of the grapevine is amorphous; it follows relationship and networking patterns within and outside the organization, rather than the formal, rational ones imposed by the organization's hierarchy. Thus, members of a carpool, or people gathering around the water cooler or in the cafeteria, may be from different divisions of a company, but share information to pass the time. The information may even pass out of the organization at one level and come back in at another as people go from one network to another. For example, a member of a civic group might casually (and confidentially) pass on interesting information to a friend at a club, who later meets a subordinate of the first speaker at a weekend barbecue.

The grapevine has several functions in the organization. For one, it carries information inappropriate for formal media. Fearing legal repercussions, most would rarely use printed media to share opinions on the competence, ethics, or behavior of others. At the same time, they will freely discuss these informally on the grapevine. Similarly, the grapevine will carry good or bad news affecting the organization far more quickly than formal media can.

The grapevine can also serve as a medium for translating what top management says into meaningful terms. For example, a new and seemingly liberal policy on casual dress may be translated as it moves along the grapevine to clarify what the limits of casual dress actually are. As it informally fleshes out or clarifies what is also traveling in the formal channels, the grapevine can also serve as a source of communication redundancy. And when these corporate-sanctioned channels are inaccurate, especially in an unhealthy communication climate, what is on the grapevine is usually trusted far more by those using it than what passes on the formal channels.

Participants in the grapevine play at least one of several roles. The first of these, the liaison, is the most active participant since he both sends and receives information on the grapevine. This person often has a job with easy access to information at different levels of the organization (and often with little commitment to any level). This might be a secretary, a mailroom clerk, a custodian, or a computer technician. Often, too, the liaison is an extrovert and likable. While this role means that the liaison is in on much of what is going on in the organization, he also takes a chance since the information he passes on might be linked back to him.

Another role played in the grapevine is the dead-ender. This person generally receives information, but rarely passes it on. By far the most common participant in the grapevine, this person may have access to information from one or more liaisons. This role is the safest one to play in the grapevine since the dead-ender is not linked

Table 1
Proxemic Distances in the North America Culture

Zone	Distance	Persons Tolerated
Intimate	0" to 18"	Partner/spouse, parents, children
Personal	1.5' to 4'	Close friends
Social	4' to 12'	Business associates
Public	12' and up	Strangers

Adapted from Smeltzer and Waltman et al., pp. 234-235

to the information as it moves through the organization. Many managers wisely play this role since it provides useful information on what is happening within the organization without the additional risk passing it on to others might entail.

The third role is the isolate. For one or more reasons, she neither sends nor receives information. Physical separation may account for the role in a few instances (the classic example is the lighthouse keeper), but the isolation may also be due to frequent travel that keeps the individual away from the main office. Frequently, the isolation can be traced to interpersonal problems or to indifference to what is happening in the organization (many plateaued employees fit in this category). Not surprisingly, top management often plays the role of isolate, although often unwillingly or unknowingly. This isolation may be owing to the kinds of information passing on the grapevine or to the lack of access others have to top management.

Of course, what is passing on the grapevine may affect a person's behavior or role played. The isolate who is close to retirement and indifferent to much of what is going on around him may suddenly become a liaison when rumors of an early retirement package or a cut in health benefits circulate. Meanwhile, the youngest members of the organization may not give a passing thought to this seemingly irrelevant information.

COMMUNICATION CHANNELS

Communication channels—or the media through which messages are sent—can have an influence on the success of communication. Typical channels used in business communication are face-to-face conversations, telephone conversations, formal letters, memos, or e-mails. Each channel has its own advantages and disadvantages in communicating a particular message.

Media richness theory indicates that the various communication channels differ in their capability to provide rich information. Face-to-face interaction is highest in media richness, because a person can perceive verbal and nonverbal communication, including posture, gestures, tone of voice, and eye contact, which can aid the perceiver in understanding the message being sent. Letters and e-mails have fairly low media richness; they provide more opportunity for the perceiver to misunderstand the sender's intent. Thus, messages should be communicated through channels that provide sufficient levels of media richness for their purpose. For instance, when managers give negative feedback to employees, discipline them, or fire them, it should be done in person. However, disseminating routine, nonsensitive information is properly done through memos or e-mails, where media richness is not critical.

E-MAIL

E-mail, a common business tool used to spread messages across company structures, can also come with pitfalls. The ease of composing and sending e-mails creates a sometimes lax environment where messages can become garbled, and laziness on the part of the sender can lead to misunderstanding or confusion. Normally clear communicators might omit helpful sentence structure or assume that their tone carries over in an e-mail when, in fact, the static of time-and-place is actually ruining the message. It is common for most companies to have monitoring and collection systems on all e-mail communication, but problems can be readily solved with more careful writing techniques. The University of California offers several helpful guidelines in its *Guide to Electronic Communication*

E-mail should always have the appropriate degree of formality. The structure and tone of a business letter is a good example to follow. How would you properly speak to your organization, manager, or employees? E-mails should be written with the same professionalism. Not only are they read by the intended person, but e-mails are also often sent to or seen by others.

A reply to an e-mail should always include some summary of the original message. It is rude to force the reader to reread or reconsider what they have already written. A sentence, or even a few words, is usually enough, This is also why it is polite to include links to any articles or Web sites you are referring to within the e-mail.

When sending out a mass e-mail, it is considered polite to summarize the responses you receive. A simple tally of the replies, and communication of the general decision, is enough.

Email messages should be concise. Readers rarely have the time or patience to read a full letter. Keeping the message brief will keep the communication clear.

Messages should be formatted for easy reading. Separating sentences, bulleting points, and using short paragraphs are all ways to improve the readability of e-mail messages.

Titles and subject headings should be descriptive. It is not polite to leave readers guessing what the body of the e-mail might be about. Subject headings should communicate what information the e-mail contains.

Writers of e-mails should take care when using emotive language (such as sarcasm, humor, anger, confusion, etc.). Although e-mail is more informal than other written forms of communication, it does not communicate nonverbal cues, and expressions can be misunderstood.

BUSINESS BLOGGING

Web Logs, or blogs, were once used as online journals and private forums. Now, the blogging industry has exploded,

with hundreds of blogging sites adding information and articles daily. According to the blog-tracking company Technorati, approximately 175,000 new blogs are created daily, along with the millions of updates to existing blogs. So, how can a business profit from the blogging world? Can blogs be used as effective marketing and communication tools?

Peter Alexander, with *Enterprise.com*, believes they can. In his 2007 article, "Should You Start a Business Blog?" he gives several reasons why companies should consider the "blogosphere." A business blog can be much more personal, easy to access, and attractive than other marketing techniques. Customers do not feel as pressured by a blog as by other forms of sales media. A blog can be updated daily, giving the business an active, adaptive face—and at a low cost, since most blogs cost little to no money to begin and run.

There are several ways to approach blogging as a business. First, goals and core ideas should be established: what does the business want to communicate with their blog? What image does it want to show? What is the best tone and subject matter to enforce that image? With specific goals in mind, a blog can be tailored to the company's desires.

Blogs should be both relevant and useful. Updating blogs is vital for a company, and even minor posts concerning new products or leadership can communicate the friendliness and personal aspects of the blog. Customers will also want ways to find more information, so links to a company's Web site, ordering information, and any tips or extra information are great additional items to include in a business blog.

As with other types of marketing, the communications on a business blog should make readers eager to learn more about the company and its product or service. Different writers should create a variety of posts to keep the customers' attention, and the use of more than one voice on a blog can be engaging. Key words the company wants to associate itself with—*dedicated*, *freelance*, or *invested*, for example—should be used frequently on the blog so customers naturally pick up the idea. Videos (even vlogs, video-oriented blogs), pictures, and pdfs can also increase the attraction and usefulness of business blogs.

SMS, OR PHONE TEXT MESSAGING

Short message service (SMS), referred to usually as TM or text messaging, is sometimes considered a standby for teenagers and those with time to learn how to type on their cell phones; however, it is also starting to have many business applications. From a global perspective, America has been slow to accept TM as a form of business and social communication. According to a 2006 article in *Business 2.0*, Ecuador sends four times more text messages per person than the United States does, despite economic differences. Europeans, such as the Irish or the Danes, send approximately 100 texts per month, compared to people in the United States, whose average is not quite 50 texts.

How can a business make use of TM communication? There are several possibilities, and for some organizations TM can be an asset, enabling instant and direct communication that is more reliable than other electronic contact.

Companies that work a great deal in internet or intranet-based information might want to use text messaging as a failsafe, in case a network fails. Managers and employees may not be able to receive updates if e-mail and IM services are down, but TM notifications can be sent immediately to a widespread audience, explaining a system failure and giving updates on repairs.

There are also a number of people who work away from computers, without access points to check e-mail and receive important communication. Workers, those traveling on marketing tasks, or simply people who frequently move in their jobs can all benefit from a TM system where they can receive key information as they work.

There are several other, more specific uses of text messaging being attempted in the business world. Some marketing ploys use TM to advertise, certain companies announce events or orders over phone texting, and some security organizations (such as banks) use TM to transfer temporary, private security codes. Like other new methods of communication, TM is proving to have a number of uses throughout many industries.

INSTANT MESSAGING FOR BUSINESSES

Instant messaging (IM) works in much the same way as e-mail, but it provides a continuous flow of communication (constantly updated) and resembles a normal conversation stripped of nonverbal communication. Many businesses already use IM for training, helpdesk service, and updates. An organization can approach IM use in many different ways. The Microsoft Small Business Center has a helpful guideline for companies considering adopting IM for business use, offering key concepts to keep in mind

First, the organization should create a clear policy regarding IM use, and communicate that policy to all employees. Standards should be set, and parameters should be made on what subjects are allowed for discussion. Employees should be aware that excessive instant messaging will not be tolerated, and that all IM conversations are saved in case of potential misuse. Sensitive information should not be communicated with IM

technology. Managers should set the standard by being clear, concise users of instant messaging themselves.

Companies should be sure they know the legal precedents established in IM use, and be aware of their own liability in case of fraud, defamation, and other potential problems. Computer viruses can use IM services to hack into networks as well, so companies should be aware of possible security risks, and the dangers of transferring files over their IM system.

VOIP

Voice over Internet protocol, or VoIP, is a recent form of technology allowing audio communication through an Internet provider. Many companies are attracted to VoIP because it allows them to integrate their communication system; for example, department phone networks can be set to use VoIP, avoiding the cost of a phone service provider and allowing some services to become more efficient and integrated, such as conference calling or speaker systems. With broadband services offering high-speed Internet connection capable of high-quality VoIP, companies can consider the technology as a viable alternative.

While VoIP works the same way as a phone service provider, there are several unique points companies should be aware of when looking for VoIP service. Kristin Kiya on *Ezine* offers a short list of such points in her 2008 article, "Identifying the Best Business VoIP Solutions for Your Business:"

- Pay attention to tariffs charged for transferring calls by the VoIP provider. International calls can especially elevate costs.

- The company should always request test calls from the VoIP provider so that the quality of service can be ascertained. No company should accept fuzzy or intermittent service.

- A good VoIP provider should provide enough resources that the company can make the transition from its old phone service easily, without losing any capabilities.

- Many VoIP providers offer training along with their services. If companies desire professional training in the new technology, they should be sure to find a provider that will include it.

There is a growing number of VoIP companies available. The possible providers include Phone Power, Vonage, VoIP Your Life, via-talk, and VoIPGO.

COMMUNITIES OF INTEREST, COMMUNITIES OF PRACTICE

A community of interest, or a CoI, is described as a network of people who share the same interests, knowledge, and understanding of the best practices for any given subject matter. A community of interest can be either a live "actual" community of individuals who meet to discuss and exchange information, or it can be a virtual community that meets, discusses, and exchanges information via the Internet and various messaging tools.

A community of practice, or a CoP, generally refers to the communal use and understanding of a specific interest and knowledge of its best practices. In other words, a community of practice can be the very community of interest as described above, or it can be a loosely organized group that simply shares and practices the same understanding and methodology on a given subject matter. The term "community of practice" was originally coined to describe the type of community atmosphere created by apprenticing and mastering a trade. Now, a community of practice can refer to any loose or structured learning environment or situation where mentoring and

the fostering of knowledge of a specific trade or specialized practice or genre of knowledge occurs. As described by authority Etienne Wenger, a community of practice is a communal or joint enterprise; as such, it is consistently progressing as is best for the delivery of information that is important to the community. Engagement in the community is defined by continual negotiation and renegotiation of what the community stands for and the definition and redefinition of the community's resources, vocabulary, philosophies, and anything else which defines the group and the body of information important to its members.

The mission of a community of practice is to hone skills on both a personal as well as communal level. An additional mission for most communities of practice is to further the study and understanding of a given subject matter or theme that all members of the community have a common interest in or passion for. What defines a community of practice and makes it distinct from a common club or simple group of friends is the constant stewardship of new and old data as well as the level of education, competency, and experience of each of a community's members. Members of the community of practice do just that—they practice and are active practitioners of a subject via the sharing of data in the form of facts, stories, problem-solving techniques, and tools of the trade.

COMMUNITIES OF PRACTICE FOR ORGANIZATIONAL LEARNING AND KNOWLEDGE MANAGEMENT

One of the most important advents of communities of practice has been the creation and honing of organizational learning and knowledge management. A community of practice allows for the close proximity of teachers and students (masters and apprentices) in a given field of study. Organizational learning is the practice of learning where the established rules of a trade come to be acknowledged and followed. Additionally, organizational learning begins and follows the process of adapting the established rules and practices to the changing environment in which a given trade is practiced. Organizational learning must be both active and reactive to given environments and circumstances as well as regional, cultural, geographic, and other differences. As a concept, it can truly only be actualized when there is a community to create, use, recreate, and revolutionize the various processes that make up an actual practice, trade, or organized body of information.

Organizational learning within a community of interest or community of practice has been the primary source for the "standard operating procedures" (SOPs) of hundreds of practices, making it perhaps the most important platform for establishing best practices so far.

Knowledge management has been another important innovation created and utilized by communities of practice. Communities of practice, especially those that use the Internet to communicate virtually and constantly, create a place where information can be gathered, stored, challenged, and rethought over and over. In this process, ideas and ways of doing things within a trade can be openly questioned and changed if the occasion arises that the best practice differs from current practice. The management of this collective knowledge in a single place begins to have patterns, and basic, universal principles about best practices can begin to form. A database that is consistently managed because it is vitally important to the members of its community of practice begins to morph from simple information into what is true about the subject matter at hand as well as the community that practices it.

According to Gene Bellinger, author of the 2004 article *Knowledge Management: Emerging Perspectives*, "Information, knowledge, and wisdom are more than simply collections. Rather, the whole represents more than the sum of its parts and has a synergy of its own." Bellinger adds that it is important to remember what knowledge is and why it is important before anyone hurries to categorize and manage it. He and other experts in the field of knowledge management break data down into groups of information, knowledge, and wisdom. The relationship between these three types of data can help users to manage and categorize thoughts. Prioritizing data in this way allows for better management of whole communities of practice and helps determine what is important and why. In addition, a community of interest endeavoring to make use of particular data can do so in a much more effective fashion if the ideas and strategies are created based on information from various perspectives. Putting these new ideas into practice and using them for a time will allow important figures in a given field to establish thoughts and opinions, which will turn into the common wisdom necessary for the progression of the trade or field of study.

ADVANTAGES OF A COMMUNITY OF PRACTICE

Etienne Wenger, author of "Communities of Practice: Learning as a Social System," breaks communities of practice down in terms of their advantages to users and explains why they are effective. Wenger notes that for a community to keep information organized and for data to be maintained effectively, one consistent practice and organizational style are imperative. Ideas and information are not effective or valuable if the ways of discovery compromise the meaning, or if the data itself cannot be used in practice by the community. Wenger emphasizes

the importance of *reification*: the process by which esoteric ideals and unformed ideas become concrete, empirical data that the community can learn and put to use. Wenger discusses the importance of reifying information before it is presented to a group, team, or community so that the contents of the data are not misunderstood or presented in a manner that renders the facts useless. Understanding the more general meaning of new data and learning how to apply new information as new or to existing processes is the main goal of the reification process.

Wenger also emphasizes the importance of participation in the community. Participating in all of the community processes will ensure that all parties involved—and their opinions and perspectives—are represented in the shaping of new information. Wenger notes that participation is also a social practice, and it is therefore important to the cohesiveness of the community and fostering a level of trust amongst its members. Additionally, Wenger explains that reifying abstract ideas and information cannot be truly accomplished without a participative group of members taking part in the process. In short, participation within the community of practice is crucial to the survival of its core as well as to new data that enters and reshapes the patterns and ideals of the group itself.

PROPER CARE AND FEEDING OF A COMMUNITY OF PRACTICE

In order to function properly and to grow, a community of practice needs a common interest, a place to meet, and a means by which to practice and access tools that make that practice possible. The common interest of the group must be defined, and the group must be made up of and maintained by people who have a high level of experience and at least some level of expertise with the subject that is the common interest. The community of practice must be able to engage in activities pertaining to their interest. A true community of practice will allow users to act singularly as well as in group formats to create new ideas and methods of best practices, and to improve and help progress the field of study. Having the place and the means to engage in these activities are crucial to the upkeep of a community of practice and allow for important problem solving, discussions, use of pertinent tools and information, and development of new data into information and wisdom.

THE FUTURE OF COMMUNITIES OF PRACTICE AND INTEREST

Like many other things, today's community of practice is headed the way of the World Wide Web and will rely heavily on the Internet, wireless communication, and mobile devices more and more with each passing day. New ways of communicating more rapidly and from distances farther away allow for larger and more seasoned communities of practice to be developed. Just several decades ago, those with similar interests and practitioners of the same trades would have to live in the same geographic region in order to be a part of the same community of interest. In the twenty-first century, chat rooms, online bulletins, Web sites, and instant messenger systems have all created a virtual atmosphere that makes it possible to be a member of a community regardless of where—or when—that member practices.

COMPETITIVE ADVANTAGE

Many firms strive for a competitive advantage, but few truly understand what it is or how to achieve and keep it. A competitive advantage can be gained by offering the consumer a greater value than the competitors, such as by offering lower prices or providing quality services or other benefits that justify a higher price. The strongest competitive advantage is a strategy that that cannot be imitated by other companies.

Competitive advantage can be also viewed as any activity that creates superior value above its rivals. A company wants the gap between perceived value and cost of the product to be greater than the competition.

Michael Porter defines three generic strategies that firms may use to gain competitive advantage: cost leadership, differentiation, and focus. A firm utilizing a cost leadership strategy seeks to be the low-cost producer relative to its competitors. A differentiation strategy requires that the firm possess a "non-price" attribute that distinguishes the firm as superior to its peers. Firms following a focus approach direct their attention to narrow product lines, buyer segments, or geographic markets. "Focused" firms will use cost or differentiation to gain advantage, but only within a narrow target market.

New businesses should be especially focused on competitive advantage. In the twenty-first century business world, it is considered usual for any starting business to

already understand some advantage that it can use to enter the market, but there are those that do not spend enough time preparing their resources. According to Scott Shane's *The Illusions of Entrepreneurship* (2008), more than one-third of starting businesses say they do not have competitive advantages.

CRITICAL AND CORE TASKS

Plunkett's Almanac of Middle Market Companies 2008 defines critical tasks as parts of the company that are used to gain competitive advantage. These parts are different for every company, based on their markets and concentrations. Many companies use research and development as a critical task, the goal being to find new products for their customers, or new ways to distribute their services. Other critical tasks can include various analyses of the markets, and strategic cooperation with other businesses.

Core tasks, on the other hand, are tasks the company routinely carries out—the normal mechanics of business. Core tasks can include human resources and production. These are tasks that do not necessarily give a competitive advantage, but they are necessary for the business to operate. When seeking competitive advantage, companies should distinguish between critical and core tasks, and allocate resources accordingly.

COST ADVANTAGE RESULTING FROM EFFICIENCY

Efficiency is the ratio of inputs to outputs. Inputs can be any materials, overhead, or labor that is assigned to the product or service. The outputs can be measured as the number of products produced or services performed. The firm that can achieve the highest efficiency for the same service or product can widen the gap between cost and perceived value and may have greater profit margins.

There are many ways a company can increase efficiency. Efficiency is enhanced if, holding outputs constant, inputs are reduced; or if holding inputs constant, outputs are increased. Inputs can be reduced in many ways. Labor inputs can be reduced if employees are better trained so that time spent on each individual output is decreased.

Decreasing waste can decrease materials needed. If a method can be devised to decrease waste, it would increase efficiency. For instance, a bottling plant might determine that 10 gallons of liquid are spilled every day as a result of the bottling process. If the amount of lost liquid can be reduced, efficiency will increase.

Outputs can be increased by increasing the number of units a machine can produce in a given period of time. Decreasing downtime can also increase outputs. For example, if a machine regularly breaks down and is out of order for two hours a day, finding a way to eliminate this downtime would increase the number of outputs.

It is often argued that large companies, by definition, are able to be more efficient because they can achieve economies of scale that others are not able to reach. Large companies usually offer more products in each product line, and their products may help to satisfy many different needs. If a consumer is not sure of the exact product he needs, he can go to the larger producer and be confident that the larger producer has something to offer. The consumer might believe that the smaller producer may be too specialized. Larger companies can cater to a larger population because of sheer size, while smaller companies have fewer resources and must specialize or fall victim to larger, more efficient companies.

THE STUDY OF COMPETITION

How does an organization begin when defining competitive advantages? The study of its market and resources goes hand in hand with the study of its competition. In order to understand what makes an organization special, the managers must study competitors and the competing ways of obtaining supplies, marketing products, and innovating. Only when a company is well aware of how its competitors conduct business will it be able to separate itself and find a niche where it can perform at its best.

Mark Blazey's *Insights to Performance Excellence 2008* gives several examples of what a company should look for when studying its competitors. First, naturally, a company must know who its competitors are. Knowing how many of them exist in the market and in what nations they operate is also useful. What sort of characteristics do such competitors have? How can a company obtain information about competition, short of corporate espionage? Industry journals can be very effective, and public companies release consistent financial reports that are open to be studied. Reading publications on new technology can help a company prepare to accept new software or digital tools that can be used to further its business. Studying the competition can show a company how to create differentiation—unique and beneficial qualities that give competitive advantage.

PRODUCT DIFFERENTIATION

Product differentiation is achieved by offering a valued variation of the physical product. The ability to differentiate a product varies greatly along a continuum depending on the specific product. There are some products that do not lend themselves to much differentiation, such as beef, lumber, and notebook paper. Some products, on the other hand, can be highly differentiated. Appliances, restaurants, automobiles, and even batteries can all be customized and highly differentiated to meet various consumer needs. In *Principles of Marketing* (1999), authors Gary Armstrong and Philip Kotler note that

differentiation can occur by manipulating many characteristics, including features, performance, style, design, consistency, durability, reliability, or reparability. Differentiation allows a company to target specific populations.

It is easy to think of companies that have used these characteristics to promote their products. Maytag has differentiated itself by presenting "Old reliable," the Maytag repairman who never has any work to do because Maytag's products purportedly function without any problems and do not require repairs. The Eveready Battery Co./Energizer has promoted their products' performance with the Energizer Bunny ® that "keeps going and going."

Many chain restaurants differentiate themselves with consistency and style. If a consumer has a favorite dish at her local Applebee's restaurant, she can be assured it will look and taste the same at any Applebee's restaurant anywhere in the country.

In the auto industry, durability is promoted by Chevrolet's "Like a Rock" advertising campaign.

SERVICE DIFFERENTIATION

Companies can also differentiate the services that accompany the physical product. Two companies can offer a similar physical product, but the company that offers additional services can charge a premium for the product. Mary Kay cosmetics offers skin-care and glamour cosmetics that are very similar to those offered by many other cosmetic companies; but these products are usually accompanied with an informational, instructional training session provided by the consultant. This additional service allows Mary Kay to charge more for their product than if they sold the product through more traditional channels.

In the personal computer business, Dell claims to provide excellent technical support services to handle any glitches that may occur once a consumer has bought their product. This 24-hour-a-day tech support provides a very important advantage over other PC makers, who may be perceived as less reliable when a customer needs immediate assistance with a problem.

PEOPLE DIFFERENTIATION

Hiring and training better people than the competitor can become an immeasurable competitive advantage for a company. A company's employees are often overlooked, but should be given careful consideration. This human resource-based advantage is difficult for a competitor to imitate because the source of the advantage may not be very apparent to an outsider. As a *Money* magazine article reported, Herb Kelleher, CEO of Southwest Airlines, explains that the culture, attitudes, beliefs, and actions of his employees constitute his strongest competitive advantage: "The intangibles are more important than

the tangibles because you can always imitate the tangibles; you can buy the airplane, you can rent the ticket counter space. But the hardest thing for someone to emulate is the spirit of your people."

This competitive advantage can encompass many areas. Employers who pay attention to employees, monitoring their performance and commitment, may find themselves with a very strong competitive advantage. A well-trained production staff will generate a better quality product. Yet a competitor may not be able to distinguish if the advantage is due to superior materials, equipment, or employees.

People differentiation is important when consumers deal directly with employees. Employees are the frontline defense against waning customer satisfaction. The associate at Wal-Mart who helps a customer locate a product may result in the customer returning numerous times, generating hundreds of dollars in revenue. Home Depot prides itself on having a knowledgeable sales staff in their home improvement warehouses. The consumer knows that the staff will be helpful and courteous, and this is very important to the consumer who may be trying a new home improvement technique with limited knowledge on the subject.

Another way a company can differentiate itself through people is by having a recognizable person at the top of the company. A recognizable CEO can make a company stand out. Some CEOs are such charismatic public figures that to the consumer, the CEO is the company. If the CEO is considered reputable and is well liked, it speaks very well for the company, and consumers pay attention. Not surprisingly, national media coverage of CEOs has increased tremendously over the past two decades.

IMAGE DIFFERENTIATION

Armstrong and Kotler pointed out in *Principles of Marketing* that when competing products or services are similar, buyers may perceive a difference based on company or brand image. Thus companies should work to establish images that differentiate them from competitors. A favorable brand image takes a significant amount of time to build. Unfortunately, one negative impression can kill the image practically overnight. Everything that a company does must support their image. Ford Motor Co.'s former "Quality is Job 1" slogan needed to be supported in every aspect, including advertisements, production, sales floor presentation, and customer service.

Often, a company will try giving a product a personality. It can be done through a story, symbol, or other identifying means. Most consumers are familiar with the Keebler Elves and the magic tree where they do all of the Keebler baking. This story of the elves and the tree gives Keebler cookies a personality. When consumers

purchase Keebler cookies, they are not just purchasing cookies, but the story of the elves and the magic tree as well. A symbol can be an easily recognizable trademark of a company that reminds the consumer of the brand image. The Nike "swoosh" is a symbol that carries prestige and makes the Nike label recognizable.

QUALITY DIFFERENTIATION

Quality is the idea that something is reliable in the sense that it does the job it is designed to do. When considering competitive advantage, one cannot just view quality as it relates to the product. The quality of the material going into the product and the quality of production operations should also be scrutinized. Materials quality is very important. The manufacturer that can get the best material at a given price will widen the gap between perceived quality and cost. Greater quality materials decrease the number of returns, reworks, and repairs necessary. Quality labor also reduces the costs associated with these three expenses.

INNOVATION DIFFERENTIATION

When people think of innovation, they usually have a narrow view that encompasses only product innovation. Product innovation is very important to remain competitive, but just as important is process innovation. Process innovation is anything new or novel about the way a company operates. Process innovations are important because they often reduce costs, and it may take competitors a significant amount of time to discover and imitate them.

Some process innovations can completely revolutionize the way a product is produced. When the assembly line was first gaining popularity in the early twentieth century, it was an innovation that significantly reduced costs. The first companies to use this innovation had a competitive advantage over the companies that were slow or reluctant to change.

As one of the first Internet service providers, America Online offered a unique innovation for accessing the nascent Internet—its unique and user-friendly interface. The company grew at a massive rate, leading the rapidly developing Internet sector as a force in American business. While most innovations are not going to revolutionize the way that all firms operate, small innovations can reduce costs by thousands or even millions of dollars, and large innovations may save billions over time.

COMPETITIVE ADVANTAGE THROUGH STRATEGIC COOPERATION

In Jeschke's 2008 guide, *Gaining Competitive Advantage through Strategic Partnerships in the Supply Chain*, three different kinds of partnerships are outlined as possible ways to increase market value and gain competitive advantages through cooperation by businesses.

Jeschke's first type of cooperation is vertical cooperation, a partnership along supply or production lines. Two companies agree to sell to or buy from each other in a particular relationship from which they both profit, usually through a contract.

The second type of advantageous partnership is horizontal cooperation, the most common cooperation sought to increase competitive advantage. Two companies in the same market combine their strengths in a particular area to gain more of that market, successfully creating a gap between them and the competition. However, the two companies do not merge; instead, they remain in competition themselves, with individual interests, cooperating for the sake of the benefits they both receive.

The third type of cooperation is the conglomerate partnership. Businesses which are related neither on the vertical nor the horizontal field cooperate for a specific reason in a conglomerate relationship. Often, the companies serve complementary goods, such as two foods often served together. Though their supply and production lines do not intersect, they are both selling to the same market, and so they gain an advantage over their separate competitors through cooperation.

COMPETITIVE ADVANTAGE IN THE GLOBAL MARKET

Many organizations focus on differentiation and gaining competitive advantage internationally. This has become more common as globalization has increased. Anthony Henry, in his 2008 *Understanding Strategic Management*, gives several ways companies seek to gain advantage in international markets, capitalizing on the differences between their nation and rival nations.

Wage differences are often utilized to give international competitive advantage. One country might be able to do the same amount of work as another but at a lesser wage for its workers, saving money that can be used to develop more products or market services. Outsourcing is one common way of using this cost-difference in order to raise competitive advantage. Resource costs can also differ in the global market, allowing some companies to save on production costs in the same manner.

Henry also points out that policies across nations are often in flux, changing based on governmental decision. Sharp-eyed companies will watch for a change in policy in competing nations that it can use for its benefit. The risks of various investments are often affected. Watchful organizations can also use societal factors as advantages. Knowledge of the way business is practiced, the rules and mores that control its behavior, is very useful to companies looking for gains in other countries.

SUSTAINABLE COMPETITIVE ADVANTAGE

The achievement of competitive advantage is not always permanent or even long lasting. Once a firm establishes itself in an area of advantage, other firms will follow suit in an effort to capitalize on their similarities. A firm is said to have a "sustainable" competitive advantage when its competitors are unable to duplicate the benefits of the firm's strategy. In order for a firm to attain a "sustainable" competitive advantage, its generic strategy must be grounded in an attribute that meets four criteria. It must be:

- Valuable—it is of value to consumers.

- Rare—it is not commonplace or easily obtained.

- Inimitable—it cannot be easily imitated or copied by competitors.

- Non-substitutable—consumers cannot or will not substitute another product or attribute for the one providing the firm with competitive advantage.

SELECTING A COMPETITIVE ADVANTAGE

A company may be lucky enough to identify several potential competitive advantages, and it must be able to determine which are worth pursuing. Not all differentiation is important. Some differences are too subtle, too easily mimicked by competitors, and many are too expensive. A company must be sure the consumer wants, understands, and appreciates the difference offered.

The maker of expensive suits may offer its suits in the widest array of colors, but if 95 percent of the consumers wear only black and navy blue suits, then the wide array of colors adds little perceived value to the product. Variety would not become a competitive advantage, and would be a waste of resources. A difference may be worth developing and promoting, advise Armstrong and Kotler, if it is important, distinctive, superior, communicable, preemptive, affordable, and profitable.

A competitive advantage can make or break a firm, so it is crucial that all managers are familiar with competitive advantages and how to create, maintain, and benefit from them.

COMPETITIVE INTELLIGENCE

Intelligence is information that has been analyzed for decision making. It is important to understand the difference between information and intelligence. Information is the starting point; it is readily available numbers, statistics, bits of data about people, companies, products, and strategies. As a matter of fact, information overload is one of the leading problems of today's executive and the top reason for needing a competitive intelligence expert. Information becomes intelligence when it is distilled and analyzed. Combining this idea with those of competition or competitors leads to the concept of gathering and analyzing information about competitors for use in making management decisions. Competitive intelligence provides a link between information and business strategies and decisions. It is the process of turning vast quantities of information into action.

The field of competitive intelligence, as a profession, is relatively new in the United States. An indication of the importance of competitive intelligence is the growth, since 1986, of the Society of Competitive Intelligence Professionals (SCIP), an organization committed to developing, improving, and promulgating the methods, techniques, and ethical standards of the group. SCIP defines competitive intelligence as "the legal and ethical collection and analysis of information regarding the capabilities, vulnerabilities, and intentions of business competitors conducted by using information databases and other 'open sources' and through ethical inquiry." A major research firm in the field, Fuld & Company, Inc., defines it as "information that has been analyzed to the point where you can make a decision and a tool to alert management to early warning of both threats and opportunities. Competitive intelligence offers approximations and

best views of the market and the competition. It is not a peek at the rival's financial books." Competitive intelligence can help managers discover new markets or businesses, beat the competition to market, foresee competitors' actions, determine which companies to acquire, learn about new products and technologies that will affect the industry, and forecast political or legislative changes that will affect the company.

EXAMPLES

Examples of competitive intelligence include stock traders who analyze the data on prices and price movements to determine the best investments. These stock traders have the same data as other traders, but analysis of the data separates them from others. Another example is the Japanese automobile industry's analysis of the U.S. automobile market in the 1970s. High gasoline prices and smaller families created a demand in the United States for smaller, more fuel-efficient cars. Japanese automakers employed competitive intelligence methods to determine this trend and then made manufacturing decisions based on it, beating the U.S. Big Three to market with high quality, fuel-efficient cars. In the late 2000s, this situation is being replayed in a fashion, as high gas prices again have people turning away from large American-made SUVs and trucks and toward smaller, more fuel-efficient Asian (Japanese and Korean) cars.

ETHICAL METHODS

Competitive intelligence is not spying on the competition. It has been associated in the past with the political and military intelligence used during the Cold War era. Because of this association, many people think that competitive intelligence uses illegal, shady, or unethical means to gather information about competitors. Visions of wiretapping, bribing competitors' employees, or stealing information come to mind. This is not true today. Such techniques can damage the reputation and image of corporations and are not worth the risk. SCIP takes a strong position on the importance of ethics and developed a code of ethics for members. Note the words, "legal and ethical," and the emphasis on retrieving data from "open sources." Competitive intelligence experts use openly available information. They do dig into public records and government databases and use the latest technology (such as satellite photoreconnaissance and software tools such as spiders) to help gather and analyze large datasets. However, the professionals and companies for which they work do not use illegal methods.

THE PROCESS

The wide availability of information on the Web makes competitive intelligence more accessible to medium-size and small firms. Software tools to analyze and disseminate intelligence also make it easier to implement competitive intelligence tools. The process of competitive intelligence is outlined in the following steps:

1. Setting intelligence objectives (i.e., designing the requirements)
2. Collecting and organizing data about the industry and competitors
3. Analyzing and interpreting the data
4. Disseminating the intelligence

Setting the objectives. A clear statement of the intelligence needs of the organization should be outlined by management. If this step is ignored, the competitive intelligence department will be bogged down with too much information and possibly distracted by ad-hoc requests for data. This step is necessary regardless of where in the organization the competitive intelligence department is located. Some corporations have competitive intelligence report directly to the CEO; in others, it is located in marketing or in research and development. The role of any competitive intelligence program should be driven by the needs of the corporation, especially areas that have key performance consequences.

Collecting and organizing the data. The online revolution has enhanced ease in collecting and obtaining information, but the competitive intelligence expert must constantly be alert to new sources and places for finding information. The most obvious data collection sources include trade magazine and newspaper articles, company Web sites, newswires, chat forums, and Web search engines. Free information on industries is available via census data on government Web pages. Similarly, free public company information from U.S. Securities and Exchange Commission (SEC) filings, such as the 10-K and 10-Q report, can be easily obtained on the Web. These corporate reports yield detailed financial and product information and also identify mergers, acquisitions, and legal proceedings against the company. Other channels for fee-based data are information aggregators such as Factiva, Lexis Nexis, Hoover's Online, MergentOnline, and Standard and Poors' databases. Analyst reports and market research reports from companies such as Jupiter, Forrester Research, and Frost and Sullivan, although usually quite expensive to acquire, provide detailed analyses on companies and industries.

Analyzing and interpreting the data. Analysis and interpretation is the real core of competitive intelligence. Collected data must be transformed into "qualitative" information (i.e., intelligence). Two of the most popular

web-search tools for businesses are ComScore and Hitwise. ComScore uses a panel of people who are trained in web searches; they constantly monitor the Internet for relevant information. Hitwise uses a data-collection program to automatically search and download certain Web pages.

Regardless of what tool is used, the next step is to interpret the information. Lehmann and Winer outline four important aspects competitive intelligence professionals need to interpret about competitors: their current and future objectives, their current strategies, their resources, and their future strategies. Once this assessment is complete, competitive intelligence professionals measure their companies in comparison to competitors; this is known as benchmarking. From the benchmarking process, trend identification and prediction can be made.

Disseminating the information. Dissemination is the delivery of current, real-time intelligence to the decision makers in the firm at the time they need it. Timely dissemination is essential if the intelligence is to be perceived as trustworthy. The current philosophy is that delivering to people at all levels in the organization enhances competitive advantages.

HISTORY AND LITERATURE

Competitive intelligence is, in part, an outgrowth of the military intelligence field. Within corporations, it is a direct outgrowth, or evolution, of market research, which uses investigation (especially understanding the strategies, capabilities, and options of competitors or rivals) to examine the marketplace. Examining marketing research books at the time competitive intelligence emerged helps identify the shift. Market research differs from competitive intelligence in that it is usually conducted when a new product is in the planning or development stage and often utilizes surveys, focus groups, and other research tools to study the market. Competitive intelligence requires a more continuous and structured scanning of competitors and the environment. William T. Kelly's work introduced the field of intelligence in his 1965 text. Michael E. Porter's books, aimed at practitioners, identify competitive intelligence as a needed business function. Porter's books outline the tools for analyzing competitors and evaluating their strengths and weaknesses, which can then lead to opportunities. Leonard Fuld's work helped revolutionize and define the field. Fuld is a key writer and the founder of a major consulting firm that trains people in competitive intelligence methods and techniques.

THE COMPETITIVE INTELLIGENCE EXPERT

The competitive intelligence expert or analyst usually has a strong business background, combined with experience in the company. Likely candidates for the assignment are generally research-oriented people in sales, marketing, or research and development. Combining research skills with communication and writing skills is essential. Because of the research orientation of the job, people with library or information science backgrounds in the company are logical choices.

ORGANIZATIONS

The Society of Competitive Intelligence Professionals (SCIP). The Society of Competitive Intelligence Professionals (SCIP), established in 1986, is a global, nonprofit, membership organization for everyone involved in creating and managing business knowledge. The mission of SCIP is to enhance the skills of knowledge professionals to help their companies achieve and maintain a competitive advantage. SCIP publishes the following influential periodicals:

- *Competitive Intelligence Magazine.* A bimonthly publication with articles by peers in the competitive intelligence profession.

- *Journal of Competitive Intelligence and Management.* A quarterly, international, blind-refereed journal covering all aspects of competitive intelligence and related management fields. This journal seeks to further the development of competitive intelligence and to encourage greater understanding of the management of competition.

- *Competitive Intelligence Review.* A journal archive for peer-reviewed research and case studies focused on the practice of competitive intelligence. The archive includes contents listings, summaries, and articles from past journal issues.

- *SCIP Online.* SCIP's e-mail newsletter, sent free to all members twice a month.

Competitive Intelligence Division of The Special Libraries Association (SLA). This organization was formed in 2004 as an association for corporate librarians and information professionals who have evolved beyond collecting and managing information, to provide examination of data that can help their organizations succeed. The Competitive Intelligence Division encompasses all aspects of competitive intelligence including: (1) planning, (2) identifying decision makers' intelligence needs, (3) collecting and analyzing information, (4) disseminating intelligence products and services, (5) evaluating intelligence activities, (6) promoting intelligence services among a client base, and (7) additional industry-specific issues. Competitive Intelligence Division members concentrate on developing their competitive intelligence skills to assist them in functioning more effectively as intelligence professionals within their

respective organizations. Held in Seattle, the CI division's 2008 conference entertained such speakers as Vinton Cerf, VP of Google, and Seth Godin, business author.

Fuld & Company, Inc. Fuld & Company, Inc., is a research and consulting firm in the field of business and competitive intelligence. This company, founded by Leonard Fuld in 1979, is a full-service business intelligence firm providing: (1) research and analysis, (2) strategic consulting, (3) business intelligence process consulting, and (4) training to help clients understand the external competitive environment.

The Institute for Strategy and Competitiveness at Harvard School of Business. This institute, led by Michael E. Porter, studies competition and its implications for company strategy; the competitiveness of nations, regions and cities; and solutions to social problems. Based at Harvard Business School, the Institute is dedicated to extending the research pioneered by Professor Porter and disseminating it to scholars and practitioners on a global basis.

Strategic Insights. Strategic Insights is a company that conducts competitive intelligence research on a global level, offering companies a thorough and legal way to gain their information.

SIS International Research. SIS is a competitive intelligence firm that does extensive research and conducts interviews with relevant people, including customers, government officials, executives, and suppliers.

The Mind Company. Based in Argentina, the Mind Company utilizes teams of trained experts in competitive intelligence to help organizations across the world. They pride themselves on being internationally capable.

Competitive Intelligence Services, Inc. CIS is an American competitive intelligence company that works to establish connections with organizations, learn their goals and markets, and then aid them in gaining competitive advantage through their intelligence services. To avoid any conflict of interest, CIS only takes one business per particular industry or immediate market.

COMPLEXITY THEORY

The basic premise of complexity theory is that there is a hidden order to the behavior (and evolution) of complex systems, whether that system is a national economy, an ecosystem, an organization, or a production line. In business and finance, complexity theory places its focus on the

ways a factory or company resemble an ecosystem or market, rather than a machine "whose parts and functions have been plucked out in advance," according to David Berreby. He maintains that the organization of systems is no accident, but "the results of laws of nature that we don't yet fully understand." Once understood, managers will learn that if left to function on their own, systems organize themselves, bringing about "order for free."

Proponents of complexity theory believe specific traits are shared by most complex systems. These systems are the combination of many independent actors behaving as a single unit. These actors respond to their environment, much as stock markets respond to news of changing economies, genes respond to natural selection, or the human brain responds to sensory input. All of these "networks" also act as a single system made of many interacting components. Complexity theory attempts to explain how even millions of independent actors can unintentionally demonstrate patterned behavior and properties that, while present in the overall system, are not present in any individual component of that system.

Complexity theory was founded on researchers' attempts to rationalize the behavior of large and complex systems, believing they cannot be explained by usual rules of nature. It attempts to discover how the many disparate elements of a system work with each other to shape the system and its outcomes, as well as how each component changes over time. It is also one way to express the perceived domination of systems over their myriad smaller influences.

While complexity theory is strikingly similar to chaos theory, complexity theorists maintain that chaos, by itself, does not account for the coherence of self-organizing, complex systems. Rather, complex systems reside at the edge of chaos—the actors or components of a system are never locked in to a particular position or role within the system, but they never fall completely out of control. As M. Mitchell Waldrop states in *Complexity*, "The edge of chaos is the constantly shifting battle zone between stagnation and anarchy, the one place where a complex system can be spontaneous, adaptive, and alive."

Sherry Turkle, author of *Life on the Screen* and professor of sociology of science at the Massachusetts Institute of Technology (MIT), feels that technology has helped bring the issues of complexity theory to life. She asserts that computers helped persuade us that knowing all the parts of a system (or a computer) cannot give anyone the ability to foresee all the complexity that can arise as all of those parts interact.

ORIGINS OF COMPLEXITY THEORY

Much of the research on complexity theory originates from the Santa Fe Institute in New Mexico, a mecca for those studying complexity theory. George A. Cowan,

head of research at the Los Alamos nuclear laboratory, founded the Santa Fe Institute in the mid-1980s. Scientists at the institute claim that through the study of complexity theory, one can see not only the laws of chaos, but also those of order—through which a powerful explanation for how any collection of components will organize itself can be generated.

One of complexity theory's leading proponents is Stuart Kauffman, author of *At Home in the Universe: The Search for the Laws of Self-Organization and Complexity*. Also a member of the Santa Fe Institute, Kauffman states, "Life exists at the edge of chaos. I suspect that the fate of all complex adapting systems in the biosphere—from single cells to economies—is to evolve to a natural state between order and chaos, a grand compromise between structure and surprise." Kauffman's theories originated during his pre-medicine days, when his studies of genetics began to inspire questions about DNA and genetic structures. Kauffman felt that there had to be some kind of built-in order, that trial and error was too much of a long shot to be responsible for the perfect biomolecular structure of the human genome.

Other researchers with a stronger focus on the business side of complexity theory are Howard Sherman and Ron Schultz, authors of *Open Boundaries* and fellows at Santa Fe Center for Emergent Strategies in collaboration with the Santa Fe Institute. They believe business today is faster and nonlinear (effects are not proportional to their causes), and that "experts" cannot predict which products or companies will succeed. Sherman and Schultz assert that competitive advantage is fleeting, and that change can rapidly turn assets into dead weight.

Another major contributor to complexity theory is John Holland, a computer scientist and professor at the University of Michigan. Holland designed the genetic algorithm based on the idea that components of complex systems can be broken down into building blocks, whose characteristics can then be represented in code. In simulations, units of code recombine to make "offspring"; the best of these offspring are allowed to reproduce, while the worst are discarded. As the algorithm works, better code evolves, and the results can be translated into real-world applications.

DETAILS OF COMPLEXITY THEORY

A complex system is defined as one in which many independent agents interact with each other in multiple (sometimes infinite) ways. This variety of actors also allows for the "spontaneous self-organization" that sometimes takes place in a system. This self-organization occurs without anyone being in charge or planning the organization. Rather, it is more a result of organisms/agents constantly adapting to each other. The complex

systems are also adaptive (i.e., they always adapt in a way that benefits them). Waldrop suggests an analogy to the way the human brain adapts to learn from experience.

Another important concept in complexity theory is that there is no master controller of any system. Rather, coherent system behavior is generated by the competition and cooperation between actors that is always present. The components of a system do have different levels of organization—like an organization made up of divisions, which contain different departments, which are in comprised of different workers. However, the important differentiation from this "organization," made by John Holland in *Complexity*, is that "complex adaptive systems are constantly revising and rearranging their building blocks as they gain experience. A firm will promote individuals who do well and (more rarely) will reshuffle its organizational chart for greater efficiency. Countries will make new trading agreements or realign themselves into whole new alliances."

Far From Equilibrium. A complex system is often considered to be under the rules of chaos theory, giving it the same unpredictability that is found in weather patterns and wildfire. Most large organizations and markets fall in this category—they are not fully definable or repetitive. The *CIMA Learning System 2007* guide calls this being "far from equilibrium." Complex systems are all far from equilibrium, straddling, as it has been mentioned before, the edge of chaos. Equilibrium, an inherently predictable and static condition, is not possible or even desirable for complex systems. Instead, managers and leaders of the organization should look for regularities, patterns of behavior that resurface in the complex interactions they deal with. These regularities occur because the system has not reached complete chaos, though it is far from equilibrium.

Emergence. Another important part of complexity theory is its assumption that there are principles underlying all "emergent properties," or traits that emerge from the interactions of many different actors. David Berreby uses the analogy of an ant colony that switches to a better food source. No individual ant made the decision; it was a result of their interactions.

In organizations, negative emergence usually requires some sort of action on the part of the managers, such as new guidelines or innovation. In complex systems, emergence often generates patterns of change, which can best be thought of as friction between different organization structures. Xu, Tjoa, and Chaudhry, in their 2007 book *Research and Practical Issues of Enterprise Information Systems II*, call this friction "temporal conflicts." They are temporal because they exist as a phenomenon of emergence and are usually dealt with by the organization,

through a cooperation mechanism which brings enough order to the conflict to end it. Positive emergence can occur as well, usually through interconnectivity, and is often used as an example of the benefits of complex systems. Positive emergence requires no reaction on the part of the managers of the organization, except to seize the opportunities presented.

Connectivity. Bogg and Geyer, in their book *Complexity, Science, and Society* (2007), point out that the more complex systems become, the more they are subject to connectivity and interconnectivity. Connectivity is the sum of the multiple, often irregular, connections found in complex systems. A good example in the business world is a publicly traded company. Each of the stockholders has a personal history and a set of particular desires for the stock he or she holds, while each of the employees and managers in the company has a personal history that affects how he or she approaches his or her work. The many different desires of these individuals, though not necessarily communicated, often contradict. However, since everyone is united in trying to make the company successful, they are connected along certain common goals, while opposed along other lines. This means that the company has a vast resource—a collection of talent, skill, contacts, funds, and experience—that it can use for its benefit through the state of connectivity. If left alone this resource might work against itself, but with connectivity the actions of the company and its stockholders are all related, giving the company a powerful tool to use, if it can. Connectivity generally leads to the positive emergence such as co-evolution and creativity.

Co-evolution. Former CEO Gerard Fairtlough calls co-evolution "heterarchical...a process of learning for all involved," in his 2007 book, *The Three Ways of Getting Things Done: Hierarchy, Heterarchy, and Responsible Autonomy*. According to Fairtlough, co-evolution is superior to adaptation, because it involves more the one party. Adaptation is a one-way, close to equilibrium, a type of reaction; co-evolution occurs when there are multiple entities in the complex system, supporting each other and trying to reach common goals. Innovation is met with innovation, and every change for the better influences another positive change. Co-evolution occurs in most growing, complex systems, from the healthy internal workings of an organization to the competition seen in certain markets.

According to Fairtlough, organizations can foster co-evolution through several different approaches. Some companies may prefer to encourage organic structures, letting employees use their creativity. Others may wish to create programs through which teams and departments learn to trust each other more, leading to a greater

occurrence of connectivity and more chances for positive emergences such as co-evolution. Other companies may encourage co-evolution through negotiations with their markets or competitors.

Path-dependent and Path-creative. As analysts have studied complex systems and the types of emergence that occur within them, a behavior has been observed which was called *path-dependence*. As Uhl-Bien and Marion observe in their *Complexity Leadership* (2007), path-dependence occurs when complex systems go through the same series of actions regardless of most outside circumstances. They are stuck, in other words, in a routine neither planned nor consciously chosen—a natural result of complexity. For this reason, path-dependence is a pitfall seen in most organizations globally, regardless of government policy or even company intent. Some analysts look at path-dependence as a complex system's urge to correct itself into equilibrium, to leave the edge of chaos and assume a repetitive, predictable existence. The complex, in other words, has an inherent desire to become simple again. This can be dangerous for organizations that thrive on innovation, so Uhl-Bien and Marion advise instead that companies aim to become "path-creative" so that the state of evolution may avoid getting stuck in ruts. How an organization does this is a debated question.

Change in Complex Systems. One of the defining characteristics of complex systems is the inability to predict the outcome of any given change to the system. Because a system depends on so many intricate interactions, the number of possible reactions to any given change is infinite. Minor events can have enormous consequences because of the chain of reactions they might incite. Conversely, major changes may have an almost insignificant effect on the system as a whole. Because of this, strong control of any complex system may be impossible. While it may have order, no one absolutely governs a complex system.

Scientists create computer simulations that enable them to better identify emerging patterns in a system. They also write modification programs allowing system components to adapt to changes in the environment without the absolute necessity of radical changes to the overall structure. Computers can use these simulations to design production schedules and optimize assembly line performance.

COMPLEXITY THEORY IN BUSINESS

Complexity theory is used in business as a way to encourage innovative thinking and real-time responses to change by allowing business units to self-organize. Sherman and Schultz (as related by Hout) argue that modern business

moves in a nonlinear fashion, with no continuity in the flow of competitive events, except when observed from hindsight. In order to effectively put complexity theory to work, however, organization leaders need to give up rigid control of these systems from above. Far more can be learned by stepping back from the day-to-day running of the organization and watching for emergent properties and organizational patterns. Those conditions or patterns that bring about the best solutions should be preserved whenever possible. Managers also need to allow organizations to evolve in response to ongoing messages from customers. As Hout states:

> No intelligence from on high can match the quality of solutions to market problems that arise from players who are constantly communicating with one another on the ground level. The invisible hand of the marketplace should displace the visible hand of the manager. The markets can determine where one team or initiative or company ends and another begins. Managers interfere at their peril.

Efforts to downplay management, as related by Hout, claim that "management as we have known it is too cumbersome for today's fast, unpredictable pace. A new kind of company wins now. The best management models don't adapt to the new economy; they emerge from it. It's no longer the survival of the fittest; it's the arrival of the fittest." Even so, putting the ideas of complexity theory to work does not mean management need rest on its laurels. Hout asserts that organizations' leaders retain an obligation to formulate a guiding vision for the company, provide effective leadership, express and encourage strong values and organizational beliefs, and provide avenues for open communication. Managers need to manage the way that accident and law interact, knowing how and where to push to keep the system from neither descending into chaos nor becoming rigidly ordered.

Letting an organization self-organize does not negate the need for strategy. Rather, it means that organizational strategy should evolve based on feedback and change as it occurs. By establishing a corporate strategy first, an organization defines itself through conditions that were previously in place, and becomes non-adaptive to continuously-evolving market conditions. Sherman and Schultz recommend the "try something and see what happens" mentality.

CONTRARY BELIEFS

The idea that allowing complex systems to self-organize will yield the best solutions has validity, but complexity theory is not a panacea for all organizations. The notions of complexity theory assume that people in these companies

are enthusiastic, intelligent, and can effectively work in teams—requiring less management than workers in more traditional, hierarchical, rigidly-controlled environments. Unfortunately, however, these fast-growing, evolutionary companies with bright, ambitious workers may need more management rather than less. Companies that are shaped and reshaped on such a frequent basis—constantly adapting to a changing business environment—lose some of the stability found at traditional corporate giants such as the industrial and automotive behemoths.

Uhl-Bien and Marion suggest that one of the main tenants of complexity theory (in relation to business) is that outside help is not required to maintain order. Complex systems, indeed, are capable of evolving within themselves, coming up with their own order and innovation through emergence and connectivity. Managers practicing the hands-off style of leadership hope that their organization will develop these natural patterns of order, but encouragement and maintenance is also needed. As is seen from the studies of path-dependence and negative emergence, complexity can result in the failing of businesses as easily as success. The wise manager will be aware of both benefits and drawbacks to trusting in complexity theory.

The modern corporation has a lot at stake. There are difficulties in teamwork and collaboration, with potential issues such as nonperforming team members, personality conflicts, opposing business styles, and the effects of stress on job performance. Organizational leaders need to effectively manage personnel and job performance, reward and groom talented performers, develop business relationships and networks, resolve conflict, and divest the company of nonperformers who may be holding the company back from adapting well to emerging trends and technologies. Other business leaders see emergent strategy as a problem, rather than a cure. According to Alan Kay, head of research and development at Disney Imaginering, "Most businesses do not move so fast that foresight, commitment, preemption, deterrence, and other traditional elements of strategy have lost their ability to build value. The best way to predict the future is to invent it."

Bernard Fingleton, in his 2007 book *New Direction in Economic Geography*, postulates that complexity theory provides a meeting place for mathematical analysis and more immediate, verbal models of business practice. He calls the two separate fields *complexity modeling* and *relational dialectics*. What complexity theory needs, Fingleton suggests, is a lexicon that can unite it with studies of business markets and practical applications for organizations. Complexity theory appears to be in the process of acquiring this definition, necessary for more practical uses, and time will tell if it reaches a point where businesses will be able to use common analysis and decision-making tools derived from complexity theory.

Some of complexity theory's leading experts, such as J. Doyne Farmer and Norman Packard, make a living advising companies and practically applying the ideas behind complexity theory to business areas such as corporate investment. Organizations putting the theory into practice include Xerox's Palo Alto Research Center (PARC), Applied Biosystems, and the United States Marine Corps. Complexity theory offers companies the opportunity to create new markets and establish new ways to spread emerging knowledge throughout the company—enabling the organization, as a whole, to respond faster and better to ongoing change.

COMPUTER-AIDED DESIGN AND MANUFACTURING

Computer-aided design (CAD), also known as computer-aided design and drafting (CADD), involves the entire spectrum of drawing with the aid of a computer—from straight lines to custom animation. In practice, CAD refers to software for the design of engineering and architectural solutions, complete with two- and three-dimensional modeling capabilities.

Computer-aided manufacturing (CAM) involves the use of computers to aid in any manufacturing process, including flexible manufacturing and robotics. Often outputs from CAD systems serve as inputs to CAM systems. When these two systems work in conjunction, the result is called CADCAM, and becomes part of a firm's computer-integrated manufacturing (CIM) process.

CADCAM systems are intended to assist in many, if not all, of the steps of a typical product life cycle. The product life cycle involves a design phase and an implementation phase. The design phase includes identifying the design needs and specifications; performing a feasibility study, design documentation, evaluation, analysis, and optimization; and completing the design itself. The implementation phase includes process planning, production planning, quality control, packaging, marketing, and shipping.

CAD systems can help with most of the design phase processes, while CAM systems can help with most of the implementation processes. The contributions of CAD and CAM systems are described below.

CAD SYSTEMS

CAD systems are a specialized form of graphics software, and thus must adhere to basic principles of graphics programming. All graphics programs work in the context of a graphics device (e.g., a window on a monitor, a printer, or a plotter). Graphics images are drawn in relation to a 2-D or 3-D coordinate system, of which there are several types.

A device coordinate system is 2-D and maps images directly to the points (pixels) of the hardware device. In order to facilitate device-independent graphics, a virtual device coordinate system abstracts the 2-D points into a logical framework.

Of course, the devices being designed are generally 3-D objects, which also require a world coordinate system for representing the space in which the objects reside, and a model coordinate system for representing each of the objects in that space. CAD software includes algorithms for projecting the 3-D models onto the 2-D device coordinate systems and vice versa.

CAD systems include several primitive drawing functions, including lines, polygons, circles and arcs, rectangles, and other simple shapes. From these primitives, 3-D composites can be constructed, and include cubes, pyramids, cones, wedges, cylinders, and spheres. These shapes can be drawn in any color, and filled with solid colors or other patterns (called hatching). In addition, basic shapes can be altered by filleting (rounding) or chamfering (line segmentation).

Based on the manipulation of basic shapes, designers construct models of objects. A skeletal wire form model is a 3-D representation that shows all edges and features as lines. A more realistic-looking model is called a solid model, which is a 3-D model of the object being designed as a unitary whole showing no hidden features. The solid model represents a closed volume. It includes surface information and data determining if the closed volume contains other objects or features.

Solid modeling involves functions for creating 3-D shapes, combining shapes (via union, intersection, and difference operations), sweeping (translational and rotational) for converting simple shapes into more complex ones, skinning (for creation of surface textures), and various boundary creation functions. Solid modeling also includes parameterization, in which the CAD system maintains a set of relationships between the components of an object so that changes can be propagated to following constructions.

Common shapes are constructed into features (e.g., slots, holes, pockets), which can then be included in a solid model of an object. Feature representation helps the user define parts. It also simplifies CAD software design because features are easier to parameterize than explicit interactions. Objects built from features are called parts. Since a product being designed is composed of several parts, many CAD systems include a useful assembly model, in which the parts are referenced and their geometric and functional relationships are stored.

CAD models can be manipulated and viewed in a wide variety of contexts. They can be viewed from any angle and perspective desired, broken apart or sliced, and even put through simulation tests to analyze for strengths and defects of design. Parts can be moved within their coordinate systems via rotation operations, which provide different perspectives of a part, and translation, which allows the part to move to different locations in the view space. In addition, CAD systems provide valuable dimensioning functionality, which assigns size values based on the designer's drawing.

The movement of these images is a form of animation. Often, CAD systems include virtual reality technology, which produces animated images that simulate a real-world interaction with the object being designed. For

example, if the object is a building, the virtual reality system may allow you to visualize the scene as if you were walking around the inside and the outside of the building, enabling you to dynamically view the building from a multitude of perspectives. In order to produce realistic effects, the system must depict the expected effects of light reflecting on the surface as it moves through the user's view space. This process is called rendering.

Rendering technology includes facilities for shading, reflection, and ray tracing. This technique, which is also used in sophisticated video games, provides a realistic image of the object and often helps users make decisions prior to investing money in building construction. Some virtual reality interfaces involve more than just visual stimuli. In fact, they allow the designer to be completely immersed in the virtual environment, experiencing kinesthetic interaction with the designed device.

Some CAD systems go beyond assisting in parts design and actually include functionality for testing a product against stresses in the environment. Using a technique called finite element method (FEM), these systems determine stress, deformation, heat transfer, magnetic field distribution, fluid flow, and other continuous field problems.

Finite element analysis is not concerned with all design details, so instead of the complete solid model, a mesh is used. Mesh generation involves computing a set of simple elements giving a good approximation of the designed part. A good meshing must result in an analytical model of sufficient precision for the FEM computation, but with a minimum number of elements in order to avoid unnecessary complexity.

In addition to FEM, some CAD systems provide a variety of optimization techniques, including simulated annealing and genetic algorithms (borrowed from the field of artificial intelligence). These methods help to improve the shape, thickness, and other parameters of a designed object while satisfying user-defined constraints (e.g., allowable stress levels or cost limitations).

When a designer uses CAD to develop a product design, this data is stored into a CAD database. CAD systems allow for a design process in which objects are composed of sub-objects, which are composed of smaller components, and so on. Thus CAD databases tend to be object-oriented. Since CAD designs may need to be used in CAM systems, or shared with other CAD designers using a variety of software packages, most CAD packages ensure that their databases conform to one of the standard CAD data formats. One such standard, developed by the American National Standards Institute (ANSI), is called Initial Graphics Exchange Specification (IGES).

Modern CAD systems offer a number of advantages to designers and companies. For example, they enable users to save time, money, and other resources by automatically generating standard components of a design, allowing the reuse of previously designed components, and facilitating design modification. Such systems also provide for the verification of designs against specifications, the simulation and testing of designs, and the output of designs and engineering documentation directly to manufacturing facilities. While some designers complain that the limitations of CAD systems sometimes serve to curb their creativity, there is no doubt that they have become an indispensable tool in electrical, mechanical, and architectural design.

CAM SYSTEMS

The manufacturing process includes process planning, production planning (involving tool procurement, materials ordering, and numerical control programming), production, quality control, packaging, marketing, and shipping. CAM systems assist in all but the last two steps of this process. In CAM systems, the computer interfaces directly or indirectly with the plant's production resources.

Process planning is a manufacturing function that establishes which processes and parameters are to be used, as well as the machines performing these processes. This often involves preparing detailed work instructions to machines for assembling or manufacturing parts. Computer-aided process planning (CAPP) systems help to automate the planning process by developing, based on the family classification of the part being produced, a sequence of operations required for producing this part (sometimes called a routing), together with text descriptions of the work to be done at each step in the sequence. Sometimes these process plans are constructed based on data from the CAD databases.

Process planning is a difficult scheduling problem. For a complex manufacturing procedure, there could be a huge number of possible permutations of tasks in a process requiring the use of sophisticated optimization methods to obtain the best process plan. Techniques such as genetic algorithms and heuristic search (based on artificial intelligence) are often employed to solve this problem.

The most common CAM application is numerical control (NC), in which programmed instructions control machine tools that grind, cut, mill, punch, or bend raw stock into finished products. Often the NC inputs specifications from a CAD database, together with additional information from the machine tool operator. A typical NC machine tool includes a machine control unit (MCU) and the machine tool itself. The MCU includes a data processing unit (DPU), which reads and decodes instructions from a part program, and a control loop unit (CLU), which converts the instructions into control signals and operates the drive mechanisms of the machine tool.

The part program is a set of statements that contain geometric information about the part and motion information about how the cutting tool should move with respect to the workpiece. Cutting speed, feed rate, and other information are also specified to meet the required part tolerances. Part programming is an entire technical discipline in itself, requiring a sophisticated programming language and coordinate system reference points. Sometimes parts programs can be generated automatically from CAD databases, where the geometric and functional specifications of the CAD design automatically translate into the parts program instructions.

Numerical control systems are evolving into a more sophisticated technology called rapid prototyping and manufacturing (RP&M). This technology involves three steps: forming cross sections of the objects to be manufactured, laying cross sections layer by layer, and combining the layers. This is a tool-less approach to manufacturing made possible by the availability of solid modeling CAD systems. RP&M is often used for evaluating designs, verifying functional specifications, and reverse engineering.

Of course, machine control systems are often used in conjunction with robotics technology, making use of artificial intelligence and computer controlled humanoid physical capabilities (e.g., dexterity, movement, and vision). These "steel-collar workers" increase productivity and reduce costs by replacing human workers in repetitive, mundane, and hazardous environments.

CAM systems often include components for automating the quality control function. This involves evaluating product and process specifications, testing incoming materials and outgoing products, and testing the production process in progress. Quality control systems often measure the products that are coming off the assembly line to ensure that they are meeting the tolerance specifications established in the CAD databases. They produce exception reports for the assembly line managers when products are not meeting specifications.

In summary, CAM systems increase manufacturing efficiency by simplifying and automating production processes, improve the utilization of production facilities, reduce investment in production inventories, and ultimately improve customer service by drastically reducing out-of-stock situations.

PUTTING IT ALL TOGETHER: COMPUTER INTEGRATED MANUFACTURING

In a CADCAM system, a part is designed on the computer (via CAD) then transmitted directly to the computer-driven machine tools that manufacture the part via CAM. Within this process, there will be many other computerized steps along the way. The entire realm of design, material handling, manufacturing, and packaging is often referred to as computer-integrated manufacturing (CIM).

CIM includes all aspects of CAD and CAM, as well as inventory management. To keep costs down, companies have a strong motivation to minimize stock volumes in their warehouses. Just-in-time (JIT) inventory policies are becoming the norm. To facilitate this, CIM includes material requirements planning (MRP) as part of its overall configuration. MRP systems help to plan the types and quantities of materials that will be needed for the manufacturing process. The merger of MRP with CAM's production scheduling and shop floor control is called manufacturing resource planning (MRPII). Thus, the merger of MRP with CADCAM systems integrates the production and the inventory control functions of an organization.

One interesting application of CADCAM technology is its use in dental procedures. Manufactured by Sirona Dental Systems Inc., the CEREC product allows dentists to create a 3D model of the tooth and then carve a restoration based on that model. As a result, patients can have a crown put into place in less time with fewer anesthetic injections.

Today's industries cannot survive unless they can introduce new products with high quality, low cost, and short lead time. CADCAM systems apply computing technology to make these requirements a reality, and promise to exert a major influence on design, engineering, and manufacturing processes for the foreseeable future.

COMPUTER-INTEGRATED MANUFACTURING

As its name implies, computer-integrated manufacturing (CIM) uses computer techniques to integrate manufacturing activities. These activities encompass all functions necessary to translate customer needs into a final product. CIM starts with the development of a product concept that may exist in the marketing organization; includes product design and specification, usually the responsibility of an engineering organization; and extends through production into delivery and after-sales activities that reside in a field service or sales organization. Integration of these activities requires that accurate information be available when needed and in the format required by the person or group requesting the data. Data may come directly from the originating source or through an intermediate database, according to Jorgensen and Krause. CIM systems have emerged as a result of the developments in manufacturing and computer technology. According to Kusiak, the computer plays an important role integrating the following functional areas of a CIM system:

- **Part and product design.** There are four phases that are crucial in part and product design. They include preliminary design, refinement, analysis, and implementation.

- **Tool and fixture design.** Tooling engineers using computer-aided design (CAD) tools to develop the systems or fixtures that produce the parts.

- **Process planning.** The process planner designs a plan that outlines the routes, operations, machines, and tools required. He or she also attempts to minimize cost, manufacturing time, and machine idle time while maximizing productivity and quality.

- Programming of numerically controlled machines and material handling systems.

- **Production planning.** There are two concepts used here, including materials requirement planning (MRP) and machine loading and scheduling.

- **Machining.** This is part of the actual manufacturing process, including turning, drilling, and face milling for metal removal operations.

- **Assembly.** After they are manufactured, parts and subassemblies are put together with other parts to create a finished product or subassembly.

- **Maintenance.** Computers can monitor, intervene, and even correct machine malfunctions as well as quality issues within manufacturing.

- **Quality control.** This involves three steps, including system design, parameter design, and tolerance design.

- **Inspection.** This stage determines if there have been errors and quality issues during the manufacturing of the product.

- **Storage and retrieval.** These tasks involve raw materials, work-in-process inventory, finished goods, and equipment.

CIM ORIGIN

The term *computer-integrated manufacturing* was coined by Dr. Joseph Harrington in his 1974 book bearing that name. Until the 1970s, the most aggressive and successful automation was seen in production operations. Discrete parts manufacturing used highly mechanized machines that were driven and controlled by cams and complex devices such as automatic screw machines. Process manufacturers made use of these cam-driven controllers and limit switches for operations such as heat treating, filling and canning, bottling, and weaving, states Robert Thacker of the Society of Manufacturing Engineers. The historical approach to automation focused on individual activities that result in the incorporation of large amounts of computerized activities. In the 1980s, managing information became an important issue.

CIM BENEFITS

According to the U.S. National Research Council, CIM improves production productivity by 40 to 70 percent, as well as enhances engineering productivity and quality. CIM can also decrease design costs by 15 to 30 percent, reduce overall lead time by 20 to 60 percent, and cut work-in-process inventory by 30 to 60 percent. Managers who use CIM believe that there is a direct relationship between the efficiency of information management and the efficiency and overall effectiveness of the manufacturing enterprise. Thacker's view is that many CIM programs focus attention on the efficiency of information management and the problems that come with it instead of developing new and more sophisticated manufacturing machines, material transformation processes, manufacturing management processes, and production facilities.

Computer-integrated manufacturing can be applied to nonmanufacturing organizations by changing the manufacturing focus toward a service orientation. For

instance, CIM and Job Definition Format (JDF) are becoming increasingly beneficial to printing companies to streamline their production process.

Elanchezhian, Selwyn, and Sundar give several benefits of CIM in their 2008 guide *Computer Aided Manufacturing*, especially as it relates to factory manufacturing:

- CIM can control variables that remained out of reach by the company before implementation. Analysis that may have been left out of human communication by simple error is not missed by computer programming.

- CIM improves responsiveness of the systems in the short-run. Problems or errors result in immediate notification to employees and supervisors.

- CIM improves long-run accommodations by making product volume more efficient and production lines smaller. CIM analysis often results in more streamlined production, even when the company is not going to a lean manufacturing model. Simulations can spot areas that can be sped up and processes that waste time, leading to increased speed.

- CIM reduces inventory for a number of reasons. More efficient processes lead to fewer mistakes, creating a more streamlined process that gives the company a higher turnover rate. Also, most companies using a fully CIM system are moving to a lean manufacturing state (possible just-in-time or a similar practice) that naturally reduces inventory.

- CIM on the factory floor automatically sets up and winds down machinery—at least to a certain extent. When the systems prepares itself, the workers do not need to take the extra time themselves.

THE CIM PLAN

A plan for a CIM system should provide a description of projects for automating activities, assisting activities with technology, and integrating the information flows among these activities. The planning process includes six crucial steps:

- Project activation
- Business assessment
- Business modeling
- Needs analysis
- Conceptual design
- CIM plan consolidation and economic analysis

This process, according to Jorgensen and Krause, also acts as a building block for the future of the organization integrating these functions in order to diminish them as an impediment to integration.

CONCEPTUAL DESIGN

The conceptual design of a CIM environment consists of: individual systems that fulfill the required capabilities; an overall architecture incorporating the systems and the communication links; and a migration path from the current systems architecture. Functional requirements must be compared to the current inventory of systems and available technology to determine system availability. Jorgensen and Krause state that the following techniques are used in satisfying system requirements:

- Exploiting unused and available functional capabilities of current systems.

- Identifying functional capabilities available for, but not installed on, current in-house systems.

- Locating systems that are commercially available but not currently in-house.

- Recognizing state-of-the-art technology that is not immediately commercially available on a system.

- Foreseeing functional capabilities of systems on the technical horizon.

- Determining whether the requirement is beyond the capabilities of systems on the technical horizon.

MANAGING A CIM

Managers must understand that short-term goals must support the long-term goal of implementing a CIM. Top management establishes long-term goals for the company and envisions the general direction of the company. The middle management then creates objectives to achieve this goal. Upper management sees the focus as being very broad, whereas middle management must have a more narrow focus.

In deciding to implement a CIM, there are three perspectives that must be considered: the conceptual plan, the logical plan, and the physical plan. The conceptual plan is used to demonstrate a knowledgeable understanding of the elements of CIM and how they are related and managed. Thacker goes on to say that the conceptual plan states that by integrating the elements of a business, a manager will produce results better and faster than those same elements working independently.

The logical plan organizes the functional elements and logically demonstrates the relationships and dependencies between the elements. Thacker details that it further shows how to plan and control the business.

The physical plan contains the actual requirements for setting the CIM system in place. These requirements can include equipment such as hardware, software, and work cells. The plan is a layout of where the computers, work stations, robots, applications, and databases are located in order to optimize their use within the CIM

and within the company. According to Thacker, sooner or later it becomes the CIM implementation plan for the enterprise.

CIM is challenged by technical and cultural boundaries. The technical challenge is first complicated by the varying applications involved. Thacker claims that it is also complicated by the number of vendors that the CIM serves as well as incompatibility problems among systems and lack of standards for data storage, formatting, and communications. Companies must also have people who are well-trained in the various aspects of CIM. They must be able to understand the applications, technology, and communications and integration requirements of the technology.

CIM cultural problems begin within the division of functional units within the company such as engineering design, manufacturing engineering, process planning, marketing, finance, operations, information systems, materials control, field service, distribution, quality, and production planning. CIM requires these functional units to act as whole and not separate entities. The planning process represents a significant commitment by the company implementing it. Although the costs of implementing the environment are substantial, the benefits once the system is in place greatly outweigh the costs. The implementation process should ensure that there is a common goal and a common understanding of the company's objectives and that the priority functions are being accomplished by all areas of the company according to Jorgensen and Krause.

COMPUTER NETWORKS

Computers are an essential part of daily operations for most business in developed countries. Businesses rely on their computers to store and track information, commu-nicate with customers and suppliers, design and manufacture products, and more. Businesses, therefore, typically have multiple computers in an office and throughout their company. These computers are connected through networks that allow information to be shared between computers.

A computer network, as defined in the Merriam-Webster dictionary, is "a system of computers, peripherals, terminals, and databases connected by communications lines." In other words, networks are used to connect computers to other computers, as well as to other devices such as printers, scanners, and fax machines. Networks can be used to connect devices in the same building or they can be used to connect devices that are miles apart. By far, the most well-known network in use today is the Internet. Many individuals and businesses around the world connect to the Internet on a daily basis. Other examples of networks include library card catalogs, the displays of flight arrival and departure times used at airports, and credit card readers at retail stores.

Networking technology advances, namely the Internet, allow a business to be available 24 hours a day, seven days a week. This immediate nature of business places tremendous pressure on the underlying network infrastructure. In the twenty-first century, organizations must understand and carefully manage a very large volume and a wide variety of network devices to protect the health and performance of these real-time processes. Organizations must also make sure that configuration policies comply with both internal and external standards.

NETWORK BASICS

Basic networks have nodes connected together using hubs. As a network grows, this configuration begins to present challenges of scalability, latency, and network failure. Scalability affects the hub; hub networks have limited shared bandwidth, which makes it difficult to grow significantly and maintain performance. Hub networks keep the IT (information technology) department busy, requiring frequent redesign as organizations grow.

Latency, another issue of the hub network, is the time it takes a packet to get to its destination. Each node has to wait to transmit to avoid collisions, which happen when more than one device transmits data at the same time. Therefore, as more nodes are added to the hub, the latency effect increases.

Network failure is a huge threat for hubs. Just one device on a hub can cause problems for other devices attached to the hub due to incorrect speed settings or excessive broadcasts.

NETWORK CLASSIFICATIONS

Computer networks are classified in a variety of ways. Some of the more standard methods include the following:

- Networks are classified according to scale. These include the personal area network (PAN), local area network (LAN), campus area network (CAN), metropolitan area network (MAN), and the wide area network (WAN)).

- The network is classified according to connection method such as optical fiber, Ethernet, wireless LAN, HomePNA, or power line communication.

- The network is classified by functional relationship, such as active networking, client-server, and peer-to-peer.

- The network is classified according to network topology. These types of networks include the bus network, star network, ring network, mesh network, star-bus network, and tree or hierarchical topology network.

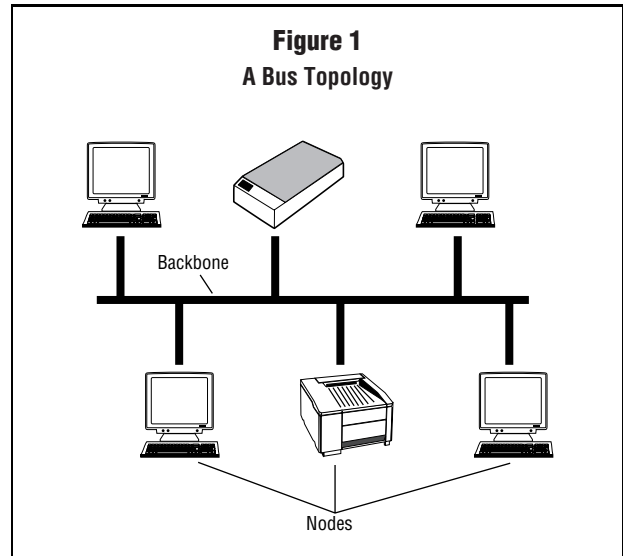
NETWORK CONFIGURATIONS

A solid network configuration strategy ensures the proper configuration of routers and switches. The IT department is charged with defining and carefully managing a specific set of device configurations designed to protect the enterprise. The implementation of this network configuration management strategy and solution can help to effectively manage compliance-related tasks and all configuration changes, such as moves, adds, and deletes, as well as automate the typical auditing activities.

Networks can be set up many different ways depending on the number of devices, the distances between those devices, the transmission speed requirements, and other factors. The topology is how computers, printers, and other devices are connected over a network. It describes the layout of wires, devices, and routing paths. The most popular configurations, or topologies, include the bus, token ring, star, and star bus topologies.

Bus. With a bus configuration, each node is connected sequentially along the network backbone. A node is any device connected to the network, such as a computer, printer, or scanner. Backbone is the term used to describe the main cables to which the network segments are connected. Resistors are placed at each end of the network to ensure that the signal is terminated when it reaches the end. When one node sends information to another node through the network, the information travels along the backbone until it reaches the desired receiving node.

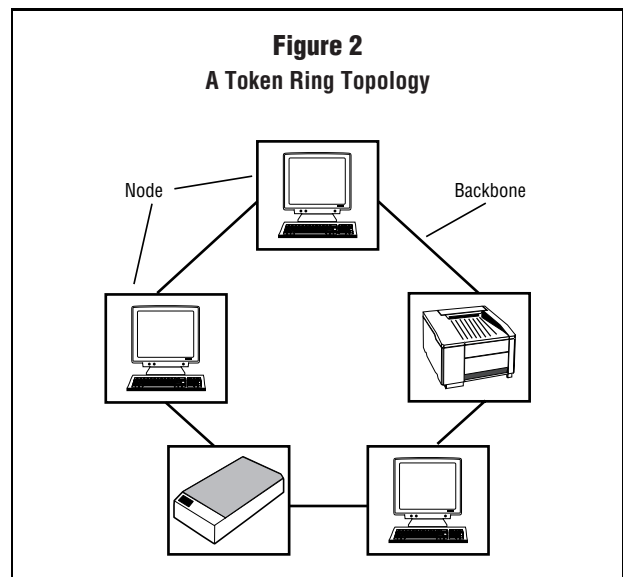
Ethernet bus topologies are relatively easy to install and don't require much cabling compared to the alternatives. Bus networks work best with a limited number of devices. If more than a few dozen computers are added to

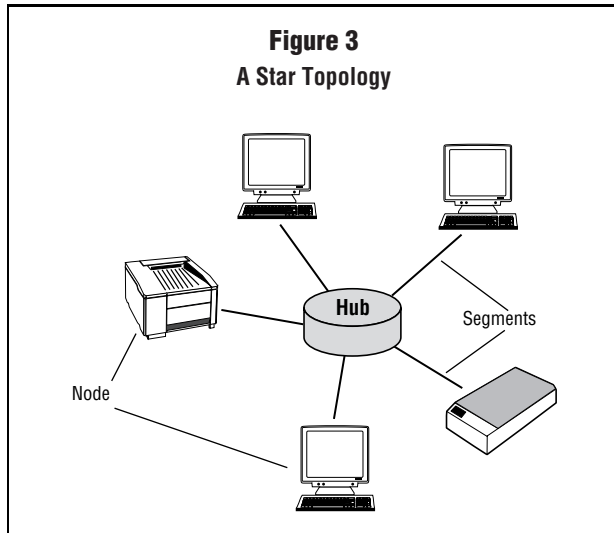
Figure 1
A Bus Topology


a network bus, performance problems will likely result. In addition, if the backbone cable fails, the entire network basically becomes unusable.

Token Ring. With a ring configuration, each node is connected sequentially along the network backbone. However, unlike the bus configuration, the end of the network connects to the first node, forming a circuit. Nodes on a token ring take turns sending and receiving information. In the token ring topology, a token travels along the backbone with the information being sent. The node with the token sends information to the next node along the backbone. The receiving node reads the information addressed to it and then passes the token and any additional information to

Figure 2
A Token Ring Topology

Figure 3
A Star Topology




the next node. This continues until the token and data make it back to the first node in the network.

To implement a ring network, one typically uses FDDI, SONET, or Token Ring technology. Ring topologies are found in some office buildings or school campuses.

Star. With a star configuration, each node is connected to a central hub via network segments. When one node sends information to another node, the information passes through the hub. The hub does not filter or route the information in any way; it simply serves as a connector between network segments. Many home networks use the star topology.

Star bus. With a star bus configuration, the hubs of multiple star networks are connected together via the backbone. This is the most common network configuration in use.

Tree topology. In a tree topology, multiple star topologies are integrated onto a bus. Only hub devices connect directly to the tree bus. Each hub is considered the root of a tree of devices. This approach is considered a bus/star hybrid; it supports future expandability of the network much better than a bus or a star alone.

Mesh topology. Mesh topologies take messages on any of several possible paths from source to destination. The Internet, and some other WANS, employ mesh routing. A full mesh is a mesh network where every device connects to every other.

LOCAL AREA NETWORKS AND WIDE AREA NETWORKS

A LAN, as the name implies, is a network that connects devices that are local, or relatively close to each other. Nodes on a LAN are usually in the same building. In TCP/

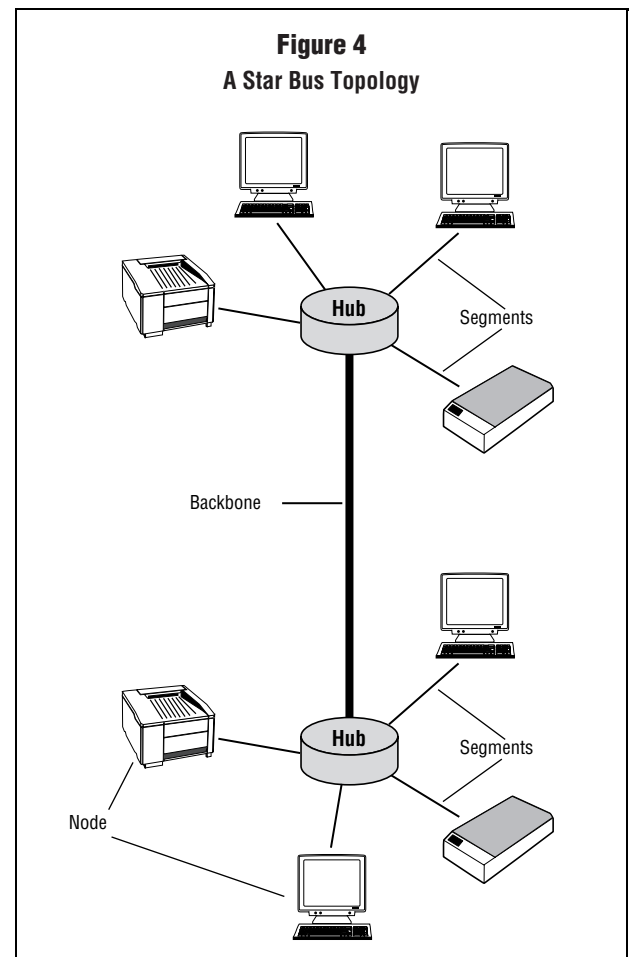
IP networking, a LAN is often but not always implemented as a single IP subnet. A WAN, on the other hand, is used to connect nodes that could be miles apart. LANs generally transmit data faster than WANs, and are usually more reliable. A WAN is a geographically-dispersed collection of LANs. A network device called a router connects LANs to a WAN. In IP networking, the router maintains both a LAN address and a WAN address.

A WAN is different from a LAN. Most WANs, like the Internet, are not owned by any one organization but exist under collective or distributed ownership and management. WANs tend to use technology like ATM, Frame Relay, and X.25 for connectivity over the longer distances. Fiber-optic cables are used for both LANs and WANs.

While LANs and WANs are the most popular network types, other networks include:

• The Wireless Local Area Network, which is a LAN based on WiFi wireless network technology.

• A Metropolitan Area Network is a network spanning a physical area larger than a LAN but smaller than a WAN, such as a city. A MAN is typically owned and

Figure 4
A Star Bus Topology


operated by a single entity such as a government body or a large corporation.

- A Campus Area Network is a network spanning multiple LANs but smaller than a MAN, such as on a university or local business campus.

- A Storage Area Network connects servers to data storage devices through a technology like fiber channel.

- A System Area Network links high-performance computers with high-speed connections in a cluster configuration. This network is also known as Cluster Area Network.

Ethernet networking. Ethernet is a LAN protocol (i.e., a set of rules that governs communications) developed in the mid-1970s by Bob Metcalfe and David Boggs at Xerox Corporation's Palo Alto Research Center. Today, Ethernet is the most widely used network technology in the world. The original Ethernet used a bus topology and provided for transfer rates of up to 10 million bits per second (Mbps). This Ethernet specification was modified slightly and became the Institute of Electrical and Electronics Engineering (IEEE) 802.3 standard, which helped solidify Ethernet as a widely-recognized, open international standard.

Although networks using Ethernet protocol generally connect devices over short distances, technological advances now allow Ethernet to connect devices that are miles apart. Ethernet is widely accepted and largely installed because it is simple and efficient and because network interface cards (NIC) for Ethernet can be easily installed in personal computers, workstations, or high-end computers. Furthermore, it can run on a variety of media, including fiber optic, twisted-pair, cable, and wireless connections.

Repeaters. When Ethernet was first implemented, most people used a copper coaxial cable. However, the maximum length of this cable was 500 meters, which was not long enough for some networks. To address this problem, network engineers used repeaters to connect several Ethernet segments.

Actual network devices that serve as repeaters usually have some other name. Active hubs, for example, are repeaters and are also called multiport repeaters. Most often, they are referred to as hubs.

Bridges. Bridges provide a simple means for connecting LANs. A bridge is a device that connects physically separate LAN segments (such as different Ethernet cables) into one logical LAN segment. Bridges filter data traffic at a network boundary. Bridges, which operate at the data link layer of the OSI model, reduce the amount of traffic on a LAN by dividing it into two segments.

There are four categories of bridges: transparent, source routing, encapsulating, and translating. Transparent bridges are used for Ethernet, whereas source routing bridges are used for token ring networks. Encapsulating bridges connect two segments of the same media (such as token ring to token ring) over a medium. The receiving bridge removes the envelope, checks the destination, and sends the frame to the destination device. Translating bridges are used to connect different types of network media such as Ethernet and FDDI (fiber distributed data interface). FDDI is a set of protocols that uses a modified form of the token-passing method over fiber-optic cable.

An Ethernet bridge, for example, inspects each incoming Ethernet frame—including the source and destination MAC addresses, and sometimes the frame size—to make individual forwarding decisions.

Routers. LAN segments joined by a router are physically and logically separate networks. In contrast to a bridge, when multiple network segments are joined by a router they maintain their separate logical identities (network address space), but constitute an internetwork.

Routers specify the destination and route for each packet, and they can be used to direct packets and interconnect a variety of network architectures. A major difference between a bridge and a router is that the bridge distinguishes packets by source and destination address, whereas a router can also distinguish packets by protocol type. Routers provide for the interfaces to WANs such as frame relay and packet switching services. Some new bridge products have added router capabilities; hence, the practical distinction is becoming blurred, giving rise to the term "brouter."

Routers can also be used to limit access to a network by the type of application (e.g., allowing electronic mail to pass, but not file transfer traffic). This capability provides a measure of security for the network, and is used extensively when creating firewalls. Firewalls are implemented to secure an organization's network when it is linked to the Internet.

Switches. Ethernet communicates across the network using the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) process. A protocol using CSMA/CD monitors, or listens to, the media for network traffic, or information traveling through the network from one node to another. If a node does not sense any traffic, it will send frames or packets of information onto the media. A network frame is like a mailed letter. The letter is put in an envelope that has a return address and the

address of its destination. Data are like the letter and the frame is like the envelope. The data is placed in the frame and the frame has the addressing information and error-checking code. Each protocol has its distinctive frame. The device continues sending until it finishes or until a collision occurs.

A collision happens when more than one device transmits data at the same time. When a collision occurs, each device waits a random amount of time before trying to retransmit the data. By having each node wait a random amount of time, there is only a slim chance that the two devices will send out the data at the same time again. The collision detection and frame retransmission are part of the protocol.

One way to reduce the number of collisions is to add switches to the network. A switch, like a hub, connects nodes to each other. Switches speed things up by allowing different nodes of a network to communicate directly with one another in a smooth and efficient manner. However, while a hub requires each node to share the bandwidth (i.e., the amount of simultaneous data traffic the network can support), a switch allows each node to use the full bandwidth.

Switches that make a separate connection for each node in a company's internal network are called LAN switches. These types of switches develop a series of instant networks that contain only the two devices communicating with each other at that particular moment.

In a fully switched network, each node is connected to a dedicated segment of the network, which in turn is connected to a switch. Each switch supports multiple dedicated segments. When a node sends a signal, the switch picks it up and sends it through the appropriate segment to the receiving node. Ethernet protocol in a fully switched environment does not require collision detection because the switches can send and receive data simultaneously, thus eliminating the chance of collision.

Most companies do not use fully switched networks, as the cost of replacing each hub with a switch can be expensive. Instead, most use a mixed network configuration in which a combination of hubs and switches are used. For example, all of the computers in each department may be connected to their own departmental hub, and then all of the departmental hubs may be connected to a switch.

ETHERNET ADVANCES

The Ethernet has become a data transmission standard. Its dominance of Ethernet as a LAN technology for desktop PCs has made it difficult for other technologies to gain acceptance. The installed base of Ethernet networks is larger than any other alternative technology deployment in the upper spectrum of data rates. This is credited to the simplicity of Ethernet standards and the cost-effective equipment. Bandwidth requirements are growing with more interest and demand for IP applications and streaming video. Some experts believe that will replace voice as the dominating traffic type.

In May 1996 eleven network vendors (including Cisco Systems and Sun Microsystems) formed the Gigabit Ethernet Alliance. The goal of the alliance was to develop a standard for 1 Gigabit per second (Gbps) Ethernet transmissions. Soon thereafter, network vendors were successful in designing networks that achieved the 1 Gbps transmissions goal, and in 2002 the IEEE approved the fibre-only 10 Gbps Ethernet. Throughout 2004 great progress was made in the development of l0 Gbps Ethernet technology and its infrastructure. The increased speed of the 10 Gbps Ethernet in terms of data storage, system backup, teleconferencing, and surveillance systems will prove beneficial to blade servers, networked enterprise switches, video servers, and other applications. The higher density, reduced power, and improved cost-effectiveness appeal to all of the major system developers.

The IEEE has worked to continuously update a standard for the Ethernet. In developing the IEEE 802.3ba spec, two different standards were supported by the IEEE standards committee. One group wanted faster server-to-switch applications, and supported a 40 Gbps standard. Other members were more interested in developing a more robust network backbone and favored the higher 100 Gbps speed. This higher speed required more costly and power intensive equipment.

Ultimately, the IEEE voted, in December 2007, to standardize both the 40 Gbps and 100 Gbps speeds as part of the IEEE 802.3ba spec. The connection equipment for speed would have different physical specifications.

NETWORK REMOTE ACCESS DEVICES

Network remote access devices are used to connect remote (off-site) users to an organization's network. There are many options available. See Table 1 for some of the common line designations.

Modems. A modem is a device that converts data from digital to analog signals so it can travel over the public switched telephone network (PSTN) to its destination. Once the signal reaches its destination, the modem converts it back to digital. As the PSTN was designed to carry voice (analog signals), it is not the best option for carrying data. Digital data networks (DDNs) are replacing the PSTN. DDNs are used to transmit both data and digitized voice. Because of their slow data transmission speeds, modems are no longer used in most business environments.

Table 1
Common Line Designations

Line Designation	Speed	Equivalents
DS0 (Digital Signal Zero)	64 Kbps	
ISDN	16 Kbps or 128 Kbps	Two DS0 lines plus signaling
T1	1.544 Mbps	24 DS0 lines
T3	43.232 Mbps	28 T1 lines
OC3 (Optical Carrier 3)	155 Mbps	84 T1 lines
OC12	622 Mbps	4 OC3 lines
OC48	2.5 Gbps	4 OC12 lines
OC192	9.6 Gbps	4 OC48 lines

Adapted from "How does a T1 line work?" How Stuff Works, Inc., 2005. Available from http://computer.howstuffworks.com/question372.htm

ISDN. Integrated services digital network (ISDN) is a switched, high-speed data service. ISDN is an international telecommunications standard for transmitting voice, video, and data over digital lines running at 64 Kbps, and reaches 1.5 Mbps in North America and 2 Mbps in Europe. ISDN uses the same copper telephone lines as modems do, but at a rate approximately five times faster. Furthermore, it is extremely reliable.

T1. A T1 line carries data approximately 60 times faster than a modem on a normal telephone line. The higher speed and extreme reliability make this a popular choice for many medium- to large-sized businesses. T1 lines can handle hundreds of users simultaneously for general browsing. However, it cannot handle that many users simultaneously downloading large files, such as MP3 files or video files. For very large companies, T1 lines may not be sufficient.

Cable Modems. A cable modem is a device used to connect a computer to a coaxial cable, such as the kind used for cable television, in order to access online services. This device modulates and demodulates signals like a conventional modem. In addition, a cable modem functions like a router designed for installation on cable television networks. The most popular application for cable modems is high-speed Internet access, which provides much faster service than standard telephone-line modems, thus enabling users to access streaming audio, video, and other services.

Wireless Technology. Mobile telephones, laptop computers, and handheld computers are so affordable that they have become a part of everyday life for many people and businesses around the world. Advances in wireless technology have made it possible for people to access networks without having to physically connect to the network through cables. For example, it is not uncommon for business travelers to access networks on their wireless fidelity (Wi-Fi)-enabled laptop PCs or handheld computers while waiting at an airport.

Bluetooth is a wireless standard developed by a group of electronics manufacturers to allow any electronic device—such as computers, cell phones, keyboards, and headphones—to find and connect to other devices without any direct action from the user. The devices find one another and transmit data without any user input at all. Because Bluetooth technology is inexpensive and does not require the user to do anything special to make it work, it is gaining wide use around the world.

Wireless products are affordable and very reliable. With wireless connections, it is possible for people to move around while connected to a network. This is useful in environments such as hospitals, where health care professionals can access patient records from various locations around the campus. Many home and small-business users also use wireless networks to avoid the need to route twisted-pair wiring around their premises.

COMPUTER SECURITY

Computing magazines often define information assurance as "the technical and managerial measures designed to ensure the confidentiality, possession or control, integrity, authenticity, availability, and utility of information and information systems." This information may be in storage, processing, or transit, and the threats to it can be accidental or intentional.

Protecting information resources is not easy. Network technology advances so quickly that IT experts are constantly challenged to keep up. The plethora of valuable information stored on computers and sent through the Web provides great potential for hackers and scammers to infiltrate computer security.

There are two main types of hackers. Some hackers use their computers to break into companies' or other people's computers to steal information, such as credit card numbers. This type of computer criminal uses increasingly sophisticated methods to obtain personal information. Other types of hackers are more interested in damaging the receivers' computers and do this by sending viruses through Web sites or e-mail.

INTERNET CRIME STATISTICS

Between 2005 and the beginning of 2008, the Privacy Rights Clearinghouse said that more than 215 million records of U.S. residents had been compromised because of a security breach. A study conducted by the Ponemon Institute showed that the total average costs for lost or exposed data was $197 for each compromised record. This represents an 8 percent increase in the two years since 2006, and a 43 percent increase since 2005.

Together, the FBI and the National White Collar Crime Center formed the Internet Crime Complaint Center. The Center has received reports of more than 200,000 Internet crimes. These crimes cost nearly $700

per complaint, or $200 million in 2006 and $240 million in 2007.

Some of these crimes are online fraud and phishing scams, which increased 57 percent from 2007 to 2008. In that year, more than 3.5 million Americans were victims of online identity theft and phishing schemes, costing $3.2 billion dollars. The United States hosts the world's greatest number of fraudulent sites, with more than 25 percent.

RECORDS PROTECTION

With the ever-constant advances in the ways that data is exchanged, companies are significantly changing how they deal with data protection and loss. Many companies are investing in security technology, employee education, and comprehensive protocol.

Hackers, too, are changing their methods. They have moved away from targeting individuals and instead are focusing more on targeting entire databases where they can find huge amounts of personal identifying information. This has prompted organizations to focus on database security and invest in technologies that monitor the information and minimize the amount of data leaving their secure networks. According to experts, this may be a problem for large enterprises, which often have numerous databases that are unknown to most security personnel.

The biggest threat to a secure company, however, is human error. Some of the largest security breaches are accidental and actually come from within the company. As companies deal with more and more data, employees leak information by sending work documents to personal e-mail addresses, or accessing e-mail from a personal computer. Insider job shifts are another threat to security. Additionally, contractors, outsourcing and offshoring pose potential security threats.

While companies are increasing the amount of security in their systems, the immense amount of business conducted over the Internet makes stealing information attractive for computer criminals. They employ a number of different methods including spyware, phishing, pharming, viruses, firewalls, and spam. These terms are household words among computer users, especially those who use the Internet.

SPYWARE

Spyware is a term used to describe a program that is put on a computer without the user's permission, and usually without the user's knowledge. A spyware program runs in the background and keeps track of the programs the user runs and the Web sites the user visits. Some spyware tracks the user's keystrokes and extracts passwords and other information as they type. It then uses the information gathered to display certain advertisements or forces

the user's browser to display certain Web sites or search results. Most spyware is written for the Windows operating system.

Spyware can be installed on a computer in any of the following ways:

- **Piggybacked software installation:** Some software applications, and especially free software downloads, install spyware as part of the program installation.

- **Drive-by download:** Some Web sites automatically try to download and install spyware on the user's machine. Users may get a pop-up warning, but not if the security setting is too low.

- **Browser add-ons:** This type of spyware adds enhancements, such as a toolbar, an animated pal, or additional search boxes, to the user's Web browser. Some enhancements, also known as browser hijackers, embed themselves deep in the user's computer, making it very hard to remove them.

- **Masquerading as anti-spyware:** Some spyware advertises that it can remove spyware, when, in reality, they are actually installing additional spyware.

Not only does spyware infringe upon users' privacy, but it can also slow down computers. Many spyware programs use up most of the computer's random access memory (RAM) and processor power, preventing other applications from using these resources. In addition, many spyware programs generate popup advertisements that slow down the user's Web browser, reset the user's homepage to display advertisements every time she opens the Web browser, and redirect the user's Web searches. Some of the more malicious spyware programs modify the user's firewall settings, increasing the opportunities for more spyware and viruses to enter the user's computer.

PHISHING

Phishing is a term used to describe e-mail scams that attempt to trick consumers into disclosing personal and/or financial information. The e-mail messages appear to be from legitimate sources, such as banks, credit card issuers, or well-known Internet sites (such as America Online, Paypal, and eBay). The content of the messages varies, but often they tell the consumer that he needs to update personal information or that there is a problem with the consumer's account. The messages usually contain links to fake Web sites. When the user clicks the link, they are taken to Web sites that look official, and may even include images from the legitimate Web sites. These fake Web sites often instruct the unsuspecting user to enter credit card numbers, social security numbers, bank personal identification numbers (PINs), and other valuable information. Once the user enters that information,

the violators use it or sell it. This leads to what is known as identity theft. The scammers use this information to assume the identity of the victims to make purchases in that person's name.

For example, some of these e-mails come for the IRS. The IRS, by the end of 2007, had been forwarded nearly 35,000 such scam e-mails, which have revealed to the agency more than 1,500 different schemes. In the last six months of 2007, there was a 5 percent increase in the number of phishing messages sent across the Internet, or a total of 207,547. That means that every day, more than 1,100 phishing messages are sent.

Nearly 94 percent of all attacks recorded in August 2007 were against financial services providers. This high number is typical. However, Google is now the target of another kind of phishing. Google customers are tricked into providing their AdWords account login details. By getting their AdWords, the traffic that would go to the site of the person creating the search words are now going to the perpetrator's site. Bigmouthmedia reported a 240 percent monthly average increase in this type of phishing e-mail in 2007.

In 2008, a group of senators, led by Olympia Snowe, introduced the Anti-Phishing Consumer Protection Act of 2008. The bill prohibits tricking recipients into providing their personal information in response to e-mails, instant messages, and misleading Web sites. The bill would also ban related abuses, such as the practice of using fraudulent or misleading domain names.

SPAM

Spam is a term used to describe unsolicited e-mail messages that usually contain an advertisement for some product or service, such as mortgage loans, pornography, or prescription drugs. Spammers send the messages to e-mail addresses on wide-scale mailing lists, which could mean that each message is sent to thousands of people. Spam has become such an annoying problem for so many people that software programmers have developed spam filters to block or delete some e-mail messages before they reach the recipient's e-mail account. Most ISPs offer some level of spam filtering to their customers. However, even with these filters, hundreds of spam messages get through.

Spam messages, according to a May 2008 statistic, account for more than 80 percent of e-mail. Spam often delivers vehicle malware and viruses. Anti-spam e-mail appliances block millions of pieces of spam every day, making these appliances a key defense in IT security. According to the Test Center, e-mail appliances catch more than 96 percent of spam.

Where do spammers get e-mail addresses? Hundreds of companies compile lists of e-mail addresses and put them on CDs, which they sell to anyone who is willing to

pay for them. Each CD can contain millions of e-mail addresses. These companies use programs to pull out screen names and e-mail addresses from newsgroups and chat rooms or the Internet itself. Some spammers use spambots, which are programs that go through the Web and look for the @ symbol and pull the e-mail addresses associated with each one. Another method spammers use to obtain e-mail addresses is to create Web sites specifically designed to attract Web surfers. These Web sites may ask you to enter your e-mail address to see what the site has to offer (for example, large amounts of money).

And finally, perhaps the most common method spammers use to get e-mail addresses is to conduct a dictionary search of the mail servers and large ISPs. Dictionary searches use a program that establishes a connection with the target mail server and then submits millions of random e-mail addresses. Often they will vary these e-mail addresses very slightly (such as by adding a number somewhere in the address). The program then collects the e-mail addresses for which the message actually goes through.

There are hundreds of companies around the world that have formed specifically to cater to spammers. They offer services for sending bulk e-mail. Some of the larger companies can send billions of messages a day. Many of these companies are set up outside the United States to avoid U.S. laws. Some claim to be "spam free." This means that the e-mail addresses they use are taken from the list of users who requested to receive bulk e-mail, or "opt-in" e-mail. A user's e-mail address can be placed on an opt-in list when ordering something online. Many online stores include a checkbox near the bottom of the order page that asks the user to clear the checkbox if they do not want to receive e-mail offers from their partners. If a user does not see that or misinterprets the checkbox, they may be placed on an opt-in list.

As mentioned above, there are many different spam filtering software programs on the market. These filters check e-mail as it arrives in the user's electronic mailbox. The user can set up the filter to check for specific words or specific e-mail addresses or specific types of attachments. If the filter detects any of these, it will either delete the message or place it in a separate folder. Unfortunately, spammers often find ways around these filters. Another problem with filters is that they sometimes filter out legitimate messages.

In 1998, Spamhaus.org was formed to track and stop spammers around the world. Australian-based Spamhaus (http://www.spamhaus.org) calls itself "an international non-profit organization whose mission is to track the Internet's Spam Gangs." Spamhaus.org also says it seeks to provide "dependable realtime anti-spam protection," works with law enforcement agencies to "identify and

pursue spammers worldwide," and lobbies for "effective anti-spam legislation."

Spamhaus continues to fight spam. The group publishes the Register of Known Spam Operations (ROKSO), which lists the Internet Protocol (IP) addresses of the 200 worst spam gangs worldwide. ISPs can use this list to avoid signing up known spammers, and law enforcement agencies can use the list to help target and prosecute spam gangs. Spamhaus also publishes four spam-blocking databases—the Spamhaus Block List (SBL), the Exploits Block List (XBL), the policy block list (PBL) and the ZEN, a new all-in-one DBSBL (DBS Blacklist). As of July 2008, the various Spamhaus products were busy protecting 1.43 billion user mailboxes.

VIRUSES

Computer viruses are programs that spread from one computer to another, causing problems on each computer they touch. As viruses propagate, they use up so much memory that it can slow down computer systems to the point that they are unusable. Some viruses actually attack files on the computer by deleting them or modifying them in some way that renders the computer unusable.

The extent of damage caused by a virus varies. Some affect a relatively small number of computers. Others have been so devastating that they can even cripple large companies. For example, in March 1999, when the Melissa virus hit, it was so destructive that it forced Microsoft and other large companies to completely shut down their e-mail systems until the virus could be contained.

There are four general types of computer viruses:

• **Viruses.** These are small programs that attach themselves to other programs. When a user runs the legitimate program, the virus program runs, too. Once on a computer, some viruses find other vulnerable programs and attach to them as well, causing even more damage. The virus spreads to other computers when the unknowing user shares or passes on an infected program via CD, for example.

• **E-mail viruses.** These are viruses that are transmitted via e-mail. When users open an e-mail message or an e-mail attachment containing a virus, they release it onto their computers. Some e-mail viruses replicate themselves by e-mailing themselves to people listed in a victim's e-mail address book.

• **Worms.** These are small programs that usually take advantage of networks and spread to all computers on the network. Worms scan networks for computers with security holes in programs or operating systems, replicate themselves on those computers, and then start all over from there. Because worms usually spread through networks, they can affect multiple

computers in a very short amount of time. The Slammer worm, released in January 2003, spread more rapidly than any other virus before it. Within 15 minutes, it had shut down cell phone and Internet service for millions of people around the world.

- **Trojan horses.** These are computer programs that claim to be one thing but are actually viruses that damage the computer when the user runs them. Trojan horses cannot replicate automatically.

Because viruses have the potential to wreak havoc on computer networks and individual computers, many virus-protection products have been developed to prevent this. Most virus-protection software scans the computer when it is first turned on and looks for known viruses. As new viruses are discovered, virus protection providers have to update their virus definitions.

FIREWALLS

A firewall is basically a barrier that prevents damaging files or programs from reaching the user's computer. Many operating systems now include a built-in firewall. There are also many after-market firewall products available for purchase. Firewalls filter the data that comes through an Internet connection. If the firewall detects any suspicious information, it does not allow that information through. Most companies and many individuals who have Internet access use firewalls to protect their computers and networks. Although some firewalls protect against computer viruses, many experts recommend that companies and individuals invest in a separate anti-virus software package.

Firewalls control the flow of network traffic using one or more of the following methods:

- **Packet filtering:** The term "packet" is used to describe a small group of data. With the packet filtering method, a firewall compares the packets of incoming and outgoing data against a set of specific rules. If the packets meet the acceptable criteria, the firewall lets the data through. Any data that does not make it through the firewall is discarded.

- **Proxy service:** Proxy servers are used to access Web pages by other computers. When a computer requests a Web page, the proxy server retrieves the information and then sends it to the user's computer. With a proxy server, the computer hosting the Web site does not come into direct contact with the user's computer.

- **Stateful inspection:** This newer method compares only certain key parts of the packet to a database of trusted information. The firewall compares outgoing data against specific criteria and then compares

incoming data against the same criteria. If the two comparisons match, the firewall lets the information through.

Several criteria that firewalls use to compare incoming and outgoing data are listed below:

- **Internet Protocol (IP) addresses:** Each computer on the Internet has a unique IP address, which consists of a 32-bit number. If a firewall detects too many files being read by a certain IP address outside of the company, it may block all traffic to and from that IP address.

- **Domain names:** Each server on the Internet has its own domain name, which is the Web site address most people recognize (as opposed to the IP address). If a company knows that certain domain names are not "safe," they will set up the firewall to block access to that domain name. On the other hand, the company may set up the firewall to allow access to only certain domain names.

- **Protocols:** Protocol is a term used to describe the way a program communicates with a Web browser. Some of the more common protocols include IP (Internet Protocol), which is the main delivery system for information over the Internet; TCP (Transmission Control Protocol), which breaks apart and rebuilds information from the Internet; HTTP (Hyper Text Transfer Protocol), which is used for Web pages; FTP (File Transfer Protocol), which is used to download and upload files; and many more. A company may set up a firewall that allows only one or two machines to handle certain protocol and prohibits that protocol on all other machines.

- **Specific words or phrases:** Companies can set up firewalls to search for specific words or phrases. If the firewall encounters packets containing any of those words, it will not allow the packet through.

INFORMATION ASSURANCE PROVIDES NEW JOBS

The year 2007 marked an active year for online criminal activity. At least part of the reason for the increase is that many companies are now required by state laws to notify affected individuals (such as customers, employees, citizens, students and alumni) when their confidential or personal information is lost, stolen, or otherwise compromised. Experts expect that all fifty states will require such notification by 2010.

Other new trends are emerging concerning stolen data, such as where data is stolen. Hackers have begun to target second tier businesses, rather than financial networks and large companies. At the same time, the

explosive growth of social networking sites, which are often used on workplace PCs, also account for much data loss.

Moving forward, business must invest more in security risk assessment and management. This means that companies will need to create key jobs for security personnel. Companies will also need to develop a system that prioritizes the most sensitive information. This will help determine what data potential attackers are most likely going to target. This might include intellectual property, and other information that could affect the value of corporate stock.

Companies are implementing standardized security risk management plans. ISP/IEC 27001:2005 is a standard specification for an Information Security Management System (ISMS). With it, companies have a roadmap to monitor and control their security. ISP/IEC 27001:2005 covers eight elements to ensure that business risk is minimized. The standard is also intended to highlight corporate, customer and legal requirements that companies are required to meet. The elements of the spec include:

- **Security policy:** This element ensures that business objectives and management direction are in sync, enabling the maintenance of an information security policy across the organization.

- **Organizing information security:** This ensures that information security is properly governed.

- **Information asset management:** In this phase, companies are charged with making sure that information assets are properly inventoried and classified.

- **Communications and operations management:** This phase ensures that technical security controls in systems and networks are properly managed.

- **Access control:** Access controls govern the access rights to networks, systems, applications, functions, and data.

- **Information systems acquisition, development, and maintenance:** This phase ensures that security is built into applications, including user-developed applications to ensure correct processing.

- **Information security incident management:** Here, a plan is developed for anticipating and responding to information security breaches.

- **Policy adherence:** Companies follow this directive to ensure conformance with information security policies and standards.

The ISO/IEC 27001:2005 is providing business and organizations with the plan to combat information security breaches, Still, both enterprises and individual users must become better informed about the dangers that exist, and take precautions. As governments and law enforcement agencies around the world are learning more about these crimes and how to deal with them, they are taking action to prosecute the perpetrators.

CONCURRENT ENGINEERING AND DESIGN

Practicing concurrent engineering, several teams within an organization work simultaneously to develop new products and services. Concurrently performing multiple aspects of development significantly reduces the amount of time involved in getting a new product. In markets where customers value time compression, fast-cycle developers have a distinct advantage. Additionally, in many high-technology areas such as electronics and telecommunications, product-technology performance is continuously increasing and price levels are dropping almost daily. In such areas, a firm's ability to sustain its competitive edge largely depends on the timely introduction of new or improved products and technologies. More and more, the time parameter makes the difference between mere survival and substantial profit generation. Concurrent engineering is a key method enabling companies to reduce a new product's time-to-market.

Companies employing concurrent engineering value cooperation, trust, and sharing, and they make decisions by consensus throughout the product lifestyle. The concurrent engineering approach is based on five key elements:

- A process
- A multidisciplinary team
- An integrated design model
- A facility
- A software infrastructure

SEQUENTIAL NEW PRODUCT DEVELOPMENT

In the past, commercial success was practically guaranteed for companies that could design, develop, and manufacture high-quality products that satisfied real needs at competitive prices. However, beginning in the early 1990s this traditional formula radically changed as time-to-market became a vital component of commercial success. Studies have demonstrated that being a few months late to market is much worse than having a 50 percent cost overrun when these overruns are related to financial performance over the lifecycle of a new product or service. In other words, time has become a key driver of competitive success, from design and development to the actual launch of a new product or service.

Traditional project planning and execution has been marked by the definition of objectives and milestones. These goals are met through a progression of networked activities, some of which must be performed sequentially, others of which may be conducted in parallel. Planning techniques such as Program Evaluation and Review Technique (PERT), Graphical Evaluation and Review Technique (GERT), and Critical Path Method (CPM) have been used to support this sequencing of tasks and activities. However, until the beginning of the 1990s time compression was not a major issue in the new product development environment. In the planning and scheduling of tasks and activities, any time compression concerns were only implicitly present.

CONCURRENT NEW PRODUCT DEVELOPMENT

Since time has become a competitive weapon, time pressures have become central to the project-based new product development organization. These pressures have led to the explicit understanding that time compression is a driver of project (and subsequent business) performance. As a consequence, methods, techniques, and organizational approaches have been designed and developed that allow for time compression needs to be handled in a proper manner. All time-centered approaches have one principle in common: they attempt to maximize the number of major design or development tasks that are performed concurrently, thus the concept of concurrent engineering.

In a concurrent engineering environment, even if certain tasks cannot be completely executed at the same time, designers and developers are encouraged to achieve maximum overlap between otherwise sequential activities. In other words, concurrent engineering aims at achieving throughput time reductions by planning and executing design and development activities in parallel, or by striving for maximum overlap between activities that cannot be completely executed in parallel (for example, when one of the tasks or activities requires information to be partially generated during a previous task or activity).

Therefore, concurrent engineering is based on the premise that the parallel execution of major design components will decrease the throughput time of projects, thus reducing the time-to-market for new products and services. For example, applying concepts of parallelism during the Boeing 777 transport design resulted in a time compression of 1.5 years as compared to its predecessor, the Boeing 767. Concurrent engineering allowed the Boeing Company to introduce the new airplane in time to limit the advantage of its competitor, Airbus Industrie.

While many companies have benefited from this approach, this trend has not been limited to individual companies. Complete industry sectors also have implemented concurrent engineering principles. At the beginning of the 1990s, the automotive industry pioneered many of the concurrent engineering concepts and their implementation. By the early 2000s, many industries, including electronics and pharmaceuticals, were behaving in much the same manner.

IMPLEMENTING CONCURRENT ENGINEERING

In a concurrent engineering environment, teams of experts from different disciplines are formally encouraged to work together to ensure that design progresses smoothly and that all participants share the same, current information. The project and problem-solving methods—and the technologies utilized—make up the essential elements through which parallelism in new product design and development can be achieved. Following is a discussion of how each of these elements contributes to concurrent engineering implementation.

Project Methods. Project methods based on teamwork, milestone management, and target-oriented work definition and follow-up are paramount. These methods also must be supported by appropriate senior management commitment and incentive systems. Each team is granted a large degree of autonomy to solve design problems where and when they occur, without much hierarchical intervention. However, management must ensure that the transfer of information between different activities or tasks is smooth and transparent. Also, the means of experimentation must allow the experts involved to rule out differences in interpretation on the functional and technical design parameters. In other words, for concurrent engineering to be successful, information and interpretation asymmetries between the experts involved must be avoided whenever possible.

Problem-Solving Methods. During design and development projects, methods are utilized that foster and support smooth interdisciplinary problem definition and problem solving. Methodologies such as brainstorming open the boundaries of the team to allow for wider ranges of alternative design definitions and solutions to be considered. The use of methodologies like Quality Function Deployment (QFD) further aids experts from different disciplinary backgrounds to jointly define a product's functional and technical requirements. Activity flow chart methods such as IDEF3 allow for detailed planning and monitoring of the different parallel and overlapping activities involved in project execution. Failure Mode and Effects Analysis (FMEA) allows for a systematic investigation of the occurrence and impact of possible flaws in the new product design. The use of Design of Experiments (DOE) enables the systematic identification of critical product/process parameters that influence performance. These are just a few of the many supportive methods that can be used in a concurrent engineering environment. The sources listed at the end of this essay provide more detailed and exhaustive overviews on these and other methodologies supporting concurrent engineering.

TECHNOLOGIES

In concurrent engineering, design technologies are utilized that foster efficient cross-disciplinary analysis, experimentation, and representation of new product designs. Some examples of these technologies include: three-dimensional (3-D) computer-aided design (CAD) systems, rapid prototyping techniques, rapid tooling and rapid testing techniques, as well as techniques that enable the representation of product designs in a virtual context. These design technologies are important because of the key information they convey: their 3-D character allows the expert to interpret design features in a more effective and efficient way.

All of these technologies contribute to the reduction of interpretation asymmetries between the experts involved, as well as to fast-cycle design and development, because they allow for high-speed iterations of analysis and experimentation on both concepts and models of the product. Thus, they modify traditional project management approaches by allowing for more systematic and flexible experimentation and iteration to be included throughout the project's design and development process. In fact, the time and cost incurred by the development and construction of prototypes generally are reduced by factors of 2 to 5 when using digital (e.g., 3-D CAD) and physical (e.g., rapid prototyping) technologies. These tools have become an important enabling factor in the concurrent engineering environment. Without their implementation and further upgrading, concurrent engineering might never be able to realize its full potential in terms of design cost and lead-time optimization.

CE AND INTEGRATED DESIGN

All downstream activities that will likely affect the product's life cycle must be considered during the design of the product. The product design team should be aware of all stages and of the implications that their decisions have in the final manufacturing specification.

For example, designers working in a conventional design-to-manufacture environment are often unaware of the potential effect of design decisions from a corporate and industry-wide perspective. The reason for this is often poor communication. Designers—working on an

integrated design on a team with employees who focus on manufacturing, assembly, materials used, attributed costs, and marketing—are provided with numerous perspectives as the product is being produced. By identifying potentially damaging downstream aspects of a product's life cycle at an early stage, companies avoid delays and costs. Companies adopting this approach design the product right the first time. These products improve their quality and enable a competitive edge over competitors.

Likewise, concurrent design involves collaboration, coordination, and co-decision making within and between cross-functional teams. These teams share information, synchronize activity, and create an environment that supports a concurrent design approach. This approach must support individual cross-functional teams and allow them to work in different styles in different situations. These teams may work in the same place, or at different locations; they may work together or individually. Cross-functional teams cooperate to facilitate complex interdependencies between activities that different teams are working on.

This brief overview has provided a summary of the why, what, and how involved in implementing a concurrent engineering philosophy for the development of new products, services, and processes. It has outlined how introducing overlap during the execution of innovation project tasks and activities has become vital because of competitive pressures that force new product developers to be more time-conscious.

However, a final caveat is warranted. Although concurrent engineering is an important method for handling the time pressures that occur during new product development, rushing products to the market can sometimes be a mistake. First, markets need time to develop. Numerous examples exist where a new product was too early for the market to absorb it or where product variety has reached limits beyond which the product choice decision becomes too complicated for customers. Second, more revolutionary new product development, which often is based on significant technological advances, typically requires longer time horizons to reach completion. Putting too much emphasis on time compression may blind an organization to this basic fact. Third, the conceptual development of new product ideas requires time or "slack." In a high-speed development organization, time-compression imperatives may undermine this need. Therefore, both managers and new product developers need to find a balance between the paradoxical needs for speed and slack in their organizations. Despite its efficiency, concurrent engineering will only prove to be effective when this balance is achieved through the experience and leadership of an organization's senior management.

CONFLICT MANAGEMENT AND NEGOTIATION

The term "conflict" refers to perceived incompatibilities resulting typically from some form of interference or opposition. Conflict management, then, is the employment of

strategies to correct these perceived differences in a positive manner. For many decades, managers had been taught to view conflict as a negative force. However, conflict may actually be either functional or dysfunctional. Whereas dysfunctional conflict is destructive and leads to decreased productivity, functional conflict may actually encourage greater work effort and help task performance. Borisoff and Victor point out, "We have come to recognize and to acknowledge the benefits dealing with conflict affords. Because of our differences, we communicate, we are challenged, and we are driven to find creative solutions to problems."

THE EVOLUTION OF CONFLICT MANAGEMENT

The early approach to conflict management was based on the assumption that all conflict was bad and would always be counterproductive to organizational goals. Conflict management, therefore, was synonymous with conflict avoidance. This left the people experiencing the conflict with essentially only one outcome: a win-lose scenario. In such cases, the loser would feel slighted and this, in turn, would lead to renewed belligerence. Therefore, most managers viewed conflict as something they must eliminate from their organization. This avoidance approach to conflict management was prevalent during the latter part of the nineteenth century and continued until the mid-1940s.

In most cases, conflict avoidance is not a satisfactory strategy for dealing with conflict. Conflict avoidance usually leaves those people who are being avoided feeling as if they are being neglected. Also, conflict avoidance usually fails to reconcile the perceived differences that originally caused the conflict. As a result, the original basis for the conflict continues unabated, held in check only temporarily until another confrontation arises to set the same unresolved tensions into motion again. Therefore, conflict avoidance strategies are not especially useful in the long run.

The human relations view of conflict management dominated from the late 1940s through the mid-1970s. This viewpoint argued that conflict was a natural and inevitable occurrence in any organizational setting. Because conflict was considered unavoidable, the human relations approach recommended acceptance of conflict. In other words, conflict cannot be eliminated and may even benefit the organization. It was during this time period that the term "conflict management" was introduced, according to Nurmi and Darling.

Since the mid-1970s a new position on organizational conflict has emerged. This theoretical perspective is the interactionist approach. This viewpoint espouses not only accepting conflict, but also encouraging it. Theorists are of the opinion that a conflict-free, harmonious,

and cooperative organization tends to become stagnant and nonreponsive to market change and advancement. Therefore, it is necessary for managers to interject a minimum level of conflict to maintain an optimal level of organizational performance. For example, Shelton and Darling suggest conflict is a necessary condition for both individual and organizational progression. They encourage managers to "embrace conflict and use it for continuous transformation."

In the twenty-first century, conflict management is commonly viewed in the context of organizational culture. In "The Conflict Skilled Organization," Lynne Elsaguirre describes how companies that operate with a clear purpose can benefit from conflict. A business team in a successful corporate culture is able to engage in a high level of debate regarding substantive issues while avoiding disputes. Creating an organizational culture that encourages opposition can diversify a company's knowledge and maintain a balanced power structure.

SOURCES OF CONFLICT

According to both Daft and Terry, several factors may create organizational conflict. They are as follows:

- **Scarce Resources.** Resources may include money, supplies, people, or information. Often, organizational units are in competition for scarce or declining resources. This creates a situation where conflict is inevitable.

- **Jurisdictional Ambiguities.** Conflicts may also surface when job boundaries and task responsibilities are unclear. Individuals may disagree about who has the responsibility for tasks and resources.

- **Personality Clashes.** A personality conflict emerges when two people simply do not get along or do not view things similarly. Personality tensions are caused by differences in personality, attitudes, values, and beliefs.

- **Power and Status Differences.** Power and status conflict may occur when one individual has questionable influence over another. People might engage in conflict to increase their power or status in an organization.

- **Goal Differences.** Conflict may occur because people are pursuing different goals. Goal conflicts in individual work units are a natural part of any organization.

- **Communication Breakdown.** Communication-based barriers may be derived from differences in speaking styles, writing styles, and nonverbal communication styles. These stylistic differences frequently distort the communication process. Faulty communication leads

to misperceptions and misunderstandings that can lead to long-standing conflict. Additional barriers to communication may emerge from the cross-gender and cross-cultural differences of participants. Such fundamental differences may affect both the ways in which the parties express themselves and how they are likely to interpret the communication they receive. These distortions, in turn, frequently result in misreading by the parties involved. Moreover, it is common for the parties involved to be oblivious to these false impressions. The resultant misunderstandings subsequently lead the parties involved to believe that a conflict based on misunderstood behavior exists when, in fact, no conflict actually does exist. Miller and Steinberg call this misreading "pseudo-conflict," that is, perceived conflict rather than actual conflict. Much of what managers take to be an actual conflict is the product of such pseudo-conflict.

CONFLICT MANAGEMENT METHODOLOGIES

Management theorists have developed and suggested a range of options for handling organizational conflict. Figure 1 outlines the various components of the Conflict Resolution Grid, which is the result of widely accepted research presented by Thomas and Kilmann.

Thomas and Kilmann identified a conflict-handling grid comprised of five conflict management styles based on two dimensions: assertiveness and cooperativeness. Assertiveness is the motivation of an individual to achieve his/her own goals, objectives, and outcomes, while cooperativeness assesses the willingness to allow or help the other party to achieve its goals or outcomes. Any of the

five conflict resolution styles might be appropriate based on the circumstances of the situation and the personalities of the individuals involved.

1. **Avoiding Conflict Resolution Style.** The avoiding style is low on both assertiveness and cooperativeness. In other words, the manager is not very cooperative in helping the other individuals to achieve their goals, but neither is he/she aggressively pursuing his/her own preferred outcomes in the situation. The original problem, conflict, or situation is never directly addressed or resolved. However, avoiding behavior might be appropriate when the issue is perceived by the manager to be trivial. It might also be an appropriate approach to use when there is no chance of winning or when disruption would be very costly.

2. **Competing Conflict Resolution Style.** The competing style of resolving conflict is also known as the win-lose approach. A manager using this style, characterized by high assertiveness and low cooperativeness, seeks to reach his/her own preferred outcomes at the expense of other individuals. This approach may be appropriate when quick, decisive action is needed, such as during emergencies. It can also be used to confront unpopular actions, such as urgent cost cutting.

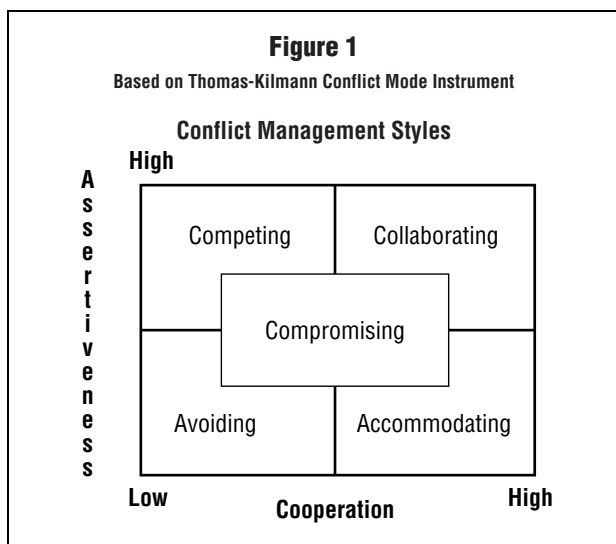
3. **Accommodating Conflict Resolution Style.** This style reflects a high degree of cooperativeness. It has also been labeled as obliging. A manager using this style subjugates his/her own goals, objectives, and desired outcomes to allow other individuals to achieve their goals and outcomes. This behavior is appropriate when people realize that they are in the wrong or when an issue is more important to one side than the other. This conflict resolution style is important for preserving future relations between the parties.

4. **Compromising Conflict Resolution Style.** This style is characterized by moderate levels of both assertiveness and cooperativeness. Compromise can also be referred to as bargaining or trading. It generally produces suboptimal results. This behavior can be used when the goals of both sides are of equal importance, when both sides have equal power, or when it is necessary to find a temporary, timely solution. It should not be used when there is a complex problem requiring a problem-solving approach.

5. **Collaborating Conflict Resolution Style.** This approach, high on both assertiveness and cooperativeness, is often described as the win-win scenario. Both sides creatively work towards achieving the goals and desired outcomes of all parties involved. The collaboration style is appropriate when the concerns are complex and a creative or novel synthesis of

Figure 1

Based on Thomas-Kilmann Conflict Mode Instrument

Conflict Management Styles


ideas is required. The downside of this approach is that the process of collaborating mandates sincere effort by all parties involved and it may require a lot of time to reach a consensus.

Of the five modes described in the matrix, only the strategy employing collaboration as a mode of conflict management breaks free of the win-lose paradigm. It has become almost habitual to fall back on the win-win alternative, but this was not the authors' original intention. They did not reject win-lose configurations out of hand. Instead, strategic considerations for managing conflict according to varied circumstances were identified. For instance, in a conflict centered on bids by two alternative suppliers, the best choice might well be a competing strategy with a winner and loser. After all, the objective in such a situation is to win the contract for one's own company. In most cases, winning the contract can be accomplished only at the expense of the competing supplier, who by definition becomes the loser.

In contrast, a competing approach almost never works well in the interpersonal conflict of people working in the same office (or even the same organization). Unlike the case of competing suppliers, coworkers—both the winner and the loser—must go on working together. Indeed, in many conflicts revolving around office politics, an accommodating strategy may actually enable individuals to strengthen their future negotiating position through allowing themselves to lose in conflicts over issues they do not feel particularly strongly about. In such situations, accommodating can be seen as a form of winning through losing. For instance, a manager may choose to concede an issue to an employee who is experiencing considerable stress as a means to motivate him or her. Similarly, an individual might choose an accommodating strategy to add balance to negotiations in which one's counterpart has already had to give up several other points. Indeed, a winner in a win-lose scenario who fails to put forth some effort to accommodate the other party may even provoke a backlash in the form of lack of commitment or open resistance.

Even the traditional approach of conflict avoidance has its place as an occasionally acceptable strategy. While conflict avoidance has justly been the subject of considerable condemnation, it can be rather useful in allowing both parties to cool off or in buying time until all the facts of a matter have been gathered. A manager might choose to avoid an employee in the throes of an emotional outburst, for example, until the employee has had sufficient time to calm down.

Finally, compromise is often a useful strategy when dealing with relatively small concerns. This differs from an accommodating strategy, in which the conceding party finds an issue unimportant that the opposing party considers comparatively important. A manager might enlist a compromise approach most effectively when both parties consider the issue to be of moderate or little importance. In such cases, compromising saves both parties the time required to employ problem-solving techniques to address the fundamental core of the conflict.

While all of these modes have their place among the strategies available to the manager, the collaborating approach to conflict management represents the most beneficial mode for most types of conflict management. In the collaborating mode, conflict itself acts as a managerial tool. The manager utilizes the conflict to guide the conflicting parties to address what essentially are obstacles faced by the organization. Through collaborative behavior, the conflicting parties pool their creative energies to find innovative answers to old problems.

It is in this key respect that the collaborative mode of conflict management differs from the other four conflict-handling modes. Accommodating, avoiding, competing, and compromising—as permutations of the win-lose scenario—are simply forms of conflict interventions. Collaboration as a conflict-handling mode, on the other hand, represents an attempt to channel conflict in a positive direction, thus enabling the manager to use conflict as a tool to resolve otherwise incompatible objectives within the organization. In other words, this method of handling conflict acts less as a conflict intervention and more as true conflict management.

However, any of the five conflict resolution styles may be appropriate and effective depending on the specific situation, the parties' personality styles, the desired outcomes, and the time available, The key to becoming more prepared is to understand the advantages and disadvantages of each method.

THE FIVE A'S TECHNIQUE

Borisoff and Victor identify five steps in the conflict management process that they call the "five A's" of conflict management: assessment, acknowledgement, attitude, action, and analysis. They assert that these five steps allow for a sustained, ongoing process of problem-solving-oriented conflict management.

Assessment. In the assessment step, the parties involved collect appropriate information regarding the problem. The parties involved also choose which of the conflict-handling modes is most appropriate for the situation. The parties collectively decide what is and what is not central to the problem. The parties involved also indicate areas in which they may be willing to compromise, and what each party actually wants.

Acknowledgement. The acknowledgement step is one in which each party attempts to hear out the other.

Acknowledgement allows both parties to build the empathy needed for the motivation of a synergistic solution to the problem. The acknowledgement acts as feedback to the other party and it demonstrates that one understands (without necessarily agreeing with) the other party's position. Acknowledgement goes beyond merely responding to what is said, however; it involves actively encouraging the other party to openly communicate its concerns. This is aided by the use of active listening techniques and overt, nonverbal encouragement.

Attitude. The attitude step tries to remove the foundation for pseudo-conflict. Stereotypical assumptions about different, culturally-based behaviors are uncovered. For example, a member of a high-context culture may misinterpret what a member of a low-context culture says as being needlessly blunt or even rude. Conversely, a member of a low-context culture may misinterpret what a person from a high-context culture says as being needlessly indirect or even outright deceptive. Such communication variations (as the works of Edward Hall have explained) have little to do with the actual intent or content of the messages, but represent instead culturally learned approaches to using implicit versus explicit communication styles. Similarly, in the attitude step, one acknowledges differences in the way that men and women are generally conditioned to communicate. Experts such as Borisoff and Merrill, for example, have delineated clearly differentiated communication styles between men and women, which are compounded by sex-trait stereotyping regarding issues of assertiveness, interruptive behavior, and perceptions of politeness. Finally, in the attitude step, one analyzes potentially problematic variations in styles of writing, speaking, and nonverbal mannerisms. Such differences may blur meanings. It is the role of the effective conflict participant to maintain an open mind toward all parties involved.

Action. The action step begins to actively implement the chosen conflict-handling mode. If the selected mode is the problem-solving approach, the manager conveys the opportunity for a conflict resolution based on trust and ongoing feedback on those points on which the parties have already agreed. Simultaneously, each individual evaluates the behavior of the other parties (often, little more than subtle hints) to ascertain where potential trouble spots might arise. Also, each individual must remain aware of his or her own communication style and general behavior. Finally, all parties must stay alert to new issues that are raised and look for productive solutions.

Analysis. In this last step participants decide on what they will do, and then summarize and review what they have agreed upon. Part of the analysis step is to ascertain whether every participant's requirements have been addressed (and met, if possible). Finally, the analysis step initiates the impetus for approaching conflict management as an ongoing process. Analysis enables participants to monitor both the short-term and long-term results of the conflict resolution.

QUANTUM SKILLS

Shelton and Darling suggest a new set of management skills, more appropriate for the ever-changing, conflict-ridden contemporary organization. They refer to these skills as the quantum skills. The suggested managerial skills are derived from the field of quantum physics. They are as follows:

1. **Quantum seeing.** This skill is defined as the ability to see intentionally. When conflict occurs, managers must explore their own assumptions about the parties and search for the underlying intentions that are creating the conflict. Each party must then come to recognize the relationship between individual thought processes and perceptions, and set clear intentions for positively resolving the situation.

2. **Quantum thinking.** This skill involves the ability to think paradoxically. Effective conflict resolution is a paradoxical process. "Win-win solutions require paradoxical thinking. They require the ability to find a fully acceptable solution to divergent points of view" (Shelton and Darling 2004, p. 30). In other words, collaborative solutions to conflicts that involve diametrically-opposed positions are unlikely to be achieved through linear problem-solving processes and thus require more unorthodox thinking.

3. **Quantum feeling.** This skill is defined as the ability to feel vitally alive. It is based on the premise that the level of organizational conflict is influenced by the negative emotions pervasive throughout the business world. As schedules have become more fast-paced and jobs have become more stressful, the level of organizational conflict has increased. Managers committed to the quantum feeling technique of conflict management must train themselves to view even negative events positively. They must challenge all parties in conflict to utilize creative, brain-storming techniques in an effort to construct "impossible" win-win solutions.

4. **Quantum knowing.** This skill is the ability to know intuitively. Managers wishing to develop this skill must integrate times of relaxation and reflection into their work routines. This skill focuses on staying mindful or aware of the organizational environment. Managers involved in conflict situations must guide

all parties towards a more centered response to the negative emotions.

5. **Quantum acting.** This skill is based on the ability to act responsibly. Quantum acting is predicated on the belief that everything in the universe is a part of a complex whole in which each part is influenced by every other part. Therefore, a manager's thoughts affect the entire organizational unit. Thus, if managers want to encourage more creative responses to conflict, they must begin by modeling this behavior themselves.

6. **Quantum trusting.** This skill is the ability to trust life's process. It is derived from chaos theory. This theory suggests that without chaos organizations will become stagnant and, if left alone, they will return to a non-chaotic state. This skill may be appealing to managers experiencing conflict. It suggests that managers must simply "ride the rapids of conflict, fully participating in the dance without attempting to actively manage the course of resolution" (Shelton and Darling 2004, p. 37). The organizational unit will eventually self-organize.

7. **Quantum being.** This skill is the ability to be in a relationship, specifically, "the ability to literally become so connected to another that one can see the world through the other's eyes" (Shelton and Darling 2004, p.38). This skill provides the foundation for all parties to learn from and understand each other. It is a relationship of continuous learning.

This set of skills is grounded in a new science: worldview. These skills provide a whole-brained alternative for managing people and conflict.

Conflict management is an ongoing procedure. It entails continual communication and supervision. "Conflict-handling behavior is not a static procedure; rather it is a process that requires flexibility and constant evaluation to truly be productive and effective" (Borisoff and Victor 1998).

CONSULTING

Management consulting is generally a contract advisory service provided to organizations in order to identify management problems, analyze them, recommend solutions to these problems, and (when requested) help implement the solutions. Although there are few formal educational or professional requirements to be a consultant, these services are ideally provided by individuals who are specially trained or qualified in a particular field, such as information technology or organizational change, and who strive to provide independent, objective advice to the client organization.

Only a moderate amount of research has been done on the management consulting industry, although the industry has experienced a phenomenal growth rate since essentially emerging during the 1980s. Management consultants perform a variety of services and use many different methods to complete their tasks. These external consultants do not take the place of managers and have no formal authority, although they are responsible for the value of their advice—occasionally in a legal sense.

The practice itself has existed since the early twentieth century. Management consulting pioneers such as Arthur D. Little and Harrington Emerson contributed much to the foundations of the concept. The two were also involved with the founding of the first consulting firms. In the first half of the twentieth century, consultants began to expand on the earlier work. They began offering what was termed "business research" and introduced such business practices as budgeting, divisionalized organization, merit-based compensation schemes, and forecasting methods.

During the early postwar years (and in many cases growing out of wartime experience), consulting experienced a big rush, with the formation of such firms as Cresap, McCormick & Paget, William E. Hill, Hay

Associates, and Towers Perrin. In the 1960s, major accounting firms began to take notice of the growing market for consulting and began to offer consulting services of their own. (However, by the late 1990s charges of conflicts of interest would cause some of these firms to distance their accounting practices from their consulting activities). Also at this time, with the formation of the Cambridge Research Institute and Management Analysis Center, consulting firms began to integrate methodology of the bigger firms and consolidate practices.

In the early 1980s, there were an estimated 18,000 management consultants; about 30 to 40 percent were employed in the large, institutionally organized firms. For the next decade, the industry experienced phenomenal growth, finally plateauing with the U.S. stock market bust of 2000 and the bursting of the dot-com bubble. Worldwide, the consulting industry also declined at that time, as many of the developed countries were suffering from a global economic downturn.

The industry bounced back in 2005, and again experienced significant growth. Plunkett Research estimates that consulting services—management, scientific, and technical—generated about $160.3 billion in revenues in the U.S. during 2007, a 3 percent increase over 2006. According to Kennedy Information, the global consulting market reached about $310 billion in 2007. Outside the United States the consulting industry has experienced a similar growth pattern.

The year 2008 posed a new challenge to American and global consultants, when the economic crisis ushered in another downturn. However, analysts advised those in the industry not to be alarmed, predicting a promising outlook for management consulting through 2010.

CONSULTING AREAS AND CATEGORIES

The consulting industry has four basic areas. Management consulting consists of looking at a company's organization to assess its ability to achieve its goals. Strategic consulting focuses on the direction and goals of a company as they relate to their specific industry. Information technology (IT) consulting brings technology advice to a company to improve its effectiveness and efficiency. Industry specific consulting brings expertise to highly specialized businesses.

E.H. Schein has divided the role of the management consultant into three categories. These roles are classified as purchase of expertise, doctor-patient, and process consultation. The purchase of expertise role is considered a "hands-off" approach in which the consultant brings his/her own views or opinions into the situation. The doctor-patient role is a more personal relationship between the client and consultant in which the consultant analyzes

and assesses the threats to the company. In the process-consultation method, the consultant plays more of a facilitator role. The client provides the information necessary while the consultant defines the problems and creates the possible solutions. The client makes the final decision on how to resolve the problem.

D.B. Nees and L.E. Greiner have also divided the interaction between consultants and clients into five similar categories. The "mental adventurer" assesses long-term scenarios by using economic models and personal experience. The "strategic navigator" makes decisions based on quantitative data of the industry and makes choices without input from the client. The "management physician" makes decisions based on knowledge of the organization as opposed to the industry as a whole. The "system architect" directs the client by redefining and improving the routines and processes of the organization. Lastly, the "friendly copilot" acts as a counselor to senior management and does not offer any new ideas or knowledge to the client. The mental adventurer role correlates to Schein's expert model; the strategic navigator, management physician, and system architect to Schein's doctor-patient model; and the friendly co-pilot to Schein's process-consultation model.

Over the years, the relationship between the client and consultant has evolved into an intimate partnership. A.N. Turner has developed several task categories to describe management consulting approaches. These categories include supplying information to the client; figuring out clients' problems; making a diagnosis of problems; producing proposals based on the diagnosis; aiding with the implementation of recommended actions; providing client learning; and perpetually improving organizational effectiveness. The first categories represent traditional roles of consultants, while the last represent newer, evolving tasks. Although the relationship is becoming more sophisticated and complex, it still has a long way to go. An executive is still more likely to be influenced by his or her own instincts—followed by the advice of the planning staff, board of directors, and investment bankers—before he or she is persuaded by management consultants.

Often, companies seek management consultants for specific areas of their businesses. Analysts predict that the following areas will seek increased consultant services through the year 2013:

1. **Infrastructure:** Services will be requested in physical asset management, capital spending optimization, project management, and commissioning services.

2. **Learning and development:** Consultancies with a proven track record in training and employee development will thrive, including areas such as Internet

training technologies and remote consulting techniques.

3. **Communication:** Companies will seek help with writing, including technical writing, blogging, and copywriting; speaking in front of groups, communicating ideas to a team; and public relations.

4. **SaaS (Software as a Service):** Enterprises seek assistance with business processes, delivery of niche programs, or integrating business processes that accompany IT advances.

5. **Recruitment:** Consultants with innovative recruiting methods and the ability to deliver hard-to-find skills for openings will continue to be in demand.

The existence and phenomenal growth rate of the management consulting industry cannot be easily explained. However, Marvin Bower of McKinsey & Company, a large consulting firm, offers six reasons why companies should hire consultants. First, consultants offer extensive knowledge and access to resources not available internally. Consultants also contribute broad experience in the field. Next, consultants possess the time to research and analyze the problem. Consultants are also professionals. They are also independent of their clients and are able to make objective decisions the client might not be able to make. Lastly, consultants have the ability to implement the recommendations they provide to their clients. In large organizations, many of the problems encountered should be able to be handled internally because they have dealt with them in the past. In this case, time would be the deciding factor on whether the problems were handled internally or outsourced to management consultants.

Depending on the respective firms, consultants most often have certain requirements for targeting potential clients. The level of engagement or difficulty is one factor to be considered. Some firms such as Gemini Consulting, another major player, are looking for "multidimensional engagements that address bottom-line business issues." These companies would rather deal with "high-end engagements" as opposed to routine supply chain work. The length of time involved is another factor to be considered. Some firms like to work with long-term engagements, where strategy can be developed and implemented over time. Other firms are content with taking on short-term discrete jobs. Larger firms tend to focus their attention on larger companies, and companies like McKinsey & Company tend to focus on engagements that "excite" their consultants. They enjoy making transformations and radical changes not only to the companies themselves, but to the industry as a whole.

Management consultants are becoming increasingly discriminating about the clients they accept in order to protect their reputations and ensure the success of the engagements. Some consultants base their evaluations on whether the proposed project will have a profound impact on the company. Some will only accept a client if they believe the project will be successful, while others look for clients that share their core values. It is not uncommon for prospective clients to ask for a proposal over the telephone. A work session is usually conducted to gather information and address problems. If the prospect states it does not have the time for a work session, the case is usually not taken. Consultants clearly avoid prospective clients who have already decided what they want to do before soliciting the consultant. It is estimated that up to 70 percent of clients begin the consulting process by asking the wrong questions. It is the consultant's responsibility to get the client's priorities in line and have the management focus on problems facing the company. This may explain the current rise in "relationship consulting," whereby a consultant works with a company for several years to see strategies implemented and changed as new challenges are faced by the company.

Meanwhile, many types of consulting and accounting projects are being offshored. Initially North American firms did this as a cost advantage. Offshoring, however, has become necessary as multinational companies continue to open offices, factories, and research facilities in other nations.

Information Technology (IT) is one of the fastest-growing segments of consulting; it includes consultants focused on e-commerce; telecommunications; intranet and Internet strategies and functionality; hardware systems design and implementation; software design, acquisition and implementation; and Web site design and operations. Successful consultancies that started with an IT focus have evolved into full-service companies. In many cases, they are integral departments within larger technology-based companies. The IBM Global Services unit is a good example.

CONSUMER BEHAVIOR

A consumer is the ultimate user of a product or service. The overall consumer market consists of all buyers of goods and services for personal or family use, more than 300 million people (including children) spending trillions of dollars in the United States as of the early twenty-first century.

Consumer behavior essentially refers to how and why people make the purchase decisions they do. Marketers strive to understand this behavior so they can better formulate appropriate marketing stimuli that will result in increased sales and brand loyalty. There are a vast number of goods available for purchase, but consumers tend to attribute this volume to the industrial world's massive production capacity. Rather, the giant known as the marketing profession is responsible for the variety of goods on the market. The science of evaluating and influencing consumer behavior is foremost in determining which marketing efforts will be used and when.

To understand consumer behavior, experts examine purchase decision processes, especially any particular triggers that compel consumers to buy a certain product. For example, one study revealed that the average shopper took less than 21 minutes to purchase groceries and covered only 23 percent of the store, giving marketers a very limited amount of time to influence consumers. And 59 percent of all supermarket purchases were unplanned. Marketers spend a great deal of time and money discovering what compels consumers to make such on-the-spot purchases. Market researchers obtain some of the best information through in-store research, and will often launch new products only in select small venues where they expect a reasonable test of the product's success can be executed. In this manner, they can determine whether a product's success is likely before investing excessive company resources to introduce that product nationally or even internationally.

CONSUMER NEEDS

Consumers adjust purchasing behavior based on their individual needs and interpersonal factors. To understand these influences, researchers try to ascertain what happens inside consumers' minds and to identify physical and social exterior influences on purchase decisions.

On some levels, consumer choice can appear to be quite random. However, each decision that is made has some meaning behind it, even if that choice does not always appear to be rational. Purchase decisions depend on personal emotions, social situations, goals, and values.

People buy to satisfy all types of needs, not just for utilitarian purposes. These needs, as identified by Abraham Maslow in the early 1940s, may be physical or biological, for safety and security, for love and affiliation, to obtain prestige and esteem, or for self-fulfillment. For example, connecting products with love or belonging has been a success for several wildly popular campaigns such as "Reach Out and Touch Someone," "Fly the Friendly Skies," and "Gentlemen Prefer Hanes." This type of focus might link products either to the attainment of love and belonging, or by linking those products with people similar to those with whom people would like to associate.

Prestige is another intangible need, and those concerned with status will pay for it. However, goods appealing to this type of need must be viewed as high-profile products that others will see in use. One benefit of targeting this type of market is that the demand curve for luxury products is typically the reverse of the standard; high-status products sell better with higher prices.

Some equate the type of need to be met with certain classes of goods. For instance, a need for achievement might drive people to perform difficult tasks, to exercise skills and talents, and to invest in products such as tools, do-it-yourself materials, and self-improvement programs, among others. The need to nurture or for nurturing leads consumers to buy products associated with things such as parenthood, cooking, pets, houseplants, and charitable service appeals.

Personality traits and characteristics are also important to establish how consumers meet their needs. Pragmatists will buy what is practical or useful, and they make purchases based more on quality and durability than on physical beauty. The aesthetically inclined consumer, on the other hand, is drawn to objects that project symmetry, harmony, and beauty. Intellectuals are more interested in obtaining knowledge and truth and tend to be more critical. They also like to compare and contrast similar products before making the decision to buy. Politically motivated people seek out products and services that will give them an "edge," enhancing power and social position. And people who are more social can best be motivated by appealing to their fondness for humanity with advertising that suggests empathy, kindness, and nurturing behavior. One successful way an insurance company targeted this market was through its "You're in good hands with Allstate" campaign.

Consumers also vary in how they determine whose needs they want to satisfy when purchasing products and services. Are they more concerned with meeting their own needs and buying what they want to, for their own happiness? Or do they rely on the opinions of others to determine what products and services they should be using? This determines, for example, whether or not they will make a purchase just because it's the newest, most popular item available or because it is truly what they need and/or want.

This also influences the way marketers will advertise products. For example, a wine distributor trying to appeal to people looking to satisfy their personal taste will emphasize its superior vintage and fine bouquet; that same distributor, marketing to those who want to please others, will emphasize how sharing the wine can improve gatherings with friends and family.

Cultural and social values also play large roles in determining what products will be successful in a given market. If great value is placed on characteristics such as activity, hard work, and materialism, then companies who suggest their products represent those values are more likely to be successful. Social values are equally important. If a manufacturer suggests their product will make the consumer appear more romantic or competitive in a place where those values are highly regarded, it is more likely consumers will respond.

PURCHASE PATTERNS

While all of this information might be helpful to marketers, it is equally important to understand what compels the consumer to actually make a purchase, as opposed to just generating interest. For example, some consumers respond based on how they are feeling, while some are focused on making the wisest economic decision. Knowing the different elements that stimulate consumer purchase activity can help marketers design appropriate sales techniques and responses.

A 1999 study conducted by Susan Powell Mantel focused on analyzing the roles of "attribute-based processing" and "attitude-based processing" when analyzing consumer preference. According to the study, product attributes (qualities such as price, size, nutritional value, durability, etc.) are often compared disproportionately, i.e., one is the more focal subject of comparison, thus eliciting more consideration when the consumer decides which brand is the "best." The order of brand presentation in these cases is particularly important.

Adding to the complexity of the issue is the fact that purchase decisions are not always made on the basis of an "attribute-by-attribute" comparison (attribute-based processing). Consumers also make decisions based on an overall evaluation of their impressions, intuition, and knowledge based on past experience, or attitude-based processing. Learned attitudes also influence these decisions. For example, parents who drank Kool-Aid as children often buy it for their kids, either because they associate it with fond memories or just because of brand familiarity or loyalty.

There is time and effort associated with each of these strategies, though attribute-based processing requires significantly more effort on the consumer's part. To dedicate the time required for an attribute-by-attribute comparison, consumers need the combination of motivation and the time or opportunity to use such a strategy.

Other contributing factors were discussed in Mantel's study, such as personality differences and each individual's "need for cognition." Need for cognition reflects to what extent individuals "engage in and enjoy thinking." People with a high need for cognition tend to evaluate more and make more optimal in-store purchase decisions. This is in part because they do not react to displays and in-store promotions unless significant price reductions are offered. Low-need cognition people react easily when a product is put on promotion regardless of the discount offered.

Consumers are also affected by their perceived roles, which are acquired through social processes. These roles create individuals' needs for things that will enable them to perform those roles, improve their performance in those roles, facilitate reaching their goals, or symbolize a role/relationship, much in the way a woman's engagement ring symbolizes her taking on the role of a wife.

Other factors that influence purchase decisions include the importance attributed to the decision. People are not likely to take as much time doing brand comparisons of mouthwash as they are a new car. The importance of the purchase, as well as the risk involved, adds to how much time and effort will be spent evaluating the merits of each product or service under consideration. In cases of importance such as the purchase of a car or home appliance, consumers are more likely to use rational, attribute-based comparisons, in order to make the most informed decision possible.

In some cases, consumers make very little effort to evaluate product choices. "Habitual evaluation" refers to a state in which the consumer disregards marketing materials placed in a store, whether because of brand loyalty, lack of time, or some other reason. Indeed, evaluating all relevant marketing information can become time consuming if it is done every time a person shops.

On the opposite side of the coin, "extensive evaluation" is the state in which consumers consider the prices and promotions of all brands before making a choice. There are also in-between states of evaluation, depending again on the importance of the purchase and the time available to make a decision. Some consumers, usually those who earn higher incomes, value their time more than the cost savings they would incur. Decisions on whether to compare various products at any given time may be a factor of the anticipated economic returns, search costs or time constraints, and individual household purchasing patterns.

When it comes time to actually make purchases, however, one person in the family often acts as an "information filter" for the family, depending on what type of purchase is being made and that person's expertise and

interest. The information filter passes along information he or she considers most relevant when making a purchase decision, filtering out what is considered unimportant and regulating the flow of information. For example, men are more often the family members who evaluate which tools to purchase, while children pass along what they consider to be seminal information about toys. At times, family members may take on additional roles such as an "influencer," contributing to the overall evaluation of goods being considered for purchase. Or one person may act as the "decider," or the final decision-maker. Ultimately, purchase decisions are not made until consumers feel they know enough about the product, they feel good about what they're buying, and they want it enough to act on the decision.

INTERPRETING CONSUMER BEHAVIOR

When market researchers begin evaluating the behavior of consumers, it is a mistake to rely on conventional wisdom, especially when it is possible to study the actual activity in which consumers are engaged when using a product or service. Where are they when they buy certain items? When do they use it? Who is with them when they make the purchase? Why do they buy under certain circumstances and not others? Researchers need to determine the major needs being satisfied by that good or service in order to effectively sell it.

There are two principal ways to evaluate the motivation behind consumer purchases. These are by direction (what they want) and intensity (how much they want it). Direction refers to what the customer wants from a product. For example, customers selecting a pain reliever may like the idea that one pain reliever is cheaper than another, but what they really want is fast pain relief, and will probably pay more if they think the more expensive brand can do that more effectively. Marketers need to understand the principal motivation behind each type of product to correctly target potential customers.

The other way to evaluate consumer behavior, intensity, refers to whether a customer's interest in a product is compelling enough that she will go out and make the purchase. Good marketing can create that kind of intensity. A successful example of such a campaign was Burger King's "Aren't You Hungry?" campaign, which aired on late-night television and was compelling enough for people to leave their homes late at night to go out and buy hamburgers. Understanding consumer motivation is the best way to learn how to increase buyer incentive, as well as a better alternative to the easy incentive—decreasing the price.

While it is easy to speculate on all these elements of consumer motivation, it is much harder to actively research motivating factors for any given product. It is rare that a consumer's reasons for buying a product or service can be accurately determined through direct questioning. Researchers have had to develop other ways to get real responses. These include asking consumers "How do you think a friend of yours would react to this marketing material?" While consumers do not like to admit that marketing affects them at all, they are often willing to speculate on how it would affect someone else. And most often they answer with what would be their own responses.

Another tactic that has proven successful is to ask consumers "What kind of person would use this type of product?" By asking this question, market researchers can determine what the consumer believes buying the product would say about them, as well as whether or not they would want to be seen as that type of person.

INFLUENCING CONSUMER BEHAVIOR

One of the best ways to influence consumer behavior is to give buyers an acceptable motive. This is somewhat related to the idea of asking what type of person would buy a certain product in evaluating consumer behavior. Consumers want to feel they're doing something good, being a good person, eating healthy, making contacts, keeping up appearances, or that they just deserve to be spoiled a little bit. If marketers can convince consumers that they need a product or service for some "legitimate" reason, customers will be more likely to make a purchase.

In addition, sensory stimuli are important to marketing. When food packages are appealing or associated with other positive qualities, people often find that they "taste" better. For example, people often "taste" with their eyes, discerning differences in products where they do not see any difference during a blind taste test. One of the best examples of this was a test of loyal Coca-Cola customers who were totally unwilling to concede that any other soda was its equal. While able to see what they were drinking, they maintained this position. But during blind testing, some were unable to tell the difference between Coke and root beer.

Finally, another alternative for influencing customer behavior is by offering specialized goods. Marketers have exploited the trend toward specialized products by creating the illusion that a product is available in limited supply in order to stimulate demand. On a Harvard Business Online blog, professor John Quelch discusses how publicity for the iPhone and the seventh Harry Potter book both gave customers the impression that supplies were scarce to encourage people to buy sooner, when in fact the marketers had gauged demand fairly accurately.

PREFERENCES CHANGE

While commonality was once popular, more and more people are seeking diversity in taste, personal preferences, and lifestyle. In 2004 Chris Anderson coined the term "The Long Tail" to refer to the consumer demographic that contributes to the success of niche businesses, such as Amazon, which sell small volumes of hard-to-find items to a wide customer base, rather than large volumes of a small number of popular items.

In fact, marketers are quite successful at targeting "rebels" and the "counterculture," as it is referred to in *Commodify Your Dissent*. As Thomas Frank writes, "Consumerism is no longer about 'conformity' but about difference. It counsels not rigid adherence to the taste of the herd but vigilant and constantly updated individualism. We consume not to fit in, but to prove, on the surface at least, that we are rock 'n' roll rebels, each one of us as rule-breaking and hierarchy-defying as our heroes of the 60s, who now pitch cars, shoes, and beer. This imperative of endless difference is today the genius at the heart of American capitalism, an eternal fleeing from 'sameness' that satiates our thirst for the New with such achievements of civilization as the infinite brands of identical cola, the myriad colors and irrepressible variety of the cigarette rack at 7-Eleven."

CONTENT MANAGEMENT SYSTEM

A content management system (CMS) is a program used to provide a structure for material featured on a Web site or enterprise portal. A CMS is data-driven, meaning that it uses a database and templates to create and manage pages. The CMS allows the designers to define both the graphical user interface and the functionality of the site.

There are hundreds of content management systems available. Some are based on open-source software, or software with code that is publicly available. Others are proprietary, meaning that they use code that is not public. Prices for a CMS can range from free (for some open-source systems) to hundreds of thousands of dollars.

BENEFITS OF USING A CONTENT MANAGEMENT SYSTEM

There are many reasons businesses choose a CMS to run their organization's Web site.

- **Efficiency.** A CMS makes updating a site faster and easier. Due to the data-driven nature of the CMS, content creators and site designers will not have to touch every page when making an update. Instead, the site's designers and editors can make a single change that can then be pushed out sitewide. This saves time and money.

- **Process.** A CMS also offers a process for publication. This drastically reduces the chance that something unintended will be published. Usually, a CMS has permissions set so that only authorized individuals can publish content. A CMS also generally provides documentation of what was published, by whom, and when.

- **Definition of roles.** Many content management systems allow for an improved workflow, which in turn makes staffing more efficient. Each person is able to focus on his or her area of expertise. For example, an editor can focus on creating content, while a Web designer can create a global look and feel that will easily be applied. Each of these specialists can work separately within the CMS to maintain a professional Web site.

TRENDS IN CONTENT MANAGEMENT SYSTEMS

There is a dramatic trend toward consolidation of CMS vendors, especially among enterprise content management systems providers. Large software companies—including Oracle and IBM—have acquired multiple smaller vendors at a rapid pace over the last decade. The overall goal of

these acquisitions has been to assemble and provide CMS customers with a comprehensive package of services.

Partially as a result of this consolidation, companies often can find a solution that addresses all aspects of content within the company, including such items as internal document management, Web content, and security and business-process management. Buyers should take into account the most important features for their organization and ensure that any system they choose will seamlessly integrate with their existing technology processes.

In summary, a CMS can provide important data-management services for almost any organization. Choosing a CMS can be one of the most challenging decisions made by an organization but one that will typically reap rewards in terms of efficiency and productivity. It is important to understand the overall content management vision and, especially, the issues most important to overcome when selecting a CMS.

CONTINGENCY APPROACH TO MANAGEMENT

The contingency approach to management is based on the idea that there is no single best way to manage. Contingency refers to the immediate contingent circumstances. Effective organizations must tailor their planning, organizing, leading, and controlling to their particular circumstances. In other words, managers should identify the conditions of a task, the requirements of the management job, and people involved as parts of a complete management situation. The leaders must then work to integrate all these facets into a solution that is most appropriate for a specific circumstance.

The contingency approach to management assumes that there is no universal answer to many questions because organizations, people, and situations vary and change over time. Often there is no one right answer when managers ask: "What is the right thing to do? Should we have a mechanistic or an organic structure? A functional or divisional structure? Wide or narrow spans of management? Tall or flat organizational structures? Simple or complex control and coordination mechanisms? Should we be centralized or decentralized? Should we use task or people oriented leadership styles? What motivational approaches and incentive programs should we use?" Thus, the answer depends on a complex variety of critical environmental and internal contingencies.

The contingency theory is similar to situation theory in that there is an assumption that no simple way is always right. Situation theory, however, focuses more on the behaviors that the leader should use. The contingency theory takes a broader view that includes contingent factors about leader capability and also includes other variables within the situation.

Factors that influence the contingency theory are numerous. These include the following:

- The size of the organization
- How the firm adapts itself to its environment
- Differences among resources and operations activities
- Assumption of managers about employees
- Strategies
- Technologies being used

HISTORICAL OVERVIEW

Classical management theorists such as Henri Fayol and Frederick Taylor identified and emphasized management principles that they believed would make companies more successful. However, the classicists came under fire in the 1950s and 1960s from management thinkers who believed that their approach was inflexible and did not consider environmental contingencies. Taylor, however, emphasized the importance of choosing the general type of management best suited to a particular case. Fayol also found that there is nothing rigid or absolute in management affairs. So while the criticisms were largely invalid, they created the contingency school of management.

It is relevant to note here that similar ideas were expressed three decades earlier. In the 1920s, Mary Parker Follett related individual experience to general principles. Her concept of the "law of the situation" referred to the necessity of acting in accordance with the specific requirements of a given situation. She noted that requirements were constantly changing and continuous efforts were needed to maintain effective working relationships.

Nonetheless, research in the 1960s and 1970s focused on situational factors that affected the appropriate structure of organizations and the appropriate leadership styles for different situations. Although the contingency

perspective purports to apply to all aspects of management, and not just organizing and leading, there has been little development of contingency approaches outside organization theory and leadership theory. The following sections provide brief overviews of the contingency perspective as relevant to organization theory and leadership.

CONTINGENCY PERSPECTIVE AND ORGANIZATION THEORY

Environmental change and uncertainty, work technology, and the size of a company are all identified as environmental factors impacting the effectiveness of different organizational forms. According to the contingency perspective, stable environments suggest mechanistic structures that emphasize centralization, formalization, standardization, and specialization to achieve efficiency and consistency. Certainty and predictability permit the use of policies, rules, and procedures to guide decision making for routine tasks and problems. On the other hand, unstable environments suggest organic structures that emphasize decentralization to achieve flexibility and adaptability. Uncertainty and unpredictability require general problem solving methods for nonroutine tasks and problems.

Paul Lawrence and Jay Lorsch suggest that organizations have developed separate departments to confront differing environmental segments. Organizational units operating in differing environments develop different internal unit characteristics. The researchers say that as internal difference become greater, additional coordination between units is needed.

Joan Woodward found that financially successful manufacturing organizations with different types of work technologies (such as unit or small batch; large-batch or mass-production; or continuous-process) differed in the number of management levels, span of management, and the degree of worker specialization. She linked differences in organization to firm performance and suggested that certain organizational forms were appropriate for certain types of work technologies.

For some time, there also existed a business myth that blue collar workers should be able to do their jobs without thinking, thus taking away the need for contingency management when dealing with assembly line employees. However, theorists quickly recognized that there are many very participative initiatives in manufacturing plants throughout the world. For example, in Japan, manufacturing companies have had great success engaging workers in shop-floor decision making, which has resulted in large positive productivity and quality results.

Organizational size is another contingency variable thought to impact the effectiveness of different organizational forms. Small organizations can behave informally while larger organizations tend to become more formalized. The owner of a small organization may directly control most things, but large organizations require more complex and indirect control mechanisms. Large organizations can have more specialized staff, units, and jobs. Hence, a divisional structure is not appropriate for a small organization but may be for a large organization.

In addition to the contingencies identified above, customer diversity and the globalization of business may require product or service diversity, employee diversity, and even the creation of special units or divisions. Organizations operating within the United States may have to adapt to variations in local, state, and federal laws and regulations. Organizations operating internationally may have to adapt their organizational structures, managerial practices, and products or services to differing cultural values, expectations, and preferences.

The availability of support institutions and the availability and cost of financial resources may influence an organization's decision to produce or purchase new products. Economic conditions can affect an organization's hiring and layoff practices as well as wage, salary, and incentive structures.

Technological change can significantly affect an organization. The use of robotics affects the level and types of skills needed in employees. Modern information technology both permits and requires changes in communication and interaction patterns within and between organizations. For example, advanced information and communication technologies have changed the way businesses operate and conduct commerce. The more secure Internet and new transmission standards make it easier and cheaper for businesses to conduct inter-organizational commerce. Managers have implemented new technologies such as Electronic Data Interchange (EDI) and Web-based e-commerce to enhance communication exchanges throughout the company.

CONTINGENCY PERSPECTIVE AND LEADERSHIP

Dissatisfaction with trait-based theories of leadership effectiveness led to the development of contingency leadership theories. Fred Fiedler, in the 1960s and 1970s, was an early pioneer in this area. Various aspects of the situation have been identified as impacting the effectiveness of different leadership styles. For example, Fiedler suggests that the degree to which subordinates like or trust the leader, the degree to which the task is structured, and the formal authority possessed by the leader are key determinants of the leadership situation. Task-oriented or relationship oriented leadership should each work if they fit the characteristics of the situation. Other

contingency leadership theories were developed as well. However, empirical research has been mixed as to the validity of these theories.

CONTINUING EDUCATION AND LIFELONG LEARNING TRENDS

"Continuing education," "professional development," and "lifelong learning" are all terms used to describe an educational or training process that is a key component for successful organizations. The term *continuing education* often elicits several definitions, however one of the most comprehensive and applicable is Liveright and Haygood's 1969 version, "a process whereby persons who no longer attend school on a regular full-time basis . . . undertake sequential and organized activities with the conscious intention of bringing about changes in information, knowledge undertaking, skill appreciation and attitudes or for the purpose of identifying or solving personal or community problems."

Continuing education and the adult education movement began with the twentieth century. As the world moved to an industrialized economy, the need for continued education and improved access for adults challenged traditional educational venues and created opportunities for both professional and personal skill enhancement and enrichment. Several environmental factors are driving the demand for lifelong learning in the twenty-first century: abundant access to information, rapid technology changes, increased global interactions, industry shifts, as well as increasing entry-level-credentials and skill requirements.

Employers depend on continuing education as a tool for ensuring a highly skilled and knowledgeable workforce. Individuals use continuing education for upward career mobility, job enhancement, and personal enrichment.

The continuing education activity can take place at virtually any time or any place. The format for the continuing education learning should be driven by the content and learning goals. Internet and satellite technology allow employees to engage in educational coursework on the job or at home, which results in a tremendous savings of travel costs and time. Continuing education courses are offered for academic or university level credit, and as non-credit courses. Universities, community colleges, k-12 school districts, private consultants and corporations all participate in offering continuing education content and courses.

CONTINUING EDUCATION UNITS AND ACADEMIC CREDIT

Many industry boards, accreditation agencies, and associations have established mandatory continuing professional education (CPE) requirements for licensure or certification. For example, the American Institute of Certified Public Accountants (AICPA) has established mandatory continuing professional education (CPE) for all members. Most state boards of accountancy have also phased in mandatory CPE as prerequisites for licensure of accounting and auditing practice units. Research has supported this trend. In a 1998 empirical study of the Texas State Board of Public Accountancy, Thomas, Davis, and Seaman found evidence of an association between results of an employee's quality review and levels of continuing professional education in the profession. Other organizations have established a certification process for their respective field such as the Society for Human Resource Management (SHRM), which has partnered with educational institutions to deliver the Professional Human Resource Management (PHRM) content and certification test nationally. Non-credit continuing education courses

often carry state-board or association continuing education units (CEU). Participants generally receive a certificate of completion and should maintain personal records of the units earned.

Post-secondary higher education also falls within the sphere of continuing education. As entry-level requirements continue to increase (such as the demand for graduate level credentials), employers and employees search for flexible degree programs. Many employers offer a tuition reimbursement program for employees enrolled in college-level degree programs when applicable to the workplace. Colleges and universities recognize the growing demand from adult learners for academic degree programs, and many offer academic courses off campus, online or at the workplace in accelerated and non-traditional formats.

CORPORATE UNIVERSITIES

The corporate university is generally some blend of higher education and organizational training and development. Corporate colleges or universities are characterized as institutions that may grant degrees, academic credit or non-credit training and are chartered by a parent company whose primary mission is not education. Some corporate universities have evolved from a mission to serve the corporation's training and development needs to a full-service private higher education institution. Northrop University began in 1942 as a training division of Northrop Aircraft and evolved to an institution offering undergraduate and postgraduate degrees. Kettering Institution (an independent university) grew out of General Motors. Many corporations identify a university or college partner to customize training and academic degree programs specifically to the corporation's business practices. Corporations are using these customized programs as a source for developing future corporate leaders and a means to focus on content areas that are critical to the company's strategic business plans. Multinational companies are developing corporate universities that allow employees around the world to participate in training and educational programs with cost-effective delivery methods. The American Council on Education (ACE) consistently evaluates corporate college or university credits that are offered independent of a regionally accredited institution. ACE establishes recommendations for transfer credit to regionally accredited universities and colleges. Most of the individuals participating in corporate college or university programs are employed full-time which requires that the educational programs are offered in flexible formats. Generally, employees do not have the luxury of attending academic programs on a full-time basis or in a traditional fifteen to eighteen week semester format. Accelerated formats as well as weekend and dis-

tance education designs address the needs of working adult learners.

Companies choose to form corporate universities for many reasons. Different colleges, such as a College of Finance or a College of Manufacturing, can teach employees necessary skills, raise the overall quality of the organization, and give the business a new focus and collective concept. Rob Paton and Geoff Peters define the unique qualities of corporate universities in their 2005 book, *Handbook of Corporate University Development*, listing three features that set such institutions apart:

First, corporate universities—described as "corporate-level initiatives in large, highly complex and differentiated settings,"—clearly separate from the regular departments of the company. Corporate universities (CUs) are usually located near a central office or corporate headquarters, and they strive to give employees skills that they would not receive at normal, local-level posts with normal training. For this reason, CU structure is planned and overseen by the lead managers in the company, and there is often a seat on the board devoted to the education system.

Second, corporate universities serve as an attempt by the organization to follow its strategy and reach its goals. A CU is established as a means to reach a level of education, skill, and ability that the organization has previously planned for in its mission statement. CUs are purpose-driven: they exist only to give the organization particular focus. What that focus is, and how the university achieves it, are decisions made by the lead managers.

Third, corporate universities raise the "standards, expectations, and impact" of the organization's training and development abilities. CUs go beyond human resources services, creating a new kind of training the company did not have previously. This allows employees to evolve and grow into leaders and managers within the organization.

Organizations looking to create a CU must consider its structure carefully. Areas such as the scope of the university, the range of learners to attend, and the nature of the university's contribution to the organizations must all be examined and defined. As Lori Freifeld advises in her 2006 article, "CU There," employees should be aware of any plans to create a corporate university ahead of time. If the employees are not comfortable with the courses and teaching methods of the new CU, then they will not participate fully in the necessary corporate development. Freifeld gives several points to consider when forming—or planning to form—a CU:

- The support of leading managers and board members should be obtained. Full analysis and business plans are required, with supporting evidence that a CU would increase a company's profitability.

- Determine what a CU would accomplish.

- Decide on specific strategies and fund allocations.

- Create a governing board capable of good administration, with representation from all necessary areas of business.

- Hold concept meetings.

- Choose a technology that is easy for employees to use.

Corporate universities have gone through several phases since their inception. Paton and Peters define three different types of CUs. The first and most original is the campus-based CU, created in the classic college structure with centralized buildings, professors, and classes that employees attend. Many of the most notable CUs belong to this classic model. The second type of CU involves CBT (computer based training), most often conducted over a company's intranet. This type of university does not need a centralized campus and can stretch across an organization's borders. The third type of CU is a management-training concept, a place or meeting where the leaders of the company gather to reform their vision and create new ideas.

There are several facets to the CU concept that make critics uneasy. Some argue that corporate universities pose a danger both to colleges and corporate stability by blurring the line between education and training. They fear that corporation-sponsored classes in universities may compromise university integrity, and that potential employees—instead of seeking higher education or trade schools—will simply bypass these options and attend corporate universities to gain the skills they need.

Notable companies who offer CU training include Bank of America, Coca-Cola Enterprises, FedEx Ground, IBM Corporation, Harley Davidson, MasterCard, Home Depot, Gap International Inc., Proctor and Gamble, and McDonald's.

DISTANCE EDUCATION

The second form of CU involves the use of intranet-based training. This is part of distance education, or the idea that classes and skill-courses can be taught by organizations online, creating a university situation through their electronic network. This has been successful for several state universities, who have well-established "e-Learning" programs that students can participate in online. This system has great potential over a company's more secure intranet system, and is an option for organizations that do not wish to invest as much in a corporate campus but still want a system to teach their employees new skills.

Distance education began with correspondence study and has grown significantly as technology advancements create new opportunities for learning and content delivery. As computer technology became prevalent in business, the print-based correspondence courses progressed to computer-based training, which included simulations and ultimately interactive course content that provided participant feedback and enhanced learning. At the end of the twentieth century, educators and employers invested in telecommunication equipment that distributed educational or training activities from one video conferencing site to another. These interactive television programs allow companies to synchronously connect employee groups regardless of their physical distance.

The online training and education market is very competitive offering many choices for organizations and learners. Colleges and universities throughout the world are offering online courses as well as thousands of training and consulting groups. Organizations either select educational programs and courses ala carte or build a portfolio of e-Learning options. Many large organizations have integrated e-Learning into their corporate university entity. These groups generally have a planned web presence that includes a portal and learning management system (LMS) or course management system (CMS).

ON-SITE AND OTHER TYPES OF CORPORATE TRAINING

There are other types of training and education services that companies give beyond corporate university courses. Many organizations offer training programs for many things, from new technology to advancement positions. Such necessary education is on-site training, meaning that employees are trained in their own offices with the technology they will be using. On-site training can include company updates, meetings to improve marketing skills, and management concepts. The advances being made in globalization and economics require much training by organizations so that their employees are able to successfully adapt to the changing world.

Rana Sinha divides the concept of corporate training into three elements in the 2008 article "Corporate Training: A Capital Idea." These three skill sets are human capital, cultural capital, and social capital. Human capital refers to the skills that employees personally develop-talents to use technology or understand processes, the most common type of training that occurs within organizations. The second element, cultural capital, refers to the interactions, morals, and understanding of the applicable nations where the employee works. Cultural capital training would impart the moral guidelines and helpful practices of the culture to the employee. Social capital refers to the connections employees have with each other and suppliers, which with training they can use more effectively.

Organizations considering new branches of training should attempt to succeed in several areas. Training should be agreed to be the best way of communicating the necessary information. The employees and teams who will be trained should be involved in the process of creating the training system. Changes should not be expected too rapidly, but instead be segmented into a certain number of levels which employees can climb. Strategies should be in place to continue helping employees learn and change with the new software or skills after the main phase of training is completed. There are many other elements to be considered when training employees, but most are company-specific and should be decided by leaders of the organization.

CONTINUING EDUCATION AND THE GLOBAL ECONOMY

The global economy has increased the need for organizations around the world to understand the culture and business practices of their peers, competitors and partners. Both foreign and domestic organizations abroad are implementing continuing education experiences in an effort to enhance cultural understanding and address skill and knowledge gaps. U.S. universities are partnering with both U.S. and foreign companies around the world to deliver educational courses and programs that are critical to organizational competitiveness. A central ministry of education in collaboration with a ministry of commerce generally drives these programs. For instance, China has placed a high priority on the field of Human Resource Development and Entrepreneurship as well as encouraging Chinese organizations to partner with foreign organizations in an effort to implement vocational and applied skill training. India has created a new industry as an outsource venue for customer service which creates customer service training opportunities in India. Korean manufacturers have a solid history of identifying corporate and educational partners that satisfy their organizational educational needs. Continuing education helps global companies to connect the workforce with the organizational vision.

THE FUTURE OF CONTINUING EDUCATION

The abundant access of information, rapid technology changes, increased global interactions, industry shifts as well as increasing entry level credentials and skill requirements ensures that continuing education will remain a valuable resource for managers in the future.

Managers will continue to depend on continuing education as a tool for ensuring a highly skilled and knowledgeable workforce. Individuals will engage in life-long learning as a means for upward career mobility, job enhancements, and enriched quality of life.

The increased interest in lifelong learning coupled with rapid technology advancements and demands on individual personal time will guarantee that educational options will continue to be flexible and fit within the constraints of personal time and organizational priorities. The growing global economy will continue to drive the development of learning activities that span geographical regions and time zones allowing individuals around the world to collaborate and learn together.

Organizations around the world will depend on continuing education to maintain competitive positions and adopt current innovations. Managers will depend on lifelong learning to produce a workforce with the knowledge and solution-based skill-set that is required for organizational growth.

CONTINUOUS IMPROVEMENT

Continuous improvement in a management context means a never-ending effort to expose and eliminate root causes of problems. Usually, it involves many incremental or small-step improvements rather than one overwhelming innovation. From a Japanese perspective, continuous improvement is the basis for their business culture. Continuous improvement is a philosophy permeating the Japanese culture, which seeks to improve all factors related to the transformation process (converting inputs into outputs) on an ongoing basis. It involves everyone, management and labor, in finding and eliminating waste in machinery, labor, materials and production methods.

The Japanese word for continuous improvement, *kaizen,* is often used interchangeably with the term *continuous improvement.* From the Japanese character *kai,* meaning "change," and the character *zen,* meaning "good" (taken literally), it means *improvement.*

Although kaizen is a Japanese concept, many U.S. firms have adopted it with considerable success by combining the best of traditional Japanese practices with the strengths of Western business practice: in other words, by merging the benefits of teamwork with the creativity of the individual. Some refer to its implementation in the West as lean manufacturing since, when combined with the principles of just-in-time (JIT), kaizen or continuous improvement forms the foundation for the concept of lean manufacturing.

HISTORY OF CONTINUOUS IMPROVEMENT

Following the defeat of Japan in World War II, America wanted to encourage the nation to rebuild; to accomplish this, General MacArthur asked a number of leading experts from the United States to visit Japan and advise them on how to proceed with the rebuilding process. As history would have it, one of these experts was Dr. W. Edwards Deming. Deming was a statistician with experience in census work, so he came to Japan to set up a census. While in Japan, he noticed some of the difficulties being experienced by some of the newly emerging industries. Many Japanese manufacturers were faced with huge difficulties stemming from a lack of investment funds, raw materials, and components, and from the low morale of the nation and the workforce. Based on his recent experience in reducing waste in U.S. war manufacture, he began to offer his advice.

By the mid-1950s, Deming was a regular visitor to Japan. He taught Japanese businesses to concentrate their attention on processes rather than results; concentrate the efforts of everyone in the organization on continually improving imperfection at every stage of the process. By the 1970s many Japanese organizations had embraced Deming's advice and were very quickly enjoying the benefits of their actions. Most notable is the Toyota Production System, which spawned several business improvement practices utilized heavily in Japan, including JIT and Total Quality Management (TQM).

Despite the fact that much of the foundation of continuous improvement and other Japanese concepts originated in the United States, Western firms showed little interest until the late 1970s and early 1980s. By then the success of Japanese companies caused other firms to begin to reexamine their own approaches. Hence, kaizen or continuous improvement began to emerge in the United States concurrent with the increasing popularity and use of Japanese techniques such as JIT and TQM. In fact, continuous improvement is a major principle of and a goal of JIT, while it is one of the two elements of TQM (the other is customer satisfaction). In some organizations, quality circles have evolved into continuous improvement teams with considerably more authority and empowerment than is typically given to quality circles. In fact, management consultants in the West have tended to use the term *kaizen* to embrace a wide range of management practices primarily regarded as Japanese, practices responsible for making Japanese companies strong in the areas of continual improvement rather than innovation.

KAIZEN ATTITUDES NECESSARY FOR IMPLEMENTATION

Most Japanese people are, by nature or by training, very attentive to detail and feel obligated to make sure everything runs as smoothly as possible, whether at work or at home. This attitude enhances the functionality of kaizen. However, this is not typically the case in the West. To encourage the kaizen attitude, organizations require a major change in corporate culture; one that admits problems, encourages a collaborative attitude to solving these problems, delegates responsibility, and promotes continuous training in skills and development attitudes.

The driving force behind kaizen is dissatisfaction with the *status quo,* no matter how good the firm is perceived to be. Standing still will allow the competition to overtake and pass any complacent firm. The founder of Honda has been quoted as saying, "In a race competing for a split

second, one time length on the finish line will decide whether you are a winner or a loser. If you understand that, you cannot disregard even the smallest improvement." Although continuous improvement involves making incremental changes that may not be highly visible in the short term, they can lead to significant contributions in the long term.

Organizational performance can improve from knowledge gained through experience. Lessons learned from mistakes mean those mistakes are less likely to be repeated, while successes encourage workers to try the same thing again or continue to try new things. While this learning process occurs throughout the system it is particularly important for accomplishing the long-term improvement associated with continuous improvement. In order for continuous improvement to be successful, the organization must learn from past experience and translate this learning into improved performance.

Part of the learning process is trying new approaches, exploring new methods and testing new ideas for improving the various processes. So experimentation can be an important part of this organizational learning. Naturally, many of these worker-led experiments will fail, so it is important to recognize that there is some risk associated with this experimentation. If management is uncomfortable with risk, it may be reluctant to allow any real degree of experimentation. Obviously, management cannot risk disabling the production process itself or endanger the well-being of the workforce, but the complete absence of risk can reduce the vision of those involved in the continuous improvement process. Improvements will generally come in modest increments of progress. Therefore, management must recognize that some experiments will fail as part of the learning process, and avoid the temptation to harshly judge the perpetrator as having new but unsuccessful ideas. Some even feel that it is critical to establish an environment that reinforces the notion that risk is good. Again, this involves consistency in management's attitude toward change and the empowerment of employees.

The achievement of continuous improvement requires a long-term view and the support of top management. But it is also important that all levels of management actively support and become involved in the process. Proper support structures of training, management, resource allocation, measurement, and reward and incentive systems must be in place for successful adoption. This includes a willingness to provide financial support and to recognize achievements. It is desirable to formulate goals with the workers' help, publicize the goals, and document the accomplishments. These goals give the workers something tangible to strive for, with the recognition helping to maintain worker interest and morale.

Kaizen also requires that all employees in the organization be involved in the process. Every employee must be motivated to accept kaizen as a means by which the firm can achieve a competitive advantage in the marketplace. All involved must push continuously at the margins of their expertise, trying to be better than before in every area. Japanese companies have been very successful with the use of teams composed of workers and managers. These teams routinely work together on problem solving. Moreover, the workers are encouraged to report problems and potential problems to the teams; their input is as important as that of management. In order to establish a problem-solving orientation, workers should receive extensive training in statistical process control, quality improvement, and problem solving.

Problem solving is the driving force behind continuous improvement. Workers are trained to spot problems that interrupt, or have the potential to interrupt, the smooth flow of work through the system. When such problems do occur, it is important to resolve them quickly. Also, workers are trained to seek improvements in the areas of inventory reduction, set-up time and cost reduction, increasing output rate, and generally decreasing waste and inefficiency.

There are two particular types of kaizen that occur within practicing companies on a day-to-day basis. The first is point kaizen, which occurs on the spot, immediately, usually within a factory or office setting. An employee, often a manager, will notice a problem in the business process. The problem could be anything from a cluttered workstation to an improper sales pitch, but once the issue is pointed out, immediate action is taken. A system is developed and put into place at once, solving the problem.

The second kind of kaizen involves a more orchestrated, company-wide change, or system kaizen. System kaizen focuses on transition, moving the organization from one particular state to another. One state is where the company currently stands in regard to inventory and production, and the second state is where the company plans to be, marked within a certain time frame of weeks or months. A series of steps are planned and executed to reach the second state. System kaizen is the method developed and used by many companies, whereas point kaizen is the application of the method at problem areas.

Unfortunately, workers in a continuous improvement system have more stress than their counterparts in more traditional systems. This stress comes not only from the added authority and responsibility but also from the fast pace inherent in the system. There is little slack built into the system and a continual push to improve. For this reason, firms stressing continuous improvement have suffered severe criticism from some labor unions.

SIX SIGMA

A concept often associated with continuous improvement is the Six Sigma system. Developed by Motorola in the 1980s, Six Sigma is a method focusing on what causes defect and error in companies. Whatever the errors may be for the company—from lost clients to malfunctioning products—Six Sigma strategies are designed to eliminate them, or make errors so rare they are statistically nonentities. This involves heavy analysis and carefully created steps toward achieving excellent production, and it can take different forms in different companies. Six Sigma is often connected with kaizen activity because the two both seek perfection, continuous change, adaptability, and quality improvement throughout every level of the organization. There are many Six Sigma programs and instructional aids active today.

MANAGERIAL KAIZEN

Continuous Improvement, Six Sigma, Lean Manufacturing, and JIT inventory all have ramifications for the ways managers lead, conduct accounting, and plan for success. Bookkeeping, for instance, functions differently under leaner, more flexible styles of manufacturing. Mike Rogers, in the 2008 *CIMA Managerial Studies*, refers to backflush costing as one method of dealing with continuous improvement activities.

Backflush costing accounts the costs of production when the product is completed and error free. Instead of assigning costs in a series of steps as products are assembled, backflush costing counts the costs of the finished items, assuming that all the products sold or assembled as finished goods are, collectively, an accurate picture of the costs incurred during manufacturing. This assumption is usually safe to make in lean manufacturing scenarios, where Six Sigma techniques reduce errors and continuous improvement assures production will be steady. Backflush costing, however, does not work as well in manufacturing systems that have not developed on-the-spot improvement techniques. However, in many TQM systems there is little to no supply of raw materials, works in progress, or finished good inventory to take account of, so backflush costing is able to work very well.

KAIZEN EXAMPLES

There are many case studies available for inspection on kaizen methods, showing how continuous improvement has made a marked difference in companies and the way they produce, serve their customers, and operate their organization.

DPA, or Daniel Penn Associates, a management consulting firm specializing in creating continuous improvement processes (CIPs) for organizations, gives a case study involving a mutual fund company that con-

tracted the firm to create a continuous improvement plan for their 1,500 employee business across five divisions. The plan focused on several key areas, including:

- The creation of a framework to help customer services achieve new quality and cost effectiveness.

- The streamlining of processes designed to move the company toward a paperless method of conducting business, involving the use of new technologies.

- The creation and maintenance of a number of immediate quality changes to enhance the overall profits and abilities of the company.

After thirteen months of work with more than 400 separate quality projects, the mutual fund company found they had, through the help of DPA and their new CIP system:

- Created a 30 percent to 50 percent increase in productivity

- Enhanced customer service

- Consolidated organizational units that reduced cost

- Reduced paperwork costs by moving their company to a paperless service system

Some of the greatest examples of kaizen can be found in European companies, which have begun embracing the continuous improvement concept. This can be seen in the 2008 kaizen example for the International Leading Practices Symposium, the Aberdeenshire Council of Aberdeenshire, Scotland, which won the European Improvement Award of 2006 through continuous improvement methods.

Aberdeenshire, an ocean-bordering county in Scotland, decided to increase the quality of public service to its people through two kaizen projects. These projects involved focusing on key components of the kaizen process, such as removing waste, encouraging flexibility, directing efforts at the customer, and daring to be different. Taking the customer as the people of Aberdeenshire, the Aberdeenshire Council hired outside kaizen consultants and began developing specific kaizen roles for their continuous improvement projects, including supporting managers, project leaders, and kaizen specialists. The organization of the public servants into kaizen teams produced an almost immediate difference, as once unwilling employees became eager to implement long-desired changes.

Soon, the Aberdeenshire kaizen service directors were submitting "kaizen blitz" plans, all to be executed within six months. The organizational structure between the Aberdeenshire IT department and the other services had to be reworked to create enough efficiency to meet deadlines. After massive amounts of training, instructional DVDs, and learning the kaizen process from scratch, the Aberdeenshire Council began to reap the benefits of their

efforts, winning first an award from the Scottish Local Authority and then the prestigious European Excellence Award. Their kaizen teams were renamed and made permanent.

CORPORATE GOVERNANCE

Corporate governance is the responsibility of a firm's board of directors. While management runs the company and oversees day-to-day operations, it is the board of directors that "governs" the corporations by overseeing management and representing the interests of the firm's shareholders.

By law, a corporation of any size must have a board of directors elected by its shareholders. The directors have a fiduciary duty to the shareholders (who are the corporation's owners), and directors as well as corporate officers can be held liable for failing to meet their fiduciary duties to stockholders. A passive board can get into trouble by relying on an influential CEO.

Investors and the public are particularly interested in the financial reports that publicly-traded companies release, and boards of directors of these companies have a legal obligation to ensure that these reports are fair and accurate. Recent business failures, auditor malfeasance, and material deficiencies in financial disclosures, however, have caused a serious erosion of public confidence in the financial reporting of these companies.

SARBANES-OXLEY

Several major cases of corporate fraud and accounting scandal occurred in the early 2000s, including the widely-known cases of Enron, Tyco, and WorldCom. This sudden surge in board misconduct led to investor doubt, the loss of billions in market capital, and harsh penalties for the company leaders found responsible. There was a general outcry for new standards and more specific laws.

Consequently, Congress, with nearly no dissenting votes, enacted the Sarbanes-Oxley Act of 2002, named after Democrat Senator Paul Sarbanes and Republican Representative Michael Oxley, who sponsored the legislation. Common law has traditionally held that corporate directors have a primary fiduciary duty to the corporation and a secondary duty the shareholders. Sarbanes-Oxley, referred to as SOX or Sarbox, has essentially made directors primarily responsible to the shareholders.

There are several specific requirements in SOX's eleven titles, most aimed at corporate boards and the way they authorize financial information. In addition to harsher penalties for corporate fraud and white collar crime, SOX also addresses the authorization of company financial reports. The board members reviewing the reports are now required to sign their certification that they have studied the financial reports, that the information within the reports is factual and not misleading, that the data represents the financial state of the company correctly, that analysis of the data has been conducted by the board to prove it accuracy, and that the report gives any information pertaining to fraud or the change of internal controls.

In addition to the authorization requirements, which affected most managers across the nation, SOX requires

publicly held companies to immediately notify the public concerning any drastic changes to their financial state, communicating the information so that it is easy for the investors to understand. These and other compliance laws in SOX make it much more difficult for companies to withhold incriminating data, or to hide fraud in accounting costs, as had been done in the notorious cases.

For altering or intentionally deceiving investigators through financial records, SOX imposes heavy fines and/or up to twenty years imprisonment for the company leaders involved. Accountants—usually from outside the company—who ignore attempts at fraud when auditing receive fines and up to ten years imprisonment.

KEY GOVERNANCE ISSUES

Historically, corporate boards of directors have had a myriad of duties, most of them set by common law and the corporation's own by-laws. These duties often include: hiring, supervising, and sometimes firing the chief executive officer (CEO); approving major strategic decisions; meeting with shareholders; establishing executive compensation; making decisions about mergers and acquisitions; assessing the viability of potential takeover bids; taking action if the corporation fails; overseeing financial reporting and audits; nominating board candidates; and refining board rules and policies.

One of the most difficult governance duties of the board of directors is the removal of the firm's CEO. This can occur when the board, representing the interests of the shareholders, disagrees with the strategic direction being pursued by the CEO, or if they merely want to show they are "doing their duty" as board members. For example, when Carly Fiorina was ousted as CEO of Hewlett-Packard (HP) in 2005, she was viewed by many to be hard-driving and fearless. The HP board of directors, however, had grown increasingly uncomfortable with her inability to deliver the profits that she promised she was going to deliver. Her refusal to relinquish some operating control, or to make any changes that the board requested, led to her downfall during a period of low profits and falling stock prices.

One measure of good governance is whether the company has a CEO who can maximize the company's performance. Whereas part of the governance function of the board of directors is to select the firm's CEO, another is to endorse the CEO's strategy—if it is the right one. For example, boards can support the CEO's strategic direction by endorsing proposed acquisitions. It can push the CEO to accomplish even more by encouraging him or her to think more broadly or by setting higher sales targets. The board can also support the CEO's leadership by making sure that the CEO is able to put together a strong management team to achieve those goals. In some

cases the following CEO will be recruited from the management team built by the present CEO.

Another difficult time for boards occurs when the firm is the target of a takeover attempt. It is vitally important at such a time that the board have a clear sense of the value of the firm and that it is enabled to fully evaluate takeover offers. During a takeover it is the board's responsibility to accept or reject offers, and in so doing it must represent the shareholders' interests when negotiating the sale of the firm.

GOVERNANCE COMMITTEES

Boards often administer their governance responsibilities by establishing committees to oversee different areas of concern. Typical committees include audit, nominating, and compensation committees. This is largely in line with U.S. regulatory guidance. On August 16, 2002, the Securities and Exchange Commission (SEC) updated earlier proposals related to corporate governance that would recommend, but not mandate, that boards establish three oversight committees: a nominating committee, a compensation committee, and an audit committee. The SEC recommended that these oversight committees be composed entirely of independent directors.

Each committee oversees a specific area of corporate governance and reports to the full board. The nominating committee's area of oversight consists of issues related to management succession, including the CEO, and to the composition of the board of directors. The compensation committee oversees compensation of the firm's CEO and its officers, as well as director compensation. The audit committee is concerned with the company's financial condition, internal accounting controls, and issues relating to the firm's audit by an independent auditor.

Almost all publicly held corporate entities in the United States have an audit committee. Since 1978, the New York Stock Exchange (NYSE) has required corporations to have audit committees composed entirely of independent outside directors as a condition for being listed. The audit committees of corporate boards of directors are generally expected to serve as watchdogs for the investors and the creditors. Audit committees are expected to protect the interests of both investors and creditors, as well as steward corporate accountability. Moreover, audit committees should make sure that management, the internal auditors, and the external auditors understand that the committee will hold them accountable for their actions (and in some cases, inaction).

The independent audit committee plays a key role in stewardship of the corporation it serves. The audit committee should help ensure that the financial statements are fairly stated, the internal controls are operating effectively, management risk is being reduced, and new processes are

minimizing risks. Moreover, the audit committee members should be independent of management and maintain a close working relationship with the independent auditors.

In an article in the *Pennsylvania CPA Journal,* author John M. Fleming sets forth the primary responsibilities of the corporate audit committee: (1) Evaluating the processes in place to assess company risks and the effectiveness of internal controls, and assisting management in improving these processes where necessary; (2) monitoring the financial reporting process both internally and externally; and (3) monitoring and evaluating the performance of internal and external auditors.

A board will sometimes establish a fourth committee, the governance committee. The governance committee is concerned with overseeing how the company is being run, including evaluation of both management and the board of directors. In some cases the nominating committee will evolve into, or function as, a governance committee.

ACTIVE GOVERNANCE

Historically, corporate boards have been described as either active or passive. Some corporate CEOs relished having what they thought were "rubber stamp" boards of directors who would approve virtually any actions they chose to pursue. Sarbanes-Oxley has dramatically changed that dynamic. Corporate directors must now be much more independent, and their legal liability to shareholders has increased significantly.

One example in which a traditionally "quiet" board stepped up and became more active occurred with the Walt Disney Company. For years, Michael Eisner ruled the Disney empire with an allegedly brutal iron fist. After Roy E. Disney, Walt Disney's nephew, led a shareholder revolt of sorts and complained that investor votes were being ignored or circumvented, the Walt Disney Company board of directors finally decided to step in. In early 2004, the board took the chairmanship away from Eisner after more than 45 percent of votes cast at the company's annual meeting opposed his board re-election. It was a resounding vote of no confidence. But the board then chose an Eisner ally, former U.S. Senator George Mitchell, as chairman, over the objections of several larger shareholders. Ironically, a year later, Eisner was easily re-elected to the board, with only 8.6 percent of voters withholding their support for him.

Boards can take simpler steps to ensure they are not passive without voting out the CEO. They can establish a non-executive chairman, a chairperson who is separate from the CEO. The board can also staff all board committees with independent outside directors, except the president and CEO.

ENVIRONMENTAL GOVERNANCE

Lobbyist groups and investors who are concerned with environmental responsibility are becoming increasingly involved in influencing companies whose practices are seen as environmentally unfriendly. The new, easier access to information encouraged by such legislation as Sarbanes-Oxley gives such interested groups the tools to make a difference in the business market. Companies, seeing the short- and long-term benefits to be gained by practicing environmental responsibility, are willingly changing policy in new marketing strategies and creating initiatives to become more "green" and environmentally conscious.

Some corporate boards choose to publish their new policies concerning greener ways of production and manufacturing, or like Advanced Micro Devices, Inc., to create a commitment plan for climate protection. Others, such as Disney, create a separate environmental mission statement. By investing in sustainability and environmentally friendly systems, organizations are finding ways to cut costs, create new goals for themselves, launch new marketing endeavors, and even produce revolutionary technology.

According to a 2007 article *The Encyclopedia of Earth* by Brian Roach, between the years 1995 and 2003, socially responsible investing by corporations grew approximately 40 percent faster than overall investment, and by 2003 approximately 11 percent of United States investments pertained to environmentally conscious activities.

The environmental policies boards are creating pertain to many different areas, and while many concepts are unique to the company that produces them, some are more general. For instance, *eco-labeling* is a common practice; this is the labeling of products to include pertinent environmental information. If a bottle is made of recyclable material, the company can include an eco-label noting the information, making their product more desirable in environmentally conscious markets. If food is grown naturally, or if wood is produced locally, eco-labels can indicate it for the benefit of interested customers. Eco-labels can also include information on the environmental impact the product had in being manufactured, or will have on being consumed.

Examples of corporate environmental responsibility are becoming increasingly common. In Europe, the European Automobile Industry Association agreed to try to reduce their emissions to 140 g per kilometer by 2008. Car companies developed light, small cars such as the SMART car developed by Daimler-Chrysler. In 2007, the British retailer Marks and Spencer revealed a five-year plan, estimated to cost 200 millions pounds, to make the company carbon neutral. For many companies, carbon

footprints have become an area of concern, and reducing carbon output has turned into a strong initiative for many organizations.

In America, companies such as Kimberly-Clark are working on research to develop products that have helpful social and environmental effects. Some, such as 3M, are turning their focus to products that are more environmentally disposable.

THE ROLE OF INVESTOR ACTIVISM

Finding qualified people to serve on corporate boards of directors can be a challenging task. Corporate board members are learning in the current legal environment that serving on such board can open them to a wide range of legal liability issues. The reforms of Sarbanes-Oxley and the SEC all seem well-intended, but will they make a difference for board members who get in over their heads or choose to look away?

Many critics argue that the proposed and enacted reforms do little to solve the real problems that exist with corporate boards. For example, one issue that has been repeatedly raised is the fact that corporate boards tend to meet only a couple of times a year. Yet it is further argued that more frequent meetings do little to solve the major problem, which is the fact that most corporate board members do not have enough access to information to fulfill their duties of stewardship to the shareholders.

Another issue that has been raised after continuous corporate failures revolves around the financial knowledge and competence of corporate board members. One proposed reform to remedy this problem has been to offer more generous pay for corporate board members, particularly those who serve on audit committees. The theory behind the increased pay is that it would help attract more chief financial officers and former chief executive officers from major accounting firms to serve on audit committees.

Proponents of such a move argue that former CFOs and CEOs are ideal audit committee members. But, there remains a limited pool of these professionals available to serve on audit committees. Furthermore, increased disclosure requirements are likely to raise liability for individual audit committee members, thus having a negative impact on their willingness to serve. Increased compensation may not persuade highly-qualified potential committee members to accept the burdensome legal responsibility of vouching for a multinational company's complex and intricate accounting system.

Finally, it is important to realize that having the best and most qualified corporate board of directors is no guarantee that financial reporting or other problems will not occur. Many of the corporate failures, large and small, that occur every year have arisen as a result of inattention,

reckless disregard, or malfeasance. While some of the new and proposed regulations may address specific issues that have occurred in certain situations, they will never fully compensate for flaws in human nature. Many corporate failures would still have occurred under the new rules set by Congress and the SEC if board members found ways to ignore or circumvent them. As long as human judgment and discretion is permitted to operate within the corporate board function, there is room for error and wrongdoing.

CORPORATE SOCIAL RESPONSIBILITY

In their 2003 book, *Business and Society: Ethics and Stakeholder Management,* Carrol and Bucholtz describe corporate social responsibility (CSR) as the "economic, legal, ethical, and discretionary expectations that society has of organizations at a given point in time." The concept of

corporate social responsibility means that organizations have moral, ethical, and philanthropic responsibilities in addition to their responsibilities to earn a fair return for investors and comply with the law. A traditional view of the corporation suggests that its primary, if not sole, responsibility is to its owners, or stockholders. However, CSR requires organizations to adopt a broader view of its responsibilities that includes not only stockholders, but many other constituencies as well, including employees, suppliers, customers, the local community, local, state, and federal governments, environmental groups, and other special interest groups. Collectively, the various groups affected by the actions of an organization are called "stakeholders." The stakeholder concept is discussed more fully in a later section.

Corporate social responsibility is related to, but not identical with, business ethics. While CSR encompasses the economic, legal, ethical, and discretionary responsibilities of organizations, business ethics usually focuses on the moral judgments and behavior of individuals and groups within organizations. Thus, the study of business ethics may be regarded as a component of the larger study of corporate social responsibility.

Carroll and Buchholtz's four-part definition of CSR makes explicit the multi-faceted nature of social responsibility. The economic responsibilities cited in the definition refer to society's expectation that organizations will produce goods and services that are needed and desired by customers and sell those goods and services at a reasonable price. Organizations are expected to be efficient, profitable, and to keep shareholder interests in mind. The legal responsibilities relate to the expectation that organizations will comply with the laws set down by society to govern competition in the marketplace. Organizations have thousands of legal responsibilities governing almost every aspect of their operations, including consumer and product laws, environmental laws, and employment laws. The ethical responsibilities concern societal expectations that go beyond the law, such as the expectation that organizations will conduct their affairs in a fair and just way. This means that organizations are expected to do more than just comply with the law, but also make proactive efforts to anticipate and meet the norms of society even if those norms are not formally enacted in law. Finally, the discretionary responsibilities of corporations refer to society's expectation that organizations be good citizens. This may involve such things as philanthropic support of programs benefiting a community or the nation. It may also involve donating employee expertise and time to worthy causes.

Wilhelm Autischer, the CSR project manager for an Austrian business, divides corporate social responsibility into three different dimensions. The first dimension is economic. CSR practices help not only the company, but the industry the company is in, by raising the bar of expected behavior overall. Investors, seeing one company adopt CSR policies will be naturally inclined to invest in that company, having seen it demonstrate responsibility. Other companies in the same field, seeing the benefits to CSR, will adopt similar policies as an act of competition, and the attitude of the industry will gradually change. This saves economies from suffering declines through fraudulent business practices.

The second dimension is social. By this Autischer does not necessarily mean creating a better society through specific initiatives by the business, but rather refers to a more internal change. As a company integrates CSR practices into its structure, the way it treats employees will inevitably change. Individual interests are treated with more respect in CSR-conscious companies, and concerns such as employee health and family relations are considered. Employees, benefiting from increased care from the company (in whatever form it takes), carry the positive influence home, influencing their families and society as well.

The third and last dimension is ecological. Companies take ecological responsibility primarily in two ways. First, they adopt precautionary practices, or practices that attempt to secure a healthy and productive ecological environment for future generations and the future of the company. This forward-looking action can include research into alternative technologies and waste management in production processes. The second action of the ecological dimension is eco-efficiency, or the increase in economic efficiency through better ecological practices. These sort of actions reduce unhealthy emissions, replace unsafe chemicals with harmless versions, and market more natural products. Many eco-efficent policies are also precautionary, but the main difference is that companies are looking for better profits through eco-efficiency, while precautionary actions are taken primarily on ethical grounds.

The three dimensions of CSR are practiced in a number of ways. Some of the more common policies, seen often in companies' social information sections, include:

- Reform of internal controls and accounting habits, seen especially after the series of accounting scandals that produced the Sarbanes-Oxley legislation.

- Policies encouraging diversity in the workplace and discouraging any type of discrimination.

- Reversal in corporate thinking regarding employees, a change from looking at them as costs to looking at them as assets.

- Resource productivity, or the use of more natural resources in production and manufacturing, leading

to an ecologically cleaner product and often creating recyclable products.

- Polices regarding treatment of contract employees, especially in outsourced positions located in other countries.

Companies have taken an increased interest in CSR for a combination of reasons. The role government has played in legislations requiring certain social behaviors has decreased, giving businesses more freedom to decide their social responsibilities themselves. Investors and customers alike have begun to demand stricter policies on the part of companies regarding not only their attitudes toward the environment and the people they interact with, but also how much information they reveal. Faced with more open inspection encouraged by such acts as Sarbanes-Oxley, companies are beginning to pay more attention to what their financial records prove they are doing. Many investors, realizing that ethical issues play a large part in how much they know and how successful their investments become, are forcing companies to show that ethical practices are being established.

Many companies have applied their CSR guidelines to the hiring process as well, seeking out employees who have ethical credentials or who agree with the company's moral standards. To keep such employees, businesses are paying more attention to the way they treat their work force, including the incentives they provide for performance and working conditions. Externally, many of the same policies are being applied up and down the supply chain, as companies look for suppliers and distributors who share their ethical concerns. Partnerships are formed with social responsibility as a factor in the contracts.

HISTORY

The nature and scope of corporate social responsibility has changed over time. The concept of CSR is a relatively new one—the phrase has only been in wide use since the 1960s. But, while the economic, legal, ethical, and discretionary expectations placed on organizations may differ, it is probably accurate to say that all societies at all points in time have had some degree of expectation that organizations would act responsibly, by some definition.

In the 1960s and 1970s the civil rights movement, consumerism, and environmentalism affected society's expectations of business. Based on the general idea that those with great power have great responsibility, many called for the business world to be more proactive in (1) ceasing to *cause* societal problems and (2) starting to participate in *solving* societal problems. Many legal mandates were placed on business related to equal employment opportunity, product safety, worker safety, and the environment. Furthermore, society began to expect busi-

ness to voluntarily participate in solving societal problems whether they had caused the problems or not. This was based on the view that corporations should go beyond their economic and legal responsibilities and accept responsibilities related to the betterment of society. This view of corporate social responsibility is the prevailing view in much of the world today.

The sections that follow provide additional details related to the corporate social responsibility construct. First, arguments for and against the CSR concept are reviewed. Then, the stakeholder concept, which is central to the CSR construct, is discussed. Finally, several of the major social issues with which organizations must deal are reviewed.

NEGATIVE ASPECTS OF CSR

The major arguments for and against corporate social responsibility are shown in Exhibit 1. The "economic" argument against CSR is perhaps most closely associated with the American economist Milton Friedman, who has argued that the primary responsibility of business is to make a profit for its owners, albeit while complying with the law. According to this view, the self-interested actions of millions of participants in free markets will, from a utilitarian perspective, lead to positive outcomes for society. If the operation of the free market cannot solve a social problem, it becomes the responsibility of government, not business, to address the issue.

The "competitive" argument recognizes the fact that addressing social issues comes at a cost to business. To the extent that businesses internalize the costs of socially responsible actions, they hurt their competitive position relative to other businesses. This argument is particularly

Exhibit 1

Arguments For and Against CSR

For	Against
The rise of the modern corporation created and continues to create many social problems. Therefore, the corporate world should assume responsibility for addressing these problems.	Taking on social and moral issues is not economically feasible. Corporations should focus on earning a profit for their shareholders and leave social issues to others.
In the long run, it is in corporations' best interest to assume social responsibilities. It will increase the chances that they will have a future and reduce the chances of increased governmental regulation.	Assuming social responsibilities places those corporations doing so at a competitive disadvantage relative to those who do not.
Large corporations have huge reserves of human and financial capital. They should devote at least some of their resources to addressing social issues.	Those who are most capable should address social issues. Those in the corporate world are not equipped to deal with social problems.

relevant in a globally competitive environment if businesses in one country expend assets to address social issues, but those in another country do not. According to Carroll and Buchholtz, since CSR is increasingly becoming a global concern, the differences in societal expectations around the world can be expected to lessen in the coming years.

Finally, some argue that those in business are ill-equipped to address social problems. This "capability" argument suggests that business executives and managers are typically well trained in the ways of finance, marketing, and operations management, but not well versed in dealing with complex societal problems. Thus, they do not have the knowledge or skills needed to deal with social issues. This view suggests that corporate involvement in social issues may actually make the situation worse. Part of the capability argument also suggests that corporations can best serve societal interests by sticking to what they do best, which is providing quality goods and services and selling them at an affordable price to people who desire them.

POSITIVE ASPECTS OF CSR

There are several arguments in favor of corporate social responsibility. One view, held by critics of the corporate world, is that since large corporations create many social problems, they should attempt to address and solve them. Those holding this view criticize the production, marketing, accounting, and environmental practices of corporations. They suggest that corporations can do a better job of producing quality, safe products, and in conducting their operations in an open and honest manner.

Finally, some suggest that businesses should assume social responsibilities because they are among the few private entities that have the resources to do so. The corporate world has some of the brightest minds in the world, and it possesses tremendous financial resources. (Wal-Mart, for example, has annual revenues that exceed the annual GNP of some countries.) Thus, businesses should utilize some of their human and financial capital in order to "make the world a better place."

The BSD, or Business and Sustainable Development, organization separates CSR benefits into three categories. The first category is company benefits. These positive effects are the most pertinent to the companies themselves and include lower operating costs, increased sales and customer loyalty, greater productivity, more ability to attract and keep skilled employees, access to more capital through more willing investors, decreased liability through better product safety, and reduced regulatory oversight. Many companies enhance their brand image and better their reputation through CSR actions, as previously discussed.

The second category includes all benefits to the community the business is connected to through its products and policies. Charitable contributions fall under this category, whether local or national, along with any social initiatives on the part of the company, such as education programs and homeless care activities. Employee volunteering is also included in community benefits.

The third category gathers all the environmental benefits, some of which have already been discussed. In addition to material recyclability, companies can also develop better product durability and functionality through ecologically thoughtful practices, use more renewable resources at lesser costs, and create several new analysis tools, such as life-cycle assessment and eco-efficiency.

THE STAKEHOLDER CONCEPT

According to Post, Lawrence, and Weber, stakeholders are individuals and groups that are affected by an organization's policies, procedures, and actions. A "stake" implies that one has an interest or share in the organization and its operations, per Carroll and Buchholtz. Some stakeholders, such as employees and owners, may have specific legal rights and expectations in regard to the organization's operations. Other stakeholders may not have specific rights granted by law, but may perceive that they have moral rights related to the organization's operations. For example, an environmental group may not have a legal right in regard to a company's use of natural resources, but may believe that they have a moral right to question the firm's environmental policies and to lobby the organization to develop environmentally friendly policies.

All companies, especially large corporations, have multiple stakeholders. One way of classifying stakeholder groups is to classify them as primary or secondary stakeholders. Primary stakeholders have some direct interest or stake in the organization. Secondary stakeholders, in contrast, are public or special interest groups that do not have a direct stake in the organization but are still affected by its operations. Exhibit 2 classifies some major stakeholder groups into primary and secondary categories.

The owners of a firm are among the primary stakeholders of the firm. An organization has legal and moral obligations to its owners. These obligations include, but are not limited to, attempting to ensure that owners receive an adequate return on their investment. Employees are also primary stakeholders who have both legal and moral claims on the organization. Organizations also have specific responsibilities to their customers in terms of producing and marketing goods and services that offer functionality, safety, and value; to local communities, which can be greatly affected by the actions of resident

organizations and thus have a direct stake in their operations; and to the other companies with whom they do business. Many social commentators also suggest that companies have a direct responsibility to future generations and to the natural environment.

An organization's responsibilities are not limited to primary stakeholders. Although governmental bodies and regulatory agencies do not usually have ownership stakes in companies in free-market economies, they do play an active role in trying to ensure that organizations accept and meet their responsibilities to primary stakeholder groups. Organizations are accountable to these secondary stakeholders. Organizations must also contend with civic and special interest groups that purport to act on behalf of a wide variety of constituencies. Trade associations and industry groups are also affected by an organization's actions and its reputation. The media reports on and investigates the actions of many companies, particularly large organizations, and most companies accept that they must contend with and effectively "manage" their relationship with the media. Finally, even an organization's competitors can be considered secondary stakeholders, as they are obviously affected by organizational actions. For example, one might argue that organizations have a social responsibility to compete in the marketplace in a manner that is consistent with the law and with the best practices of their industry, so that all competitors will have a fair chance to succeed.

GLOBAL ISSUES

Corporations increasingly operate in a global environment. The globalization of business appears to be an irreversible trend, but there are many opponents to it. Critics suggest that globalization leads to the exploitation of developing nations and workers, destruction of the environment, and increased human rights abuses. They also argue that globalization primarily benefits the wealthy and widens the gap between the rich and the poor. Proponents of globalization argue that open markets lead to increased standards of living for everyone, higher wages for workers worldwide, and economic development in impoverished nations. Many large corporations are multinational in scope and will continue to face legal, social, and ethical issues brought on by the increasing globalization of business.

Whether one is an opponent or proponent of globalization, however, does not change the fact that corporations operating globally face daunting social issues. Perhaps the most pressing issue is that of labor standards in different countries around the world. Many corporations have been stung by revelations that their plants around the world were "sweatshops" and/or employed very young children. This problem is complex because societal standards and expectations regarding working conditions and the employment of children vary significantly around the world. Corporations must decide which is the responsible option: adopting the standards of the countries in which they are operating or imposing a common standard worldwide. A related issue is that of safety conditions in plants around the world.

Another issue in global business is the issue of marketing goods and services in the international marketplace. Some U.S. companies, for example, have marketed products in other countries after the products were banned in the United States.

SPECIFIC CSR PRACTICES

In their 2006 book, *Developing Corporate Social Responsibility: a European Perspective*, authors Perrini, Pogutz, and Tencati give several specific CSR practices by business that are worth a close look, as most can be applied to and adopted by any organization as an extra form of analysis or a new marketing/mission concept.

Capital valuation is the practice of defining and publishing the various types of capital a company has. This refers not only to financial assets, but social, environmental, human, moral, and intellectual capital as well. Defining the types of capital a company has not only shows investors and customers that the company is aware of the connections it has to the people and communities around it, but it also gives the company several starting places to begin CSR initiatives.

Corporate community involvement reporting is the practice of assembling periodic reports concerning community outreach and activities, such as financial aid and

employee volunteer movements. The reports usually contain the activities, descriptions of the effects produced, and future plans. Some form of measurement is often included, whether by how much time or money was spent in community involvement, or how much involvement the company has compared to competitors.

Ethical accounting statements are reports made directly to the investors concerning the ethics of the company's financial controls and practices. Since ethical activity can be debatable, EASs should be the result of a continuing dialogue between the investors and the company as to what ethical matters are important to both, and how the company can meet its ethical standards. The EAS is used primarily as a planning tool, documenting the company's intentions for future practices.

Ethical auditing is the practice of hiring an outside firm to conduct an audit of the company's policies, focused on ethical standards that the investors and the company have previously developed. The auditing process examines primarily the company's performance in social and environmental settings.

Social auditing is similar to ethical auditing but focuses only on the social performance of the company, and is more common.

Social balance is an accounting practice designed to assemble all CSR financial activity from across the company and combine it in one report. This report usually classifies the financial data in forms that are useful to CSR regulators in the company, showing where funds where allocated regarding social activities, how much separate departments have spent, and where the company stands as a whole in terms of social aid.

Value-added statements are created in order to show the investors the added benefits certain company activities have. Investors may not be aware of CSR practices by the company, and this statement allows the company to show its social activity in succinct form. Other investors may not understand how certain company policies are socially responsible or lead to added value. This report is designed to summarize and show the effects of the company's CSR activity.

Statements of principles and values are created by the company to give focus and enthusiasm to CSR policies. Akin to a mission statement, a statement of principles and values clearly states what the company's social, environmental, and financial responsibilities are, and how it intends to fulfill those responsibilities. Such responsibility statements are becoming a more common tool, and are useful for companies beginning CSR movements. Statements of principles and value should be easily accessible by customers, so that the public can see what the company's social goals are at any time.

Sustainability reporting involves a company's goals of sustainability, and the policies it has in place to meet them. Production companies often have goals of creating more recyclable products with renewable energy sources. Others may have a goal of becoming a paperless business by a certain date, or of adopting a new technology. Whatever the sustainability goal may be, sustainability reporting is a periodic assessment of the company's current endeavors to reach the goal, and its success in attaining sustainability.

ORGANIZATIONS INVOLVED IN CSR

There are many organizations that support or mandate CSR activity in businesses. An international example is the United Nations, which produced the Global Compact initiative in 1999. The Global Compact asks for signatures from major businesses across the world agreeing to nine specific principles of social and environmental activity. These nine principles include:

- To support and respect internationally proclaimed human rights

- To avoid complicity in human rights abuses

- To uphold freedom of association and the right to collective bargaining

- To eliminate all forms of forced labor

- To abolish child labor

- To eliminate discrimination in regard to business hiring and occupation

- To support a cautionary approach to environmental challenges

Another important international organization is the OECD, or the Organization for Economic Cooperation and Development. This organization puts together a set of social guidelines for international companies to follow, created with the help of over thirty different nations. It was updated in 2000 to include new CSR concerns.

In 2004, the International Standards Organization began a process to create a set of guidelines of their own, the ISO 26000. In 2005, more than 225 CSR specialists from forty-three countries and twenty-four other organizations attended the initial meeting. Their goal was to devise a practical guide to international CSR that would, as they say, "aim to encourage voluntary commitment to social responsibility and...lead to common guidance on concepts, definitions and methods of evaluation." The original date for the publication of ISO 26000 was 2008, but has since been moved to 2010.

COST ACCOUNTING

Cost accounting, often referred to as managerial or management accounting, is the branch of accounting that provides economic and financial information to decision makers within a company. The idea of providing information for use within the company (to aid management to plan, direct, and control operations) differentiates cost accounting from other segments of the accountancy profession. For example, financial accounting serves the public by providing financial reporting via financial statements or financial press releases. This public information is prepared and presented based on generally accepted accounting principles (GAAP), the broad rules that assure the user of the underlying framework supporting the information.

On the other hand, cost accounting is limited predominantly to use within the company to aid management in the process of making choices that will benefit the stockholders by maximizing company profits that translate into maximizing stockholder wealth. Since the information is used internally, the information may be presented on any logical basis just so long as it will aid the manager to reach an appropriate, informed decision.

A few concepts in cost accounting, however, form the bridge between financial and managerial accounting topics. One such concept is that of product costing for a manufacturing company. Not only is this information used internally in decision making (e.g., does a company make or buy a component?), product costing is also used to determine the historical basis to account for the cost of products sold during a period and the cost of the unsold inventory that remains as an asset on the statement of financial position at the end of the period.

OVERVIEW

Numerous cost accounting concepts can benefit management in decision making, both for manufacturing and service companies. While many of the concepts discussed below are applicable to both types of companies, the basis for ease of discussion will be that of a manufacturing company. Therefore, some of the concepts to be discussed include understanding the distinction between manufacturing and non-manufacturing costs (and how these are disclosed in the financial statements), computing the cost of manufacturing a product (or providing a service), identifying cost behavior in order to utilize cost-volume-profit relationships, setting prices, budgeting and budgetary controls, and capital budgeting. These topics will be briefly discussed below.

MANUFACTURING VS. NON-MANUFACTURING COSTS

Manufacturing costs are those costs incurred by a producer of goods that are needed to transform raw materials into finished products, ready to sell. These costs consist of the cost of basic materials and components, plus the costs of labor and factory overhead needed to convert the materials into finished products.

Materials and labor can be classified as either direct or indirect in relation to the final product. Direct materials are those major components that can be easily traced to the finished good and are accounted for carefully due to their significance to the product. In the case of manufacturing a lawn mower, for example, these types of materials would include the engine, housing, wheels, and handle. Indirect materials would include those minor items that are essential but which cannot be easily traced to the finished product. Examples of these would be screws, nuts, bolts, washers, and lubricants. One might say that the cost of keeping an account of each of these indirect items exceeds the benefit derived from having the information. Consequently, the costs of these items are accumulated as part of factory overhead and prorated to products on some appropriate basis.

Direct labor refers to the efforts of factory workers that can be directly associated with transforming the materials into the finished product, such as laborers who assemble the product. Indirect laborers are those whose efforts cannot be traced directly or practically to the finished product. The indirect laborers would include maintenance personnel and supervisors.

Factory overhead includes all factory costs that can only be indirectly associated with the finished inventory, that is, all factory costs incurred in making a product other than the costs of direct materials and direct labor. In terms of cost behavior, some of these costs do not change in total even if the number of products manufactured increases or decreases from period to period; the behavior of these costs is said to be a fixed cost. For example, the amount of the monthly factory rent would not fluctuate based on the number of units produced during a particular month.

Other factory overhead costs that change in total in direct proportion to changes in the number of products manufactured are known as variable costs. For example, the number of nuts and bolts needed to assemble lawn mowers would increase and decrease exactly in proportion to the number of mowers produced and are therefore considered to be a variable cost. In summarizing this brief discussion of factory overhead costs, these costs include such things as depreciation of factory buildings and machinery, factory utilities, factory insurance, indirect materials, and indirect labor; some of these costs are variable while others are fixed in total for a specific time period.

All material, labor, and factory overhead costs are summarized into totals that represent the cost of the goods manufactured during a period of time. The cost of products that have been completed and sold during a time period are deducted from the related sales revenue total to determine the gross profit for the period. Thus it is logical that these manufacturing costs are referred to as product costs. The cost of unsold completed units at period's end is shown as finished goods on the balance sheet. Any costs of goods that are only partially completed at period's end are shown as work in process inventory, and any materials that have not yet entered into the manufacturing process are disclosed as raw materials inventory.

All the costs incurred by a manufacturing company other than the cost of factory operations are collectively known as non-manufacturing costs. These include all selling, administrative, and financing costs; all these costs are deducted as expenses from sales revenues as they are incurred each period. Costs other than manufacturing costs are called period costs for this reason. None of the period costs are deferred to a future period because none

of them represent an asset as defined by the accounting profession.

The discussion above has focused on the costs incurred by a manufacturer of goods. The discussion is also pertinent to a business that provides a service to its customers. Providers of services still incur material costs (such as cleaning supplies), labor costs, and general overhead related to providing the services. The major distinction is that, since no tangible product is created, no "product" costs can be deferred to a later period in which they will be sold.

COMPUTING THE COSTS OF PRODUCING A PRODUCT OR SERVICE

Manufacturing companies use a variety of production processes in creating goods. These processes include job shops, batch flows, machine-paced line flows, worker-paced line flow, continuous flows, and hybrids that consist of more than one of the previous separate flow process. The type of production process to a certain extent determines the type of product costing system that a company utilizes.

Job shops, such as machine shops, receive orders for products that are manufactured to the unique blueprint specifications of the requesting customer. As such, it would be rare for these products to meet the needs of any other customer. Thus each "job" must be accounted for separately as the goods are produced and no goods would be produced on a speculative basis. An appropriate method to determine the cost of each unique item produced is activity-based costing (ABC). The essence of ABC costing is that the exact costs of materials and labor, and a highly accurate estimate of factory overhead costs based on the specific activities (cost drivers) incurred to produce the goods, are determined for each unique product.

Batch flow processes (such as clothing manufacturers use) and worker-paced line flows (such as found in fast-food operations) can both use traditional product costing. This product costing system captures the exact costs of materials and labor while using some predetermined overhead rate to associate an appropriate amount of overhead with each product made. A very common basis for determining the overhead rate is the amount of labor time required to produce each unit of product. To determine the overhead rate, management must first estimate the total overhead costs for the upcoming year. Then an estimate of direct labor hours expected for the same period must be made. Finally the estimated overhead is divided by the estimated total direct labor hours and the resulting overhead rate per hour can be established. As each batch of products is completed and the total direct

labor hours used is made known from time cards, the overhead rate is multiplied by the actual hours and the overhead is said to be "applied" to the products.

The traditional product costing method was especially popular in the United States until the mid-1980s when labor costs were still a significant portion of the total cost of products. However, with technological changes (such as computer-integrated manufacturing) and more capital intensive approaches to production (such as robotics), the use of a dwindling labor component of product cost as a basis to apply overhead cost was no longer adequate. This was the impetus for the development of ABC costing mentioned above.

Machine-paced line flow processes (such as used by automobile manufacturers) lend themselves to process cost accounting. In this system of product costing, products' costs are accumulated during each of the numerous processes through which the products flow. In the case of an automobile manufacturer, some of the processes might include subassembly stations that reside offline from the main conveyor system where engine assembly, dashboard assembly and the like occur. These major components and their related material, labor, and overhead costs are then carried forward to the next process and new material, labor, and overhead costs are added in each successive process until completion. Thus the individual costs incurred in each process and the total costs incurred are available for financial statements and decision-making purposes.

Companies that use a continuous flow process of production, such as a paper manufacturing company that operates 24/7, would likely use a standard costs system. This product costing system not only accumulates the actual costs incurred in manufacturing the product, but it also determines the standard costs that should have been incurred (based on predetermined standards for material, labor, and factory overhead). By allowing comparisons between actual and standard totals, any discrepancy or variance can be noted and investigated. In particular, any unfavorable costs being incurred can be corrected in a timely manner.

COST BEHAVIOR

One of the critical steps in decision making is the estimation of costs to be incurred for the particular decision to be made. To be able to do this, management must have a good idea as to how costs "behave" at different levels of operations; i.e., will the cost increase if production increases or will the cost remain the same? A common use of cost behavior information is the attempt by management to predict the total production costs for units to be manufactured in the upcoming month. There are several methods used to estimate total product costs:

the high-low method, a scatter-graph, and least-squares regression. Each of these methods attempts to separate costs into components that remain constant (fixed) in total, regardless of the number of units produced and those that vary in total in proportion to changes in the number of units produced. Once the behavior of costs is known, predictive ability is greatly enhanced.

Use of the high-low method requires the use of only two past data observations: the highest level of activity (such as the number of units produced during a time period) and the associated total production cost incurred at that level, and the lowest level of activity and its associated cost. All other data points are ignored and even the two observations used must represent operations that have taken place under normal conditions. The loss of input from the unused data is a theoretical limitation of this method.

The scatter-graph method requires that all recent, normal data observations be plotted on a cost (Y-axis) versus activity (X-axis) graph. A line that most closely represents a straight line composed of all the data points should be drawn. By extending the line to where it intersects the cost axis, a company has a fairly accurate estimate of the fixed costs for the period. The angle (slope) of the line can be calculated to give a fairly accurate estimate of the variable cost per unit. The inclusion of the effect of all data points is a strength of this method, but the unsophisticated eyeballing of the appropriate line is a weakness.

The most robust method is the least-squares regression method. This method requires the use of thirty or more past data observations, both the activity level in units produced and the total production cost for each. This technique is known for its statistical strengths but its sophistication requiring the use of software packages can be a hindrance.

Assuming that a company has used one of the techniques above and has separated costs of manufacturing its products into fixed and variable components, it can use the following general model and substitute derived fixed and variable amounts to create a specific model:

General Model: Total cost = Fixed Costs for a Month + Variable Cost per Unit

Specific Model: Total Cost Expected = $10,000 per Month + $5.00 per Unit

Given this specific model, a prediction can easily be made of the total costs expected when any number of units are budgeted, as long as the number of units is far within the normal range of operations for the company.

For example, if 5,000 units are budgeted for the next month's production, the total expected cost would be:

$$\$10,000 + \$5.00 \ (5,000) = \text{Total Cost} = \$35,000$$

If the cost separation technique is fairly accurate, we are in a position to review whether actual costs are in line with our projected cost. Any significant variation between anticipated cost and actual costs should be investigated. The identification of any variances does not answer any questions; the variances merely note that investigation to ascertain the answers is needed.

One other idea is worth mentioning. Considering total production costs in the example above, the same techniques used to separate total costs into fixed and variable components can be utilized to separate any individual cost that isn't readily identifiable as being fixed or variable. A company could, for instance, take the past monthly factory electrical utility bills or the sales wages and use any of the three techniques to separate this individual cost into its fixed and variable components.

SETTING PRICES

Setting the price for goods and services involves an interesting interaction of several factors. The price must be sufficient to exceed the product and period costs and earn a desirable profit. For normal sales to external customers, most companies are unable to unilaterally set prices. Prices are typically set in these competitive markets by the laws of supply and demand. However, if a company manufactures a product unique to customer specifications, or if the company has a patent to its product, then the company can set its own price. One approach to accomplish this is cost-plus pricing. As discussed above, the company must have knowledge of the costs that it will incur. Then the company can apply the proper markup, given the competitive market conditions and other factors, to set its target-selling price.

Some companies add their markup to their variable costs, rather than using the full cost needed for cost-plus pricing. Variable cost pricing is especially useful in special instances such as in pricing special orders or when the company has excess capacity. In both of these cases, production and sales at normal prices to regular customers will be sufficient to cover the total fixed and variable costs for typical sales levels and the concern is only for the incremental units above normal sales levels.

Nissan Motors and other automobile manufacturers take what might be considered a "backward" approach to setting the prices of their vehicles relative to their expected costs. This approach is known as target costing. Once these companies determine what type of vehicle and market niche they wish to pursue, they test the market

to see what "target price" the market will bear for their vehicle. From this number they deduct their "desired profit" in order to determine the "target cost" for their product. Then they gather the experts needed to ascertain if they will be able to produce the vehicle for this targeted cost.

If a company has two or more divisions and the output of one division can be used as input to a subsequent division, a price can be set for "sale" from one division to the next in order to measure profitability for each division. This internal transfer price should be set so as to encourage division managers to purchase and sell internally, thus maximizing overall company profits. Transfer prices can be determined based on negotiations between the affiliated divisions, based on the existence of excess capacity by the producing division, based on marking up the variable cost of the goods sold internally, or based on market prices for similar goods, and other approaches.

BUDGETING AND BUDGETARY CONTROLS

Managers use budgets to aid in planning and controlling their companies. A budget is a formal written expression of the plans for a specific future period stated in financial terms. Jerry Weygandt, Donald Kieso, and Paul Kimmel's book, *Managerial Accounting: Tools for Business Decision Making* lists the following benefits of budgeting:

1. It requires all levels of management to plan ahead and formalize goals on a repetitive basis.

2. It provides definite objectives for evaluating performance at each level of responsibility.

3. It creates an early warning system for potential problems so that management can make changes before things get out of hand.

4. It facilitates the coordination of activities within the company by correlating segment/division goals with overall company goals.

5. It results in greater management awareness of the company's overall operations including the impact of external factors such as economic trends.

6. It motivates personnel throughout the company to meet planned objectives.

The master budget is the set of interrelated budgets for a selected time period. The specific parts to the master budget are the operating budgets and the financial budgets. The operating budgets begin with a sales budget derived from the sales forecasts provided by the marketing department, followed by the related unit production budget with detail budgets for direct materials, direct labor, and factory overhead. Finally a budget for selling

and administrative expenses provides the final information needed for a budgeted income statement. The financial budgets, based on data from the budgeted income statement, are composed of a cash budget, a budgeted balance sheet, and a budget for capital expenditures.

Budgetary control is the process of comparing actual operating results to planned operating results and thereby identifying problem areas in order to take corrective actions. A starting point in this effort is the conversion of the master budget (determined at the start of the period and based on the most probable level of operations) into a flexible budget for the actual level of operations attained. Developing a flexible budget requires identifying the variable costs and the fixed costs for the period as discussed above. Once these cost behavior determinations have been made, total variable costs for the actual level of operations and the total fixed costs for the period can be combined into a flexible budget that discloses the costs that should have been incurred for the actual level of operations achieved.

In taking corrective actions, one must be aware of whether or not a manager is responsible for a particular cost that has been incurred. While all costs are controllable at some level of responsibility within a company, only the costs that a manager incurs directly are controllable by them. Any costs that are allocated to the manager's responsibility level are not controllable at the manager's level.

The information above focused on budgetary controls for total costs, including product costs for units being produced and sold, general and administrative expenses, selling expenses, and any financial expenses incurred during the period. When comparing actual to standard costs for material, labor, and factory overhead costs, the use of a standard product costing system is needed to provide the detail to analyze each separate product cost component.

CAPITAL BUDGETING

Companies with excess funds must make decisions as to how to invest these funds to maximize their potential. The choices that involve long-term projects require the use the technique of capital budgeting, that is, choosing among many capital projects to find those that will maximize the return on the invested capital. Several methods of capital budgeting are available to management; among these are the payback period method, the net present value method, and the internal rate of return method. All of these methods require the use of estimated cash flow amounts.

The payback period method is especially simple if future inflows from the project being considered happen to be equal in amount each year. In this case, the formula for computing the payback period is:

$$\text{Cost of Capital Project} \div \text{Net Annual Cash Inflow} = \text{Payback Period}$$

If the project has uneven cash flows, creating a table with a cumulative net cash-flow column will identify the year and an estimate of the portion of a year in which the project recoups its cost. A weakness of this method is that it does not consider the time value of money over the life of the project. However, the shorter the payback period is, the sooner the project's cost is recovered and the more attractive the project is.

A strength of the net present value method is that it uses the same cash flow information as described above and it requires that each cash flow be discounted by an appropriate discount rate to allow for the time value of money. The appropriate discount rate could be the company's weighted average cost of capital or its required rate of return. After each cash inflow has been discounted to the point in time at which the investment is made, the total of the discounted cash inflows is compared to the cost of the capital project. If the present value of the net cash inflows equals the cost of the investment in the project, then the project is earning exactly the interest rate chosen for discounting. The exact discount rate at which the two values are equal is known as the internal rate of return. If the present value of the net cash inflows exceeds the cost of the capital project, the project is earning more than the discount rate. If the cost of the capital project exceeds the present value of the net cash inflows, that is, the net present value is negative; then the project is not earning at least the discount rate. While the project is profitable if the cash inflows exceed the cash outflows, it would be rejected since it is not earning the return that is needed.

Modern management theory stresses that setting and reaching goals requires that test readings and adjustments along the way are essential. The recent period of increased international competition has led to the need for cost cutting; some companies have been successful by downsizing, expanding globally, and capturing long-term contracts to minimize the increase in costs. Cost accounting can greatly benefit management by providing product or service cost information for use in planning, directing, and controlling the operations of the business.

While many firms vigorously support cost accounting, it does have its detractors as well. For instance, cost accounting has been criticized for being too focused on cutting costs rather than maximizing efficiency. In 1984 Eliyahu M. Goldratt (1948-) wrote *The Goal*, which described an alternative management-accounting theory called throughput accounting (TA) based on the

performance measures used in the theory of constraints (TOC). According to TA, the method of applying overhead rates in cost accounting distorts figures by assuming that all parts of a system are equally valuable. TA seeks to maximize profit by increasing throughput, defined as the rate at which a system generates money. The TOC contends there is a limiting factor in all production processes, which can be identified and managed to increase throughput.

CULTURE— ORGANIZATIONAL

SEE *Organizational Culture*

CUSTOMER RELATIONSHIP MANAGEMENT

By definition, customer relationship management (CRM) uses technology that enables organizations to provide fast and effective customer service by developing a relationship with each customer through the effective use of customer database information systems. CRM objectives are to acquire new customers, retain the right current customers, and grow the relationship with an organization's existing customers. CRM is actually a combination of organizational strategy, information systems, and technology focused on providing better customer service. Businesses that successfully implement CRM systems follow an integrated business model that ties together technology, information systems, and business processes along the entire value chain of an organization.

CRM is a fundamental approach to doing business. As mentioned above, CRM implementations stretch beyond technology and must consider and include broader organizational requirements. The goal is to be customer-focused and customer-driven, running all aspects of the business to satisfy the customers by addressing their requirements for products and by providing high-quality, responsive customer service. Companies that adopt the CRM approach are customer-centric, rather than product-centric.

To be customer-centric, companies need a comprehensive customer database to collect and store meaningful information about individual customers or prospects. The database must be current, accessible, and actionable in order generate leads for new customers while supporting sales and the maintenance of current customer relationships. Smart organizations collect information every time a customer comes into contact with the organization. Based on what is known about the individual customer, organizations can customize market offerings, services, programs, messages, and choice of media. A customer database ideally contains the customer's history of past purchases, demographics, activities/interests/opinions, preferred media, and other useful information. Also, this database should be available to any organizational units that have contact with the customer.

CRM is further enhanced when various departments within a business (such as sales, technical support, and marketing) share the information they collect from customer interactions. Feedback from a tech-support center, for example, could be used to inform marketing staffers about specific services and features requested by customers. In this practice (called collaborative CRM), the ultimate goal is to use information collected from all departments to improve the quality of customer service, and, as a result, increase customer satisfaction and loyalty.

EVOLUTION OF CRM

CRM initially referred to technological initiatives to make call centers less expensive and more efficient. The concept of CRM evolved from there as organizations began looking at more macro-organizational changes. For instance, many organizations began asking how they could change their business processes to use the customer data that they have gathered. CRM strategies now cover customer interaction across the entire organization. Many commercial CRM software packages provide features that serve sales, marketing, event management, project management, and finance.

Since its mid-1990s beginnings, CRM has already gone through several overlapping stages. Originally focused on automation of existing marketing processes, CRM has made a major leap forward to a customer-driven, business process management orientation.

The first stage began when firms purchased and implemented single-function client/server systems to support a particular group of employees such as the sales force, the call center representatives, or the marketing department. CRM initially meant applying automation to existing marketing activities and processes. However, automating poorly performing activities or processes did little to improve the quality of the return on investment.

In the second stage, organizations demanded more cross-functional integration to create a holistic view of their customers' relationships. Also, the integrated system's goal was to provide a single face to the customer by enabling employees to work from a common set of customer information gathered from demographics, Web hits, product inquiries, sales calls, and so forth. Cross-functional integration allowed the whole organization to take responsibility for customer satisfaction and allowed for better predictive models to improve cross-selling and improved products and delivery options.

The Internet heavily influenced the third stage of CRM. In this stage, the big CRM vendors used new Internet-based systems to extend the reach of CRM to thousands of employees, distribution partners, and even the customers themselves. Also, most organizations at this stage tie together their CRM systems with their ERP (Enterprise Resource Planning) system and other organizational operational systems. By rethinking the quality and effectiveness of customer-related processes, many organizations began to eliminate unnecessary activities, improve outdated processes, and redesign systems that had failed to deliver the desired outcomes.

NEW USERS OF CRM

CRM systems in the twenty-first century are based on the things that matter most to the customer. Customers often have direct access to all of the information they need in order to do business with an organization. But because some customer relationships are not profitable, many CRM systems focus heavily on financial results. CRM systems help organizations to identify existing profitable customer segments and develop the business requirements to support sustained relationships with these profitable segments.

Banks, for instance, are able to deploy technology solutions that may have artificial intelligence (AI) capabilities. These AI characteristics allow the banks to set dynamic limits for certain programs (such as overdraft protection programs), and enable the bank to offer differ-

ent services to customers based on their usage and past history of repayment. At the same time, using these types of CRM solutions, financial institutions are able to provide cost effective alternatives for current non-buyers or low-margin customers.

Banking giant Chase has taken advantage of CRM by grouping and analyzing data pulled from the bank's tellers, ATM machines, Web site, and telephone service reps. Chase can pinpoint which of millions of customers in its huge network of banks have wealth potential, and subsequently provide better customer service for them. With these types of CRM programs, Chase improves its sales and services by integrating and mining customer information.

The scope of CRM technology grows in importance when companies complete mergers and acquisitions. Researchers say that merged companies need a centralized CRM system to capitalize on the strengths of the combined entity. CRM systems also enable the organization to provide consistent, high levels of client care. CRM systems in these companies will help to ensure revenue growth and consistent client service.

THE FUTURE OF CRM

In 2008, it was reported that 67 percent of CRM implementations result in a successful return on investment (ROI). The reason for this is that CRM is being treated as a formally constructive corporate initiative, rather than an ad hoc operation as it was in its earliest incarnation.

When queried in 2005, 60 percent of midsize businesses planned to adopt or expand their CRM usage in the next two years, according to the Gartner Group. That fast rate of adoption has continued. AMI-Partners Research predicted that global CRM market will increase at an average annual rate of 13 percent through 2012. AMI-Partners credited this growth to the large number of CRM vendors who are offering more targeted solutions with a wide range of prices and more accountability. DataMonitor expects the CRM market profits to nearly double from $3.6 billion to $6.6 billion during the same time period.

DataMonitor and KensingtonHouse credit the growing acceptance of the SaaS (Software as a Service) delivery model as a key driver behind CRM growth. DataMonitor also found that vertical sectors such as health care and life sciences have a growing interest in CRM, and these verticals are being targeted by niche vendors. At the same time, smaller companies are deploying more CRM technologies. Companies with fewer than one thousand employees will make up 42 percent of the market by 2012, DataMonitor predicts.

ASPECTS TO CONSIDER FOR CRM

CRM marketers focus on customer retention, loyalty, and profitability. To do this, they focus on the following initiatives: increasing attention on data analysis, enhancing the customer experience, providing more personalization and customization, and increasing mobile marketing. Many companies with a core CRM system will add more functionality before 2010 to reach these goals. The areas targeted for expansion include: sales force collaboration, lead generation management, sales analytics/forecasting, sales knowledge management, CRM/sales process integration, and incentive management.

PROBLEMS WITH CRM

In a study, Forrester Research found that companies give customers an average of 3.5 ways to reach them. But often, that information isn't linked. Data on purchases that shoppers make at a company's retail store resides in one database, information on Web site activity lives in another, and customer-service reps in a company's telephone help center might not have real-time access to either one. Also, not all customers want a relationship with the company; some may resent the organization collecting information about them and storing it in a database.

However, several hurdles of CRM deployment have been crossed. Cost has decreased with the advent of packaged applications that take a considerable amount of risk out of any CRM implementation. Development and testing time is reduced and, as a result, costs are typically lower. With standardized CRM building blocks, packaged applications enable companies to focus on the business value and making sure their CRM systems meet their business needs. These packaged applications are implemented faster and enable companies to more quickly reach their ROI.

HOW TO SUCCEED WITH CRM

CRM projects require careful planning and implementation. To be successful, CRM involves major cultural and organizational changes that often are met with much resistance. CRM should be enterprise-wide in scale and scope. However, it is usually better to take an incremental approach starting with a CRM pilot. Once the pilot succeeds, introducing one CRM application at a time is recommended. Also, it is important to be skeptical of vendor claims and to know that user expectations for CRM are often unreasonable.

CYCLE TIME

Time has become a key success measure in business. Oftentimes, it is more important than other performance measures. In marketing, for example, a product's success or failure often depends on "time-to-market," or how quickly a new product becomes available to the customer. "Time-to-market" is one of many cycle-time measures used in management. Cycle time is the measure of a business cycle from beginning to end. Production cycle time refers to production activities, such as the total time required to produce a product. Order-processing cycle time is used in the front office to determine the total time required to process an order. From a financial perspective, cash-to-cash cycle time describes the amount of time a company takes to recover its financial investment. From a management perspective, cycle time is used to evaluate performance in all aspects of a business.

Cycle time is a key measurement tool for the performance of a number of management concepts, including supply chain management (SCM), just-in-time (JIT) management, enterprise resources planning (ERP), theory of constraints management, and lean management. Cycle-time improvements in any of these areas have been linked to reduced costs, reduced inventories, and increased capacity. The resource areas that are measured by cycle time include the measurement of financial flow, materials flow, and information flow. In each case, a delay or failure of any of these measures would indicate a failure of the entire business process.

Cycle time is best illustrated by a few examples. In marketing, time-to-market cycle time is the critical measure of success in the fashion, apparel, and technology industries. Companies that cannot get products to market quickly may get completely washed out. Time-to-market is the measure of time from idea inception through idea development, design and engineering, pilot, and finally production and customer availability. For example, the United States led the world in the idea phase of automotive airbag development. However, a slow design and engineering process enabled the Japanese to offer airbags in their vehicles several years before the United States.

Another example of cycle time is the production cycle time. This starts when an order is released on the production floor and ends when the product is available for shipment to the customer. Production cycle time became a key performance indicator in the automobile industry when, in the 1980s and 1990s, a system of manufacturing pioneered by the Japanese company Toyota was imported to the United States. Prior to the introduction of the Toyota Production System (TPS), American manufacturing operated on a volume-driven batch-and-queue system. This was characterized by long cycle times and the staging of large amounts of work-in-process inventories. Now that many American manufacturers have adopted the principles of lean manufacturing (by reducing inventories to increase efficiency and shorten production cycle times), companies seek to gain a competitive advantage by practicing lean product development in order to shorten the time-to-market cycle.

Another example of cycle time is order-processing time. Unfortunately, in far too many factories the time it takes to process an order is longer than the time it takes to manufacture the product. Order processing time starts when a phone call or fax initiates the order, and ends when the order is sent to production scheduling. This cycle time includes all paperwork-related steps, such as credit verification and order form completion.

In finance, performance measures such as cash-to-cash cycle time reflect a company's cash performance. This is the amount of time it takes from the time money is spent on a customer's product for the purchase of components until the "cash" is recovered from the customer in the form of a payment. In 2007, the median cash-to-cash cycle time in the computers and peripherals sector was thirty-six days. Apple Computers led the industry's top revenue earners with a cash cycle of negative thirty-six days, followed by Dell at negative twenty-three days. Apple and Dell have the advantage of being able to utilize its customers' cash to earn interest. Dell can then use this advantage to offer price incentives that the other computer manufacturers cannot.

A variant use of the term "cycle time" is found in industrial engineering. In this specific example, cycle time has a number of meanings, depending on the situation in which the term is used and the industry to which it is applied. Generally it is considered to be a manufacturing term applied to an environment where a series of activities or tasks (each with a predetermined completion time known as the task time) are performed in a specified sequence known as a "precedence relationship." However, the term can be used in the service sector if the rendering of the service requires a sequential series of tasks. As these tasks are completed at each operation or workstation, the product is passed on to the next workstation in the sequence until the product is complete and can be defined as a finished good.

The predetermined task times govern the range of possible cycle times. The minimum cycle time is equal to the longest task time in the series of tasks required to produce the product, while the maximum cycle time is equal to the sum of all the task times required for a finished good. For example, consider a product that requires five sequential tasks to manufacture. Task one takes 10 minutes to complete; task two, 12 minutes; task three, 20 minutes; task four, 8 minutes; and task five, 10

minutes. The minimum cycle time for this product would be 20 minutes (the longest time). Any cycle time less than 20 minutes would not allow the product to be made, because task three could not be completed. The maximum cycle time would be 60 minutes, or the sum of all task times in the sequence. This implies a range of possible cycle times of 20 to 55 minutes. However, the maximum cycle time would really only be feasible if there was no waste or non-value-added time in the process, such as delays between tasks. Some people refer to the sum of the task times as throughput time or the time required to move a product completely through the system.

However, in its more general usage, cycle time is how long it takes for material to enter and exit a production facility. Depending on the industry, this definition is appropriate with slight modifications. For example, in the automobile collision repair industry, cycle time refers to the time a car enters the facility for repair until the repair is completed.

D

DATA PROCESSING AND DATA MANAGEMENT

Most data management methods draw distinction between data, information, and knowledge. Data is specifically a collection of mathematical truths and facts, an *is* statement of some sort, without any interpretation. Information is data that has context, showing movement and action of some specific entity. When data communicates a clear change, it has become information. Knowledge is the third form, essentially information in the hands of an experienced analyzer. Knowledge communicates what is likely to happen, how a company can use information, and what the implications of information are for the company.

In the eLearning Training company's 2007 *Making Sense of Data and Information*, several ways are given to convert data to information, and information to knowledge. Data is made of facts, often factual numbers such as sales figures, accident records, production output, costs of resources, and so on. Upon conversion to information, the data is put into a specific framework. This framework could be something like charts that identify certain trends, averages, and/or significant variables. Generally, to convert data to information, a clear set of data must be specified as affecting the business, followed by a clear and regular method of collecting the pertinent data, and joined by the ability to convert the data in some form of analysis, such as computer programs and mathematical formulas.

There are many processes used to collect, define, and organize data into information. Some of the tools analysts use include the following:

1. Data cleaning is the process of removing unnecessary or cluttering data that has no relevance to factors the analysis is focusing on.

2. Data integration is the process of combining similar sets of data to make analysis easier.

3. Data selection is the process, often automated, of retrieving pertinent sets of data from some type of data collection.

4. Data transformation involves placing the data into a form in which it can be accessed for specific types of analysis.

5. Data mining involves using carefully designed methods to access and gather data.

Changing information to knowledge is a more nebulous area, affected largely by the skills of the analysts and the needs of the company. Some business knowledge comes directly from information: production methods based on reliable manufacturing data is one type of knowledge directly branching from collected information. Reliable company policies use such knowledge as the basis of their operation. Other types of knowledge exist in companies but are more difficult to trace to information. This includes intuitive and experiential knowledge, such as the skills of an employee who is able to predict the outcome of data analysis because of previous work with sets of data.

Most of the methods discussed below pertain to changing data, the raw facts, into types of information. Data management includes the methods, concepts, and trends connected to this process.

CHARACTERISTICS OF VALUABLE INFORMATION

According to Ralph M. Stair in his 1999 book, *Principles of Information Systems,* in order for information to be valuable, it must be:

1. **Accurate.** Accurate information is free from error.

2. **Complete.** Complete information contains all of the important facts.

3. **Economical.** Information should be relatively inexpensive to produce.

4. **Flexible.** Flexible information can be used for a variety of purposes, not just one.

5. **Reliable.** Reliable information is dependable information.

6. **Relevant.** Relevant information is important to the decision-maker.

7. **Simple.** Information should be simple to find and understand.

8. **Timely.** Timely information is readily available when needed.

9. **Verifiable.** Verifiable information can be checked to make sure it is accurate.

DATA GOVERNANCE

Data governance refers to the methods, people, and policies involved in managing data. Those who work in data governance develop the strategies the company uses to sort information and change it into useful knowledge. There are a number of titles given to those involved in data governance, including data trustee, data steward, data registrar, data administrator, director of information flow, and director of application development. Although the tasks for these employees vary, database security and database development are the two primary areas of data governance. For those who wish to develop a data governance system or department for their organization, David Loshin, in his 2001 book, *Enterprise Knowledge Management,* suggests several steps for bringing together the right individuals:

1. Identify those who have a clear interest in the results of developed data. This could include specific investors, members of the corporate board who are in charge of security or information systems, and other company leaders who would be involved in data governance.

2. Create a full list of the data sets to be put under the data governance system.

3. Define who is currently in charge of the data systems, and determine whether or not those titles and employee positions should persist.

4. Create the necessary new roles in data governance, and assign those roles to interested parties.

5. Develop a registry that contains all information involved in data governance, as well as the lists and roles that have so far been created.

Once a data governance system has been established, there are many ways to begin managing the company data itself. In their 2007 book, *Master Data Management and Customer Data Integration for Global Enterprise*, Berson and Dubov give three activities often undertaken by data governance systems.

First, the process should be defined and implemented. This requires setting up the proper connections between the main storage of data and those who need to use it—the analysts and data governance leaders. How is the data going to get into the system? How many people will able to use it? To what standard is the data going to be set? How will like sets of data be linked for easy access? How will duplicate sets of data be resolved into one form? These are the sort of questions the data governance process needs to answer. This is done through a detailed integration of the system and the users, setting up steps to download the data, refine the data, and gather the data into proper families. In addition to setting up these important methods, the process should also include a manual way to investigate and delete unnecessary data (this is a correlation to automatic correction systems).

Second, some form of technology should be chosen and implemented to organize and deliver the data. There are many programs capable of doing this, and the company should choose a system tailored to meet its specific needs. Who will be using the data technology? Will it be a subset of an established intranet system? How will it label the data for those who need to access it? When considering a form of data software, there are several abilities data governance leaders should watch for, including:

- The ability to automatically monitor incoming data from all offices or data hubs

- The ability to track changes in data standards and organization over time, to better understand the accuracy and usability of the data presented

- The ability to incorporate data from other systems besides the company's, and deal with sudden changes in data or data organization

- The ability to provide a consistent and reliable platform to base data decisions on

Third, a company should make sure all their data is available for auditing and accountability purposes. Outside confirmation of the quality and purposes of a company's data is essential. Legislation such as the 2002 Sarbanes-Oxley law requires that businesses sign off on the accuracy and clarity of their information, so having checks and balances set up within a data governance system can be crucial in compliance issues. Data stewards often have the task of ensuring data accountability.

Data can be organized and connected in several ways, one of the most common electronic methods being the database approach. The database approach is such that multiple business applications access the same database. Consequently, file updates are not required of multiple files. Updates can be accomplished in the common database, thus improving data integrity and eliminating redundancy. The database approach provides the opportunity to share data, as well as information sources. Additional software is required to implement the database approach to data management. A database management system (DBMS) is needed. A DBMS consists of a group of programs that are used in an interface between a database and the user, or between the database and the application program. Advantages of the database approach are presented in Table 1. Disadvantages of the database approach are presented in Table 2.

METADATA

Metadata is defined most commonly as "data about data," and is essential in creating data management methods. At its basic form, metadata is the labels and categories placed on data to make analysis easier. For instance, the metadata for a book would contain—not the book itself—but the author, language, and ISBN of the book. Most people encounter and manipulate metadata when searching for subjects on the Internet. The bits of information pertaining to Web sites that most search engines list is all metadata, and it is sifted through by the searcher to find pertinent data.

In a company's data governance system, metadata is used to classify and control the data available. When analysts chose and manipulate large data groups, they do so through the information collected from metadata. The file type, the name, the timestamp, the physical and electronic location, the owner, and the access permissions are all common types of metadata found in company file systems.

DATABASE MODELS

The structure of the relationships in most databases follows one of three logical database models: hierarchical, network, and relational.

- A hierarchical database model is one in which the data are organized in a top-down or inverted tree-like

Table 1
Advantages of the Database Approach

Advantages	Explanation
Reduced data redundancy	The database approach can reduce or eliminate data redundancy. Data is organized by the DBMS and stored in only one location. This results in more efficient utilization of system storage space.
Improved data integrity	With the traditional approach, some changes to data were not reflected in all copies of the data kept in separate files. This is prevented with the database approach because there are not separate files that contain copies of the same piece of data.
Easier modification and updating	With the database approach, the DBMS coordinates updates and data modifications. Programmers and users do not have to know where the data is physically stored. Data is stored and modified once. Modification and updating is also easier because the data is stored at only one location.
Data and program independence	The DBMS organized the data independently of the application program. With the database approach, the application program is not affected by the location or type of data. Introduction of new data types not relevant to a particular application does not require the rewriting of that application to maintain compatibility with the data file.
Better access to data and information	Most DBMSs have software that makes it easier to access and retrieve data from a database, in most cases, simple commands can be given to get important information. Relationships between records can be more easily investigated and exploited, and applications can be more easily combined.
Standardization of data access	A primary feature of the database approach is a standardized, uniform approach to database access. This means that the same overall procedures are used by all application programs to retrieve data information.
A framework for program	Standardized database access procedures can mean more standardization of program development. Because programs go through the DBMS to gain access to data in the database, standardized database access can provide a consistent framework for program development. In addition, each application program need only address the DBMS, not the actual data files, reducing application development time.
Better overall protection of the data	The use of and access to centrally located data is easier to monitor and control. Security codes and passwords can ensure that only authorized people have access to particular data and information in the database, and ensure privacy.
Shared data and information resources development	The cost of hardware, software, and personnel can be spread over a large number of applications and users. This is a primary feature of DBMS.

structure. This type of model is best suited for situations where the logical relationships between data can be properly represented with the one-parent-many-children approach.

- A network model is an extension of the hierarchical database model. The network model has an owner-

---

Table 2

Disadvantages of the Database Approach

Disadvantages	Explanation
Relative high cost of purchasing and operating a DBMS in a mainframe operating environment	Some mainframe DBMSs can cost millions of dollars.
Specialized staff	Additional specialized staff and operating personnel may be needed to implement and coordinate the use of the database. It should be noted, however, that some organizations have been able to implement the database approach with no additional personnel.
Increased vulnerability	Even though databases offer better security because security measures can be concentrated on one system, they also may make more data accessible to the trespasser if security is breached. In addition, if for some reason there is a failure in the DBMS, multiple application programs are affected.

---

member relationship in which a member may have many owners, in contrast to a one-to-many relationship.

- A relational model describes data using a standard tabular format. All data elements are placed in two-dimensional tables called relations, which are the equivalent of files. Data inquiries and manipulations can be made via columns or rows given specific criteria.

Network database models tend to offer more flexibility than hierarchical models. However, they are more difficult to develop and use because of relationship complexity. The relational database model offers the most flexibility and was very popular during the early 2000s.

DATABASE MANAGEMENT SYSTEMS

As indicated previously, a database management system (DBMS) is a group of programs used as an interface between a database and an applications program. DBMSs are classified by the type of database model they support. A relational DBMS would follow the relational model, for example. The functions of a DBMS include data storage and retrieval, database modifications, data manipulation, and report generation.

A data definition language (DDL) is a collection of instructions and commands used to define and describe data and data relationships in a particular database. File descriptions, area descriptions, record descriptions, and set descriptions are terms the DDL defines and uses.

A data dictionary also is important to database management. This is a detailed description of the structure and intended content in the database. For example, a data dictionary might specify the maximum number of characters allowed in each type of field and whether the field content can include numbers, letters, or specially formatted content such as dates or currencies. Data dictionaries are used to provide a standard definition of terms and data elements, assist programmers in designing and writing programs, simplify database modifications, reduce data redundancy, increase data reliability, and decrease program development time.

The choice of a particular DBMS typically is a function of several considerations. Economic cost considerations include software acquisition costs, maintenance costs, hardware acquisition costs, database creation and conversion costs, personnel costs, training costs, and operating costs.

Most DBMS vendors are combining their products with text editors and browsers, report generators, listing utilities, communication software, data entry and display features, and graphical design tools. Consequently, those looking for a total design system have many choices.

DATA MINING

The process of collecting applicable data is referred to as data mining. Most data governance systems have automatic data-mining programs designed to fit the analysts' needs. These programs sort through and summarize data according to certain parameters. If a company wanted to cut costs in manufacturing, for instance, a data-mining activity would be done to search for figures and facts concerning manufacturing, collect that data into different categories such as supply costs and worker costs, and finally transmit the categorized data to the proper people.

To identify patterns, data mining is controlled by strict guidelines. For instance, one analysis might require a data mine of all associative information events that connected to each other through some type of relationship. Sequential patterns are another type of data mining parameter, where data is found in events that naturally lead to one another, such as the supply chain. Some data mining activities focus on classification and the search for new patterns in the available data. Still more data mining might be done to predict trends or outcomes of particular events.

Although data mining is an immensely popular tool, it does have blind spots. For the data mining to be useful, a skilled analyst must set clear parameters and interpret the data correctly. Data mining does not make value judgments or attribute importance.

DATA CLUSTERING

Data clustering is often confused with data mining, but the two are separate actions. Data clustering is a subset of data mining, and is usually performed first in a data-

mining activity. It is an automatic function, based on mathematic principles, that groups data into similar categories. When a data-mining operation is run, the data is clustered into applicable areas such as "Costs" and "Profits." The data-mining operation then goes on to apply more required parameters to the data.

DATA WAREHOUSING

Data warehousing involves taking data from a main computer for analysis without slowing down the main computer. In this manner, data are stored in another database for analyzing trends and new relationships. Consequently, the data warehouse is not the live, active system, but it is updated daily or weekly. For example, Wal-Mart uses a very large database (VLDB) that is 4 trillion bytes (terabytes) in size. Smaller parts of this database could be warehoused for further analysis to avoid slowing down the VLDB.

FUTURE TRENDS

A private database is compiled from individual consumer or business customer names and addresses maintained by a company for use in its own marketing efforts. Such a database may have originated as a public database, but typically once the company begins adding or removing information it is considered a private database. By contrast, public databases are those names, addresses, and data that are complied for resale in the list rental market. This is publicly available data (i.e., any business can purchase it on the open market) rather than lists of specific customers or targets.

However, a new trend is combining features of the two approaches. Cooperative databases are compiled by combining privately held response files of participating companies so that costs are shared. Many consider this to be a future trend, such that virtually all catalog marketers, for example, would use cooperative databases.

Geographic Information Systems (GIS) are becoming a growing area of data management. GIS involves combining demographic, environmental, or other business data with geographic data. This can involve road networks and urban mapping, as well as consumer buying habits and how they relate to the local geography. Output is often presented in a visual data map that facilitates the discovery of new patterns and knowledge.

Customer Resource Management (CRM) is another area where data process and data management is deeply involved. CRM is a set of methodologies and software applications for managing the customer relationship. CRM provides the opportunity for management, salespeople, marketers, and potentially even customers, to see sufficient detail regarding customer activities and contacts. This allows companies to provide other possible products or useful services,

as well as other business options. Security of this information is of significant concern on both sides of the equation.

DEBT VS. EQUITY FINANCING

Equity financing takes the form of money obtained from investors in exchange for an ownership share in the business. Such funds may come from friends and family members of the business owner, wealthy "angel" investors, or venture capital firms. The main advantage to equity financing is that the business is not obligated to repay the money. Instead, the investors hope to reclaim their investment out of future profits. The involvement of high-profile investors may also help increase the credibility of a new business. Additionally, the company's assets do not have to be used as collateral to obtain equity, and the business does not have to make debt payments. The main disadvantage to equity financing is that the investors become part-owners of the business, and thus

gain a say in business decisions. "Equity investors are looking for a partner as well as an investment, or else they would be lenders," venture capitalist Bill Richardson explained in Pacific Business News (Jefferson, 2001). As ownership interests become diluted, managers face a possible loss of autonomy or control. In addition, an excessive reliance on equity financing may indicate that a business is not using its capital in the most productive manner.

Both debt and equity financing are important ways for businesses to obtain capital to fund their operations. Deciding which to use or emphasize depends on the long-term goals of the business and the amount of control managers wish to maintain. Ideally, experts suggest that businesses use both debt and equity financing in a commercially acceptable ratio. This ratio, known as the debt-to-equity ratio, is a key factor analysts use to determine whether managers are running a business in a sensible manner. Although debt-to-equity ratios vary greatly by industry and company, a general rule of thumb holds that a reasonable ratio should fall between 1:1 and 1:2. Some experts recommend that companies rely more heavily on equity financing during the early stages of their existence, because such businesses may find it difficult to service debt until they achieve reliable cash flow. However, start-up companies may have trouble attracting venture capital until they demonstrate strong profit potential. One advantage of debt funding is that interest payments are tax deductible, whereas payments to investors in C-corporations are not.

Hybrid securities are a broad group of securities that have characteristics of both debt and equity. These securities became popular in 2005 when the rating agency Moody's established a new set of guidelines that allowed institutions to classify securities on a debt-equity continuum. The previous policy had been to treat the entire amount as debt. Companies are attracted to hybrids because they tend to include enough equity-like features not to be classified as debt on the balance sheet, and have enough debt-like features to achieve tax-deductions and inexpensive capital.

In any case, all businesses require sufficient capital in order to succeed. The most prudent course of action is to obtain capital from a variety of sources, using both debt and equity, and hire professional accountants and attorneys to assist with financial decisions.

DECISION RULES AND DECISION ANALYSIS

A decision rule is a logical statement of the type "if [condition], then [decision]." The following is an example of a decision rule experts might use to determine an investment quality rating:

> If the year's margin is at least 4.27 percent and the year's ratio of shareholder funds to fixed assets is at least 35.2 percent, then the class of rating is at least lower investment grade (LIG).

The condition in this decision rule is "the year's margin is at least 4.27 percent and the year's ratio of shareholder funds to fixed assets is at least 35.2 percent," while "the class of rating is at least lower investment grade" is the decision part of the rule.

Decision rules give a synthetic, easily understandable, and generalized representation of the knowledge contained in a data set organized in an information table. The table's rows are labeled by objects, whereas columns are labeled by attributes; entries in the body of the table are thus attribute values. If the objects are exemplary decisions given by a decision maker, then the decision rules represent the preferential attitude of the decision maker and enable understanding of the reasons for his or her preference.

People make decisions by searching for rules that provide good justification of their own choices. However, a direct statement of decision rules requires a great cognitive effort from the decision maker, who typically is more confident making exemplary decisions than explaining them. For this reason, the idea of inferring preference models in terms of decision rules from exemplary decisions provided by the decision maker is very attractive. The induction of rules from examples is a typical approach of artificial intelligence. It is concordant with the principle of posterior rationality, and with aggregation-disaggregation logic. The recognition of the rules by the decision maker justifies their use as a powerful decision support tool for decision making concerning new objects.

There are many applications of decision rules in business and finance, including:

- Credit card companies use decision rules to approve credit card applications.

- Retailers use associative rules to understand customers' habits and preferences (market basket analysis) and apply the finding to launch effective promotions and advertising.

- Banks use decision rules induced from data about bankrupt and non-bankrupt firms to support credit-granting decisions.

- Telemarketing and direct marketing companies use decision rules to reduce the number of calls made and increase the ratio of successful calls.

Other applications of decision rules exist in the airline, manufacturing, telecommunications, and insurance industries. Another area where decision rules are being tested is in setting foreign policy, where small groups representing different and often conflicting perspectives must reach agreement. The way groups manage internal conflict can have a substantial affect on the agreement they reach. The group's decision will change based upon the type of decision rules followed as well as each member's primary allegiance.

DESCRIBING AND COMPARING INFORMATION ATTRIBUTES

The examples (information) from which decision rules are induced are expressed in terms of some characteristic attributes. For instance, companies could be described by the following attributes: sector of activity, localization, number of employees, total assets, profit, and risk rating. From the viewpoint of conceptual content, attributes can be one of the following types:

- Qualitative attributes (symbolic, categorical, or nominal), including sector of activity or localization

- Quantitative attributes, including number of employees or total assets

- Criteria or attributes whose domains are preferentially ordered, including profit, because a company having large profit is preferred to a company having small profit or even loss

The objects are compared differently depending on the nature of the attributes considered. More precisely, with respect to qualitative attributes, the objects are compared on the basis of an indiscernibility relation: two objects are indiscernible if they have the same evaluation with respect to the considered attributes. The indiscernibility relation is reflexive (i.e., each object is indiscernible with itself), symmetric (if object A is indiscernible with object B, then object B also is indiscernible with object A), and transitive (if object A is indiscernible with object B and object B is indiscernible with object C, then

object A also is indiscernible with object C). Therefore, the indiscernibility relation is an equivalence relation.

With respect to quantitative attributes, the objects are compared on the basis of a similarity relation. The similarity between objects can be defined in many different ways. For example, if the evaluations with respect to the considered attribute are positive, then the following statement may define similarity:

$$\frac{\text{Evaluation of A} - \text{Evaluation of B}}{\text{Evaluation of B}} \leq \text{Threshold}$$

For instance, with respect to the attribute "number of employees," fixing a threshold at 10 percent, Company A having 2,710 employees is similar to Company B having 3,000 employees. Similarity relation is reflexive, but neither symmetric nor transitive; the abandon of the transitivity requirement is easily justifiable, remembering, for example, Luce's paradox of the cups of tea (Luce, 1956). As for the symmetry, one should notice that the proposition $y\text{R}x$, which means "y is similar to x," is directional; there is a subject y and a referent x, and in general this is not equivalent to the proposition "x is similar to y."

With respect to criteria, the objects are compared on the basis of a dominance relation built using outranking relations on each considered criterion: object A outranks object B with respect to a given criterion if object A is at least as good as object B with respect to this criterion; if object A outranks object B with respect to all considered criteria then object A dominates object B. An outranking relation can be defined in many different ways. Oftentimes, it is supposed that outranking is a complete preorder (i.e., transitive and strongly complete). For each couple of objects, say object A and object B, at least one of the following two conditions is always verified: object A outranks object B and/or object B outranks object A. A dominance relation, built on the basis of the outranking relation being a complete preorder, is a partial preorder (i.e., it is reflexive and transitive, but in general not complete).

DECISION RULE SYNTAX

The syntax of decision rules is different according to the specific decision problem. The following decision problems are most frequently considered:

- Classification

- Sorting

- Choice

- Ranking

Following is a presentation of the syntax of decision rules considered within each one of the above decision problems.

Classification. Classification concerns an assignment of a set of objects to a set of predefined but non-ordered classes. A typical example of classification is the problem of market segmentation; in general there is no preference order between the different segments. The objects are described by a set of (regular) attributes that can be qualitative or quantitative. The syntax of decision rules specifies the condition part and the decision part.

With respect to the condition part, the following types of decision rules can be distinguished:

1. Decision rules based on qualitative attributes: "if the value of attribute q_1 is equal to r_{q1} and the value of attribute q_2 is equal to r_{q2} and...and the value of attribute q_p is equal to r_{qp}, then [decision]," where $r_{q1}, r_{q2},...,r_{qp}$ are possible values of considered attributes.

2. Decision rules based on quantitative attributes: "if the value of attribute q_1 is similar to r_{q1} and the value of attribute q_2 is similar to r_{q2} and...and the value of attribute q_p is similar to r_{qp}, then [decision]," where $r_{q1}, r_{q2},..., r_{qp}$ are possible values of considered attributes.

3. Decision rules based on qualitative and quantitative attributes: "if the value of attribute q_1 is equal to r_{q1} and the value of attribute q_2 is equal to r_{q2} and...and the value of attribute q_t is equal to r_{qt} and the value of attribute q_{t+1} is similar to r_{qt+1} and the value of attribute q_{t+2} is similar to r_{qt+2} and...and the value of attribute q_p is similar to r_{qp}, then [decision]," where $q_1 q_2...,q_t$ are qualitative attributes, $q_{t+1}, q_{t+2},..., q_p$ are quantitative attributes, and $r_{q1}, r_{q2},..., r_{qp}$ are possible values of considered attributes.

With respect to the decision part, the following types of decision rules can be distinguished:

1. Exact decision rule: "if [condition], then the object belongs to Y_j," where Y_j is a decision class of the considered classification.

2. Approximate decision rule: "if [condition], then the object belongs to Y_{j1} or Y_{j2} or...Y_{jk}," where $Y_{j1}, Y_{j2},..., Y_{jk}$ are some decision classes of the considered classification.

3. Possible decision rule: "if [condition], then the object could belong to Y_j," where Y_j is a decision class of the considered classification.

Sorting. Sorting concerns an assignment of a set of objects to a set of predefined and preference-ordered classes. The classes are denoted by Cl_1 Cl_2 and so on, and we suppose that they are preferentially ordered such that the higher the number, the better the class (i.e., the elements of class Cl_2 have a better comprehensive evaluation than the elements of class Cl_1 the elements of class Cl_3 have a better comprehensive evaluation than the elements of class Cl_2 and so on. For example, in a problem of bankruptcy risk evaluation, Cl_1 is the set of unacceptable-risk firms, Cl_2 is a set of high-risk firms, Cl_3 is a set of medium-risk firms, and so on. The objects are evaluated by a set of attributes that generally include criteria and qualitative and/or quantitative (regular) attributes. The syntax of the condition depends on the type of attributes used for object description. If there are criteria only, then the following types of decision rules can be distinguished:

1. Exact D≥ decision rule: "if evaluation with respect to criterion q_1 is at least as good as r_{q1} and evaluation with respect to criterion q_2 is at least as good as r_{q2} and...evaluation with respect to criterion q_p is at least as good as r_{qp}, then the object belongs to at least class t," where $r_{q1}, r_{q2},..., r_{qp}$ are possible values of considered criteria.

2. Exact D≤ decision rule: "if evaluation with respect to criterion q_1 is at most as good as r_{q1} and evaluation with respect to criterion q_2 is at most as good as r_{q2} and...evaluation with respect to criterion q_p is at most as good as r_{qp}, then the object belongs to at most class t," where $r_{q1}, r_{q2},...z, r_{qp}$ are possible values of considered criteria.

3. Approximate D≥≤ decision rule: "if evaluation with respect to criterion q_1 is at least as good as r_{q1} and evaluation with respect to criterion q_2 is at least as good as r_{q2} and...evaluation with respect to criterion q_h is at least as good as r_{qh} and evaluation with respect to criterion q_{h+1} is at most as good as r_{qh+1} and evaluation with respect to criterion q_{h+2} is at most as good as r_{qh+2} and...evaluation with respect to criterion q_p is at most as good as r_{qp}, then the object belongs to at least class t and at most to class t" where criteria $q_1 q_2...,q_k$ are not necessarily different from $q_{k+1}, q_{k+2},..., q_p$ and $r_{q1}, r_{q2},..., r_{qp}$ are possible values of considered criteria.

4. Possible D≥ decision rule: "if evaluation with respect to criterion q_1 is at least as good as r_{q1} and evaluation with respect to criterion q_2 is at least as good as r_{q2} and...evaluation with respect to criterion q_p is at least as good as r_{qp}, then the object could belong to at least class t," where $r_{q1}, r_{q2},..., r_{qp}$ are possible values of considered criteria.

5. Possible D≤ decision rule: "if evaluation with respect to criterion q_1 is at most as good as r_{q1} and evaluation with respect to criterion q_2 is at most as good as

r_{q2} and...evaluation with respect to criterion q_p is at most as good as r_{qp}, then the object could belong to at most class *t*," where r_{q1}, rq2,..., r_{qp} are possible values of considered criteria.

Choice and Ranking. Choice concerns selecting a small subset of best objects from a larger set, while ranking concerns ordering objects of a set from the best to the worst. In these two decision problems, the objects are evaluated by criteria and the decision is based on pairwise (relative) comparison of objects rather than on absolute evaluation of single objects. In other words, in these two cases the decision rules relate preferences on particular criteria with a comprehensive preference. The preferences can be expressed on cardinal scales or on ordinal scales: the former deal with strength of preferences and use relations like indifference, weak preference, preference, strong preference, absolute preference, while for the later the strength is meaningless.

Given objects *x, y, w* and *z,* and using a cardinal scale of preference, it always is possible to compare the strength of preference of *x* over *y* with the strength of preference of *w* over *z* and say whether the preference of *x* over *y* is stronger than, equal to, or weaker than the preference of *w* over *z.* Using an ordinal scale, the strengths of preference can be compared only if, with respect to the considered criterion, object *x* is at least as good as *w* and *z* is at least as good as *y.* Given an example of car selection, for any decision-maker, car *x,* with a maximum speed 200 kilometers per hour (124.28 miles per hour) is preferred to car *y,* with a maximum speed of 120 kilometers per hour (74.57 miles per hour) at least as much as car *w,* with a maximum speed 170 kilometers per hour (105.64 miles per hour) is preferred to car *z,* with a maximum speed 140 kilometers per hour (87 miles per hour). This is because it is always preferable to pass from a smaller maximum speed (car *y* versus *z*) to a larger maximum speed (car *x* versus *w*). The syntax of the decision rules in the choice and ranking problems depends on the distinction between cardinal and ordinal criteria:

1. Exact D≥ decision rule: "if with respect to cardinal criterion *q* 1, *x* is preferred to *y* with at least strength $h(q\ 1)$ and...and with respect to cardinal criterion *qe,* *x* is preferred to *y* with at least strength $h(qe)$ and with respect to ordinal criterion *qe* + 1, evaluation of *x* is at least as good as r_{qe+1} and evaluation of *y* is at most as good as s_{qe+1} and...and with respect to ordinal criterion q_{p+1}, evaluation of *x* is at least as good as r_{qp+1} and evaluation of *y* is at most as good as s_{qp+1}, then *x* is at least as good as *y,*" where $h(q\ 1),\ldots, h(qe)$ are possible strengths of preferences of considered criteria and $r_{qe+1},\ldots, r_{qp}$, and $s_{qe+1},\ldots, s_{qp}$ are possible values of considered criteria. A more concise illustration: "if

with respect to comfort (cardinal criterion) car *x* is at least strongly preferred to car *y* and car *x* has a maximum speed (ordinal criterion) of at least 200 kilometers per hour (124.28 miles per hour) and car *y* has a maximum speed of 160 kilometers per hour (99.42 miles per hour), then car *x* is at least as good as car *y.*"

2. Exact D≤ decision rule: "if with respect to cardinal criterion *q* 1, *x* is preferred to *y* with at most strength $h(q\ 1)$ and...and with respect to cardinal criterion *qe,* *x* is preferred to *y* with at most strength $h(qe)$ and with respect to ordinal criterion *qe* + 1, evaluation of *x* is at most as good as r_{qe+1} and evaluation of *y* is at least as good as s_{qe+1} and...and with respect to ordinal criterion *qp,* evaluation of *x* is at most as good as r_{qp} and evaluation of *y* is at least as good as s_{qp+1}, then *x* is not at least as good as *y,*" where $h(q\ 1),\ldots, h(qe)$ are possible strengths of preferences of considered criteria and $r_{qe+1},\ldots, r_{qp}$, and $s_{qe+1},\ldots, s_{qp}$ are possible values of considered criteria. An example of a D≤ decision rule: "if with respect to aesthetics (cardinal criterion) car *x* is at most indifferent with car *y* and car *x* consumes (ordinal criterion) at most 7.2 liters (1.90 gallons) of fuel per 100 kilometers (62.14 miles) and car *y* consumes at least at 7.5 liters (1.98 gallons) of fuel per 100 kilometers (62.14 miles), then car *x* is at most as good as car *y.*"

3. Approximate D≥≤ decision rule: the "if" condition has the syntax composed of the "if" parts of the D≥ rule and the D≤ rule. The "then" decision represents a hesitation: "*x* is at least as good as *y*" or "*x* is not at least as good as *y.*"

Using decision rules, it always is possible to represent all common decision policies. For instance, let us consider the lexicographic ordering: the criteria considered are ranked from the most important to the least important. Between two objects, the object preferred with respect to the most important criterion is preferred to the other; if there is an *ex aequo* (a tie) on the most important criterion, then the object preferred with respect to the second criterion is selected; if there is again an *ex aequo,* then the third most important criterion is considered, and so on. If there is an *ex aequo* on all the considered criteria, then the two objects are indifferent. The lexicographic ordering can be represented by means of the following D≤ decision rules:

1. If *x* is (at least) preferred to *y* with respect to criterion *q* 1, then *x* is preferred to *y.*

2. If *x* is (at least) indifferent with *y* with respect to criterion *q* 1 and *x* is (at least) preferred to *y* with respect to criterion *q* 2, then *x* is preferred to *y.*

3. If x is (at least) indifferent with y with respect to all the considered criteria except the last one and x is (at least) preferred to y with respect to criterion qn, then x is preferred to y.

4. If x is (at least) indifferent with y with respect to all the considered criteria, then x is indifferent to y.

Induction of decision rules from information tables is a complex task, and a number of procedures have been proposed in the context of such areas like machine learning, data mining, knowledge discovery, and rough sets theory. The existing induction algorithms use one of the following strategies: (a) generation of a minimal set of rules covering all objects from an information table; (b) generation of an exhaustive set of rules consisting of all possible rules for an information table; (c) generation of a set of "strong" decision rules, even partly discriminant, covering relatively many objects each but not necessarily all objects from the information table.

Artificial intelligence takes these systems a step further. Expert systems (a branch of artificial intelligence) implement human reasoning and a set of decision rules. In healthcare, for example, such a system can be used in conjunction with physical symptoms and laboratory analyses to make a suggestion for diagnosis. When the structure becomes too complex for an expert system, another branch of AI—neural networks, which are developed based on brain structure—are used to help make decisions. Like the brain, artificial neural networks can recognize patterns, manage data and learn. These programmed systems go through the options based on the decision-making rules implemented into the software.

CREDIBILITY OF DECISION RULES

Decision rules also can be considered from the viewpoint of their credibility. From this point of view, the following classes of decision rules can be distinguished:

1. Crisp, exact decision rules (i.e., the rules presented above whose "then" part is univocal).

2. Crisp, approximate decision rules, induced from an inconsistent part of a data set identified using the rough sets theory; the "then" part of approximate decision rules specifies several possible decisions that cannot be reduced to a single one due to inconsistent information.

3. Possible decision rules covering objects that may belong to the class suggested in the "then" part; the objects that may belong to a class are identified using the rough sets theory as objects belonging to so-called upper approximation of the class.

4. Fuzzy decision rules induced from a vague or imprecise data set using the fuzzy sets theory.

Informally, a fuzzy set may be regarded as a class of objects for which there is a graduality of progression from membership to nonmembership: an object may have a grade of membership intermediate between one (full membership) and zero (nonmembership).

5. Probabilistic decision rules covering objects from the class suggested in the "then" part (positive objects), but also objects from other classes (negative objects); the ratio between the positive objects and the negative objects should be at least equal to a given threshold.

APPLICATIONS

Decision rules have been used for description of many specific decision policies, in particular for description of customers' decisions. The most well known decision rules of this type are the association rules, whose syntax is the following: for p percent of times if items $x_1 x_2 \ldots, x_n$ were bought, then items $y_1 y_2 \ldots, y_m$ were bought as well, and q percent of times $x_1 x_2 \ldots, x_n, y_1 y_2 \ldots, y_m$ were bought together. For example, 50 percent of people who bought diapers also bought beer; diapers and beer were bought in 2 percent of all transactions.

The following example illustrates the most important concepts introduced above. In Table 1, six companies are described by means of four attributes:

- A_1 capacity of the management
- A_2 number of employees
- A_3 localization
- A_4 company profit or loss

The objective is to induce decision rules explaining profit or loss on the basis of attributes A_1 A_2 and A_3 Let us observe that:

- Attribute A_1 is a criterion, because the evaluation with respect to the capacity of the management is

Table 1

Sample Information Table

Warehouse	Attributes			
	A_1	A_2	A_3	A_4
C1	high	700	A	profit
C2	high	420	A	loss
C3	medium	530	B	profit
C4	medium	500	B	loss
C5	low	400	A	loss
C6	low	100	B	loss

preferentially ordered (high is better than medium and medium is better than low).

- Attribute A_2 is a quantitative attribute, because the values of the number of employees are not preferentially ordered (neither the high number of employees is generally better than the small number, nor the inverse). Similarity between companies is defined as follows: Company A is similar to Company B with respect to the attribute "number of employees" if:

$$\frac{\text{Employees of A} - \text{Employees of B}}{\text{Employees of B}} \leq 10\%$$

- Attribute A_3 is a qualitative attribute, because there is not a preferential order between types of localization: two companies are indiscernible with respect to localization if they have the same localization.

- Decision classes defined by attribute A_4 are preferentially ordered (trivially, profit is better than loss).

From Table 1, several decision rules can be induced. The following set of decision rules cover all the examples (within parentheses there are companies supporting the decision rule):

Rule 1. If the quality of the management is medium, then the company may have a profit or a loss (C3, C4).

Rule 2. If the quality of the management is (at least) high and the number of employees is similar to 700, then the company makes a profit (C1).

Rule 3. If the quality of the management is (at most) low, then the company has a loss (C5, C6).

Rule 4. If the number of employees is similar to 420 and the localization is B, then the company has a loss (C2).

Decision rules are based on elementary concepts and mathematical tools (sets and set operations, binary relations), without recourse to any algebraic or analytical structures. Principal relations involved in the construction of decision rules, like indiscernibility, similarity, and dominance, are natural and non-questioned on practical grounds. Decision rule representation of knowledge is not a "black box," or arcane methodology, because the rules represent relevant information contained in data sets in a natural and comprehensible language, and examples supporting each rule are identifiable. Because contemporary decision problems are associated with larger and larger data sets, induction of decision rules showing the most important part of the available information is increasingly in demand.

DECISION SUPPORT SYSTEMS

Decision support systems (DSS) are computer information systems that perform complex data analysis in order to help users make informed decisions. In general, a DSS retrieves information from a large data warehouse, analyzes it in accordance with user specifications, then publishes the results in a format that users can readily understand and use. DSS applications are interactive, and they are valuable in a wide range of business settings.

According to ComputerWorld Magazine, the rise of the decision support system can be traced to the late 1960s when businesses started to use computer mainframes. These mainframe computers first enabled businesses to interactively query data so they could enhance their previously-static reports. Other experts generally agree that computerized decision support systems became practical with the development of minicomputers, time-share operating systems, and distributed computing.

In the 1970s, however, decision support systems experienced a huge boom. Query systems, what-if spreadsheets, and rules-based software were developed. The advent of packaged algorithms made it easier to get better, faster decisions. As technology evolved, new computerized decision support applications were developed and studied. Researchers used multiple frameworks to help build and understand these systems. Today, one can organize the history of DSS into the five broad DSS categories, including: communications-driven, data-driven, document driven, knowledge-driven, and model-driven decision support systems.

Trends in all these categories are emerging. Data-driven DSS continuously use faster, real-time access to larger, better integrated databases. Trends suggest that model-driven DSS will grow more complex. Systems built using simulations and accompanying visual displays are becoming increasingly realistic. Communications-driven DSS provide more real-time video communications support. Document-driven DSS access larger repositories of data; the systems present appropriate documents in more

useable formats. Finally, knowledge-driven DSS are usually more sophisticated and comprehensive. The advice from knowledge-driven DSS is often considered better, and the applications cover broader domains.

Technology advances continue to make it easier and more efficient to collect relevant data. However, collecting, analyzing, correlating, and applying these massive amounts of data pose a challenge to businesses. Even so, companies are eager to respond in real-time to customer queries. They strive to anticipate customer needs, create opportunities, and avoid potential problems, for the end goal is to establish a predictive business.

The airline industry provides a good example of using data to instantaneously respond to customer queries. In the past, most customers called the airlines to purchase their airline tickets—a process that typically took about twenty minutes. That all changed with Web transactions, which can provide more information, more quickly. Ultimately, these types of DSS enable customers to book a ticket in just a few minutes.

With decision support systems, companies correlate information about their operations and performance with information about expected behavior and business rules. Decision makers anticipate and respond to threats and capitalize on opportunities before they occur. This ability makes predictive business, which is considered the next step in the evolution of a real-time enterprise, a reality.

DECISION SUPPORT SYSTEMS FIRST TESTED IN PORTFOLIO MANAGEMENT

Decision support systems were first tested in portfolio management, which poses one of the most essential problems in modern financial theory. It involves the construction of a portfolio of securities (stocks, bonds, treasury bills, etc.) that maximizes the investor's utility. The process leading to the construction of such a portfolio consists of two major steps. In the first step, the decision-maker (investor, portfolio manager) has to evaluate the securities that are available as investment instruments. The vast number of available securities, especially in the case of stocks, makes this step necessary, in order to focus the analysis on a limited number of the best investment choices. Thus, on the basis of this evaluation stage, the decision-maker selects a small number of securities that constitute the best investment opportunities. In the second step of the process, the decision maker must decide on the amount of the available capital that should be invested in each security, thus constructing a portfolio of the selected securities. The portfolio should be constructed in accordance with the decision-maker's investment policy and risk tolerance.

The portfolio theory assumes that the decision-maker's judgment and investment policy can be represented by a utility function that is implicitly used by the decision-maker

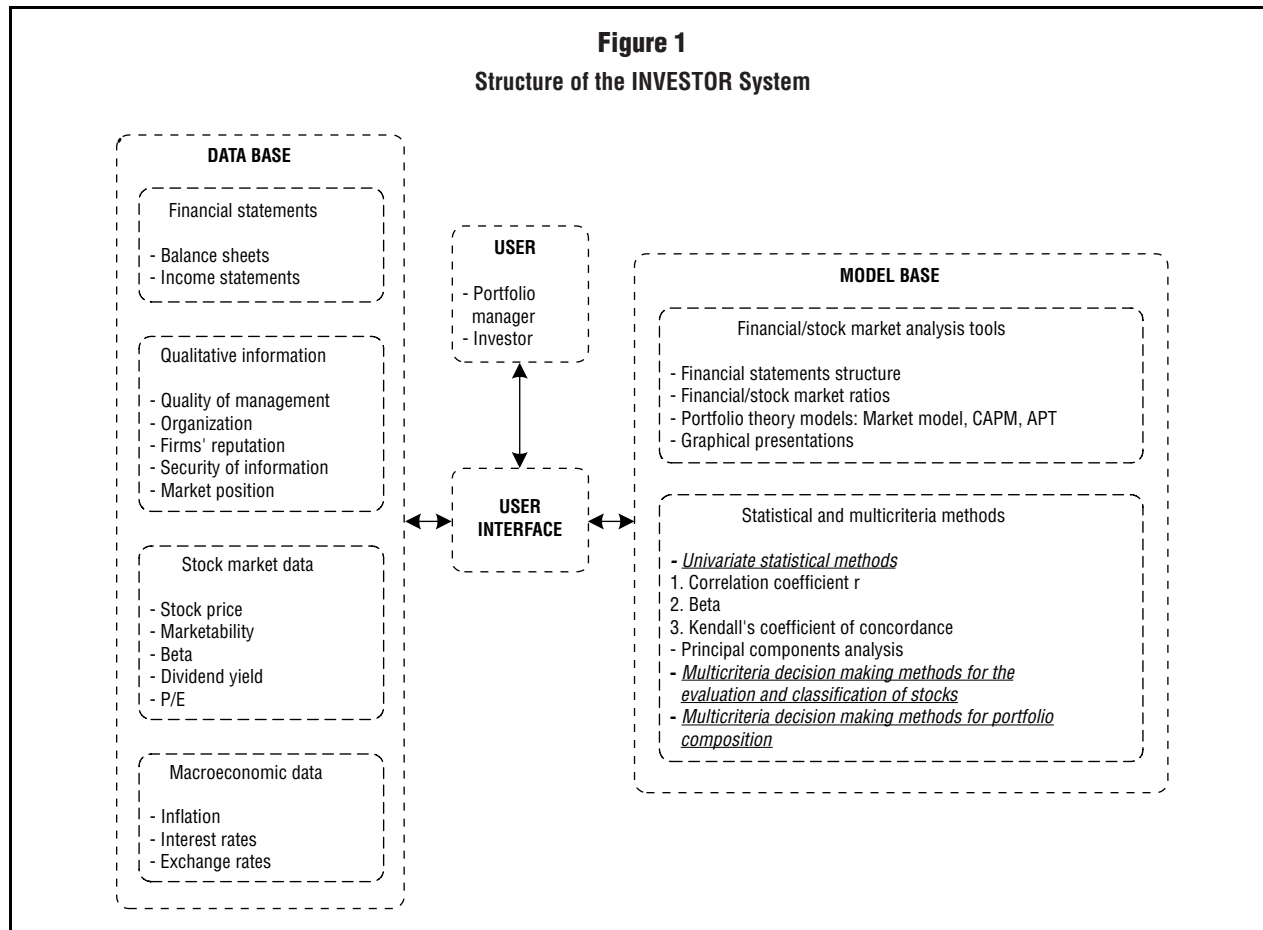
in making his investment decisions. Thus, the maximization of this utility function will result in the construction of a portfolio that is as consistent as possible with the decision-maker's expectations and investment policy. However, it is quite difficult to determine the specific form of this utility function.

The founder of portfolio theory, Harry Markowitz (recipient of the 1990 Nobel prize in economics), developed a framework according to which the decision-maker's utility is a function of two variables: the expected return of the portfolio and its risk. Thus, he formulated the maximization of the decision-maker's utility as a two-objective problem: maximizing the expected return of the portfolio and minimizing the corresponding risk. To consider the return and the risk, Markowitz used two well-known statistical measures, the *mean* of all possible returns to estimate the return of the portfolio, and the *variance* to measure its risk. On the basis of this mean-variance framework, Markowitz developed a mathematical framework to identify the efficient set of portfolios that maximizes returns at any given level of allowable risk. Given the risk aversion policy of the investor, it is possible to select the most appropriate portfolio from the efficient set.

This pioneering work of Markowitz motivated financial researchers to develop new portfolio management techniques, and significant contributions have been made over the last decades. The most significant of the approaches that have been proposed for portfolio management include the capital asset pricing model (CAPM), the arbitrage pricing theory (APT), single- and multi-index models, as well as several optimization techniques.

DECISION SUPPORT SYSTEMS IN PORTFOLIO MANAGEMENT

The concept of decision support systems (DSS) was introduced, from a theoretical point of view, in the late 1960s. DSS can be defined as computer information systems that provide information in a specific problem domain using analytical decision models and techniques, as well as access to databases, in order to support a decision maker in making decisions effectively in complex and ill-structured problems. Thus, the basic goal of DSS is to provide the necessary information to the decision-maker in order to help him or her get a better understanding of the decision environment and the alternatives available.

A typical structure of a DSS includes three main parts: the database, the model base, and the user interface. The database includes all the information and data that are necessary to perform the analysis on the decision problem at hand. Data entry, storage, and retrieval are performed through a database management system. The model base is an arsenal of methods, techniques, and models that can be used to perform the analysis and support the decision maker. These models or techniques are applied to the raw data in order to produce analysis or more meaningful output for the decision maker. A model base management system is responsible for performing all tasks that are related to model management, such as model development, updates, storage, and retrieval. Finally, the user interface is responsible for the communication between the user and the system, while it further serves as a link between the database and the model base. The appropriate design of the user interface is a key issue towards the successful implementation of the whole system, so as to ensure that the user can take full advantage of the analytical capabilities that the system provides. Advances in computer hardware and software have enabled user-friendly graphical user interfaces (GUIs) to serve this function.


During the last four decades, DSS have been developed and implemented to tackle a variety of real world decision-making problems, in addition to financial problems and portfolio management. The portfolio management process involves the analysis of a vast volume of information and data, including financial, stock market, and macroeconomic data. Analyzing a continuous flow of such a vast amount of information for every available security in order to make real time portfolio management decisions is clearly impossible without the support of a specifically designed computer system that will facilitate not only the data management process, but also the analysis.

Thus, the contribution of DSS to portfolio management becomes apparent. They provide an integrated tool to perform real-time analyses of portfolio-management-related data, and provide information according to the decision-maker's preferences. Furthermore, they enable the decision maker to take full advantage of sophisticated analytic methods, including multivariate statistical and econometric techniques, powerful optimization methods, advanced preference modeling, and multiple-criteria decision-making techniques. DSS incorporating multiple-criteria decision-making methods in their structure are known as multicriteria DSS, and they have found several applications in the field of finance.

PORTFOLIO MANAGEMENT DSS IN PRACTICE: AN ILLUSTRATION OF THE INVESTOR SYSTEM

The Investor system is a DSS designed and developed to support the portfolio management process and to help construct portfolios of stocks. The system includes a combination of portfolio theory models, multivariate statistical methods, and multiple criteria decision-making techniques for stock evaluation and portfolio construction. The structure of the system is presented in Figure 1.

Financial Data. The database of the system includes four types of information and data. The first involves the financial statements of the firms whose stocks are considered in the portfolio management problem. The balance sheet and the income statement provide valuable information regarding the financial soundness of the firms (e.g., sales, net profit, net worth, liabilities, assets, etc.). The system contains such financial data spanning a five-year period, so that users can reach informed conclusions about the firms' financial evolution.

Qualitative Information. In addition to these financial data, information on some qualitative factors is also inserted in the database. The management of the firms, their organization, their reputation in the market, their technical facilities, and their market position affect directly the operation and the performance of the firms; thus, they constitute fundamental factors in the analysis of the firms whose stocks are considered in the portfolio management problem.

Market Data. The third type of information included in the database involves the stocks' market histories. This information involves the stock prices, the marketability of the stocks, their beta (β) coefficient (a measure of risk representing the relationship between the changes in the price of individual stocks with the changes in the market), the dividend yield, the price/ earnings ratio, and so forth.

Macroeconomic Data. Finally, information regarding the macroeconomic environment is also included. Inflation, interest rates, exchange rates, and other macroeconomic variables have a direct impact on the performance of the stock market, thus potentially affecting any individual stock. The combination of this information with the financial and stock histories of individual firms enables portfolio managers to perform a global evaluation of the investment opportunities available, both in terms of their sensitivity and risk with respect to the economic environment, and to their individual characteristics.

Analysis Tools. The analysis of all this information is performed through the tools incorporated in the system's model base. Two major components can be distinguished

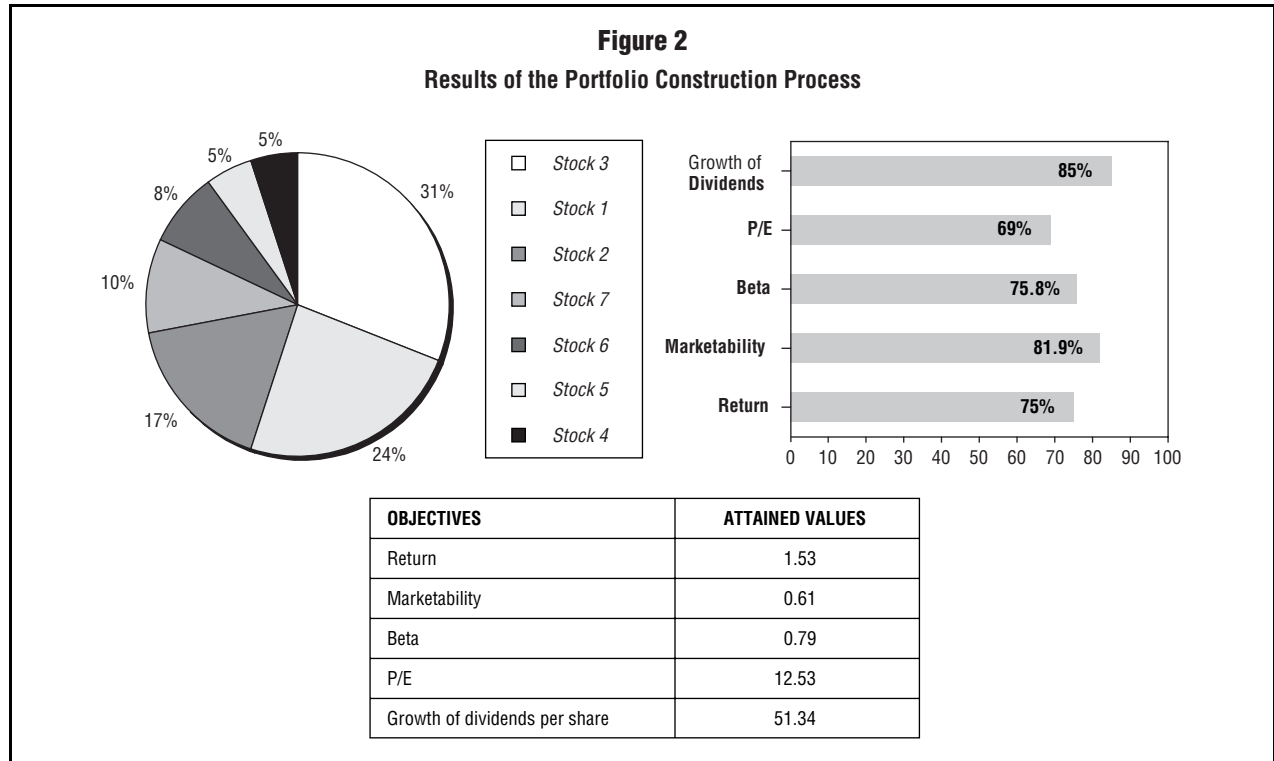
Growth of dividends per share	51.34


in the model base. The first one consists of financial and stock market analysis tools. These can analyze the structure of the financial statements of the firms, calculate financial and stock market ratios, apply well-known portfolio theory models (e.g., the market model, the CAPM, the APT), and present several graphical summaries of the results obtained through these tools to facilitate drawing some initial conclusions about the stocks' performance.

The second component of the model base involves more sophisticated analysis tools, including statistical and multiple-criteria decision-making techniques. More specifically, univariate statistical techniques are used to measure the stability of the beta coefficient of the stocks, while principal components analysis (a multivariate technique) is used to identify the most significant factors or criteria that describe the performance of the stocks, and to place the stocks into homogeneous groups according to their financial and stock market characteristics. The criteria identified as most crucial can be used to evaluate the stocks and thereby construct a portfolio that meets the investment policy of the investor/portfolio manager. Of course, the portfolio manager interacts with the system, and he or she can also introduce into the analysis the evaluation criteria that he or she considers important, even if these criteria are not found significant by principal components analysis.

The evaluation of the stocks' performance is completed through multiple-criteria decision-making meth-

ods. Multiple-criteria decision-making is an advanced field of operations research that provides an arsenal of methodological tools and techniques to study real-world decision problems involving multiple criteria that often lead to conflicting results. The multiple-criteria decision-making methods that are incorporated in the model base of the investor system enable the investor to develop an additive utility function that is fairly consistent with his or her investment policy, preferences, and experience. On the basis of this additive utility function a score (global utility) is estimated for each stock that represents its overall performance with respect to the selected evaluation criteria. The scores of the stocks are used as an index so they may be placed into appropriate classes specified by the user. Thus, the portfolio manager can develop an evaluation model (additive utility function) to distinguish, for instance, among the stocks that constitute the best investment opportunities, the stocks that do not have a medium-long term prospect but they can be considered only for the short run, and the stocks that are too risky and should be avoided. Of course, any other classification can be determined according to the objectives and the policy of the portfolio manager.

On the basis of this classification, the investor/portfolio manager can select a limited number of stocks to include in the actual portfolio, which represent the best investment opportunities. Constructing the portfolio is accomplished through multiple-criteria decision-making

techniques that are appropriate for optimizing a set of objective functions subject to some constraints. The objective functions represent the investor/portfolio manager's objectives on some evaluation criteria (return, beta, marketability, etc.), while constraints can be imposed to ensure that the constructed portfolio meets some basic aspects of the investment policy of the investor/portfolio manager.

For instance, the investor/portfolio manager can introduce constraints on the amount of capital invested in stocks of specific business sectors, the amount of capital invested in high-risk or low-risk stocks (high and low β coefficient, respectively), to determine a minimum level of return or a maximum level of risk, and so on. Once such details are determined, an interactive and iterative optimization procedure is performed that leads to the construction of a portfolio of stocks that meets the investor's investment policy and preferences. The results presented through the screen of Figure 2 show the proportion of each stock in the constructed portfolio, the performance of the portfolio on the specified evaluation criteria (attained values), as well as the rate of closeness (achievement rate) of the performance of the portfolio as opposed to the optimal values on each evaluation criterion (the higher this rate is, the closer the performance of the portfolio to the optimal one for each criterion).

Since the development of the portfolio theory in the 1950s, portfolio management has gained increasing interest within the financial community. Periodic turmoil in stock markets worldwide demonstrates the necessity for developing risk management tools that can be used to analyze the vast volume of information that is available. The DSS framework provides such tools that enable investors and portfolio managers to employ sophisticated techniques from the fields of statistical analysis, econometric analysis, and operations research to make and implement real-time portfolio management decisions.

DSS research in the twenty-first century has been oriented toward combining the powerful analytical tools used in the DSS framework with the new modeling techniques provided by soft computing technology (neural networks, expert systems, fuzzy sets, etc.) to address the uncertainty, vagueness, and fuzziness that is often encountered in the financial and business environment.

DSS EVOLUTION

Business intelligence (BI) practices are often cited as key to the evolution of decision support systems. BI refers to the technologies, applications, and practices used for collecting, integrating, analyzing, and presenting business information. It is the variety of software applications used to analyze an organization's raw data and extract useful insights from it. Therefore, like DSS, business intelligence systems are data-driven. They use fact-based support systems to improve business decision-making, making BI a reporting and decision support tool.

Used at the operational level, BI projects have great potential to transform business processes. For example, well-known companies use BI technologies to improve corporate sales and customer service processes. Used correctly, BI systems can transform companies from regionally-operated businesses to unified global businesses.

Like many technological advances, there are obstacles. A key impediment to BI progress is lack of corporate understanding. Often, companies don't know their own business processes well enough to determine how to improve them. Before commencing a BI project, companies must consider and understand all of the activities that make up a particular business process, how information and data flow across various processes, how data is passed between business users, and how people use it to execute their part of the process. In order to motivate upper management to standardize such processes company-wide, BI systems must have a direct impact on revenue.

Implementation of BI systems requires a change in thinking about the value of information inside organizations. Everyone involved in the BI process must have full access to information to be able to change the ways that they work. This necessitates a trusting working environment.

Well-known firm McKinsey Consulting noted that decision support systems were one of eight technology trends to watch in 2008. DSS technologies will advance as more innovative data collection and processing methods are introduced. This, according to McKinsey, will result in more granular segmentation and low-cost experimentation. The resulting information will help managers acquire more data, make smarter decisions, and develop competitive advantages and new business models.

DELEGATION

Delegation is the process of giving decision-making authority to lower-level employees. For the process to be successful, a worker must be able to obtain the resources and cooperation needed for successful completion of the delegated task. Empowerment of the workforce and task delegation are closely intertwined. Empowerment occurs when upper-level employees share power with lower-level employees. This involves providing the training, tools, and management support that employees need to accomplish a task. Thus, an enabled worker has both the authority and the capability to accomplish the work. Although authority can be delegated, responsibility cannot—the person who delegates a task is ultimately responsible for its success. The assigned worker is therefore accountable for meeting the goals and objectives of the task.

BENEFITS OF DELEGATION

Effective delegation can benefit the manager, the employee, and the organization. Perhaps the most important benefit for the company is a higher quality of work. Delegation can improve quality of work by allowing the employees who have direct knowledge of products and services to make decisions and complete tasks. Quality can also improve through enhanced employee motivation. Employees may do a better job because they feel a personal accountability for the outcome, even though responsibility ultimately rests with the individual who made the delegation. Motivation should also be enhanced as delegation enriches the worker's job by expanding the types of tasks that are involved in it.

Managers who delegate effectively also receive several personal benefits; most importantly, they have more time to do their own jobs when they assign tasks to others. Given the hectic nature of managerial work, time is a precious commodity. Effective delegation frees the manager to focus on managerial tasks such as planning and control. Managers also benefit from the development of subordinates' skills. With a more highly skilled workforce, they have more flexibility in making assignments and are more efficient decision makers. Managers who develop their workforce are also likely to have high personal power with their staff and to be highly valued by their organization.

DRAWBACKS OF DELEGATION

Although delegation can provide benefits to the organization, many managers lack the motivation or knowledge to delegate effectively, and thus delegation (or lack of delegation) may be detrimental to the company. Managers' lack of motivation to delegate may be associated with a number of fallacies associated with delegations. Many managers believe that "if you want it done right, you have to do it yourself." While this is at times untrue, because the ultimate responsibility for a task lies with the manager, this attitude often prevents delegation. Other reasons for a lack of motivation to delegate are lack of trust in subordinates, fear of being seen as lazy, reluctance to take risks, and fear of competition from subordinates. Some of these barriers are correctable through management training and development, but others may not be easily overcome. Managers may also lack the competencies necessary to delegate effectively. They may choose the wrong tasks to delegate, the wrong subordinate to trust, or they may provide inadequate direction to the subordinate when delegating.

Excessive sub-delegating and cross-delegating also creates a problem. This practice usually occurs when a hot issue in the company is passed around from person to person. The theory is that nobody wants to be the one working on it when senior management steps in. Managers should recognize and acknowledge when unnecessary and excessive sub-delegation is occurring. This move will lead to the long-term improvement in employee morale and contribute to achieving company goals.

Improper delegation can cause a host of problems, primary of which is an incorrectly completed task, which may hurt the overall productivity of the organization. Additionally, the careers of the manager and subordinate may suffer. The manager is likely to take the blame for delegating the wrong task, delegating to the wrong person, or not providing proper guidance. The subordinate may also take the blame for doing the task incorrectly. Thus, poor delegation may detract from the personal success of managers and employees.

PLANNING

Delegation is not difficult. Anyone can give an assignment to someone. However, effective delegation (assigning a

task to the correct person) is a highly skilled process that requires planning, thought, and managerial skill.

Defining Success. Two planning activities should be undertaken before delegating an assignment: defining success and assessing qualifications needed. Defining success requires a determination of what will constitute successful performance on the assigned task. An effective delegator assigns workers to tasks on which they have a high probability of succeeding. If a manager can't identify the successful outcome of a task, how can that manager determine if a worker is capable of performing it? The failure to define success turns delegation into a gamble, rather than a prediction. An effective delegator makes a prediction of success based on the match between job requirements and the worker's competencies. An ineffective delegator hopes that the worker will be successful but really has no basis for this hope, since success has not been defined. If success is well defined and communicated to the subordinate, the worker has a clear understanding of the task requirements and can focus his/her efforts on important activities. Similarly, clearly defining success helps the delegator coach the worker, which further enhances the probability of a positive outcome.

There are two components to defining success. The first is to define the successful outcome of the task, and the second is to determine the appropriate processes needed to complete the task. Both are needed in order to make an effective delegation. For example, a manager might be considering assigning a different salesperson to a particularly difficult client. Prior to making the delegation, the manager should reflect on the desired outcomes from this assignment (e.g., increased sales, decreased complaints) and the types of processes (e.g., better client education, greater empathy) that might be needed to produce the desired result. Only after understanding what is needed can a rational delegation be made. Thus, managers should first ask themselves: "How will I judge the success of this delegation and what do I expect someone to do to be successful?"

Assessing Qualifications Needed. The second step in planning delegation involves determining subordinate capabilities. There is always a choice in delegation, both as to which subordinates to delegate the assignment to, and whether to delegate the assignment at all. To make either decision, the manager needs to assess subordinate's capabilities. In making the assessment, a manager should ask, "What has this worker done to make me feel he or she will be effective on this assignment?" Managers should also ask themselves, "How do I think this person will perform on this assignment and why do I feel this way?" A worker could be effective in obtaining desired results, but could use an unacceptable process to obtain the results that

negates the positive outcomes. Managers are very unlikely to make an accurate prediction of success for an assignment when they have no basis for the prediction. Thus, the better a manager knows a worker's past behaviors and accomplishments, the greater the chance of an effective future delegation. Often, however, managers have to delegate assignments to people who lack the relevant training or experience. The general process still applies in this situation, although the specific questions change. Here, the manager should carefully consider, "How has this person performed on previous assignments where he or she lacked training or experience?" Again, there must be a basis for the delegation, or it becomes a wild guess.

PROCESS

The process of delegation is as critical as the planning, because a poor process can reduce the effectiveness of the delegation in several ways. First, it can lower the worker's motivation to perform the task. A qualified worker who is not motivated to complete the assignment is not likely to produce the desired results. Second, lack of proper communication of standards for the task may lead to less than desirable outcomes. Finally, the delegation process may create some artificial barriers or fail to eliminate others barriers to performance. The failure to share information and discuss real or perceived problems can reduce efficiency and may lead to failure. To avoid these obstacles, the following items should be considered when making an assignment.

Allow Employees to Participate in the Delegation Process. Employees who accept their assignments are much more likely to be committed to their success. This acceptance is enhanced when employees have some say in the process. Thus, subordinates should be allowed to participate in determining when and how the delegated task will be accomplished and, when possible, what the assignment will be. At the most basic level, a manager can ask an employee if he or she is available to do a task, rather than telling him/her to do it. Participation can also increase supervisor/subordinate communication, which may minimize problems due to misunderstandings.

Specify Standards. Many communication problems occur because of the failure to clearly consider and specify the performance standards of the assignment. Some of the things to consider include the limitations of a subordinate's tasks, (e.g., gathering information only, or making a decision), their expected level of performance, their deadlines for reporting, and the constraints under which they will be operating. Where subordinates are given a choice in accepting the assignment, these issues should be discussed and negotiated prior to the delegation. Even when subordinates do not have the option of rejecting the

assignment, these issues should be clearly described and subordinates should be asked for their input.

Balance Responsibility and Authority. A typical delegation error is to delegate work but avoid matching the responsibilities with the freedom to make decisions and the authority to implement them. This creates frustration, since the subordinate knows what needs to be done and how to do it, but is not given the opportunity to do it. Managers can avoid this problem by communicating to all individuals affected by the assignment that it has been delegated and who has the authority to complete the work. Managers can ask subordinates what resources they need for a task and then empower them to secure those resources.

In addition to providing authority, managers should also provide adequate support for the delegated task. This might involve continually providing important information and feedback that are needed to accomplish the task. Finally, managers should publicly bestow credit when the task has been accomplished. This will enhance the subordinate's motivation and authority for future assignments. It also provides an important message to others that successful completion of tasks is acknowledged and rewarded.

Delegate Consistently. Some managers delegate only when they are overworked or in a crisis. This can send a message to subordinates that they are being used since they only receive assignments when it benefits the manager. Ideally, delegation should benefit both the subordinate and the manager. Managers can send this message by delegating assignments that develop or stretch subordinates' talents and skills. Delegating to develop workers builds up a pool of talent for those inevitable crisis situations. It also enhances worker motivation and confidence since they acquire experience and benefit from the new or improved skills. Care should be taken to assure that the employee has the capability to succeed in the assignment. Employees should not be set up to fail. Certainly some failure will occur. Managers must recognize this and provide helpful, developmental feedback in those situations. Emphasis should be placed on the positive things that were done on the assignment and what actions could have been taken to overcome the problems.

Balance the Assignments. Managers need to ensure that delegation isn't viewed as getting someone else to do their dirty work. Thus, an effective manager should delegate the pleasant and the unpleasant, the challenging and the boring assignments. Similarly, assignments should be balanced across workers. For example, it is quite common for managers to delegate the most unpleasant task to the best worker since that person can be counted on to do a good job. Alternatively, a poor worker may avoid receiving an unpleasant assignment due to the poor quality of the final product. This type of situation quickly sends the message to the productive worker that the way to get out of receiving unpleasant assignments is to lower the quality of his/her work. One way to avoid this problem is to give the productive worker other rewards and/or to increase the number of unpleasant assignments to the unproductive worker until the quality of the result improves.

Focus on Results. Once the task has been delegated, managers need to allow subordinates the freedom to make the choices needed to accomplish the task. Managers should not supervise too closely for this may create frustration and make workers feel that the manager lacks confidence in their ability. Managers should review and evaluate the results of the assignment, not the means used to accomplish the task. However, managers are responsible for making sure that both the process and the outcome of the delegated task are consistent with the goals. As noted, one way to accomplish this is through the specification of clear standards prior to the delegation. The manager needs to remember these standards and intervene only when they have been violated. Managers should avoid the tendency to intervene simply due to style differences. One of the benefits of allowing subordinates to make their own choices is that this can be an important source of innovation for the organization. Sometimes employees really have a better way.

GROUP VS. INDIVIDUAL DELEGATION

A particular assignment can be delegated to an individual or a group of individuals. Additionally, a manager may not wish to delegate the whole task, but to participate as a member of the team. What are the considerations in individual versus group delegation or even participation? Perhaps the most important point is that all of the previous issues apply. Prior to making the assignment, the manager must define success and assess the capabilities of the individual or group. In making the assignment, the individual or group should be allowed to participate as much as possible, authority and responsibilities should be balanced, standards should be specified and the manager should focus on results.

One difference between individual and group delegation is that individual behavior is typically easier to control and monitor. One alternative to delegating the assignment and giving entirely to a subordinate is for a manager to participate in the process as a group member. The downside of this approach is that it may send the group an unintended message of a lack of trust. Employees may feel that the manager is not there to contribute, but to check on the quality of their work. Thus, managers should carefully review their own capabilities as a team

member and answer the question, "What do I add to this group to accomplish this task?" The answer to this question should be clearly communicated to the group so they understand why the manager has undertaken a role in the group. Finally, a manager should carefully assess the group's past behavior and have a reason for predicting that the group can accomplish the task. Again, this should be a prediction, not a gamble or wish for success.

UPWARD DELEGATION

Many employees have become skilled in delegating to their supervisors. Upward delegation occurs when an employee shifts his or her assignment to a manager at a level above. This is not always easy, but is best done when a person feels that he or she lacks the skill or direction for a particular project, but that the manager above has the capabilities to perform the task. Upward delegation may start by asking the manager questions or asking for advice to help solve a particular problem. If the manager feels that the employee has too many questions or needs too much assistance, the manager may rescind the delegation and remove the task from the employee. If employees are avoiding delegated duties by overwhelming the manager with requests for assistance, the manager can require that the employee have at least one proposed solution to every problem brought to the manager. Additionally, this situation can be improved by the manager asking questions, which lead the worker to think through and resolve a problem. Questions like, "What would you do next? What do you see as our options?" and, "What do you see as the best approach?" communicate the message that the employee is expected to take the initiative to at least attempt to solve the assignment.

A manager who uses effective delegation across time and assignments will be more efficient and have more time for true managerial work and will reap the benefits of employee empowerment at the same time. This will occur because success will be clearly defined and communicated to a worker who will be matched with jobs based on his or her capabilities. When done correctly, the process of delegation empowers workers and enhances their motivation and commitment.

DEREGULATION

Deregulation refers to the deletion, abandonment, or relaxation of various laws, rules, and regulations that affect business and industry. However, the topic of deregulation is best understood by first understanding the purposes and effects of regulations.

REGULATION

It is often thought that individual firms lack the perspective and/or the incentive to protect society. Consequently, the regulation of business and industry by government is for the purposes of consumer protection and or the enhancement of business competition. Regulation is generally thought to also protect minorities, employees, investors, and the environment.

The railroad industry was one of the first industries that the federal government targeted. As a result, the Interstate Commerce Act was passed in 1887. As such, the Interstate Commerce Act created the first regulatory body in the United States—the Interstate Commerce Commission, which still regulates transportation rates, as well as establishes rules and regulations for interstate commerce.

The United States government expanded its control over industry by focusing on trusts, where a company is established for the purpose of controlling multiple companies. Consequently, the Sherman Antitrust Act was enacted in 1890 to control monopolies. In 1914, the Clayton Act amended the Sherman Act by forbidding specific business actions. For example, tying contracts interlocking directorates and discriminatory pricing were made illegal, if the results of these actions lessened competition.

The Federal Trade Commission Act, also enacted in 1914, formally established the Federal Trade Commission (FTC). Among other responsibilities, the FTC remains responsible for defining, detecting, and enforcing compliance with the Clayton Act. The Wheeler-Lea Act of 1938 expanded FTC jurisdiction to include any practice or practices that harm the public in general and those practices that harm competitors. The Robinson-Patman Act was enacted in 1938 due to the growth of large retailing conglomerates. This law covered discrimination against buyers as well as sellers.

In 1958 the National Traffic and Safety Act was enacted. This legislation provided for the creation of compulsory safety standards for automobiles and tires.

In 1966 the Fair Packaging and Labeling Act was passed. This act provided for the regulation of the packaging and labeling of consumer goods. It also required manufacturers

to state package contents, the maker of the contents, and how much of individual contents are included.

The Antitrust Procedures and Penalties Act was enacted in 1974. This legislation increased fines for violation of the Sherman Act. Two years later, the Antitrust Improvement Act required firms to notify the FTC of merger plans. This act also gave state attorney generals the power to sue for the benefit of consumers.

GOVERNMENT PERMISSIVENESS

It is generally thought that the permissiveness of the federal government began during the presidency of Richard M. Nixon, which led the way for formal deregulation. During the 1980s the government turned its focus from laws, rules, and regulations to the creation of market incentives that were thought to motivate business.

Proponents of deregulation argue that government intervention impedes the natural laws of supply and demand and ultimately increases costs to consumers. In addition, the overregulation of business is thought to thwart innovation by creating delays and increased red tape. Thus in 1981 the Ronald Reagan administration created the Task Force on Regulatory Relief to review all proposed new regulations and review old regulations. The establishment of this task force also lead to the increased use of cost-benefit analysis, which compares the cost of all regulations to their benefit.

DEREGULATION AND THE AIRLINE INDUSTRY

Approximately thirty years ago, the United States government put into practice a series of deregulation legislation concerning the airline industry. The effort was intended to encourage healthy competition and lower the inflated airfare costs. To a certain extent, the deregulation worked, and the 1990s saw the continual growth of the airline industry, with a large turnover rate of airline companies.

However, airlines went through a dramatic decline in the early period of the twenty-first century. According to a 2008 article in the *New York Times*, "Did Ending Regulation Help Fliers?," the airline industry lost more than $30 billion between 2001 and 2006 due to many problems that had not been expected at the time of deregulation. The terrorist attack of 9/11 encouraged investor doubt and customer dissatisfaction with airlines, and the rising costs of air fuel again increased airfare. It has yet to be seen if deregulation had an ultimately positive effect on the airline industry or not.

DEREGULATION AND THE AMERICAN ENERGY INDUSTRY

Certain deregulation policies, such as 1992 Energy Policy Act, encouraged free action of the companies offering electricity in the United States. As a result of this deregulation, energy companies began a series of splits and mergers, an occurrence that moved state by state as the deregulation became more common. In 1998, California initiated a series of steps designed to eliminate energy monopolies and offer its public more choices in where they got their electrical power.

At first, the results of such state deregulation practices—also attempted by Texas and Illinois—were chaotic, leading to shortages and inflated energy prices. As states regulated and deregulated their electrical energy companies, the national industry saw the rise of several large conglomerations. Powering marketing, or the trading of electricity through energy companies, become common. Long-term results, however, are expected to lead to stability and healthy growth of America's energy industry.

THE TOLLBOOTH THEORY

Among the arguments for deregulation is the concept called the Tollbooth theory. This theory proposes that in economies controlled through heavy regulation, the ethical relationship between industry and government will slowly collapse and the economy will suffer. As penalties increase and regulations become too constricting to allow free movement by companies, the Tollbooth theory says the bureaucracies will begin accepting bribes and payoffs in exchange for helpful deals; they will look the other way while companies violate the regulations. A system of corruption is then established that threatens the economy and destabilizes all industries.

Supporters of deregulation and the Tollbooth theory often use Russia as an example, citing reforming legislation passed from 2001 to 2004 and its effects. These laws pertained to certification and registration by businesses; they established clear limits to the amount of regulation possible, helping to pull Russia from what was theorized as a Tollbooth economy. The amount of red-tape businesses had to surmount was drastically lessened, and much registration was localized. Freed from over-regulation, Russia's economy is expected to continue to improve, with small business employment growing and start-up companies becoming more common. (Of course, high energy prices might be a better explanation for Russia's economic resurgence).

Opponents to the Tollbooth theory use the Public Interest model instead, which theorizes that governments use regulations to control dangerous market trends, and that regulation does not usually lead to corruption or instability.

INTERNATIONAL DEREGULATION

In recent years, deregulation has become a popular international method to improve economic conditions and open nations to more global business. Many deregulation policies effect tariffs and customs fees, giving international

companies more opportunities to conduct business overseas. In Europe, for instance, the EU nations completed a marketing directive in 2007 which was intended to fully open the European Union nations to outside trade. The directive was immensely successful, with fourteen out of the fifteen original EU nations reaching fully open markets.

Deregulation is making an impact elsewhere, as well. In 2007, European businesses formally encouraged Japan to continue its deregulation policies, which were opening many Japanese markets to foreign competition. The European businesses believed that the intense deregulation Japan had spearheaded from 2001 to 2006 had led to reform-fatigue. Japan, after breaking up its post office monopoly and opening such markets as medicine and telecommunication, is now slowing deregulation efforts, afraid that they are harming internal business.

In India, deregulation has the potential to change oil prices for the growing country. In a 2008 reaction to dropping oil subsidies, the Indian government raised fuel prices, causing an even worse spike in the continuing inflation. Another possibility, encouraged by international vendors, is for India to drop tariffs on imported oil, a deregulation activity it has already refused once but is now reconsidering.

Despite rumors that in 2008 China would attempt the deregulation of fuel industries so far refused by India, the Asian nation has instead opted for a tax cut on their windfall profit tax. China has also considered raising fuel prices, but has not yet made any moves to deregulate their fuel companies, as the government is also worried about high inflation. The Chinese tax cut, however, is expected to be highly successful and serves as an example for alternatives to deregulation.

In a different type of market, the United Kingdom is now beginning to deregulate its broadband industry. Previously to 2008, broadband companies were forced to offer broadband internet services at a fixed rate determined by the government, but new analysis showed that competition between United Kingdom broadband companies was rising. Now, if four or more broadband companies are present for consumers to choose from, the price cap regulation does not apply. As the high-speed internet market continues to grow in the UK, forecasts suggest even more widespread deregulation.

DISASTER RECOVERY

Organizations are faced with a variety of threats and vulnerabilities, and these continue to evolve. Business disruptions can include natural disasters such as floods, fires, hurricanes, and power outages. Since 9/11, the threat of man-made disasters such as terrorist attacks has taken on a sense of urgency as well. The increase in metropolitan population density further exacerbates the threats posed by both natural and man-made disasters. Although business-continuity planning and disaster-recovery planning are now generally recognized as vital, creating and maintaining a sound plan is quite complex.

Disaster recovery planning addresses the prospect that a disaster might interrupt an organization's business operations. Whether an organization is for-profit, non-profit, or governmental, the need to mitigate disaster risks has become especially salient.

Disasters can come in many forms and sometimes last indefinitely. The 2002 Disaster Recovery guide lists many types of disasters and the categories they fall under, such as:

Environmental Disasters.

- Tornado
- Hurricane
- Snowstorm
- Flood
- Fire
- Epidemic
- Contamination

Organized/Deliberate Disruption.

- Sabotage
- Terrorism
- War
- Theft
- Arson
- Labor disputes

Equipment Failures.

- Power failure
- Air conditioning failure
- Production line failure
- Cooling plant failure

Information Security Incidents.

- Cyber crime
- Loss of records or data
- Disclosure of sensitive material
- IT system failure

Certain conditions define a disaster in relation to business interruptions. Charlotte Hiatt's *A Primer for Disaster Recovery Planning in an IT Environment* lists some of these conditions, observed in organizations going through a time of crisis. Surprise and insufficient information are, of course, natural characteristics of a disaster. There is also an uncontrollable, escalating chain of chaotic events and a loss of control in key areas of the organization. A sense of keen scrutiny from outside the organization is also common, leading to several behaviors found in disaster environments, such as siege mentality, panic, and short-term focus.

Hiatt divides disasters into three different categories for businesses. The first category is composed of low-risk incidents. These events do not seriously injure anyone and cause only minimal disruption of the organization's systems. The second category is the moderate risk incident. In these incidents there are serious injuries, many minor injuries, and damage of assets and facilities. The ability to conduct business is severely hampered for a time.

Employee distress is moderate. The last category is the high risk incident. These incidents cause widespread death, injury, and severe damage to facilities, and are the most likely to impact the media and the company's investors.

DISASTER RECOVERY AND BUSINESS

A business impact analysis helps management to understand the criticality of different business functions, recovery time required, and the need for various resources. The question of which corporate functions receive top priority should be addressed. In selecting a strategy to protect the organization, cost-benefit comparisons are made with regard to the effects of doing without various services and functions (e.g., call centers, production locations, proprietary data) at specific points in time, and developing plans for optimum recovery periods for each service and function.

A central office failure brought about by a fire or power outage can also affect trading operations. Redundancy (including back-up sites and additional staff and technologies) is recommended, albeit expensive. An additional risk is that an entire network (such as a cell-phone network) might go down. Jay Pultz, research vice-president at disaster and business continuity consultancy firm Gartner, Inc., is concerned that failures will increase because the companies that provide the networks are collapsing their infrastructure to a single backbone, as opposed to separate backbones for the Internet, phone, data, etc.

Companies should be aware that back-up systems can create expenses of their own. At times, the price for backing up necessary information can put a significant drain on the company's resources. Julie Bort, with *Network World*, reports that contracts for data storage and recovery services can easily reach more than $30,000 a month. Companies are usually willing to spend somewhere between 2 percent and 4 percent of their IT budget on disaster recovery, and this is not always enough to ensure full coverage. Some companies make disaster recovery a much larger priority and budget accordingly.

Organizations that depend on electronic-based information suffer greater losses at the time of disasters, and usually make use of more security options. According to the Joint Commission Resource's *2008 Standards for Long Term Care*, a disaster recovery plan for electronic information can include several components. A plan can be based around some or all of the following:

- Procedures for scheduled and unscheduled downtime
- Contingency plans for operation interruptions
- An emergency service plan
- A back-up system (electronic or manual)
- Data retrieval procedures

SMALL BUSINESSES

Oddly enough, smaller businesses have been found to lead many midsize businesses in implementing true disaster-recovery solutions. Small businesses often rely on value added resellers (VARs) for their solutions, and larger firms use internal IT departments. Midsize firms, however, are too complex to be relocated quickly, yet lack the internal staff to restore business processes rapidly, increasing opportunities for VARs to offer business continuity services to this market.

Small businesses have yet another ally in the SBA, or Small Business Administration. The SBA, created in 1953, focuses on aiding small business through such trials as system-crashing disasters. In their 2007 Recovery Plan, the SBA focuses on its intent to help small businesses recover from natural disasters, especially those with widespread effects (such as hurricane Katrina in 2005). With the aid from the SBA, small businesses are often able to recoup their losses from disasters.

APPLICATIONS TO SUPPLY CHAIN MANAGEMENT

Companies involved in extensive outsourcing or exclusive partnerships with suppliers may have more to lose than others. A disaster affecting their supply chain would leave such companies without immediate recourse to resume production.

This "dark side" of supply chain management is discussed in a white paper appearing in a March 2005 issue of *Supply Chain Management Review.* The authors explore the notion of supply continuity planning, which is a comprehensive approach to managing supply risk. They state that by employing their supply continuity planning model, organizations can guard against a major supply disruption that could potentially delay orders and result in loss of customers.

Whereas companies previously relied on inventory buffers (safety stock, lead times, excess capacity) to protect them, today's competitive environment makes these buffers less attractive. A consequence is that today's lean supply chains are increasingly fragile, or more sensitive to shocks and disruptions.

The authors make a strong case for how devastating disruptions can be by citing several events, including a fire at a factory supplying valves to Toyota, resulting in estimated costs of $195 million; an earthquake in Taiwan, hampering the supply of computer chips and computer demand during the holiday season; a lightning strike at a radio-frequency chip plant in Albuquerque, NM, resulting in a fire, production delays, and the eventual withdrawal of Ericsson from mobile phone manufacturing (because the plant was its sole supplier); and the 9/11 terrorist attacks, resulting in loss of life and loss of information databases.

Based on case studies of four organizations that proactively manage inbound supply risk, the authors present a framework describing detailed efforts focused on four major activities: creating system awareness of supply risk, preventing the occurrence of supply disruptions, remediating supply interruptions, and managing knowledge.

BEING PREPARED

In a 2005 *Canadian Business* article titled "Always Be Prepared," an expert in enterprise risk presents a series of questions that managers should ask about the firm's state of readiness to continue business after a disruption. For example, does the business even have a plan? Is the plan tailor-made or "off the rack"? Are critical functions the basis of the plan? The maintenance of knowledge management, regular testing of the plan, and supplier preparedness are other important issues.

What should businesses look for when considering a disaster recovery plan? Clearly, a carefully defined procedure should be created, to be followed exactly during a crisis. Employee training and periodic reviews go hand in hand with this preparation. But there are also a number of outside companies and devices that specialize in information storage and recovery. Which sort of protection should a company consider? Laura Buckley, in her article "2008 Trends: Data Protection, Archiving, and Disaster Recovery Challenges," gives a short, helpful list to consider when looking at data protection. According to her, the appliance should:

- Be easy to purchase, install, manage, and support
- Optimize all back-up systems to meet corporate RTO and RPO requirements
- Comply with regulated retention policies
- Efficiently use media
- Automate daily functions to reduce administrative hours needed
- Provide an adaptable foundation so that newer data protection systems can be built on top of existing appliances

When a protection and recovery system is in place, there are several routines organizations can follow which ensure high quality results. *Disaster Recovery Information* (DRI) gives three practices that every organization can apply to their disaster recovery program.

First, DRI advises that organizations search carefully for flaws in their contingency plans. Weaknesses and faults should be carefully noted and dealt with. Brainstorming sessions and planned tests are both excellent ways to expose flaws.

Second, organizations should establish a cycle of scheduled tests for the contingency plan. Not only will this make step one easier, but it will provide the company with an opportunity to see itself under pressure. These planned tests should strive to be difficult, so that serious weaknesses can be exposed.

Last, organizations should never expect real disasters to act like their simulated tests. They should prepare for the unexpected, and always act as if the real disaster includes all the possibilities they did not test.

Being prepared for disaster is increasingly essential. The good news for those new to business continuity planning and disaster recovery planning is that information on how to prepare is proliferating. Business continuity and disaster recovery planning software explore the potential impacts of disaster, and underlying risks; constructing a plan; maintenance, testing, and auditing to ensure that the plan remains appropriate to the needs of the organization; and support infrastructure and services.

DISCRIMINATION

Discrimination, in an employment context, can be generally defined as treating an individual or group less well in recruiting, hiring, or any other terms and conditions of employment due to the person's or group's race, color, sex, religion, national origin, age, disability, or veteran's status. These categories are referred to as protected classifications because they are singled out for protection by equal employment opportunity (EEO) laws. Subcategories of people within each protected classification are referred to as protected groups. For example, male and female are the protected groups within the protected classification of sex. EEO legislation affords protection from illegal discrimination to all protected groups within a protected classification, not just the minority group. Thus, employment discrimination against a man is just as unlawful as that aimed at a woman. The lone exception to this rule concerns the use of affirmative action programs (discussed later), which, under certain circumstances, allow employers to treat members of certain protected groups preferentially.

In the United States, effective federal legislation banning employment-related discrimination did not exist until the 1960s, when Congress passed Title VII of the Civil Rights Act (1964). In the years since, several other important federal laws have been passed. In addition to the myriad federal laws banning discrimination on the basis of race, color, sex, religion, national origin, age, disability, and veteran's status, almost all states have anti-discrimination laws affecting the workplace. Most of these laws extend the protections in federal law to employers that are not covered by the federal statutes because of their size (Title VII for example, applies only to employers with 15 or more employees). Some state laws also attempt to prevent discrimination against individuals and groups that are not included in federal law. For example, approximately fourteen states have passed statutes protecting all workers in the states from employment discrimination based on sexual orientation, and

several other states prohibit public sector employers from discriminating on the basis of sexual orientation.

SPECIFIC ANTI-DISCRIMINATION LEGISLATION AFFECTING THE WORKPLACE

Title VII of the Civil Rights Act (CRA), passed in 1964, covers organizations that employ fifteen or more workers for at least twenty weeks during the year. Specifically, the law states: "It shall be an unlawful employment practice for an employer to fail or refuse to hire or discharge any individual, or otherwise to discriminate against any individual with respect to his compensation, terms, conditions, or privileges of employment, because of such individual's race, color, religion, sex, or national origin." Interpretations of Title VII by courts have clarified the specific meaning of the prohibitions against discrimination. In general, it is safe to say that virtually any workplace decision involving personnel is subject to legal challenge on the basis of Title VII, including not only decisions made relative to recruiting and hiring, but also in relation to promotion, discipline, admission to training programs, layoffs, and performance appraisal. Harassment of applicants or employees because of their membership in a protected classification is also considered a violation of Title VII.

Title VII is probably the most valuable tool that employees have for remedying workplace discrimination because it covers the greatest number of protected classifications. If a court determines that discrimination has occurred, this law entitles the victim to relief in the form of legal costs and back pay (i.e., the salary the person would have been receiving had no discrimination occurred). For instance, suppose a woman sues a company for rejecting her application for a $35,000 per year construction job because the company unlawfully excludes women from this job. The litigation process takes two years and, ultimately, the court rules in the applicant's favor. To remedy this discrimination, the court could require the company to pay her legal fees and grant her $70,000 in back pay (two years' salary).

Title VII of the Civil Rights Act of 1964 has had an enormous impact on the human resource management (HRM) practices of many companies, as it forced them to take a close look at the way they recruit, hire, promote, award pay raises, and discipline their employees. As a result of this self-scrutiny, many firms have changed their practices, making them more systematic and objective. For instance, most firms now require their supervisors to provide detailed documentation to justify the fairness of their disciplinary actions, and many firms are now more cautious with regard to their use of employment tests that restrict the employment opportunities for certain protected groups.

A number of Supreme Court decisions in the mid to late 1980s made discrimination claims under Title VII more difficult for employees to substantiate. To put more teeth into the law, Congress amended it by enacting the Civil Rights Act of 1991. This 1991 amendment expanded the list of remedies that may be awarded in a discrimination case—the employer now has more to lose if found guilty of discrimination. In addition to legal fees and back pay, an employer may now be charged with punitive and compensatory damages (for future financial losses, emotional pain, suffering, inconvenience, mental anguish, and loss of enjoyment of life). The cap for these damages ranges from $50,000 to $300,000 depending on the size of the company. Employees are entitled to such damages in cases where discrimination practices are "engaged in with malice or reckless indifference to the legal rights of the aggrieved individual" (e.g., the employer is aware that serious violations are occurring, but does nothing to rectify them).

Moreover, the CRA of 1991 adds additional bite to the 1964 law by providing a more detailed description of the evidence needed to prove a discrimination claim, making such claims easier to prove. The CRA of 1991 also differs from the 1964 law by addressing the issue of mixed-motives cases. The CRA of 1991 states that mixed-motive decisions are unlawful. That is, a hiring practice is illegal when a candidate's protected group membership is a factor affecting an employment decision, even if other, more legitimate factors are also considered. For instance, a company rejects the application of a woman because she behaves in an "unladylike" manner—she is "too aggressive for a woman, wears no makeup, and swears like a man." The company is concerned that she would offend its customers. The employer's motives are thus mixed: its concern about offending customers is a legitimate motive; its stereotyped view of how a "lady" should behave is a discriminatory one.

Congress introduced another bill, the Civil Rights Act of 2008, intended to "restore the right of individuals and to challenge practices that have an unjustified discriminatory effect based on race, color, national origin, disability, age, or gender." The bill, ultimately defeated, was questioned by some, as it stated that allowing employers to hire illegal aliens "undermine[s] the living standards and working conditions of all Americans."

OTHER MAJOR EEO LAWS

The Equal Pay Act of 1963 prohibits discrimination in pay on the basis of sex when jobs within the same company are substantially the same. The company is allowed to pay workers doing the same job differently if the differences are based on merit, seniority, or any other reasonable basis other than the workers' gender. In 2008, the Lilly Ledbetter Fair Pay Act (the Fair Pay Restoration Act) would have reversed the Supreme Court decision

that takes away the ability of women workers to sue for wage discrimination. However, it failed to get the 60-vote majority that it needed for Senate passage.

The Age Discrimination in Employment Act (ADEA) of 1967 bans employment discrimination on the basis of age by protecting applicants and employees who are forty or older. The ADEA applies to nearly all employers of twenty or more employees. The ADEA protects only older individuals from discrimination; people under forty are not protected. The act also prohibits employers from giving preference to individuals within the forty or older group. For instance, an employer may not discriminate against a fifty-year-old by giving preference to a forty-year-old. Except in limited circumstances, companies cannot require individuals to retire because of their age.

The Vocational Rehabilitation Act of 1973, a precursor to the 1990 passage of the Americans with Disabilities Act, requires employers who are federal contractors ($2,500 or more) to take proactive measures to employ individuals with disabilities. This law is limited in application since it only applies to federal agencies and businesses doing contract work with the government.

The Vietnam Veterans' Readjustment Assistance Act, passed in 1974, requires employers who are government contractors ($10,000 or more) to take proactive steps to hire veterans of the Vietnam era. The scope of this law is also limited by the fact that only government contractors must comply.

The Pregnancy Discrimination Act of 1978 amended the CRA of 1964 by broadening the interpretation of sex discrimination to include pregnancy, childbirth, or related medical conditions. It prohibits discrimination against pregnant job applicants or against women who are of child-bearing age. It states that employees who are unable to perform their jobs because of a pregnancy-related condition must be treated in the same manner as employees who are temporarily disabled for other reasons. It has also been interpreted to mean that women cannot be prevented from competing for certain jobs within a company just because the jobs may involve exposure to substances thought harmful to the reproductive systems of women.

The Immigration Reform and Control Act (IRCA) of 1986 prohibited discrimination based on national origin and citizenship. Specifically, the law states that employers of four or more employees cannot discriminate against any individual (other than an illegal alien) because of that person's national origin or citizenship status. In addition to being an anti-discrimination law, this act makes it unlawful to knowingly hire an unauthorized alien. At the time of hiring, an employer must require proof that the person offered the job is not an illegal alien.

The Americans with Disabilities Act (ADA) of 1990 was designed to eliminate discrimination against individuals with disabilities. The employment implications of the act, which are delineated in Titles I (private sector) and II (public sector) of the ADA, affect nearly all organizations employing fifteen or more workers. According to the act, an individual is considered disabled if he or she has a physical or mental impairment that substantially limits one or more of the individual's major life activities, such as walking, seeing, hearing, breathing, and learning, as well as the ability to secure or retain employment. In the years since passage of the legislation, the courts have applied a fairly broad definition of disability. The ADA only protects qualified individuals with a disability. To win a complaint, an individual who has been denied employment because of a disability must establish that, with accommodation (if necessary), he or she is qualified to perform the essential functions of the job in question. To defend successfully against such a suit, the employer must demonstrate that, even with reasonable accommodation, the candidate could not perform the job satisfactorily, or it must demonstrate that the accommodation would impose an undue hardship. The ADA defines "undue hardship" as those accommodations that require significant difficulty to effect or significant expense on the part of the employer.

An example of an ADA case would be one in which an employee is fired because of frequent absences caused by a particular disability. The employee may argue that the employer failed to offer a reasonable accommodation, such as a transfer to a part-time position. The employer, on the other hand, may argue that such an action would pose an undue hardship in that the creation of such a position would be too costly.

INTERPRETING EEO LAW

It is clear from the preceding discussion that an employer may not discriminate on the basis of an individual's protected group membership. But exactly how does one determine whether a particular act is discriminatory? Consider the following examples:

Case 1: A woman was denied employment as a police officer because she failed a strength test. During the past year that test screened out 90 percent of all female applicants and 30 percent of all male applicants.

Case 2: A woman was denied employment as a construction worker because she failed to meet the company's requirement that all workers be at least 5 feet 8 inches tall and weigh at least 160 pounds. During the past year, 20 percent of the male applicants and 70 percent of the female applicants have been rejected because of this requirement.

Case 3: A female accountant was fired despite satisfactory performance ratings. The boss claims she has violated company policy by moonlighting for

another firm. The boss was heard making the comment, "Women don't belong in accounting, anyway."

Case 4: A male boss fired his female secretary because he thought she was too ugly, and replaced her with a woman who, in his opinion, was much prettier.

The Civil Rights Acts of 1964 and 1991 prohibit sex discrimination. Yet, knowing that sex discrimination is unlawful provides very little guidance in these cases. For instance, how important are the intentions of the employer? And how important are the outcomes of the employment decisions? In the first two cases, the employer's intentions seem to be noble, but the outcomes of the employment decisions were clearly disadvantageous to women. In the third case, the employer's intentions appear questionable, but the outcome may be fair. After all, the employee did violate the company policy. In the fourth case, the employer's intentions are despicable, yet the outcome did not adversely affect women in the sense that another member of her sex replaced the discharged employee.

To determine whether an EEO law has been violated, one must know how the courts define the term *discrimination*. In actuality, there are two definitions: disparate treatment and disparate impact. Disparate treatment is intentional discrimination. It is defined as treating people unfairly based on their membership in a protected group. For example, the firing of the female accountant in Case 3 would be an example of disparate treatment if the discharge were triggered by the supervisor's bias against female accountants (i.e., if men were not discharged for moonlighting). However, the employer's actions in Cases 1 and 2 would not be classified as disparate treatment because there was no apparent intent to discriminate.

While disparate treatment is often the result of an employer's bias or prejudice toward a particular group, it may also occur as the result of trying to protect the group members' interests. For instance, consider the employer who refuses to hire women for dangerous jobs in order to protect their safety. While its intentions might be noble, this employer would be just as guilty of discrimination as one with less noble intentions.

What about Case 4, where a secretary was fired for being too ugly? Is the employer guilty of sex discrimination? The answer is no if the bias displayed by the boss was directed at appearance, not sex. Appearance is not a protected classification. The answer is yes if the appearance standard were being applied only to women; that is, the company fired women but not men on the basis of their looks.

Disparate impact is unintentional discrimination, defined as any practice without business justification that has unequal consequences for people of different protected groups. This concept of illegal discrimination was first established by the Griggs v. Duke Supreme Court decision, handed down in 1971. Disparate impact discrimination occurs, for instance, if an arbitrary selection practice (e.g., an irrelevant employment test) resulted in the selection of a disproportionately low number of females or African Americans. The key notion here is "arbitrary selection practice." If the selection practice were relevant or job-related, rather than arbitrary, the employer's practice would be legal, regardless of its disproportionate outcome. For example, despite the fact the women received the short end of the stick in Cases 1 and 2, the employer's actions would be lawful if the selection criteria (e.g., the strength test and height and weight requirements) were deemed job related. As it turns out, strength tests are much more likely to be considered job related than height and weight requirements. Thus, the employer would probably win Case 1 and lose Case 2.

WORKPLACE DISCRIMINATION IN THE TWENTY-FIRST CENTURY

The EEOC reported that nearly 7,000 racial harassment claims were filed in 2007, making it a record year for such cases. In one such case, Conectiv Energy and three subcontractors reached a $1.65 million discrimination settlement with four African American employees who, while on the job, were subjected to racial slurs, KKK graffiti, and hanging nooses. However, defense contractor Lockheed Martin holds the record for the biggest individual racial discrimination settlement in U.S. history. In 2008, the company paid $2.5 million to an African American employee who was the recipient of death threats and racial slurs.

Sex-based discrimination complaints were also high in 2007. That year, the EEOC received 24,826 charges of sex-based discrimination. The Commission resolved 21,982 sex discrimination charges and recovered $135.4 million in monetary benefits for charging parties and other aggrieved individuals. This figure did not include monetary benefits obtained through litigation.

As of 2008, most states still did not have laws that protect homosexual people from discrimination in employment, housing, and health care. However, the spring of 2008 ushered in activity surrounding employment discrimination based on sexual orientation. A bill introduced in Congress would have prohibited employment discrimination based on sexual orientation. In May 2008, the California Supreme Court ruled that same sex couples have a constitutional right to marry, making California and Massachusetts the first two states to recognize such marriages. Homosexual employees argue that they are being undercompensated by not being able to provide benefits for their

domestic partners. This is a benefit usually granted to spouses and family members. California, since 2005, has had a law that requires employers to grant the same benefits to registered domestic partners as married spouses.

Finally, a study conducted about age discrimination revealed that even the use of ageist language has negative effects for companies and employees. Such phrases used in the workplace, like "old goat" or "let's bring in the young guns," are linked to poor health and lower productivity of older workers. These comments can be costly for companies. In its 2006 fiscal year, the EEOC received nearly 17,000 workplace age discrimination charges and recovered nearly $52 million in monetary benefits.

AFFIRMATIVE ACTION

The aim of affirmative action is to remedy past and current discrimination. Although the overall aim of affirmative action is thus identical to that of EEO (i.e., to advance the cause of protected groups by eliminating employment discrimination), the two approaches differ in the way they attempt to accomplish this aim. EEO initiatives are color-blind, while affirmative action initiatives are color-conscious. That is, affirmative action makes special provisions to recruit, train, retain, promote, or grant some other benefit to members of protected groups (e.g., women, blacks).

In some cases, employers are legally required to institute affirmative action programs. For instance, Executive Order 11246, issued by President Lyndon Johnson, makes such programs mandatory for all federal government contractors. Affirmative action can also be court ordered as part of a settlement in a discrimination case. For example, in the 1970s, the state of Alabama was ordered by the Supreme Court to select one black applicant for each white hired as a state trooper. The purpose of this decree was to rectify the effects of past discrimination that had been blatantly occurring for several years.

Most firms, however, are under no legal obligation to implement affirmative action programs. Those choosing to implement such programs do so voluntarily, believing it makes good business sense. These firms believe that by implementing affirmative action they can (1) attract and retain a larger and better pool of applicants, (2) avoid discrimination lawsuits, and (3) improve the firm's reputation within the community and its consumer base.

Affirmative action implementation consists of two steps. First, the organization conducts an analysis to identify the underutilized protected groups within its various job categories (e.g., officials and managers, professionals, service workers, sales workers). It then develops a remedial plan that targets these underutilized groups. A utilization analysis is a statistical procedure that compares the percentage of each protected group for each job category within the organization to that in the available labor market. If the organiza-

---

Exhibit 1
Affirmative Action Options

Always Legal
1. Do nothing special, but make sure you always hire and promote people based solely on qualifications.
2. Analyze workforce for underutilization.
3. Set goals for increasing the percentage of minorities employed in jobs for which they are underutilized.
4. Remove artificial barriers blocking the advancement of minorities.
5. Create upward mobility training programs for minorities.
6. Advertise job openings in a way that ensures minority awareness (e.g., contact the local chapter of NOW or the NAACP).
7. Impose a rule that states that a manager cannot hire someone until there is a qualified minority in the applicant pool.

Sometimes Legal
(depends on the severity of the under-utilization problem)
8. Impose a rule that when faced with two equally qualified applicants (a minority and non-minority), the manager must hire the minority candidate.
9. Impose a rule that when faced with two qualified applicants (a minority and non-minority), hire the minority even if the other candidate has better qualifications.
10. Set a hiring quota that specifies one minority hiring for every non-minority hiring.

Never Legal
11. Do not consider any non-minorities for the position. Hire the most qualified minority applicant.
12. Fire non-minority employee and replace him or her with a minority applicant.

---

tional percentage is less than the labor-market percentage, the group is classified as being underutilized.

For example, the percentage of professionals within the organization who are women would be compared to the percentage of professionals in the available labor market who are women. The organization would classify women as being underutilized if it discovered, for instance, that women constitute 5 percent of the firm's professionals, and yet constitute 20 percent of the professionals in the available labor market.

The second step is to develop an affirmative action plan (AAP) that targets the underutilized protected groups. An AAP is a written statement that specifies how the organization plans to increase the utilization of targeted groups. The AAP consists of three elements: goals, timetables, and action steps.

The action steps specify how the organization plans to reach its goals and timetables. Action steps typically include such things as intensifying recruitment efforts, removing arbitrary selection standards, eliminating workplace prejudices, and offering employees better promotional and training opportunities.

When a company initiates an AAP as a remedy for under-utilization, it attempts to bring qualified women or minorities into the workplace to make it more reflective of the population from which the employees are drawn. This

practice sometimes involves the use of preferential treatment or giving members of underutilized groups some advantage over others in the employment process. The use of preferential treatment has triggered a storm of controversy, as detractors point to the seemingly inherent lack of fairness in giving preference to one individual over another based solely on that person's race or gender. Supporters, however, believe that preferential treatment is sometimes needed to level the playing field. The U.S. Supreme Court has ruled that preferential treatment is legal if engaged in as part of a bona fide affirmative action program that is designed to remedy underutilization. The AAP, however, must be temporary, flexible, and reasonable.

Opponents of affirmative action programs argue that reverse discrimination has resulted from some AAPs. For example, programs designed to ensure that women receive a higher education have been very effective; they now outnumber white males in college classrooms and white males are having a much harder time getting accepted. This could have future implications for the workplace.

Some states are considering doing away with affirmative action in government funded projects and public schools. In the 2008 election, voters in Arizona, Colorado, Missouri, Nebraska, and Oklahoma may get the chance to vote on the initiative: "The state shall not discriminate against or grant preferential treatment to any individual or group on the basis of race, sex, color, ethnicity or national origin in the operation of public employment, public education or public contracting."

Some AAP and diversity programs are considered counterproductive. In a Harvard review of diversity programs data filed by companies to the EEOC in 2006, it was discovered that initiatives aimed at reducing bias at the top levels of a company resulted in a 6 percent decline in the proportion of black women in management.

DISTRIBUTION AND DISTRIBUTION REQUIREMENTS PLANNING

A supply channel is composed of three structures. At one end of the channel is the manufacturer. The manufacturer focuses on the development and production of products and originates the distribution process. The terminal point in the channel is the retailer who sells goods and services directly to customers for their personal, non-business use. In between the two lies a process called distribution, which is more difficult to define. One involved in the distribution process is labeled a "distributor." The *APICS Dictionary* describes a distributor as "a business that does not manufacture its own products but purchases and resells these products. Such a business usually maintains a finished goods

inventory." The proliferation of alternative distribution forms, such as warehouse clubs, catalog sales, marketing channel specialists, and mail order, have blurred functional distinctions and increased the difficulty of defining both the distribution process and the term "distributor."

One ultimately could maintain that distributors include all enterprises that sell products to retailers and other merchants—and/or to industrial, institutional, and commercial users—but do not sell in significant amounts to the ultimate customer. According to this definition, most companies that are involved with the disbursement of raw materials and finished products belong, in one sense or another, to the distribution industry. By adopting this definition, distribution is expanded to cover nearly every form of materials management and physical distribution activity performed by channel constituents, except for the processes of manufacturing and retailing.

Distribution involves a number of activities centered around a physical flow of goods and information. At one time the term "distribution" applied only to the outbound side of supply chain management, but it now includes both inbound and outbound. Management of the inbound flow involves these elements:

- Material planning and control
- Purchasing
- Receiving
- Physical management of materials via warehousing and storage
- Materials handling

Management of the outbound flow involves these elements:

- Order processing
- Warehousing and storage
- Finished goods management
- Material handling and packaging
- Shipping
- Transportation

Distribution channels are formed to solve three critical distribution problems: functional performance, reduced complexity, and specialization.

The central focus of distribution is to increase the efficiency of time, place, and delivery utility. When demand and product availability are immediate, the producer can perform the exchange and delivery functions itself. However, as the number of producers grows and the geographical dispersion of the customer base expands, the need for both internal and external intermediaries

who can facilitate the flow of products, services, and information via a distribution process increases.

Distribution management also can decrease overall channel complexity through sorting and assistance in routinization. Sorting is the group of activities associated with transforming products acquired from manufacturers into the assortments and quantities demanded in the marketplace. Routinization refers to the policies and procedures providing common goals, channel arrangements, expectations, and mechanisms to facilitate efficient transactions. David F. Ross describes sorting as including four primary functions:

1. Sorting is the function of physically separating a heterogeneous group of items into homogeneous subgroups. This includes grading and grouping individual items into an inventory lot by quality or eliminating defects from the lot.

2. Accumulating is the function of combining homogeneous stocks of products into larger groups of supply.

3. Allocation is the function of breaking down large lots of products into smaller salable units.

4. Assorting is the function of mixing similar or functionally related items into assortments to meet customer demand. For example, putting items into kit form.

As the supply chain grows more complex, costs and inefficiencies multiply in the channel. In response, some channels add or contain partners that specialize in one or more of the elements of distribution, such as exchange or warehousing. Specialization then improves the channel by increasing the velocity of goods and value-added services and reducing costs associated with selling, transportation, carrying inventory, warehousing, order processing, and credit.

ROLE OF THE DISTRIBUTION FUNCTION

There are a number of critical functions performed by the channel distributor. Ross describes these functions as:

1. **Product acquisition.** This means acquiring products in a finished or semi-finished state from either a manufacturer or through another distributor that is higher up in the supply channel. These functions can be performed by independent channel intermediaries or by the distribution facilities of manufacturing companies.

2. **Product movement.** This implies significant effort spent on product movement up or down the supply channel.

3. **Product transaction.** Distributors can be characterized as selling products in bulk quantities solely for

the purpose of resale or business use. Downstream businesses will then sell these products to other distributors or retailers who will sell them directly to the end customer or to manufacturers who will consume the material/components in their own production processes.

Following are the separate elements contained within the three critical functions of distribution:

- **Selling and promoting.** This function is very important to manufacturers. One strategy involves the use of distribution channels to carry out the responsibilities of product deployment. In addition to being marketing experts in their industry, distribution firms usually have direct-selling organizations and a detailed knowledge of their customers and their expectations. The manufacturer utilizing this distributor can then tap into these resources. Also, because of the scale of the distributing firm's operations and its specialized skill in channel management, it can significantly improve the time, place, and possession utilities by housing inventory closer to the market. These advantages mean that the manufacturer can reach many small, distant customers at a relatively low cost, thus allowing the manufacturer to focus its expenditures on product development and its core production processes.

- **Buying and building product assortments.** This is an extremely important function for retailers. Most retailers prefer to deal with few suppliers providing a wide assortment of products that fit their merchandizing strategy rather than many with limited product lines. This, of course, saves on purchasing, transportation, and merchandizing costs. Distribution firms have the ability to bring together related products from multiple manufacturers and assemble the right combination of these products in quantities that meet the retailer's requirements in a cost-efficient manner.

- **Bulk breaking.** This is one of the fundamental functions of distribution. Manufacturers normally produce large quantities of a limited number of products. However, retailers normally require smaller quantities of multiple products. When the distribution function handles this requirement it keeps the manufacturer from having to break bulk and repackage its product to fit individual requirements. Lean manufacturing and JIT techniques are continuously seeking ways to reduce lot sizes, so this function enhances that goal.

- **Value-added processing.** Postponement specifies that products should be kept at the highest possible level in the pipeline in large, generic quantities that can be customized into their final form as close as possible to the actual final sale. The distributor can facilitate this process by performing sorting, labeling, blending, kitting, packaging, and light final assembly at one or more points within the supply channel. This significantly reduces end-product obsolescence and minimizes the risk inherent with carrying finished goods inventory.

- **Transportation.** The movement of goods from the manufacturer to the retailer is a critical function of distribution. Delivery encompasses those activities that are necessary to ensure that the right product is available to the customer at the right time and right place. This frequently means that a structure of central, branch, and field warehouses, geographically situated in the appropriate locations, are needed to achieve optimum customer service. Transportation's goal is to ensure that goods are positioned properly in the channel in a quick, cost-effective, and consistent manner.

- **Warehousing.** Warehousing exists to provide access to sufficient stock in order to satisfy anticipated customer requirements, and to act as a buffer against supply and demand uncertainties. Since demand is often located far from the source (manufacturer), warehousing can provide a wide range of marketplaces that manufacturers, functioning independently, could not penetrate.

- **Marketing information.** The distribution channel also can provide information regarding product, marketplace issues, and competitors' activities in a relatively short time.

DRP

The need for more detailed distribution planning led to the emergence of distribution requirements planning (DRP) during the 1970s. DRP is a widely used and potentially powerful technique for helping outbound logistics systems manage and minimize inbound inventories. This concept extended the time-phase order point found in material requirements planning (MRP) logic to the management of channel inventory. By the 1980s DRP had become a standard approach for planning and controlling distribution logistics activities and had evolved into distribution resource planning. The concept now embraces all business functions in the supply channel, not just inventory and logistics, and is termed DRP II.

DRP is usually used with an MRP system, although most DRP models are more comprehensive than stand-alone MRP models and can schedule transportation. The underlying rationale for DRP is to more accurately forecast demand and then use that information to develop delivery schedules. This way, distribution firms can

Figure 1

A DRP Calculation

Scheduled receipts:	1200, period 3
On-hand inventory balance:	1000
Lead time:	3 periods
Order receipt:	period due
Lot size:	600 units per pallet

Periods	1	2	3	4	5	6	7	8
Gross Requirements	500	500	500	500	500	500	500	500
Scheduled Receipts			1200					
On Hand	500			200				
Net Requirements					300	200	100	
Planned Order Receipt					600	600	600	
Planned Order Release		600	600	600				

minimize inbound inventory by using MRP in conjunction with other schedules.

One of the key elements of DRP is the DRP table, which includes the following elements:

- Forecast demand for each stock-keeping unit (SKU)
- Current inventory level of the SKU
- Target safety stock
- Recommended replenishment quantity
- Replenishment lead time

The concept of DRP very closely mimics the logic of MRP. As with MRP, gross requirements consist of actual customer orders, forecasted demand, or some combination of both; scheduled receipts are the goods the distributor expects to receive from orders that already have been released, while goods that already are received and entered into inventory constitute the on-hand inventory balance. Subtracting scheduled receipts and on-hand inventory from gross requirements yields net requirements. Based upon the distributor's lot-sizing policy and receiving behavior, planned order receipts are generated. Firms may order only what they need for the next planning period or for a designated time period. Known as economic order quantity (EOQ), this involves a lot size based on a costing model. Alternatively, firms may be limited to multiples of a lot size simply because the supplying firm packages or palletizes their goods in standard quantities. Also, some distributors may require some time interval between the arrival of goods on their docks and the entry of the goods into the inventory system. For example, a firm may have a staging area where goods remain for an average time period while awaiting quality or quantity verification. Hence, planned order receipt may be during the planning period when the goods are needed, or they may need to be received earlier depending on time requirements. Order release is then determined by offsetting the planned order receipt by the supplier's lead time. Figure 1 is a representation of a DRP calculation (ignoring possible safety stock requirements).

Today's competitive business landscape demands that companies proactively address quality issues of suppliers along the distribution chain to prevent incidents that cause significant damage to the business and/or consumers. This concept of regulatory oversight and customer demand for quality products is a strategic requirement. It is quality management's role to create a predictable product supply; this enables companies to stay competitive and mitigate risk. Organizations who fail to implement quality management into their manufacturing and value chain operations ultimately weaken their competitive standings in the market and may expose their brands to great risks.

DIVERSIFICATION STRATEGY

Diversification strategies are used to expand firms' operations by adding markets, products, services, or stages of production to the existing business. The purpose of diversification is to allow the company to enter lines of business that are different from current operations. When the new venture is strategically related to the existing lines of business, it is called concentric diversification. Conglomerate diversification occurs when there is no common thread of strategic fit or relationship between the new and old lines of business; the new and old businesses are unrelated.

DIVERSIFICATION IN THE CONTEXT OF GROWTH STRATEGIES

Diversification is a form of growth strategy. Growth strategies involve a significant increase in performance objectives (usually sales or market share) beyond past levels of performance. Many organizations pursue one or more types of growth strategies. One of the primary reasons is the view held by many investors and executives that "bigger is better." Growth in sales is often used as a measure of performance. Even if profits remain stable or decline, an increase in sales satisfies many people. The assumption is often made that if sales increase, profits will eventually follow.

Rewards for managers are usually greater when a firm is pursuing a growth strategy. Managers are often paid a commission based on sales. The higher the sales level, the larger the compensation received. Recognition and power also accrue to managers of growing companies. They are more frequently invited to speak to professional groups and are more often interviewed and written about by the press than are managers of companies with greater rates of return but slower rates of growth. Thus, growth companies also become better known and may be better able to attract quality managers.

Growth may also improve the effectiveness of the organization. Larger companies have a number of advantages over smaller firms operating in more limited markets.

1. Large size or large market share can lead to economies of scale. Marketing or production synergies may result from more efficient use of sales calls, reduced travel time, reduced changeover time, and longer production runs.

2. Learning- and experience-curve effects may produce lower costs as the firm gains experience in producing and distributing its product or service. Experience and large size may also lead to improved layout, gains in labor efficiency, redesign of products or production processes, or larger and more qualified staff departments (e.g., marketing research or research and development).

3. Lower average unit costs may result from a firm's ability to spread administrative expenses and other overhead costs over a larger unit volume. The more capital intensive a business is, the more important its ability to spread costs across a large volume becomes.

4. Improved linkages with other stages of production can also result from large size. Better links with suppliers may be attained through large orders, which may produce lower costs (quantity discounts), improved delivery, or custom-made products that would be unaffordable for smaller operations. Links with distribution channels may lower costs by better location of warehouses, more efficient advertising, and shipping efficiencies. The size of the organization relative to its customers or suppliers influences its bargaining power and its ability to influence price and services provided.

5. Sharing of information between units of a large firm allows knowledge gained in one business unit to be applied to problems being experienced in another unit. Especially for companies relying heavily on technology, the reduction of R&D costs and the time needed to develop new technology may give larger firms an advantage over smaller, more specialized firms. The more similar the activities are among units, the easier the transfer of information becomes.

6. Taking advantage of geographic differences is possible for large firms. Especially for multinational firms, differences in wage rates, taxes, energy costs, shipping and freight charges, and trade restrictions influence the costs of business. A large firm can sometimes lower its cost of business by placing multiple plants in locations providing the lowest cost. Smaller firms with only one location must operate within the strengths and weaknesses of its single location.

CONCENTRIC DIVERSIFICATION

Concentric diversification occurs when a firm adds related products or markets. For example, Microsoft's 2008 bid for Yahoo! can be seen as an attempt at concentric diversification. The goal of such diversification is to achieve strategic fit, which allows an organization to achieve

synergy. In essence, synergy is the ability of two or more parts of an organization to achieve greater total effectiveness together than would be experienced if the efforts of the independent parts were summed. Synergy may be achieved by combining firms with complementary marketing, financial, operating, or management efforts. Breweries have been able to achieve marketing synergy through national advertising and distribution. By combining a number of regional breweries into a national network, beer producers have been able to produce and sell more beer than had independent regional breweries.

Financial synergy may be obtained by combining a firm with strong financial resources but limited growth opportunities with a company having great market potential but weak financial resources. For example, debt-ridden companies may seek to acquire firms that are relatively debt-free to increase the leveraged firm's borrowing capacity. Similarly, firms sometimes attempt to stabilize earnings by diversifying into businesses with different seasonal or cyclical sales patterns.

Strategic fit in operations could result in synergy by the combination of operating units to improve overall efficiency. Combining two units so that duplicate equipment or research and development are eliminated would improve overall efficiency. Quantity discounts through combined ordering would be another possible way to achieve operating synergy. Yet another way to improve efficiency is to diversify into an area that can use by-products from existing operations. For example, breweries have been able to convert grain, a by-product of the fermentation process, into feed for livestock.

Management synergy can be achieved when management experience and expertise is applied to different situations. Perhaps a manager's experience in working with unions in one company could be applied to labor management problems in another company. Caution must be exercised, however, in assuming that management experience is universally transferable. Situations that appear similar may require significantly different management strategies. Personality clashes and other situational differences may make management synergy difficult to achieve. Although managerial skills and experience can be transferred, individual managers may not be able to make the transfer effectively.

CONGLOMERATE DIVERSIFICATION

Conglomerate diversification occurs when a firm diversifies into areas that are unrelated to its current line of business. Synergy may result through the application of management expertise or financial resources, but the primary purpose of conglomerate diversification is improved profitability of the acquiring firm. Little, if any, concern is given to achieving marketing or production synergy with conglomerate diversification.

One of the most common reasons for pursuing a conglomerate growth strategy is that opportunities in a firm's current line of business are limited. Finding an attractive investment opportunity requires the firm to consider alternatives in other types of business. Products, markets, and production technologies of the brewery were quite different from those required to produce cigarettes.

Firms may also pursue a conglomerate diversification strategy as a means of increasing the firm's growth rate. As discussed earlier, growth in sales may make the company more attractive to investors. Growth may also increase the power and prestige of the firm's executives. Conglomerate growth may be effective if the new area has growth opportunities greater than those available in the existing line of business.

Probably the biggest disadvantage of a conglomerate diversification strategy is the increase in administrative problems associated with operating unrelated businesses. Managers from different divisions may have different backgrounds and may be unable to work together effectively. Competition between strategic business units for resources may entail shifting resources away from one division to another. Such a move may create rivalry and administrative problems between the units.

Caution must also be exercised in entering businesses with seemingly promising opportunities, especially if the management team lacks experience or skill in the new line of business. Without some knowledge of the new industry, a firm may be unable to accurately evaluate the industry's potential. Even if the new business is initially successful, problems will eventually occur. Executives from the conglomerate will have to become involved in the operations of the new enterprise at some point. Without adequate experience or skills (management synergy) the new business may become a poor performer.

Without some form of strategic fit, the combined performance of the individual units will probably not exceed the performance of the units operating independently. In fact, combined performance may deteriorate because of controls placed on the individual units by the parent conglomerate. Decision-making may become slower due to longer review periods and complicated reporting systems.

DIVERSIFICATION: GROW OR BUY?

Diversification efforts may be either internal or external. Internal diversification occurs when a firm enters a different, but usually related, line of business by developing the new line of business itself. Internal diversification frequently involves expanding a firm's product or market base. External diversification may achieve the same result; however, the company enters a new area of business by

purchasing another company or business unit. Mergers and acquisitions are common forms of external diversification.

Internal Diversification. One form of internal diversification is to market existing products in new markets. A firm may elect to broaden its geographic base to include new customers, either within its home country or in international markets. A business could also pursue an internal diversification strategy by finding new users for its current product. For example, Arm & Hammer marketed its baking soda as a refrigerator deodorizer. Finally, firms may attempt to change markets by increasing or decreasing the price of products to make them appeal to consumers of different income levels.

Another form of internal diversification is to market new products in existing markets. Generally this strategy involves using existing channels of distribution to market new products. Retailers often change product lines to include new items that appear to have good market potential. Johnson & Johnson added a line of baby toys to its existing line of items for infants. Packaged-food firms have added salt-free or low-calorie options to existing product lines.

An effective way to extend a company's product line is to partner with another company. Companies can take advantage of both of the aforementioned strategies–market existing products in new markets and market new products in existing markets–by working with a complementary company. Existing customers of both partnering companies are much more likely to buy something from a business they already trust than a stranger who has no experience with their products. Good partners will have revenue streams that are different, but complementary to each other.

It is also possible to have conglomerate growth through internal diversification. This strategy would entail marketing new and unrelated products to new markets. This strategy is the least used among the internal diversification strategies, as it is the most risky. It requires the company to enter a new market where it is not established. The firm is also developing and introducing a new product. Research and development costs, as well as advertising costs, will likely be higher than if existing products were marketed. In effect, the investment and the probability of failure are much greater when both the product and market are new.

External Diversification. External diversification occurs when a firm looks outside of its current operations and buys access to new products or markets. Mergers are one common form of external diversification. Mergers occur when two or more firms combine operations to form one corporation, perhaps with a new name. These firms are usually of similar size. One goal of a merger is to achieve management synergy by creating a stronger management team. This can be achieved in a merger by combining the management teams from the merged firms.

Acquisition, a second form of external growth, occurs when the purchased corporation loses its identity. The acquiring company absorbs it. The acquired company and its assets may be absorbed into an existing business unit or remain intact as an independent subsidiary within the parent company. Acquisitions usually occur when a larger firm purchases a smaller company. Acquisitions are called "friendly" if the firm being purchased is receptive to the acquisition. (Mergers are usually friendly.) Unfriendly mergers or hostile takeovers occur when the management of the firm targeted for acquisition resists being purchased.

DIVERSIFICATION: VERTICAL OR HORIZONTAL?

Diversification strategies can also be classified by the direction of the diversification. Vertical integration occurs when firms undertake operations at different stages of production. Involvement in the different stages of production can be developed inside the company (internal diversification) or by acquiring another firm (external diversification). Horizontal integration or diversification involves the firm moving into operations at the same stage of production. Vertical integration is usually related to existing operations and would be considered concentric diversification. Horizontal integration can be either a concentric or a conglomerate form of diversification.

Vertical Integration. The steps that a product goes through in being transformed from raw materials to a finished product in the possession of the customer constitute the various stages of production. When a firm diversifies closer to the sources of raw materials in the stages of production, it is following a backward vertical integration strategy. Avon's primary line of business has been the selling of cosmetics door-to-door. Avon pursued a backward form of vertical integration by entering into the production of some of its cosmetics. Forward diversification occurs when firms move closer to the consumer in terms of the production stages. Levi Strauss & Co., traditionally a manufacturer of clothing, has diversified forward by opening retail stores to market its textile products rather than producing them and selling them to another firm to retail.

Backward integration allows the diversifying firm to exercise more control over the quality of the supplies being purchased. Backward integration also may be undertaken to provide a more dependable source of needed raw materials. Forward integration allows a manufacturing company to assure itself of an outlet for its products. Forward integration also allows a firm more control over how its

products are sold and serviced. Furthermore, a company may be better able to differentiate its products from those of its competitors by forward integration. By opening its own retail outlets, a firm is often better able to control and train the personnel selling and servicing its equipment. Since servicing is an important part of many products, having an excellent service department may provide an integrated firm a competitive advantage over firms that are strictly manufacturers.

Some firms employ vertical integration strategies to eliminate the "profits of the middleman." Firms are sometimes able to efficiently execute the tasks being performed by the middleman (wholesalers, retailers) and receive additional profits. However, middlemen receive their income by being competent at providing a service. Unless a firm is equally efficient in providing that service, the firm will have a smaller profit margin than the middleman. If a firm is too inefficient, customers may refuse to work with the firm, resulting in lost sales.

Vertical integration strategies have one major disadvantage. A vertically integrated firm places "all of its eggs in one basket." If demand for the product falls, essential supplies are not available, or a substitute product displaces the product in the marketplace, the earnings of the entire organization may suffer.

Horizontal Diversification. Horizontal integration occurs when a firm enters a new business (either related or unrelated) at the same stage of production as its current operations. For example, Avon's move to market jewelry through its door-to-door sales force involved marketing new products through existing channels of distribution. An alternative form of horizontal integration that Avon has also undertaken is selling its products by mail order (e.g., clothing, plastic products) and through retail stores (e.g., Tiffany's). In both cases, Avon is still at the retail stage of the production process.

DIVERSIFICATION STRATEGY AND MANAGEMENT TEAMS

As documented in a 2004 study by Marlin, Lamont, and Geiger, ensuring a firm's diversification strategy is well matched to the strengths of its top management team members factored into the success of that strategy. For example, the success of a merger may depend not only on how integrated the joining firms become, but also on how well suited top executives are to manage that effort. The study also suggests that different diversification strategies (concentric vs. conglomerate) require different skills on the part of a company's top managers, and that the factors should be taken into consideration before firms are joined.

There are many reasons for pursuing a diversification strategy, but most pertain to management's desire for the organization to grow. Companies must decide whether they want to diversify by going into related or unrelated businesses. They must then decide whether they want to expand by developing the new business or by buying an ongoing business. Finally, management must decide at what stage in the production process they wish to diversify.

DIVERSITY

The advent of equal employment opportunity (EEO) laws and affirmative action programs created new employment opportunities for members of protected groups that had previously been victimized by employment discrimination. The demographic mix within the twenty-first century workplace has consequently become much more diverse, a result not only of these laws but also due to the globalization of business. Furthermore, the changing demographics of the United States have affected worker diversity. The aging population has created what some refer to as the "sandwich generation": the group of the population who are charged with caring for both their parents and their children.

In today's world, fewer workers support Medicare and Social Security. To provide opportunities for the new population of workers, businesses are allowing more flextime, telecommuting, and sabbaticals. They are also training line managers to respond to the cultural, lingual, generational, and technological differences that the new workforce introduces. Finally, more retirees are returning to the workforce.

All these new realities add up to a different-looking workplace. No longer are the majority of workers white, male, and English-speaking. People of color continue to increase their shares of the labor force as these groups grow more rapidly than whites. In fact, white non-Hispanics are projected to continue to decline as a percentage of the labor force.

The Hispanic population growth will be a key and growing portion of a more diverse workforce, according to the Bureau of Labor Statistics. The Hispanic labor force will grow by 30 percent by 2015, reaching nearly 27 million. By 2025, Hispanics are predicted to make up 17 percent of the total labor force. This group gained a greater share of the market than African Americans in 2000. At that time, Hispanics made up 13 percent, and African Americans, 12.7 percent. Finally, it is estimated that Asians and other people of color will make up about 8 percent of the labor force in 2025.

In the United States, the average age of the workforce is getting older, mirroring the age demographics of the population. The number of workers 55 and older is expected to reach about 23 million by 2016. This represents a growth rate of 46.7 percent, which is almost 5.5 times the projection for the overall labor force.

The workforce is also experiencing a dramatic increase in the number of dual-income families (many of whom have young children); in 2005, women made up 46 percent of the workforce, but in 1975, they made up less than 40 percent of the total. The workforce is also reacting to an increase in single-parent families and families facing the demands of elder care. The labor market will continue to be significantly impacted by the aging of the baby-boom generation.

In the past, organizations ignored the impact that diversity had on the attitudes and behavior of employees. However, years of political, social, and legal change brought new groups of employees into the workplace. At first, organizations attempted to handle these new groups through assimilation; simply put, people were expected to fit in. Equal treatment at the workplace meant the same treatment for each employee; individual differences were ignored. Consequently, assimilation often resulted in pressure to conform, exclusion and isolation, and reinforcement of the dominant group values. The problem became compounded as the number of

diverse groups within the organization increased and the number of white males declined.

The failure to deal effectively with the diversity issue can hinder competitive advantages. For instance, firms choosing to do business as usual have been plagued with a high turnover among nontraditional employees, low morale within the organization, under-utilization of employee skills, numerous intergroup conflicts, low productivity, and an inability to attract new workers. On the other hand, if diversity is dealt with effectively, competitive advantage can be enhanced. For instance, companies that value diversity can attract a larger and better pool of applicants than companies that limit themselves to a traditional workforce.

Accommodating the needs of the diverse workforce is more important to organizations now than ever before. When properly managed, such cultural diversity can represent a key strategic advantage. Diversity in age, gender, race, and viewpoint can offer organizations a number of benefits including additional knowledge, creative ideas and insights to aid in problem solving, enhanced product positioning, better development of strategic plans and objectives, and fresh opinions. These diverse workers can bring original ideas and approaches to the workplace that can help a firm target its products and services to a marketplace that is becoming more and more diverse. This adds economic importance to the issue of diversity since, in 2007, the combined African-American, Hispanic-American, and Asian-American buying power was more than $750 billion.

MINORITIES IN THE WORKPLACE

Although minorities have been entering the workforce in record numbers, their quests to reach the top of the corporate ladder have been thwarted. Many have topped out at entry- or mid-level management positions. Minorities have failed to reach the highest levels of management partly because many have only recently entered the managerial ranks; it takes time to climb the corporate ladder. However, this explanation does not account for the magnitude of the problem. For years minorities have faced invisible, subtle, yet very real institutional barriers to promotions into higher level executive positions. The belief that minority groups reach organizational plateaus consisting of artificial barriers that derail them from senior management opportunities has been alternately termed "the glass ceiling" or "the brick wall." These barriers found in the structure of many organizations have often stymied the advancement of these select employee groups.

How can the glass ceilings be cracked or the brick walls broken down? Effective diversity training that helps decision makers overcome their biases would certainly help. But diversity training, by itself, is not enough, and

diversity management must not be confused with affirmative action. The Society for Human Resource Management recommends the following components for a successful diversity initiative:

1. **Get executive commitment.** Enlisting the visible support and commitment of your organization's CEO is fundamental to a successful diversity initiative.

2. **Articulate the desired outcomes.** Be explicit about how support and commitment are to be shown and from whom it is expected.

3. **Assess the climate, needs, and issues at your organization.** The use of focus groups can help clarify the obstacles. It will prove helpful to determine where your organization currently is on the diversity continuum before determining what interventions need to be taken.

4. **Create and maintain open channels of communication with employees at the launch of your diversity initiative and throughout the process.** Communication is crucial to the success of your diversity plan and should occur not only at the beginning of a diversity initiative, but also throughout the process.

5. **Consider forming a diversity taskforce to widen your support base.** This group can help analyze assessment data and make recommendations to top management.

6. **Develop a mechanism for dealing with systemic changes and procedural problems.** Once identified, obstacles and problems must be addressed. For example, your company may be committed to hiring persons outside of the dominant culture, but has difficulty promoting those same persons once they are with the organization.

7. **Design relevant, interactive, applicable training.** The purpose of good training is to not just increase awareness and understanding about diversity, but to also develop concrete skills that employees can use to deal with workplace diversity, its implications, and its effects.

8. **Evaluate and measure each component of your diversity initiative (training, taskforce, mentoring initiative, employee networks, etc.).** Set measurable criteria and determine what you would like to accomplish and how you will gather data.

9. **Ensure integration and accountability.** Integrate the concepts, skills and results of your diversity efforts into the fabric of the organization and hold management accountable for encouraging diversity throughout the organization.

Inclusive companies have similar characteristics. They usually support local diversity groups, have clear, written anti-discrimination policies, and allow and support diversity-employee-affinity groups to support the networking and mentoring needs of their employees. They also incorporate companywide diversity training as a standard part of their business.

Dealing with diversity is a continuing process that enhances an organization's ability to adapt and capitalize on today's increasingly complex world and global marketplace. In an online survey of more than 2,500 senior human resources executives in the United States and Canada, employers say that globalization has prompted them to enhance their diversity efforts or their inclusion programs.

Changes in American society have brought unprecedented social diversity into the workforce. Immigrants from all over the world and societal segments that have been excluded or poorly represented in the past are entering new professions and attaining management and leadership roles. Corporate cultures, employment policies, and networks of influence have been forced to change. The principal challenge for American employers today lies less in finding diverse talent but in developing it and creating an environment that supports social cohesion amid the diversity. A well-managed diverse workforce can give companies the competitive advantage necessary to compete in a global economy.

DIVESTMENT

Divestment is a form of retrenchment strategy used by businesses when they downsize the scope of their business activities. Divestment usually involves eliminating a portion of a business. Firms may elect to sell, close, or spin-off a strategic business unit, major operating division, or product line. This move often is the final decision to eliminate unrelated, unprofitable, or unmanageable operations.

While the number of divestments increases when the economy suffers, divestment is commonly the consequence of a growth strategy. Much of the corporate downsizing of the 1990s has been the result of acquisitions and takeovers that were the rage in the 1970s and early 80s. Firms often acquired other businesses with operations in areas with which the acquiring firm had little experience. After trying for a number of years to integrate the new activities into the existing organization, many firms have elected to divest themselves of portions of the business in order to concentrate on those activities in which they had a competitive advantage.

REASONS TO DIVEST

In most cases it is not immediately obvious that a unit should be divested. Many times management will attempt to increase investment as a means of giving the unit an opportunity to turn its performance around. Portfolio models such as the Boston Consulting Group (BCG) Model or General Electric's Business Screen can be used to identify operations in need of divestment. For example, products or business operations identified as "dogs" in the BCG Model are prime candidates for divestment.

Decisions to divest may be made for a number of reasons:

Market Share Too Small. Firms may divest when their market share is too small for them to be competitive or when the market is too small to provide the expected rates of return.

Availability of Better Alternatives. Firms may also decide to divest because they see better investment opportunities. Organizations have limited resources. They are often able to divert resources from a marginally profitable line of business to one where the same resources can be used to achieve a greater rate of return.

Need for Increased Investment. Firms sometimes reach a point where continuing to maintain an operation is going to require large investments in equipment, advertising, research and development, and so forth to remain viable. Rather than invest the monetary and management resources, firms may elect to divest that portion of the business.

Lack of Strategic Fit. A common reason for divesting is that the acquired business is not consistent with the image and strategies of the firm. This can be the result of acquiring a diversified business. It may also result from decisions to restructure and refocus the existing business.

Legal Pressures to Divest. Firms may be forced to divest operations to avoid penalties for restraint of trade. Service Corporation Inc., a large funeral home chain acquired so many of its competitors in some areas that it created a regional monopoly. The Federal Trade Commission required the firm to divest some of its operations to avoid charges of restraint of trade.

IMPLEMENTATION OF DIVESTMENT STRATEGIES

Firms may pursue a divestment strategy by spinning off a portion of the business and allowing it to operate as an independent business entity. Firms may also divest by selling a portion of the business to another organization. RJR Nabisco used both of these forms of divestment. In 1985 Nabisco Brands was bought by R.J. Reynolds, the manufacturer of Winston, Camel, and many other cigarette brands. Fueled in part by fears of legal liability resulting from tobacco lawsuits and by complaints from investors that the tobacco side of RJR Nabisco was dragging the food business down, in early 1999 the decision was made to spin-off the domestic tobacco operations into a separate company. Later in 1999 the decision was made to sell the overseas tobacco business to Japan Tobacco.

Another way to implement a divestment decision is to simply close a portion of the firm's operations. Faced with a decline in its market share of almost half in the 14 to 19 male age group and no introduction of a successful new product in years, and rising manufacturing costs, Levi Strauss has found it necessary to divest some of its operations. For nearly a decade, the company slashed costs by shutting dozens of factories in North America and Europe and eliminating thousands of jobs. Selling many of the plants probably was not feasible as many other clothing manufacturers are also closing plants and moving operations overseas, depressing the price for clothing manufacturing facilities. Besides, the most likely buyers for the Levi's plants would be competitors and Levi Strauss probably would not want them to have the added capacity.

In 2004 Teleflex, a U.S. 2 billion dollar industrial product manufacturer, implemented a divestment and acquisition strategy to remove underperforming units while acquiring companies in markets where it intended to expand its business.

Although a business may be identified as a target for divestment, the implementation of divestment is not always easy. First a buyer must be found. This may be difficult for a failing business unit. Once a buyer is found, then price must be negotiated. Many divestments are blocked by management's expectations for the operation. Firms may expect demand for the product to pick up. Management may also see the poor performance as a temporary setback that can be overcome with time and patience. Decisions to divest a business may be seen as an admission of failure on the part of management and may lead to escalating commitment to the struggling business as a way of protecting management's ego and public image.

Robert Haas, who was president and CEO at Levi Strauss & Co. until 2005, certainly received bad publicity and had his leadership abilities and judgment questioned as a result of his decision to close company plants and eliminate jobs. With profits already falling around the beginning of the twenty-first century, Haas and Levi Strauss & Co., missed on the timing of its divestiture. The divestiture process, which typically takes eight months or more, is easier and more profitable when companies divest at the right time. While it is difficult for companies to divest their business when it's healthy, strategists should look at its long-term potential. If none exists, the company should research divesting as an option, rather than waiting until the business has peaked and become a declining or even failing business. (Incidentally, Levi Strauss & Co., added 870 employees in 2007, a turn-around after years of lay-offs.)

Divestment is not usually the first choice of strategy for a business. However, as product demand changes and firms alter their strategies, there will almost always be some portion of the business that is not performing to management's expectations. Such an operation is a prime target for divestment and may well leave the company in a stronger competitive position if it is divested.

DOMESTIC MANAGEMENT SOCIETIES AND ASSOCIATIONS

Management societies and associations exist to promote greater professionalism within the field and provide educational opportunities for their members. Many societies and associations exist within the field of management. Some have members primarily from academia; others have members who are primarily practitioners; while still others have both. Although almost all associations within the field of management have some international members, the focus of the following paragraphs is on those societies and associations whose membership is predominantly in the United States.

The management associations discussed in this article all have similar organization structures and activities:

- All sponsor a variety of useful professional services available to their members.

- Most have local chapters that are affiliated with the national organization.

- Most have at least one and sometimes several conferences each year and sponsor publications

designed to disseminate management research findings or to communicate helpful information to management practitioners.

- Some offer professional certification programs to allow members to demonstrate their competence within their area of specialty.

ACADEMY OF MANAGEMENT

The Academy of Management (AOM) is the preeminent professional organization for those involved or interested in management research and education in the United States. It was founded in 1936, and its membership consisted of more than 18,000 individuals from 102 nations as of 2008. Most of its members are college professors teaching within the field of management or related disciplines. Most academy members have doctoral degrees in management or related disciplines. The academy also has some practitioner members. Although the academy has members from around the world, the overwhelming majority of its membership is in the United States.

AOM sponsors an annual conference each August. At this meeting, educational and professional development programs are held and scholarly research papers are presented and discussed. Other activities at the annual meeting include meetings of various divisions and interest groups and a job placement service that allows universities to recruit for qualified applicants to fill open faculty positions in management and related fields.

AOM publishes scholarly journals and a newsletter. The *Academy of Management Journal (AMJ)* features empirical papers, and the *Academy of Management Review (AMR)* features theoretical papers. The *Academy of Management Executive (AME)* publishes applied articles related to management practice and has a substantial readership among practitioners. There is also the *Academy of Management Learning and Education (AMLE)*. Additionally, the association publishes an annual meeting Best Papers Proceedings CD. The AOM started publishing the Academy of Management Annals in 2007. This new book series will be published annually.

AOM has a variety of divisions and interest groups that allow members with common interests to interact more closely. Some of these divisions include Business Policy & Strategy, Human Resource Management, Organizational Behavior, Operations Management, Social Issues in Management, Entrepreneurship, and Management History.

Within AOM, there are several associated organizations, including the Southern Management Association, the Eastern Academy of Management, the Southwest Academy of Management, the Midwest Academy of Management, and the Western Academy of Management. Each of these regional associations holds annual meetings

of its own, with activities that are similar to those that take place at the national meeting of the academy. Many management scholars also hold memberships in one or more of these regional associations.

AOM has a significant presence online (http://www.aomonline.org). The site has information of interest to management scholars and researchers, news about upcoming conferences, and links to related divisions and groups.

AMERICAN MANAGEMENT ASSOCIATION

The American Management Association (AMA) is a large, nonprofit educational association that seeks to develop organizational effectiveness. AMA has programs related to many areas of management practice, including general and administrative services, strategic management, human resources, information systems, manufacturing, purchasing, research and development, and sales and marketing. Founded in 1923, AMA has about 25,000 members, and its newsletters are delivered to 80,000 members and customers. Membership consists mainly of management practitioners based in the United States, although it attracts members from 89 countries around the world.

AMA publishes about 80 business-related books each year. It also publishes several periodicals related to management, including *Management Review, The Take-Charge Assistant, Organizational Dynamics,* and *HR Focus.* It also offers members and customers six different e-newsletters and launched *The Thinker Series* to provide inspiration to drive organizational growth.

The association holds an annual conference and sponsors numerous seminars, workshops, and forums on various management-related topics. It also offers podcasts and on-demand webcasts on the AMA Web site (http://www.amanet.org), which provides details about its programs, conferences, and seminars, as well as other useful information relevant to the practicing manager.

SOCIETY FOR HUMAN RESOURCE MANAGEMENT

The Society for Human Resource Management (SHRM), founded in 1948, is the largest professional association in its field. SHRM has 225,000 individual members in more than 125 countries. The association has a network of more than 575 affiliated chapters in the United States, and offices in China and India. Its members belong to local professional chapters or college and university student chapters.

SHRM has several professional publications, most of which are free with membership in the organization. Its premiere publication is the monthly *HR Magazine. HR News, Workplace Visions,* and *Mosaics* are primarily of interest to practitioners. *HRM Journal* features academic

research of interest to scholars in the field. Additionally, SHRM offers members several newsletters more targeted to specific audiences that are delivered via email.

SHRM sponsors professional development and certification programs. Professional development activities include seminars and certificate programs, portfolio subscriptions, and certification preparation learning modules. A certification program is administered through the Human Resource Certification Institute (HRCI). Certification is available at three levels: Professional in Human Resources (PHR), Senior Professional in Human Resources (SPHR), and Global Professional in Human Resources (GPHR). Certification requires several years of experience in an exempt HR position and the successful completion of a certification examination, which is offered to those wishing to take the test during two two-month periods during the year.

SHRM funds human resources management academic research through its Foundation. It also conducts an annual HR salary survey.

The society holds an annual conference and exposition, an employment law and legislative conference, a leadership conference, a strategy conference, and a diversity conference.

SHRM's Web site (http://www.shrm.org) contains a wide variety of resources for the HR professional, including an information center, online publications, and a placement area. Although some of the internet services are available to the public, most are restricted to SHRM members.

APICS: THE ASSOCIATION FOR OPERATIONS MANAGEMENT

APICS: The Association for Operations Management (formerly Association for Production and Inventory Control) is a professional organization for those involved or interested in operations management, and production and inventory management. It provides professional certifications, educational programs, and publications. Founded in 1957, APICS has practitioner, academic, and student members. There are more than 43,000 individuals from 15,000 companies worldwide from nearly all industries. APICS membership is concentrated in the United States.

APICS offers member discounts on educational materials, programs, and certification exam and review material. The organization also offers numerous national workshops and in-house training programs, as well as opportunities for online resources, local training, and networking. APICS offers members its award-winning publication, *APICS Magazine*.

APICS has three certification programs for professionals in the field: Certified in Production and Inventory Management (CPIM), Certified in Integrated Resource Management (CIRM), and Certified Supply Chain Pro-

fessional (CSCP). CPIM certification was developed in 1973 to provide a means for individuals to assess their knowledge of production and inventory management relative to a common core of knowledge. CIRM certification was developed in 1991 and is designed to assess cross-functional knowledge of interrelated functions within an organization. First offered in 2008, the CSCP was developed for individuals seeking in-depth knowledge and understanding of their entire supply chain. APICS created it to educate supply chain managers with changing requirements of educational needs in the field of supply chain management.

APICS holds an annual conference that allows members to learn about the latest management and manufacturing techniques. It also sponsors various research activities, including an undergraduate and graduate paper competition through its Educational and Research Foundation.

The APICS Web site (http://www.apics.org) contains information about its services and the field.

WORLD AT WORK

Founded in 1955, WorldatWork (formerly the American Compensation Association) is a professional organization for those involved or interested in the management of employee compensation and benefits policies and procedures. WorldatWork provides information, training, research support, and networking opportunities to its 30,000 members and customers in 75 countries. Specific benefits of membership include discounts on WorldatWork educational and training programs, career placement and networking opportunities, and updates in the field through various publications.

WorldatWork offers various educational and professional training programs. Seminars provide training in all areas of compensation and benefits management. In-house training programs allow organizations to sponsor training for their employees on-site.

WorldatWork sponsors a certification program that enables members to increase their credibility as compensation and benefits management professionals. Certification is available along three tracks: Certified Compensation Professional (CCP), Certified Benefits Professional (CBP), and the Work-Life Certified Professional (WLCP).

WorldatWork holds an annual conference and sponsors various research activities at leading U.S. universities. It publishes several journals and newsletters, including *Workspan* and *WorldatWork Journal*. Its highest visibility online newsletter is called *Workspan Weekly*.

WorldatWork also attempts to increase linkages between practitioners and academia through its Academic Partnership Network. This concept is designed to foster increased communication between practitioners and academics.

WorldatWork's Web site (http://www.worldatwork. org) includes information resources for the compensation and benefits professional.

INSTITUTE FOR SUPPLY MANAGEMENT

The Institute for Supply Management (ISM) is a professional association designed to advance the purchasing and supply management profession. Founded in 1915, its membership consists of more than 40,000 supply management professionals, mostly in the United States. To be eligible for membership, a person must be involved in the purchasing or materials process, be employed by an affiliated association, or be a full-time professor or administrator at a college or university whose academic responsibility includes purchasing or material management courses.

ISM offers a variety of educational and development programs and products. Conferences, seminars, and other educational activities allow purchasing and material managers to expand their professional skills.

The ISM flagship publication is *Inside Supply Management.* Blackwell Publishing puts out *The Journal of Supply Chain Management* on behalf of the ISM. The association also develops a number of online newsletters including *Supply Line 2055: Certification Update, Just in ETime,* and*ISM eDigest: Chemicals Electronic Newsletter,* which ISM creates with its ISM Chemical Group.

ISM sponsors three certification programs: the Certified Purchasing Manager, which allows purchasing or materials management professionals to demonstrate their mastery of the requirements of the field; and the Accredited Purchasing Practitioner, designed primarily for entry-level buyers engaged in the operational side of purchasing and materials management. The Certified Professional in Supply Management (CPSM) program was first offered in 2008. It addresses the additional education, skills, and experiences that supply managers need as the professional continues to evolve in the twenty-first century.

ISM provides information about its conferences, seminars, professional forums, products, and other information of interest to the purchasing and materials management professional on its Web site at (http://www.ism.ws).

DOWNSIZING AND RIGHTSIZING

Downsizing refers to the permanent reduction of a company's workforce and is generally associated with corporate reorganization, or creating a "leaner, meaner" company.

For example, a sluggish U.S. economy forced several American companies to downsize in 2008. General Motors was forced to lay off about 3,500 workers at its pickup truck and large sport utility vehicle plants in several locations throughout the United States. High gasoline prices decreased consumer demand for trucks, shifting their preference to cars. Simultaneously, a housing slowdown and tight credit market forced Citigroup, a company with more than 300,000 worldwide employees, to plan layoffs of more than 13,000 jobs throughout 2008.

Downsizings such as these are also commonly called reorganizing, reengineering, restructuring, or rightsizing. Regardless of the label applied, however, downsizing essentially refers to layoffs that may or may not be accompanied by systematic restructuring programs, such as staff reductions, departmental consolidations, plant or office closings, or other forms of reducing payroll expenses. Corporate downsizing results from both poor economic conditions and company decisions to eliminate jobs in order to cut costs and maintain or achieve specific levels of profitability. Companies may lay off a percentage of their employees in response to these changes: a slowed economy, merging with or acquiring other companies, the cutting of product or service lines, competitors grabbing a higher proportion of market share, distributors forcing price concessions from suppliers, or a multitude of other events that have a negative impact on specific organizations or entire industries. In addition, downsizing may stem from restructuring efforts to maximize efficiency, to cut corporate bureaucracy and hierarchy and thereby reduce costs, to focus on core business functions and outsource non-core functions, and to use part-time and temporary workers to complete tasks previously performed by full-time workers in order to trim payroll costs.

The following sections discuss trends in downsizing, the growth of downsizing, downsizing and restructuring, criticisms of downsizing, support for downsizing, and downsizing and management.

TRENDS IN DOWNSIZING

As a major trend among U.S. businesses, downsizing began in the 1980s and continued through the 1990s largely unabated and even growing. During this time, many of the country's largest corporations participated in the trend, including General Motors, AT&T, Delta Airlines, Eastman Kodak, IBM, and Sears, Roebuck and Company. In the twenty-first century, downsizing continued after a sharp decline in the stock market early in the century and followed by continued pressure on corporate earnings in the aftermath of the September 11, 2001, terrorist attacks. Skyrocketing gas prices, a housing slowdown, and a market credit crunch were factors in 2008 layoffs. Downsizing affects most sectors of the labor

Table 1

Number of U.S. Unemployed Workers by Month

Type of Downsizing	December 2007	January 2008	February 2008	March 2008	April 2008	May 2008	June 2008	July 2008	August 2008
Temporary downsizing	1,061,000	1,614,000	1,351,000	1,341,000	1,053,000	856,000	949,000	1,134,000	1,126,000
Permanent downsizing	2,066,000	2,110,000	2,204,000	2,276,000	2,114,000	2,220,000	2,341,000	2,512,000	2,656,000

Adapted from: U.S. Department of Labor, Bureau of Labor Statistics. 2008. Unemployed Persons by Reason of Unemployment. Employment Situation Summary.

market, including retail, industrial, managerial, and office jobs, impacting workers in a wide range of income levels. Table 1 compares the number of temporarily downsized workers with the number of permanently downsized workers.

While layoffs are a customary measure for companies to help compensate for the effects of recessions, downsizing also occurs during periods of economic prosperity, even when companies themselves are doing well. Consequently, downsizing is a controversial corporate practice that receives support and even praise from executives, shareholders, and some economists, and criticism from employees, unions, and community activists. Reports of executive salaries growing in the face of downsizing and stagnant wages for retained employees only fan the flames of this criticism. In contrast, announcements of downsizing are well received in the stock markets. It is not uncommon for a company's stock value to rise following a downsizing announcement.

However, economists remain optimistic about downsizing and the effects of downsizing on the economy when the rate of overall job growth outpaces the rate of job elimination. A trend toward outsourcing jobs overseas to countries with lower labor costs is a form of downsizing that affects some U.S. employees. These jobs are not actually eliminated, but instead moved out of reach of the employees who lose their jobs to outsourcing. Some economists, however, suggest that the overall net effect of such outsourced jobs will actually be an increase in U.S. jobs as resulting corporate operating efficiencies allow for more employment of higher-tier (and thus higher-wage) positions. Regardless of whether downsizing is good or bad for the national economy, companies continue to downsize and the trend shows few signs of slowing down. For some sectors, this trend is projected to be particularly prevalent through 2012, as shown in Table 2.

THE GROWTH OF DOWNSIZING

The corporate downsizing trend grew out of the economic conditions of the late 1970s, when direct international competition began to increase. The major industries affected by this stiffer competition included the automotive, electronics, machine tool, and steel industries. In contrast to their major competitors—Japanese manufacturers—U.S. companies had significantly higher costs. For example, U.S. automobile manufacturers had approximately a $1,000 cost disadvantage for their cars compared to similar classes of Japanese cars. Only a small percentage of this cost difference could be attributed to labor costs, however, but labor costs were among the first to be cut despite other costs associated with the general structure of the auto companies and their oversupply of middle managers and engineers. Auto workers were among the first to be laid off during the initial wave of downsizing. Other U.S. manufacturing industries faced similar competitive problems during this period, as did some U.S. technology industries. Companies in these industries, like those in the auto industry, suffered from higher per-unit costs and greater overhead than their Japanese counterparts due to lower labor productivity and a glut of white-collar workers in many U.S. companies.

To remedy these problems, U.S. companies implemented a couple of key changes: They formed partnerships with Japanese companies to learn the methods behind their cost efficiencies and they strove to reduce

Table 2

Projected Job Decline in Selected Occupations, 2006-2016

Occupation	Projected Decline
Photographic processing machine operators	-50%
File clerks	-41%
Electrical and electronic equipment assemblers	-27%
Sewing machine operators	-27%
Computer operators	-25%
Bindery workers	-22%
Prepress technicians and workers	-21%

Adapted from: U.S. Department of Labor, Bureau of Labor Statistics. 2007. Occupations With the Largest Job Decline, 2006-2016.

costs, and expedite decision-making by getting rid of unnecessary layers of bureaucracy and management. Nevertheless, some companies began simply to cut their workforce without determining whether or not it was necessary and without any kind of accompanying strategy. In essence, they downsized because they lacked new products that would have stimulated growth and because their existing product markets were decreasing.

DOWNSIZING AND RESTRUCTURING

Downsizing generally accompanies some kind of restructuring and reorganizing, either as part of the downsizing plan or as a consequence of downsizing. Since companies frequently lose a significant number of employees when downsizing, they usually must reallocate tasks and responsibilities. In essence, restructuring efforts attempt to increase the amount of work output relative to the amount of work input. Consequently, downsizing often accompanies corporate calls for concentration on "core capabilities" or "core businesses," which refers to the interest in focusing on the primary revenue-generating aspects of a business. The jobs and responsibilities that are not considered part of the primary revenue-generating functions are the ones that are frequently downsized. These jobs might then be outsourced or handled by outside consultants and workers on a contract basis.

Eliminating non-core aspects of a business may also include the reduction of bureaucracy and the number of corporate layers. Since dense bureaucracy frequently causes delays in communication and decision making, the reduction of bureaucracy may help bring about a more efficient and responsive corporate structure that can implement new ideas more quickly.

Besides laying off workers, restructuring efforts may involve closing plants, selling non-core operations, acquiring or merging with related companies, and overhauling the internal structure of a company. The seminal work on restructuring or reengineering, *Reinventing the Corporation*, by Michael Hammer and James Champy, characterizes the process as the "fundamental rethinking and radical redesign of business processes to achieve dramatic improvements in critical, contemporary measures of performance such as cost, quality, service, and speed."

Reengineering was envisioned as a mechanism for transforming bureaucracy-laden organizations into productive market leaders. The goal of the movement is to create lean, streamlined organizations. Reengineering has introduced many process management principles into the workplace: Workflows are more efficient, cross-functional operations are better coordinated, and overhead costs have been reduced. For example, the introduction of the personal computer into the office has facilitated instantane-ous communication and has reduced the need for office support positions, such as secretaries.

Reengineering has had a significant effect on the airline industry. Midwest Airlines, a midsized provider, has followed the lead of several large airlines, reengineering its company with the goal to make it easy for the customer to do business. With information technology, the airline has provided the ability to redeem frequent flyer miles and find the best deals on fares. Midwest also offers services like web check-in and loading flight schedules on PDAs. The airline takes advantage of technology to optimize several business processes, including revenue management, pricing, and crew scheduling. With wireless communications, dispatchers quickly send critical information to pilots, and mechanics obtain engine performance data and access systems right from the aircraft. These IT enhancements have changed the way Midwest does business and how people there do their jobs. Unlike many other airlines, Midwest has been successful in the early 2000s with a major acquisition closing in 2008.

Done right, business reengineering positively transforms the workings of an office. Often, the reengineered office does require fewer, but more highly skilled people with more complex jobs.

CRITICISM OF DOWNSIZING

While companies frequently implement downsizing plans to increase profitability and productivity, downsizing does not always yield these results. Although critics of downsizing do not rule out the benefits in all cases, they contend that downsizing is over-applied and often used as a quick fix without sufficient planning to bring about long-term benefits. Moreover, downsizing can lead to additional problems, such as poor customer service, low employee morale, and bad employee attitudes. Laying workers off to improve competitiveness often fails to produce the intended results because downsizing can lead to the following unforeseen problems and difficulties:

- The loss of highly-skilled and reliable workers and the added expense of finding new workers.

- An increase in overtime wages.

- A decline in customer service because workers feel they lack job security after layoffs.

- Employee attitudes that may change for the worse, possibly leading to tardiness, absenteeism, and reduced productivity.

- An increase in the number of lawsuits and disability claims, which tends to occur after downsizing episodes.

- Restructuring programs sometimes take years to bear fruit because of ensuing employee confusion and the

amount of time it takes for employees to adjust to their new roles and responsibilities.

Some studies have indicated that the economic advantages of downsizing have failed to come about in many cases, and that downsizing may have had a negative impact on company competitiveness and profitability in some cases.

Downsizing has repercussions that extend beyond the companies and their employees. For example, governments must sometimes enact programs to help displaced workers obtain training and receive job placement assistance. Labor groups have reacted to the frequency and magnitude of downsizing, and unions have taken tougher stances in negotiations because of it.

Through downsizing and reengineering, it can be argued that many companies have lost some of their critical, long-term capabilities that did not seem essential to short-term survival. Intangible assets such as employee commitment, productivity, innovation, and risk-taking have been weakened. Too often, reengineering becomes a catch-all term used to describe any and all corporate change programs—including downsizing. The result, then, of reengineering for some companies has been overworked and demoralized employees, bad customer service, and poor quality products.

Instead of laying employees off, critics recommend that companies eliminate jobs only as a last resort; not as a quick fix when profits fail to meet quarterly projections. Suggested alternatives to downsizing include early retirement packages and voluntary severance programs. Furthermore, some analysts suggest that companies can improve their efficiency, productivity, and competitiveness through quality initiatives such as Six Sigma, empowering employees through progressive human resource strategies that encourage employee loyalty and stability, and other such techniques.

SUPPORT FOR DOWNSIZING

Advocates of downsizing counter critics' claims by arguing that, through downsizing, the United States has maintained its position as one of the world's leading economies. Economists point out that despite the downsizing that has become commonplace since the 1970s, overall U.S. standards of living, productivity, and corporate investment have grown at a healthy pace. They reason that without downsizing, companies would not remain profitable and hence would go bankrupt when there is fierce competition and slow growth. Therefore, some executives and economists see downsizing as a necessary albeit painful task, and one that ultimately saves the larger number of jobs that would be lost if a company went out business.

Advocates of downsizing also argue that job creation from technological advances offsets job declines from downsizing. Hence, displaced workers are able find new jobs relatively easily, especially if those workers have skills that enhance the technological competence of prospective employers. In other words, despite the admitted discomfort and difficulties that downsizing has on displaced workers, some workers are able to locate new jobs, and companies are able to achieve greater efficiency, competitiveness, and profitability. Moreover, even though downsizing may not solve all of a company's competitive problems or bolster a company's profits indefinitely, downsizing can help reduce costs, which can lead to greater short-term profitability. In addition, advocates of downsizing contend that staff-reduction efforts help move workers from mature, moribund, and obsolete industries to emerging and growing industries, where they are needed. Economists argue that this process strengthens the economy and helps it grow. This process also enables companies with growing competitive advantages to maintain their positions in the market in the face of greater domestic and global competition, and it is the difficult but necessary result of the transition toward a global economy.

DOWNSIZING AND MANAGEMENT

Downsizing poses the immediate managerial problem of dismissing a large number of employees in a dignified manner in order to help minimize the trauma associated with downsizing. Employees who are laid off tend to suffer from depression, anxiety, insomnia, high blood pressure, marital discord, and a host of other problems. A 2007 Finnish study showed that those most at risk of mental health problems were men who had left their jobs. This group was 64 percent more likely than the average person to be given a drug prescription for anxiety problems.

Thus, when companies decide that downsizing is the best course of action, managers should do so in a way that does the least harm to employees and their families. This includes taking the time to allow dismissed employees to air their thoughts, instead of laying them off quickly and impersonally, and providing assistance in finding new jobs.

Because of the possible negative effects that occur after downsizing, managers may have to implement measures to counteract employee apathy, improve customer service, and restore employee trust. Analysts of downsized companies argue that managers should take steps immediately after workforce reductions to provide the remaining workers with the support and guidance they need. Staffs who survive a round of corporate downsizing run a significantly increased risk of suffering mental health problems because of the increased workload they face once colleagues have left. The Finnish study mentioned

above also found that men who continue to work for a downsized company are 50 percent more likely than those whose had not been through downsizing efforts to be given a prescription for drugs such as antidepressants or sleeping pills.

Managers, aware of the possible outcomes, should provide employees with clear indications of what is expected of them and how they can meet increased productivity goals. Managers should confer with employees regularly to discuss performance and strategies for meeting the goals. In addition, managers should encourage employee initiative and communication and provide employees with rewards for excellent work. By promoting employee initiative and even employee involvement in decision-making, managers can help restore employee trust and commitment and help increase employee motivation.

The aftermath of downsizing also places greater demands on managers to make do with less. In other words, managers must strive to maintain or increase productivity and quality levels despite having a smaller workforce. Since downsizing often brings about a flatter corporate structure, the flow of information and communication no longer requires the effort needed prior to restructuring. Therefore, reports used for communication between layers of the old corporate hierarchy, for example, can be eliminated. If redundant but nonessential work cannot be completely eliminated, it perhaps can be reduced. By studying particular tasks and determining their essential components, managers can get rid of unnecessary tasks and eliminate unnecessary jobs altogether.

Southwest Airlines, which historically has had a culture of trust between management and employees, provides a good example of effective organizational downsizing. Growth in online bookings—a technological event outside of management control—necessitated the need for layoffs. In its reduction, Southwest focused on both the employees who were being let go and employees who were keeping their jobs, hoping to keep the latter group motivated and committed to the company. Management did not make the cuts until all employees could see that the move was necessary, and then offered employees the choice of moving to a different call center, or taking a severance package and leaving the company.

Downsizing appears to be an ongoing practice for the foreseeable future. Top managers with responsibility for making downsizing decisions are in a difficult predicament. Failure to downsize may result in inefficiencies, while downsizing clearly has a number of potentially negative effects on individuals and communities. Finding the balance between these outcomes is the primary challenge facing these managers.

DUE DILIGENCE

Due diligence is a legal term that describes the level of care or judgment that a reasonable person would be expected to exercise in a given situation. The term, synonymous with "background check," finds application in a wide range of business settings, including mergers and acquisitions, occupational health and safety, environmental impact assessments, supplier and vendor relationships, asset purchase decisions, and employee hiring or promotion practices. Performing a due diligence analysis in such situations helps managers make informed decisions and reduce the risks incurred by the business. "Real due

diligence analyzes and validates all the financial, commercial, operational, and strategic assumptions underpinning the decision," an analyst for Price Waterhouse Coopers told *Mondaq Business Briefing.* "Due diligence is a strategy to reduce the risk of failure, as well as the embarrassment of discovering what underlies spectacular success," Herrington J. Bryce added in *Nonprofit Times.*

In the area of workplace safety, employers have a responsibility to exercise due diligence in eliminating hazards and creating a work environment that minimizes the risk of accidents or injuries. In fact, due diligence is the legal standard used to determine whether employers can be held liable under occupational health and safety laws. Employers are generally not held liable for accidents if they can prove that they took reasonable precautions to protect workers from injury. Companies can establish due diligence by putting workplace safety policies and procedures in writing, providing appropriate training to employees, and holding managers accountable for following safety guidelines.

Due diligence also applies to the process of making investments, whether personal investments in shares of stock, corporate investments in technology, or the purchase of one company by another. In the area of mergers and acquisitions, a due diligence analysis is an important part of the process of evaluating potential investments and confirming basic information before entering into a transaction. "Quite often, a proposed merger or acquisition gets canned or valued down following conflicts over intellectual property rights, personnel, accounting discrepancies, or incompatibilities in integrating operating systems," wrote Lee Copeland in *Computer World.* "The process of researching, understanding and, in some cases, avoiding these risks is known as due diligence."

When a business makes a purchase offer of any kind, it is often a matter of policy to make the offer contingent on the results of a due diligence analysis. This analysis might include reviewing financial records, hiring experts to examine the assets in question, and taking other reasonable steps to make sure that all questions are answered and expectations met. Experts suggest that sellers also perform due diligence analysis prior to entering into a transaction. Going through this process helps sellers be prepared for any questions that might arise out of the buyer's due diligence analysis, and also gives sellers a basis on which to evaluate the merits of potential purchase offers.

Changing accounting rules are prompting companies to consider tweaking the structure and timing of due diligence when entering into a corporate merger. The rules, two released by the Financial Accounting Standards Board and two companion mandates issued by the International Accounting Standards Board, affect companies both in the United States and abroad. The most sweeping

changes happen in America; for example, buyers must value the amount paid for a target company on the day the transaction closes, rather than the day of the deal announcement, as the earlier rules stipulated. The rule is effective for all acquisitions that close in fiscal years that start after December 15, 2008, and includes recording the value of stock the buyer may use to pay for all or part of an acquisition.

Although the legal concept of due diligence endured for half a century, it came under siege in the early 2000s following a spate of accounting scandals and revelations of deceit and ethical lapses by senior executives at major corporations. "The issue of due diligence arises whenever a financial transaction generates questions, such as: How could this have happened? How could this have gone undetected for so long?" Bryce noted in *Nonprofit Times.* Rather than dismissing due diligence as an outdated concept, however, some analysts argued that such incidents underlined the importance of due diligence as a way for managers to be informed about and exercise judgment over all transactions that affect the welfare of the business.

In a critique of traditional due diligence practices for *Mondaq Business Briefing,* Charles F. Bacon warned that traditional due diligence tends to be reactive. For example, senior management might order a due diligence analysis after making the decision to purchase a competitor. "In effect, they bought the car and now that the tires are getting kicked, they don't want to hear about the bad transmission or leaky gaskets because that would tarnish the fun of deal-making," Bacon explained. Instead, he recommended that businesses take a systemic approach to due diligence starting at the top and incorporating due diligence into all organizational decision-making. The ultimate goal is to create a culture of due diligence in which all employees are encouraged to question and explore the implications of financial and strategic decisions.

ECONOMICS

The study of economics leads to the formulation of the principles upon which the economy is based. History, politics, and the social sciences cannot be understood without the basic understanding of economic principles. The science of economics is concerned with the scientific laws that relate to business administration, and attempts to formulate the principles that relate to the satisfaction of wants.

The term "economics" covers such a broad range of meaning that any brief definition is likely to leave out some important aspect of the subject. It is a social science concerned with the study of economies and the relationships between them. Economics is the study of how people and society choose to employ scarce productive resources, which could have alternative uses, to produce various commodities and distribute them for consumption. Economics generally studies problems from society's point of view rather than from the individual's. Finally, economics studies the allocation of scarce resources among competing ends.

OBJECTIVES

As a science, economics must first develop an understanding of the processes by which human desires are fulfilled. Second, economics must show how causes that affect production and consumption lead to various results. Furthermore, it must draw conclusions that will serve to guide those who conduct and, in part, control economic activity.

MICRO AND MACRO VIEWS OF THE ECONOMY

While there are numerous specialties within the academic field, at its most basic level economics is commonly divided into two broad areas of focus: microeconomics and macroeconomics. Microeconomics is the study of smaller levels of the economy, such as how an individual firm or a small group of firms operate. Macroeconomics is the study of whole economies or large sectors of economies.

Microeconomics. Microeconomics is the social science dealing in the satisfaction of human wants using limited resources. It focuses on individual units that make up the whole of the economy. It examines how households and businesses behave as individual units, not as parts of a larger whole. For instance, microeconomics studies how a household spends its money. It also studies the way in which a business determines how much of a product to produce, how to make the best use of production factors, and what pricing strategy to use. Microeconomics also studies how individual markets and industries are organized, what patterns of competition they follow, and how these patterns affect economic efficiency and welfare.

Macroeconomics. Macroeconomics studies an economy at the aggregate level. It is concerned with the workings of the whole economy or large sectors of it. These sectors include government, business, and households. Macroeconomics deals with such issues as national economic output and growth, unemployment, recession, inflation, foreign trade, and monetary and fiscal policy.

For example, many political leaders in the United States believed that economic stimulus packages (sending Americans tax rebates) from the U.S. government in 2001 and again in 2008 would spur on the national economy when the Americans spent their rebates. Economists generally agree that the economy gets a boost; however, they argue that the full impact is less than the total value of the stimulus package because people may opt to save their checks or invest in imported goods. These rebates, economists say, create temporary changes to the economy. Instead, politicians should focus on developing policies that promote healthy, long-term growth.

BASIC ECONOMIC PRINCIPLES

Basic economic principles include the law of demand, demand determinants, the law of supply, supply determinants, market equilibrium, factors of production, the firm, gross product, as well as inflation and unemployment.

The Law of Demand. When an individual want is expressed as an intention to buy, it becomes a demand. The law of demand is a theory about the relationship between the amount of a good that a buyer both desires and is able to purchase per unit of time, and the price charged for it. The ability to pay is as important as the desire for the good, because economics is interested in explaining and predicting actual behavior in the marketplace, not just intentions. At a given price for a good, economics is interested in the buyer's demand that can effectively be backed by a purchase. Thus, it is implied with demand that a consumer not only has the desire and need for a product, but also has the money to purchase it. The law of demand states that the lower the price charged for a product, resource, or service, the larger will be the quantity demanded per unit of time. Conversely, the higher the price charged, the smaller will be the quantity demanded per unit of time—all other things being constant. For example, the lower the purchase price for a six-pack of Coca-Cola, the more a consumer will demand (up to some saturation point, of course).

Demand Determinants. Movement along the demand curve—referred to as a change in quantity demanded—means that only the price of the good and the quantity demanded change. All other things are assumed to be constant or unchanged. These things include the prices of all other goods, the individual's income, the individual's expectations about the future, and the individual's tastes. A change in one or more of these things is called a change in demand. The entire demand curve will move as a result of a change in demand.

Law of Supply. The law of supply is a statement about the relationship between the amount of a good that a supplier is willing and able to supply and offer for sale, per unit of time, and each of the different possible prices at which that good might be sold. This law also states that suppliers will supply larger quantities of a good at higher prices rather than lower prices. In other words, supply generally is governed by profit-maximizing behaviors. The supply curve indicates what prices are necessary in order to give a supplier the incentive to provide various quantities of a good per unit of time. Just as with the demand curve, movement along the supply curve always assumes that all other things are constant.

Supply Determinants. At the opportunity for sale at a certain price, a part of total supply becomes realized market supply. Economics emphasizes movement along the supply curve in which the price of the good determines the quantity supplied. As with the demand curve, the price of the good is singled out as the determining factor with all other things being constant. On the supply side, these things are the prices of resources and other production factors, technology, the prices of other goods, the number of suppliers, and the suppliers' expectations.

Market Equilibrium. Supply and demand interact to determine the terms of trade between buyers and sellers. In theory, supply and demand mutually determine the price at which sellers are willing to supply just the amount of a good that buyers want to buy. The market for every good has a demand curve and a supply curve that determine this price and quantity. When this price and quantity are established, the market is said to be in equilibrium. The price and quantity at which this occurs are called the equilibrium price and equilibrium quantity. In equilibrium, price and quantity have the tendency to remain unchanged.

FACTORS OF PRODUCTION.

Factors of production are economic resources used in the production of goods, including natural, man-made, and human resources. They may be broken down into two broad categories: (1) property resources, specifically capital and land; and (2) human resources, specifically labor and entrepreneurial ability.

Managers often speak of capital when referring to money, especially when they are talking about the purchase of equipment, machinery, and other productive facilities.

Financial capital is the more accurate term for the money used to make such purchases. An economist would refer to these purchases as investments. The economist uses the term *capital* to mean all the man-made aids used in production. It is sometimes referred to as investment goods. Capital consists of machinery, tools, buildings, transportation and distribution facilities, and inventories of unfinished goods. A basic characteristic of capital goods is that they are used to produce other goods. Capital goods satisfy wants indirectly by facilitating the production of consumable goods, while consumer goods satisfy wants directly.

To an economist, land is the fundamental natural resource that is used in production. This resource includes water, forests, oil, gas, and mineral deposits. These resources are rapidly becoming scarce. Land resources, which include natural resources above, on, and below the soil, are distinguished by the fact that man cannot make them.

Labor is a broad term that covers all the different capabilities and skills possessed by human beings. While this often means direct production labor, it includes management labor as well. The term *manager* embraces a host of skills related to the planning, administration, and coordination of the production process.

Entrepreneurial ability also is known as enterprise. Entrepreneurs have four basic functions. First, they take initiative in using the resources of land, capital, and labor to produce goods and services. Second, entrepreneurs make basic business policy decisions. Third, they develop innovative new products, productive techniques, and forms of business organization. Finally, entrepreneurs bear the risk. In addition to time, effort, and business reputation, they risk their own personal funds, as well as those of associates and stockholders.

THE FIRM

The economic resources of land, capital, and labor are brought together in a production unit that is referred to as a business or a firm. The firm uses these resources to produce goods that are then sold. The money obtained from the sale of these goods is used to pay the economic resources. Payments to those providing labor services are called wages. Payments to those providing buildings, land, and equipment leased to the firm are called rent. Payments to those providing financial capital, such as loans, stocks, and bonds, are called dividends and interest. In other words, capital goods tend to increase the productivity of labor through being man-made and reproducible.

GROSS PRODUCT

The total dollar value of all the final goods produced by all the firms in an economy is called the gross product. This commonly is measured by one or both of the following:

1. Gross national product (GNP) includes the value of all goods and services produced by firms originating in a single nation. This means that foreign direct investment (FDI)—such as a Japanese auto plant in the United States—is not included in GNP, even though the plant might employ U.S. workers and sell its output exclusively to U.S. consumers. Conversely, the value of production by U.S.-based firms abroad would be considered part of the U.S. GNP.

2. Gross domestic product (GDP) includes the value of all goods and services produced within a nation, regardless of where the owners of production are based. In this case, FDI into the United States would contribute to U.S. GDP, while U.S. investment in other countries would contribute to those countries' GDP, not that of the United States.

GDP is the preferred measure of gross product for many kinds of economic analyses. This is because foreign investment has grown rapidly around the world, and because foreign-owned assets, such as a manufacturing facility, tend to have a greater net influence on the domestic economy in which they are situated. Both measures of gross product calculate the value of products and services on a value-added basis so that output is not double-counted, such as when products are resold through different phases of the supply and distribution chain.

In order to make comparisons, economists often use "real" GNP or GDP, which means the figure has been adjusted to hide the effects of inflation, or the general rise of prices relative to the quantity or quality of goods produced. Therefore, real gross product is commonly taken as an indicator of overall economic health. A rise at a moderate, sustainable pace is considered healthiest. However, if gross product is declining or rising at an unsustainably fast pace, it usually is interpreted as a negative signal.

INFLATION AND UNEMPLOYMENT

The economic health of a nation, of which gross product is one measure, is directly affected by two other important factors: inflation and unemployment.

Inflation. Inflation is an ongoing general rise in prices without a corresponding rise in the quantity or quality of the underlying merchandise or services (i.e., getting "less for more"). Ultimately, inflation represents an economic imbalance and diminishes a currency's real and nominal purchasing power. The steeper the rise, the faster the decline of the currency's purchasing power. Rapid economic expansion is one factor that can lead to price inflation, as can lax or inconsistent control of the money supply (such as through central bank monetary policy). Leading measures of inflation in the United States are the

Consumer Price Index (CPI) and the Producer Price Index (PPI). When inflation data are used to adjust the estimate of GDP, it is known as the GDP deflator.

Unemployment. The unemployment rate measures the percentage of the total number of workers in the labor force who are actively seeking employment but are unable to find jobs. While this seems straightforward, there are some measurement issues to consider, such as what constitutes looking for a job, how part-time labor is interpreted (i.e., being underemployed rather than unemployed), and what happens when an individual is technically employable but not actively seeking employment for whatever reason.

Measurement difficulties aside, in general the higher the unemployment rate, the more the economy is wasting labor resources by allowing people to sit idle. Still, when unemployment rates are low there is a tendency toward wage inflation because new employees are harder to find and workers often require additional incentives in order to take or keep a job. Because having a moderate pool of unemployed workers serves as a buffer to rising labor costs, most economists view full employment (zero or negligible unemployment) as impractical and even undesirable. Structural unemployment seemingly allows human capital to flow more freely (and cheaply) when there are changes in demand for labor in various parts of the economy. Of course, this does not mean that high unemployment is viewed as positive.

SCHOOLS OF ECONOMIC THOUGHT

While many of the aforementioned basic economic principles and ideas are widely accepted by economists, there have been—and continue to be—differing theories about some areas of economic behavior. Following is a brief overview of the three most influential theoretical perspectives.

Classical Economics. Dating back to eighteenth-century Europe, classical economics posited the market system would ensure full employment of the economy's resources. Classical economists acknowledged that abnormal circumstances such as wars, political upheavals, droughts, speculative crises, and gold rushes would occasionally deflect the economy from the path of full employment. However, when these deviations occurred, automatic adjustments in prices, wages, and interest rates within the market would soon restore the economy to the full-employment level. A decrease in employment would reduce prices, wages, and interest rates. Lower prices would increase consumer spending, lower wages would increase employment, and lower interest rates would boost investment spending. Classical economists believed in Say's Law, which states

that supply creates its own demand. Although more recent economic philosophies differ in some of the specifics, particularly on the role of governments, central banks, and international trade, many tenets of classical economics are still accepted today.

Keynesian Economics. As a consequence of the 1936 publication of British economist John Maynard Keynes's *General Theory of Employment, Interest, and Money*, mainstream economists came to give less importance to the role of money in the economy than had classical economists. Keynes sought to explain why there was cyclical employment in capitalistic economies. It was Keynes's analysis of how total demand determines total income, output, and employment, and the potentially key role for fiscal policy in the process, that captured the attention of most economists.

Moreover, the General Theory seemed to make compelling arguments for the use of government fiscal policy to avoid such problems and to smooth out economic instability. Keynesian followers believe that savings must be offset by investment. They termed propensity to consume as a person's decision on how much of total income will be allocated to savings and how much will be spent. The Keynesian view sees the causes of unemployment and inflation as the failure of certain fundamental economic decisions, particularly saving and investment decisions. In short, the Keynesian view is one of a demand-based economy.

Monetarism. More recently, the monetarists, led by Nobel laureate economist Milton Friedman, argued that money plays a much more important role in determining the level of economic activity than is granted to it by the Keynesians. Monetarism holds that markets are highly competitive and that a competitive market system gives the economy a high degree of macroeconomic stability. Monetarists argue that price and wage flexibility provided by competitive markets cause fluctuations in total demand rather than output and employment. Monetarism is thus concerned with controlling the money supply and not injecting excess liquidity into markets. This view is somewhat compatible with, but not identical to, the supply-side school of economics.

ECONOMIES OF SCALE AND ECONOMIES OF SCOPE

Economies of scale are reductions in average costs attributable to production volume increases. They typically are defined in relation to firms, which may seek to achieve economies of scale by becoming large or even dominant producers of a particular type of product or service. A distinction can be made between internal and external economies of scales. Internal economies of scale occur when a firm reduces costs by increasing production. External economies of scale occur when an entire industry benefits from expansion, for example, through the creation of an improved transportation system, a skilled labor force, or by sharing technology.

Economies of scope are reductions in average costs attributable to an increase in the number of goods produced. For example, fast food outlets have a lower average cost producing a multitude of goods than would separate firms producing the same goods. This occurs because the preparation of the multiple products can share storage, preparation, and customer service facilities (joint production).

ECONOMIES OF SCALE

The basic notion behind economies of scale is well known: As a plant gets larger and volume increases, the average cost per unit of output is expected to drop. This is partially because relative operating and capital costs decline, since a piece of equipment with twice the capacity of another piece does not cost twice as much to purchase or operate. If average unit production cost equals variable costs plus fixed costs/output, one can see that as output increases the fixed costs/output figure decreases, resulting in decreased overall costs.

Plants also gain efficiencies when they become large enough to fully utilize dedicated resources for tasks such as materials handling. The remaining cost reductions come from the ability to distribute nonmanufacturing costs, such as marketing and research and development, over a greater number of products. This reduction in average unit cost continues until the plant gets so big that coordination of material flow and staffing becomes very expensive, requiring new sources of capacity.

This concept can be related to best operating levels by comparing the average unit cost of different sized firms. In many types of production processes, the most efficient types of production facilities are practicable only at high output levels. It is very expensive to build custom-made cars by hand, and would be equally or more expensive to use a large General Motors assembly plant to build just a few Chevrolets per year. However, if the plant is used to build 6 million cars per year, the highly specialized techniques of the assembly line allow a significant reduction in costs per car.

Suppose, for example, that Honda were constrained to produce only 10,000 motorcycles a year instead of a possible 1 million. With this circumstance, the need for an assembly line would become obsolete. Each motorcycle could be produced by hand. Honda could rule out benefits that might be derived from the division and specialization of labor. In producing such a small number, the use of any production techniques that reduce average cost would become obsolete. In these two examples, Honda and General Motors would enjoy economies of scale with reduced average cost simply by increasing the scale of their operations.

More broadly, economies of scale can occur for a number of reasons, including specialization efficiencies, volume negotiating/purchasing benefits, better management of byproducts, and other benefits of size that translate into savings or greater profitability for a large-scale producer.

Specialization. In a small firm, labor and equipment must be used to perform a number of different tasks. It is more difficult for labor to become skilled at any one of them and thereby realize the gains in productivity and reduction in per-unit costs that specialization permits. In the same way, management functions cannot be as specialized in a smaller firm. Supervisors may have to devote time to screening job applicants, a task usually more efficiently handled by a personnel department in a larger firm. Executives may have to divide their attention between finance, accounting, and production functions that could be handled more proficiently by departments specializing in each of these areas in a larger firm.

According to Langlois, some economies of scale result from the specialization and division of labor. Mass production allows the use of specialized equipment and automation to perform repetitive tasks. The larger the output of a product, plant, or firm, the greater will be the opportunities for specialization of labor and capital equipment. Similarly, machinery and equipment cannot be used as efficiently when it has to be switched back and forth between tasks.

Increased specialization in the use of labor is feasible as a plant increases in size. Hiring more workers means

that jobs can be divided and subdivided. Instead of performing five or six distinct operations in the productive process, each worker may now have just one task to perform. Workers can be used full-time on those particular operations at which they have special skills. In a small plant a skilled machinist may spend half his time performing unskilled tasks, resulting in higher production costs. Furthermore, the division of work operations made possible by large-scale operations gives workers the opportunity to become very proficient at the specific tasks assigned to them. Finally, greater specialization tends to eliminate the loss of time that accompanies the shifting of workers from one job to another.

Volume Discounts. Oftentimes, the suppliers of raw materials, machinery, and other inputs will charge a lower price per unit for these items if a firm buys in large quantities. When a firm produces at high output levels, it needs a large volume of inputs and can take advantage of the associated price discounts to reduce its per-unit costs; if the company is large enough it may have strong negotiating power on this point. There may be similar economies of scale for stocks of raw materials, and intermediate and final products, part of which may be held to meet interruptions to the supply of raw materials, a temporary breakdown of firms, and the uncertain flow of orders from customers.

Economic Use of Byproducts. The production of many types of goods gives rise to economically valuable byproducts. Large-scale firms are often able to recycle "waste" byproducts that smaller size firms simply have to throw away because it is not economical to do anything else with them. For example, a small sawmill may simply throw away sawdust and old wood scraps. Many processing firms find that the volume of these waste products is large enough to warrant their resale. For example, sawdust can be sold as a sweeping compound for cleaning floors and hallways in large buildings. Wood scraps may be packaged, processed, and sold as kindling wood and artificial logs for home barbecues and fireplaces. In this way, the sale of byproducts effectively reduces the per-unit costs of producing lumber in large volumes. For the same reasons, large oil firms often produce a host of petroleum byproducts, and meatpacking firms produce fertilizers, glue, leather, and other byproducts of meat production.

External Economies of Scale. The growth of supporting facilities and services is encouraged by a firm's large scale of operation. As a firm's scale of operations gets larger, it often becomes worthwhile for other firms and local governments to provide it with unique services that result in direct or indirect cost advantages. If a firm builds a large plant in a particular area, an improvement in highways and expanded transportation services may soon follow.

Smaller suppliers that find a large part of their sales going to the larger firm may move closer to reduce transportation costs. All of these developments could result in lower per-unit costs for the large firm.

Large Economies of Scale. Larger firms have a cost advantage over their competitors. Not only does a larger plant gain from economies of scale, it also will produce more. Companies often use this advantage as a competitive strategy by first building a large plant with substantial economies of scale, and then using its lower costs to price aggressively and increase sales volume. Large economies of scale cause the firm's long-run average total cost curve to fall over a sizeable range as output is increased. In industries where the technology of production leads to economies of scale, the long-run average total cost curve for a single firm may fall over almost the entire range of output covered by the industry demand curve. When long-run average total cost falls in this fashion, it is possible for a firm that gets into this market ahead of others to obtain a competitive advantage. The ever lower per-unit costs it realizes at higher and higher levels of output permit the firm to charge a price lower than the average per-unit costs that prevail at lower levels of output. In this way, the firm is able to satisfy the entire market demand at a price below that which potential new rival firms must charge when getting started. These new firms would thus not be able to charge a price low enough to compete for sales with the established firm. Therefore, the established firm is able to keep rivals out of the market and maintain a monopoly position.

ECONOMIES OF SCOPE

According to David Kass in his 1998 article, "Economies of Scope and Home Healthcare," economies of scope exist if a firm can produce several product lines at a given output level more cheaply than a combination of separate firms each producing a single product at the same output level. Economies of scope differ from economies of scale in that a firm receives a cost advantage by producing a complementary variety of products with a concentration on a core competency. While economies of scope and scale are often positively correlated and interdependent, strictly speaking the benefits from scope have little to do with the size of output.

For instance, in the paper products industry it is common for large firms to produce their own pulp, the primary ingredient in paper, before manufacturing the paper goods themselves. However, smaller firms may have to purchase pulp from others at a higher net cost than the large companies pay. The savings from producing both pulp and paper would be an economy of scope for the large producers, although the large companies probably also have economies of scale that make it feasible to invest in pulping operations in the first place.

In another example, banks have economies of scope when they offer a variety of related financial services, such as retail banking and investment services, through a single service infrastructure (i.e., their branches, ATMs, and Internet site). Clearly, the costs of providing each service separately would be much greater than the costs of using a single infrastructure to provide multiple services.

Research concerning hospitals has suggested that other types of services, such as pediatric care, may have economies of scope. With increasing competition and emphasis on service, economies of scope are necessary for hospitals to provide these services profitably.

DISECONOMIES OF SCALE

When a firm grows beyond the scale of production that minimizes long-run average cost, diseconomies of scale may result. When diseconomies of scale occur, the firm sees an increase in marginal cost when output is increased. This can happen if processes become "out of balance," or when one process cannot produce the same output quantity as a related process. Diseconomies of scale also can occur when a firm becomes so large that:

- Transportation costs increase enough to offset the economies of scale.

- Monitoring worker productivity becomes too imperfect or costly.

- Coordinating the production process becomes too difficult.

- Frequent breakdowns result.

- Maintaining efficient flows of information becomes too expensive.

- Workers feel alienated and become less productive.

- The focus of the firm is reduced, leading to inefficiencies and loss of strategic position.

An example of long-perpetuated diseconomies of scale was provided in a 2008 report by the Pew Charitable Trusts and Johns Hopkins Bloomberg School of Public Health that showed that economies of scale used to justify factory-farming practices are largely false. Their continuing practice has resulted in a failure to account for associated costs, including human illnesses and the degradation of land, water, and air quality.

EFFECTIVENESS AND EFFICIENCY

Efficiency and effectiveness are two ways of judging the activities of an enterprise, whether business, government, or otherwise. Efficiency was originally an industrial engineering concept that came of age in the early twentieth century. Management theorists like Frederick Taylor and Frank and Lillian Gilbreth designed time and motion studies primarily to improve productive efficiency by eliminating waste in the production process. The concept of effectiveness, on the other hand, first became popular in the United States in the early 1980s, when Americans perceived Japanese products such as cars and electronics to offer greater value and quality. In contrast with efficiency, effectiveness takes into consideration creating value and pleasing the customer. While efficiency and effectiveness may be closely related in a given enterprise, they are actually two separate concepts. Each is used, separately and together, to evaluate an enterprise in an attempt to make improvements if possible.

EFFICIENCY V. EFFECTIVENESS

The words *efficiency* and *effectiveness* are often considered synonyms, along with terms like *competency, productivity,* and *proficiency.* However, in more formal management discussions, the words *efficiency* and *effectiveness* take on very different meanings. In the context of process reengineering, Lon Roberts defines efficiency as "to the degree of economy with which the process consumes resources—especially time and money," while he defines effectiveness as "how well the process actually accomplishes its intended purpose." Another way to look at it is this: efficiency is doing things right, and effectiveness is doing the right things.

Some examples might help elucidate the difference. Consider a company that was successfully making buggy whips as automobiles became the primary mode of transportation. Assume that the processes used to produce buggy whips had been highly perfected, and the buggy whips were delivered on or ahead of schedule at the lowest possible cost. This company was operating very efficiently. However, the company and its strategists were not very effective. The company was doing the wrong things efficiently. If they had been effective, they would have anticipated the impending changes in the transportation industry and begun developing new product lines in synch with industry developments.

Consider another example from medicine. A surgeon is very skilled, perhaps the best in the country. The impending job is to operate on the patient's left knee. However, the surgeon doesn't perform all the steps of the process leading up to the surgery. Someone else marks the right knee for surgery. However skilled this surgeon is, however fast he performs the surgery—that is, however efficient he or she is—this process is obviously not effective, as the injured knee is not fixed and a healthy knee is subjected to invasive surgery. When the patient awakens from the surgery, he or she will not be a satisfied customer. This is another case of a divorce between efficiency and effectiveness.

It should be evident from these examples that efficiency can occur in the absence of effectiveness, but the reverse is usually not the case. While an inefficient process may result in a product that meets the needs or wants of a given customer base, the possibility of improving this process means that costs could be reduced. If costs could be reduced, the firm is not being as effective as possible at meeting customers' desire for the lowest possible price. In other words, an efficient process may be ineffective, but an inefficient process cannot be optimally effective. Without efficiency, there cannot be optimal effectiveness.

PROBLEMS THAT LEAD TO INEFFICIENCY AND INEFFECTIVENESS

There are several ways for an enterprise to fall short of being efficient and effective. The examples above indicated how an efficient process might be an ineffective one. Processes may also be inefficient, hence ineffective, if there are unnecessary steps in the process, or if the steps of the process are completed serially when they could be completed simultaneously.

Consider a process for preparing a bulk mailing. Say that three clerical employees are assigned to this task. Before them are three piles of materials: first, a pile of letters to be folded and stuffed into the envelopes that make up the second pile, and third, a pile of address labels to be applied to the envelopes. One way of accomplishing

this job is for the three employees to divide the three piles into thirds and each work on one-third of the task. This, however, would not be as efficient as setting up an assembly line with one employee folding the letters, the second stuffing the envelopes, and the third applying the labels. The former process is inefficient because each employee will be required to perform extra movements as they move from one task to another; also, focusing on three tasks rather than one will reduce the possibility for learning to do each step more quickly. With an assembly line, wasted motion is eliminated, and each employee is able to focus solely on getting very good at his or her specific task.

Another problem can be a process that uses serial rather than simultaneous steps. Look at a university curriculum/course approval process done serially that takes an average of two to three years. The steps of the process are identified as follows:

1. A professor suggests to the department chairman that a quality management course be added to the curriculum.

2. The department chairman reviews the course, agrees, and submits the suggestion to all the colleagues in the department.

3. The colleagues review the course, agree, and submit their recommendation to the department chairman.

4. The department chairman reviews their recommendation and submits it, along with all materials, to the dean of the business school.

5. The dean reviews the materials and recommendations, agrees, and submits them to all the department chairmen in the school.

6. The chairmen all agree, and submit the recommendations and materials back to the dean with their recommendation.

7. The dean submits the materials and recommendations to the entire faculty in the business school.

8. The faculty reviews all materials and sends recommendations back to the dean.

9. The dean submits all materials and recommendations to the associate vice president for academic affairs.

10. The associate vice president agrees and submits everything to the vice president.

11. The vice president agrees and submits everything back to the associate.

12. The associate submits everything to the faculty senate.

13. The faculty senate agrees and submits everything, with its recommendation, back to the vice president.

14. The vice president submits everything to the president.

15. The president signs the materials and submits them back to the associate vice president.

16. The associate vice president submits the recommendation for course approval to the coordinating board.

17. The coordinating board approves and submits the materials back to the associate vice president.

It should be fairly obvious that this is not a particularly efficient process. A professor who wishes to add a new course to the curriculum—perhaps responding to an important change in the field—may be dissuaded from doing so by the daunting task ahead. If the process were streamlined by putting the material in a shared computer file, the first 14 steps (or, at least steps 4 through 14) of this process could occur simultaneously, or at least in overlapping fashion. As a result, the first 14 steps of this process could be accomplished in a matter of weeks, rather than months.

MEASURING EFFICIENCY, EFFECTIVENESS, AND FLEXIBILITY

Efficiency and *effectiveness* are often considered synonyms, but they mean different things when applied to process management. Efficiency is doing things right, while effectiveness is doing the right things. A third related concept is flexibility or adaptability, which is the capability of the organization to respond quickly to changing circumstances. It is this capability for an organization to reinvent itself that ensures its long-term survival and success.

Organizational leaders can't comprehend the extent to which their organizations and processes are efficient, effective, and flexible unless they know how to measure these things. Measures of efficiency, effectiveness, and flexibility are of great interest to all stakeholders: process owners, internal and external customers and suppliers, and executives. Inefficient processes are costly in terms of dollars, waste, rework, delays, resource utilization, and so on. Ineffective processes are costly as well because they don't do what they are supposed to do. Processes that are not capable of rapid adaptation (flexibility and innovation) are costly because they are not capable of rapidly responding to customers' needs in terms of customization and rapid decision-making. The greatest risk is that stakeholder loyalty will diminish.

In order to measure processes in terms of efficiency, effectiveness, and capability of rapid adaptations, people should ask themselves what, who, when, where, and how questions.

Perhaps the first question about a process is, why do it at all? Many steps exist simply because of organizational inertia ("We have always done it that way"). The second question might be, why do we do it this way? Then you might consider questions like these: What is being done? What should be done? What can be done? When should it happen? and so forth. These questions, and the concepts of efficiency and effectiveness, apply to all processes, all jobs, all types of organizations, all industries.

Some process efficiency measures are as follows:

- Cycle time per unit, transaction, or labor cost
- Queue time per unit, transaction, or process step
- Resources (dollars, labor) expended per unit of output
- Cost of poor quality per unit of output
- Percent of time items were out of stock when needed
- Percent on-time delivery
- Inventory turns

Here are some effectiveness measures:

- How well the output of the process meets the requirements of the end user or customer
- How well the output of the sub process meets the requirements of the next phase in the process (internal customers)
- How well the inputs from the external suppliers meet the requirements of the process

By contrast, measures of ineffectiveness include the following:

- Defective products
- Customer complaints
- High warranty costs
- Decreased market share
- Percent of activities that customers perceive to be non-value-added

Some measures of adaptability are as follows:

- The average time it takes to respond to special customer requests compared to routine requests
- The percent of time special customer requests are denied compared to the denial of routine requests
- The percent of special customer requests that have to be escalated to higher levels of management compared to the escalation of routine requests
- The capability to respond to product changes versus process changes

Organizations should establish baselines for efficiency, effectiveness, and adaptability metrics. In other words, they should determine their current performance levels. Then they should benchmark best-in-class or world-class organizations and set aggressive goals or targets for improvement. Finally, they should determine root causes of problems and eliminate them or minimize their impact.

TOOLS AND CONCEPTS

Generally, management and non-management employees have not had experience with the concepts and tools that will help them evaluate the processes which they own. In this case, training and opportunities to apply the concepts and tools should be provided. Examples of concepts and tools include the following:

- Statistical process control, which measures variability in a process.

- Trend charts, which measure performance over time.

- Pie charts, which depict measurements compared to each other.

- Process flow charts, which allow staff to quickly identify serial versus simultaneous processes, items which do not add value (like too many signatures, unnecessary travel and handling, long queues, etc.), and sub-processes that do not meet the needs of internal customers.

In addition to process concepts and tools, people should learn interrelationship concepts such as teamwork, communication, and leadership skills to streamline relationships as well as processes and organizations. This way, the results of measurements of efficiency, effectiveness, and flexibility can be fed back to the process owners so that they can improve the organization and the processes. This includes management processes as well as lower-level work processes. By their very nature, management processes can positively or negatively impact other work processes because they quite often deal with approvals (signature cycles) including requisitions for the purchase of essential equipment.

Answers to who, what, where, when, and how questions can be used to determine if the work should be done at all, who should do it, where and when it should be done, and how the work should be done. If these questions are answered truthfully, many activities in a process will be eliminated because they do not add value. Sometimes, entire processes will be eliminated.

ENHANCING EFFICIENCY, EFFECTIVENESS, AND FLEXIBILITY

Employees need to learn about and use various concepts and tools which will help them and their processes to be more efficient, effective, and flexible. For example, flow-charting the curriculum process mentioned above would have highlighted the need to replace serial sub-processes with sub-processes that were simultaneous and the need to eliminate duplications of effort and long waiting times. In addition, workers should learn interpersonal and leadership skills in order to be able to refine relationships as well as processes and organizations. Understanding the relationship between efficiency, effectiveness, and flexibility is an essential aspect of ensuring the success of any enterprise.

EFFICIENCY

SEE *Effectiveness and Efficiency*

ELECTRONIC COMMERCE

Electronic commerce (EC) consists of the buying and selling of products and services via the Internet. This can take many forms. Business to business (B2B) buying is estimated to be the most common e-commerce activity, comprising 70 percent to 80 percent of the business conducted online. Business to customer (B2C) activity makes extensive use of search engines and online tools such as easy price comparison. B2PA, or business to public administration, often involves online bidding and the downloading of documents. Public administration to public administration business is often the result of government initiatives to encourage e-commerce. PA2C, or public administration to consumers, usually involves providing e-services to the public. And finally, C2C, or consumer to consumer business, has been popularized by such auction sites as eBay.

These transactions can include online retail sales, supplier purchases, online bill paying, and Web-based auctions. Electronic commerce utilizes a variety of technologies including electronic data interchange, electronic fund transfers, credit cards, and e-mail.

The term e-commerce is often used interchangeably with e-business. The common element is the effective implementation of business activities using Internet technologies. However, e-business is the broader, more encompassing strategy and related activities. In addition to retail sales it includes vendor-partner communication, electronic procurement, customer relationship management, data-mining, and numerous other business functions.

DOT-COMS

Internet use gave a large jump toward the turn of the century, from being common in 26 percent of households in 1998 to 55 percent in 2003. Usage rates continue to climb in the United States and worldwide. This widespread use caused the rise—later followed by the collapse—of many Internet-based businesses, called "dot-coms" for their adoption of the suffix ".com" at the end of their names, referring to their Web site addresses. They used the three Cs method of business—commerce, content, and connection—offering one of the three to possible customers. Although the dot-coms formed the basis for today's e-commerce, inflated expectations and inexperience in online business transactions lead to the dot-com bubble of 2000 and 2001, when many purely online businesses imploded, costing investors millions. Some of the more famous dot-com busts include Flooz.com, 360Hiphop, Pets.com, Kibu.com, and GovWorks.com, which was featured in the documentary *Startup.com*.

After the dot-com bubble, the surviving companies dropped the coms from the end of their names and went on, some becoming successful businesses. For most companies, however, a combination of physical-based customer service and products with online components offering similar services has proven to be a more trustful method of incorporating e-commerce. In response to the dot-com bust and the continued growing interest in online trade, the Federal Trade Commission, or FTC, began to elaborate on their previous online business regulations.

Chief among the FTCs regulations is the policy that all online advertisement must tell the truth and not mislead customers. As in physical markets, all online claims must be substantiated. Disclaimers can be particularly complex on Web sites, and the FTC requires that all disclaimer information must be easily accessible and readable. In response to worries of online security issues such as account and identity theft, the FTC has also made it clear that online companies should notify customers when collecting personal data, and several Privacy Protection Acts created during the dot-com era were made to enforce that policy.

STRATEGIES

One of the first challenges involved in moving to online commerce is how to compete with other e-commerce sites. A common problem in addressing this challenge is that e-commerce is often analyzed from a technical standpoint, not a strategic or marketing perspective. E-commerce provides several technical advantages over off-line commerce. It is much more convenient for the buyer and the seller, as there is no need for face-to-face interaction and Web-based stores are open 24 hours a day. Also, e-commerce purchasing decisions can be made relatively quickly, because a vendor can present all relevant information immediately to the buyer. These factors lend themselves to a transactional approach, where e-commerce is seen as a way to reduce the costs of acquiring a customer and completing a sale.

In contrast, most successful e-commerce Web sites take a relational view of e-commerce. This perspective views an e-commerce transaction as one step among many in building a lasting relationship with the buyer. This approach requires a long-term, holistic view of the e-commerce purchasing experience, so that buyers are attracted by some unique aspect of an e-commerce Web site, and not by convenience. Since consumers can easily switch to a competing Web site, customer loyalty is the most precious asset for an e-commerce site.

While the primary focus of most Internet activity is on the business-to-business and business-to-consumer facets of e-commerce, other transaction methods are included. The success of eBay and its consumer-to-consumer portal for auction-based transactions has dramatically changed how people and companies conduct business. In addition to having a significant effect on business-to-business transactions, retailers are beginning to tap into this new and dynamic approach to commerce.

WIDGETS AND E-COMMERCE

A widget is a transferrable piece of code that can move itself in and out of Web site data, collecting information or executing a particular function for a metadata program. Some of the most visible widgets are the advertisements seen on most Web sites. These are in fact pieces of code from a third-party business that are being used to communicate marketing messages.

Widgets are one of the most important tools for e-commerce, used most often for distribution of information and online promotional activities. A 2008 article by Ori Soen with *TechNewWorld* explores the new possibilities widgets offer companies interested in e-commerce. Not only are widget-advertisements inexpensive and relatively

easy to employ, they can be combined with present marketing efforts and visual productions with the added effect of animation, if desired.

The problem most cited with present-day widget use by e-commerce companies is that online users no longer pay attention to widget advertisement. Most business Web sites accessible today have a multitude of widgets, and the advertisements are often diluted. Like emerging problems with TV commercials, users have learned to simply stop paying attention. Soen, however, sees this as an opportunity for companies to develop more innovative marketing techniques, better online animations, and more effective branding strategies aimed at online users.

Still, e-commerce Web sites are often crowded, and Soen suggests a different focus for widget advertisement: social networks. Social applications, such as MySpace and Facebook, are another field open to creative widget use, but they also offer a more open demographic, namely, people who are more likely to be attracted to creative widgets and—more importantly—have the ability to spread the word to their friends about advertisements that have caught their eye, giving companies two ways to promote instead of one.

Widgets serve a third purpose for e-commerce companies: the ability to collect important data concerning what advertisements are most effective to customers. When widgets are combined with analysis tools, they can be very useful gatherers of marketing information. They can judge how long a potential customer spends with the widget, and to what extent they interact with the animation. Promotional activities and marketing analysis can be effectively combined.

PERSONALIZATION

One of the key practices to a successful e-commerce company is personalization. Rachelle Crum's 2008 article, "Personalization: Telling E-tail Customers What They Really Want," lists several ways businesses can personalize their customers' online experiences.

When customers buy products online, they often receive a short list of other items they may be interested in. This is known as *recommendation*, and because of the ease and access in online business, it is relatively easy for businesses to include in their e-commerce activity. Customers are much more likely to order from the company when they receive a personalized list of products.

Tailored Web pages are another important part of personalization. Many companies have designed their e-commerce businesses to use the data from returning customers to create specific Web pages advertising new products the customer may be interested in, deals that may appeal particularly to the customer, and other information tailored especially for them.

MOBILE WEB

Certain devices, such as the iPhone, are becoming popular for their ability to access the Internet remotely. New technology has allowed remote Web access through phone and other handheld devices to become faster and easier to use. Some e-commerce companies have begun developing Web applications specifically for mobile Web users. This entails creating streamlined Web pages that condense information and allow customers to find what they looking for quickly and without hassle. Since these streamlined applications can be easier to navigate than normal Web pages, and can be accessed from nearly any location, some predictions say the mobile Web will become a powerful tool in the e-commerce field.

There are several different ways companies can make e-commerce more available to mobile Web users. Web designers can simply remove graphics from the Web site for mobile applications, giving users a simplified, text-only site to navigate. Style sheets can also be used, to create other versions of online stores, tailored to specific devices. Or, if a company wanted to devote more time to the project, a second Web site could be created solely for mobile Web users.

WEB SITE CREATION TIPS

Beyond technology tools such as widgets and mobile Web devices, there are simple ways to improve Web pages and how they read and look. Slight changes in the way a Web page integrates marketing, product information, and visuals can create an enormous difference in the perceptions of customers. Most Web surfers spend a very short time inspecting online stores before moving on, and the right words or the right information, displayed correctly, can make a great difference.

As David Needle says in his 2008 article for *Smallbusinesscomputing.com*, there are three different kinds of written cues or signposts that companies can place in their Web sites. The first type of signpost is navigation-oriented. This involves the way the online store is constructed—where the links to products are and where they go, how far down the Web site pages scroll, and links to related sites. "Bread crumbs," or easy ways for customers to return to the sites they have previously seen, are an excellent tool to give online stores structure and usability.

The second type of signpost is microcontent-related. This refers to Web site headings, URLs, and titles that organize online information. All information in the company's online store should be clear and easy to read and understand.

The third type of signpost is metadata, which is data concerning the information of the Web site itself, such as how many users have accessed it and the keywords

within the site that would come up in a search engine or analytical program.

BARRIERS TO SUCCESS

Despite the growing number of e-commerce success stories, plenty of e-commerce Web sites do not live up to their potential. There were two primary causes of e-commerce failures during the early 2000s.

First, most Web sites offer a truncated e-commerce model, meaning that they do not give Web users the capability to complete an entire sales cycle from initial inquiry to purchase. As analyzed by Forrester Research, the consumer sales cycle has four stages. First, consumers ask questions about what they want to buy. Second, they collect and compare answers. Third, the user makes a decision about the purchase. If the purchase is made, the fourth phase is order payment and fulfillment (delivery of the goods or services). The problem is that many Web sites do not provide enough information or options for all four phases. For example, a site may provide answers about a product, but not answers to the questions that the consumer has in mind. In other cases, the consumer gets to the point where he or she wants to make a purchase, but is not given an adequate variety of payment options to place the actual order.

The second problem occurs when e-commerce efforts are not integrated properly into the corporate organization. A survey by *Inter@ctiveWeek* magazine found that in most companies e-commerce is treated as part of the information system (IS) staff's responsibility, and not as a business function. While sales and marketing staff generally assist in the development of e-commerce Web sites, final profit and loss responsibility rests with the IS staff. This is a major source of breakdowns in e-commerce strategy because the units that actually make products and services do not have direct responsibility for selling them on the Web. One promising trend is that more companies are beginning to decentralize the authority to create e-commerce sites to individual business units, in the same way that each unit is responsible for its part of a corporate intranet.

SUCCESS FACTORS

After studying many aspects of electronic commerce, several consulting and analytic firms created guidelines on how to implement and leverage it successfully. In particular, two organizations have developed lists of critical success factors that seem to capture the state of thinking on this topic. First is the Patricia Seybold Group, which publishes trade newsletters and provides consulting services related to using information technology in corporations. This firm identified five critical e-commerce success factors:

1. **Support customer self-service.** If they so desire, Web users should be enabled to complete transactions without assistance.

2. **Nurture customer relationships.** Up-front efforts should focus on increasing customer loyalty, not necessarily on maximizing sales.

3. **Streamline customer-driven processes.** Firms should use Web technology to reengineer back-office processes as they are integrated with e-commerce systems.

4. **Target a market of one.** Each customer should be treated as an individual market, and personalization technology should be employed to tailor all services and content to the unique needs of each customer.

5. **Build communities of interest.** A company should make its e-commerce Web site a destination that customers look forward to visiting, not simply a resource people use because they have to conduct a transaction.

A quick review of two successful e-commerce sites, the Amazon.com bookstore site and Dell Computer's Web site, illustrate how many of these principles combine to help develop a strategic e-commerce capability.

Amazon.com, which has one of the highest sales volumes of any Web-based business, has optimized its site for the nature of its products and the preferences of its customers. The site is highly personalized; each visitor to the site, once registered, is greeted by name. The site content also is customized. Using software based on pattern recognition, Amazon.com compares a particular customer's purchase history to its overall record of transactions and generates a list of recommended books that seem to fit his or her interests and tastes. The company has a very integrated customer service support system, so that any customer service representative can access all data on the transactions, purchasing information, and security measures of each customer. The system also supports communications using e-mail, fax, and telephone.

Finally, Amazon.com helps to build a community of users through its Associates Program. Under this program, a Web site can host a hyperlink directly to the Amazon.com site. Any time that a visitor to that site buys books through Amazon.com, the Web site owner receives a share of the transaction revenues. This is a very inexpensive way for Amazon.com to extend its marketing and advertising reach across the Web.

Dell Computer also uses personalization and customization tools. For every major corporate customer, Dell creates a special Premier Page, which shows all products covered under purchasing contracts with that firm, as well as the special pricing under those contracts. This ensures

that employees of that firm always get the right price for each purchase. Ford Motor Company reports that by encouraging employees to buy PCs from its Premier Page, the company saved $2 million in one year.

Dell also has integrated its e-commerce Web site with all back-office systems, so that when a customer orders a custom-configured PC, that information is automatically transferred to the production system to ensure that the unit is built according to specifications. This also improves customer service; Dell will proactively notify any customer if a production problem or inventory shortage will delay delivery.

Electronic commerce, as used by U.S. firms, has already undergone several generations of evolution. Early experiences helped to stabilize e-commerce technology and set the development path for more sophisticated and useful technologies. Later experiences provided guidelines on strategic approaches and operational models that will help to improve e-commerce success.

Three key issues will determine the long-term viability of electronic commerce. These are:

1. Technological feasibility, or the extent to which technology—bandwidth availability and information reliability, tractability, and security—will be able to sustain exponentially increasing demands worldwide.

2. Socio-cultural acceptability, or the extent to which different global cultures and ways of doing business will accommodate this new mode of transacting, in terms of its nature (not face-to-face), speed, asynchronicity, and unidimensionality.

3. Business profitability, or the extent to which this way of doing business will allow for profit margins to exist at all (e.g., no intermediaries, instant access to sellers, global reach of buyers).

As technology continues to develop and mature, the ability to assess the impact of electronic commerce will become more cogent. Moreover, the significance of privacy, security, and intellectual property rights protection as prerequisites for the successful worldwide diffusion, adoption, and commercial success of Internet-related technologies—especially in places with less democratic political institutions and highly regulated economies—is continually increasing. The differentiation between the Internet (the global network of public computer networks) and intranets (corporate-based computer networks that involve well-defined communities and potentially more promising technology platforms for fostering Internet-related commerce) became significant in the late 1990s and early 2000s. Intranet development has surpassed the Internet in terms of revenue—by 2005 more than half of the world's Web sites were commercial in nature.

ADVERSE POSSIBILITIES OF E-COMMERCE

Ned Kock, in his book *Encyclopedia of E-collaboration* (2008), gives several possible negative effects of e-commerce, if the trend continues at the same rate it is currently growing.

Global companies with highly developed online stores may already possess the extra edge to attract potential customers. This may leave beginning companies, eager to enter the online market, without much chance to make an impact. International competition may become skewed and lead to an unhealthy type of oligopoly in the e-commerce world.

Some also fear that e-commerce will allow companies to evade certain tax laws, especially when it comes to international trade. New regulations might need to be set for customs concerning online exchanges.

Others wonder how e-commerce will change the job market. While online business offers jobs to those with newer IT skills, it can also displace many traditional jobs.

ELECTRONIC DATA INTERCHANGE AND ELECTRONIC FUNDS TRANSFER

Electronic data interchange (EDI), or electronic data processing, is the electronic transmission of data between computers in a standard, structured format. EDI allows companies to process routine business transactions, such as orders and invoices, more rapidly, accurately, and efficiently than they could through conventional methods of transmission.

Electronic funds transfer (EFT) is the term used for EDI that involves the transfer of funds between financial institutions. Thus, EFTs are only one specific form of EDI, albeit the form most familiar to lay users and bank customers. While EDI has been around for decades, it wasn't until the late 1990s that this basic principle became a driving force in the rollout of electronic commerce, corporate extranets linking suppliers and customers, and related network-based technologies. Advances in EDI, combined with the rise and spread of the Internet, have led to wide use of EFTs at the same time that EDI has almost completely taken over business-to-business data transfers.

THE DEVELOPMENT OF EDI

EDI has been present in the United States in some form since the mid-1960s. Businesses had been trying to resolve the difficulties intrinsic to paper-dependent commercial transactions. These difficulties include transmission speed (because of delays in entering the data onto paper and transporting the paper from sender to receiver); accuracy (because the data had to be recreated with each paper entry); and labor costs (labor-based methods of transmitting data are more expensive than computer-based methods).

In 1968, a group of railroad companies—concerned with the accuracy and speed of intercompany transportation data transmissions—formed an organization called the Transportation Data Coordinating Committee (TDCC) to study the problem and recommend solutions. Large companies such as General Motors and Kmart also reviewed the problems, which arose when they used their intracompany proprietary formats to send electronic data transmis-

sions to outside parties. Because each company had its own proprietary format, there was no common standard among transmitting parties. A company doing business electronically with three other companies would need three different formats, one for each company.

By the 1970s, several industries had developed common EDI programs for their companies within those industries, and a third-party network often administered these systems. Some examples of these systems include ORDERNET, which was developed for the pharmaceutical industry, and IVANS, which was developed for the property and casualty insurance industry. While these systems were standardized for each industry, they likewise could not communicate with other industries' proprietary systems. By 1973 the TDCC began developing a set of standards for generic formats to handle this problem. What emerged were the EDI standards.

HOW EDI WORKS

EDI standards were intended to operate independently of the software and communication technologies responsible for sending and receiving information. EDI functions through a defined set of standards for transmitting business information, allowing data to be interpreted correctly, independent of the platforms used on the computers that transmit and receive the data. When a sender transmits data, such as a purchase order, the EDI translation software converts the proprietary format of the sender's document-processing software into a mutually recognized standard format. When the receiver obtains the data, the EDI translation software automatically converts the standard format into the receiver's proprietary document processing format. Because of the speed and accuracy of an EDI, users find that the system saves time and reduces costs over paper-based business transactions.

This makes EDI quite different from other types of electronic communication. It is unlike a facsimile transmission (fax), which is the transfer of completely unstructured data through a digitized image. EDI also differs from other types of electronic communications among computers, such as electronic mail, network file sharing, or downloading information through a modem. In order to access electronic mail messages, shared network files, or downloaded information, the format of the computer applications of both the sender and the receiver must agree.

MODERN EDI

By 2005, major retailers relied heavily on EDI to exchange purchase orders, invoices, and other information with their trading partners. In a June 2004 poll of twenty retailers, the majority said that they were either adding new trading partners or increasing the number of EDI transactions. Estimates place EDI usage at nearly 90

percent of business-to-business traffic. Retail giants such as Wal-Mart Stores Inc., J.C. Penney Co., Supervalu Inc., and Hallmark Cards Inc. have been regular users of EDI. In fact, Wal-Mart has been one of the most influential companies driving new technology trends.

Since 2003, many companies have turned to a new technology in which data is transmitted over the Internet using the Applicability Statement 2 (AS2) protocol. The AS2 rules describe how to send data securely and ensure that the messages are received. In September 2002, Wal-Mart asked its suppliers to switch from value-added networks (VANs) to AS2. Other companies have followed suit. One company claimed to have cut its costs by 70 percent after switching from a VAN to AS2. However, others have decided not to make the switch because of the costs involved.

Retailers are not the only businesses to take advantage of this technology. The healthcare industry also uses EDI to exchange patient information between medical providers and insurance companies. EDI is such a reliable means of transmitting data that a growing number of third-party payers, including Medicare, Medicaid, and commercial insurers, have started to require providers to submit claims electronically.

The Electronic Data Interchange rule was developed as part of the Health Insurance Portability and Accountability Act (HIPAA) and required compliance by October 16, 2003. This law requires all entities that transmit clinical data (including claims, referrals, and eligibility verification) to use the same electronic data file format. This can be accomplished by purchasing and maintaining a HIPAA-compliant practice management system (PMS) or by transmitting the data through a clearinghouse. The PMS is not the most cost-effective option for smaller entities, as it usually requires an administrator to maintain and upgrade the system as necessary. With the clearinghouse option, the entity sends data to a clearinghouse. The clearinghouse then sends the data to the appropriate recipients in the appropriate format.

EDI STANDARDS

Although the idea of EDI is to standardize data transfers between businesses, there are currently four different sets of EDI standards, all of which first appeared during the 1980s.

- UN/EDIFACT, the system recommended by the United Nations—used predominantly outside of North America.

- ANSI ASC X12, the U.S. system that predominates in North America.

- TRADACOMS, developed by the Article Numbering Association—dominant in the United Kingdom retail industry.

- ODETTE, used in the automotive industry in Europe.

All EDI standards prescribe the formatting, character sets, and data elements that are to be used in the electronic exchange of documents; they also indicate both mandatory and optional pieces of information for a given document and provide rules that structure the document itself. These standards leave a lot of room for constructing documents differently, according to the needs of different businesses and industries. For example, dairy companies may indicate a product's expiration date, while textile companies may indicate color, pattern, and material information. In essence, the standards operate like building codes, allowing different types of construction within a standardized set of rules. Just as two houses can be built "to code" but look completely different, two different documents can use the same EDI standard yet still contain different sets of information.

ELECTRONIC FUNDS TRANSFER

An electronic funds transfer (EFT) is an EDI among financial institutions in which money is transferred from one account to another. Some examples of EFTs include electronic wire transfers; automatic teller machine (ATM) transactions; direct deposit of payroll; business-to-business payments; and federal, state, and local tax payments.

In general, EFT transactions are transferred through an automated clearing house (ACH) operator. An ACH operator is a central clearing facility operated by a private organization or a Federal Reserve bank on behalf of participating financial institutions, to or from which financial institutions transmit or receive ACH transactions. The ACH network is a nationwide system for interbank transfers of electronic funds. It serves a network of regional Federal Reserve banks processing the distribution and settlement of electronic credits and debits among financial institutions.

ACH transactions are stored in an ACH file, which is a simple ASCII-format file that adheres to ACH specifications. A single ACH file holds multiple electronic transactions, each of which carries either a credit or debit value. Typically, a payroll ACH file contains many credit transactions to employees' checking or savings accounts, as well as a balancing debit transaction to the employer's payroll account. An originating bank sends electronic payment instructions to a receiving bank. In those instances, the electronic transfers are processed in batches and settled within a few days.

The National Automated Clearing House Association (NACHA) oversees the ACH network and is primarily responsible for establishing and maintaining its operating rules. All financial institutions moving electronic funds through the ACH system are bound by the NACHA Operating Rules, which cover everything from participant relationships and responsibilities

to implementation, compliance, and liabilities. While the NACHA rules are specific and quite detailed, adhering to a strict set of rules is crucial to the smooth and successful operation of the ACH system.

ONLINE BANKING

With the widespread ownership of PCs and the ever increasing use of the Internet, online banking has surged in popularity. By the beginning of 2005, there were nearly 40 million online banking customers in the United States, a trend largely driven by the popularity of electronic bill payment, a popular EFT function. Banks routinely allow their customers to access account information over the Internet, transfer funds between accounts, make investments, and pay bills online. Many credit card companies and utility companies allow customers to pay their bills online through EFTs, and most taxing authorities have developed systems to enable online filing and payment of taxes.

This trend towards greater use of online banking was given a further boost by the passage of the Check Clearing for the 21st Century Act of 2003, also known as Check 21. This federal law allows banks to transmit checks electronically and substitute electronic images for original paper checks. Check 21 provides many advantages for banks and financial institutions. By transmitting checks electronically, banks can reduce the amount of time it takes to receive funds. This is because they no longer have to wait for another bank to receive paper checks before they send the funds. In addition to saving time, Check 21 has the potential to save banks millions of dollars in transportation and storage costs.

While some consumer-advocacy groups complain that this law increases the chances of fraud, error, bounced check fees, and inconvenience, the Federal Reserve's 2007 Report to Congress on the first two years of the law's implementation indicates that few consumers have filed complaints or expressed concerns. However, the report also noted that during the first 18 months of the law's implementation, many banks had not yet completely adopted practices taking advantage of the new law. As the Federal Reserve report states, "Overall, the banking industry is still adjusting to the new business environment created by Check 21." However, the report also stated that there were indications that the use of Check 21 authority was about to grow rapidly. Given past trends in the use of EDIs and EFTs, it seems likely that the use of Check 21 provisions will soon come to dominate the banking industry.

EMPLOYEE ASSISTANCE PROGRAMS

Employee assistance programs (EAPs) are employer-sponsored benefit programs designed to improve productivity by helping employees to identify and resolve personal concerns. Most EAPs employ mental health professionals (usually on a contract basis) to provide confidential counseling and referral services to workers who are experiencing personal problems that interfere with their work attendance or productivity. For example, an EAP might help employees to resolve problems such as drug or alcohol abuse, emotional distress, child or elder care issues, anxiety, marital or family relationship concerns, emotional distress, depression, or financial difficulties. Employees may seek help on a voluntary, confidential basis, or may be referred by a supervisor who suspects that declining job performance is being caused by personal problems.

WELLNESS PROGRAMS

EAPs are often instituted as part of an employee wellness program. Employee wellness is a relatively new human resource management focus that seeks to eliminate certain debilitating health problems (e.g., cancer, heart disease, respiratory problems, hypertension) that can be caused by poor lifestyle choices (e.g., smoking, poor nutrition, lack of exercise, obesity, stress). Stress, for instance, is being

called the fastest-growing occupational disease in the United States by some experts. Excessive amounts of stress can have debilitating health effects, leading to problems like ulcers, colitis, hypertension, headaches, lower back pain, and cardiac conditions. Stressed workers may perform poorly, quit their jobs, suffer low morale, generate conflicts among coworkers, miss work, or exhibit indifference toward coworkers and customers. These stress-induced outcomes cost U.S. businesses somewhere between $150 and $300 billion per year.

Lifestyle-related health problems have become quite prevalent: cancer, heart, and respiratory illnesses alone account for 55.5 percent of all hospital claims, and they can cause workplace problems such as absenteeism, turnover, lost productivity, and increased medical costs. For instance, people who have high blood pressure are 68 percent more likely than others to have medical claims of more than $5,000 per year, and the cost of medical claims for smokers is 18 percent higher than it is for nonsmokers.

To combat these problems, employee wellness programs provide employees with physical fitness facilities, on-site health screenings, and programs to help them quit smoking, manage stress, and improve nutritional habits. The employee wellness program at Apple Computer offers fitness facilities, health education, and preventative medicine that includes:

- A smoking cessation program.
- Seminars on nutrition and weight management.
- Health assessments that measure blood pressure and resting pulse.
- Fitness evaluations that assess cardiopulmonary fitness level, strength, flexibility, body composition, and nutritional status.
- Medical examinations that include physical exams and exercise strength tests to determine cardiovascular fitness.

OTHER FUNCTIONS OF EAPs

EAPs also play an important role in the prevention of (and intervention in) workplace violence incidents. Workplace violence and crisis intervention have received increased emphasis in EAPs since the terrorist attacks of September 11, 2001. Not only can counselors help employees to deal with the emotional impact of crises, they also can provide ongoing preparedness training for companies.

Many EAPs also provide management consultation services. In such cases, a supervisor may request assistance in dealing with a problem employee. EAP counselors might help the supervisor develop initiatives to change the employee's disruptive behavior. "Having an EAP sends a message to employees that the employer cares," noted Kevin M. Quin-

ley in his 2003 article in *Compensation and Benefits Report*. "Just knowing that can be a powerful incentive and hasten an employee's desire to return to work."

COST-EFFECTIVENESS

Companies that implement EAPs have documented improvements in worker health, functioning, productivity, and performance. They also have seen significant reductions in absenteeism, medical-benefits costs, disability and worker's compensation claims, workplace accidents, and employee turnover. Surveys indicate that between 50 and 80 percent of large companies offer EAPs. "Divorce, drug addiction, alcohol abuse, care-giving for a disabled relative, and uncontrolled gambling can all cause employee disabilities and absences that exact a high workplace toll," wrote Quinley. "Addressing these problems—even if they are rooted in nonoccupational causes—can boost employee productivity and curb disability costs."

Employee wellness programs can be both effective for employees and cost-effective for employers. Research indicates that participation in a wellness program increases productivity and reduces both absenteeism and turnover. A study conducted at Mesa Petroleum, for example, found that the productivity difference between participants and non-participants amounted to $700,000 in the program's first year and $1.3 million in the second.

The potential payoff of an EAP is evidenced by a study which found that every dollar spent on an EAP returned an estimated three to five dollars to the company in reduced absenteeism and greater productivity. Other studies have noted that even very small reductions in risk factors are enough to make wellness initiatives pay off. Many employers can expect to recover their costs with only a 0.2 percent reduction in risk factors, and nearly all employers could do so with only a 1 percent reduction. A 2004–2005 study funded by the Centers for Disease Control (CDC) that considered specific companies, found that Union Pacific would have to achieve a 0.49 percent reduction in risk factors for a wellness program to pay for itself, while Motorola's break-even point was 0.67 percent. The number for Dow Chemical was even lower—a mere 0.17 percent. In Dow's case, a 1 percent reduction would yield a return on investment of 300 percent—that is, a return of three dollars for every one dollar spent. For a company with 26,000 employees, that translates to $50 million over five years.

OBSTACLES

Wellness programs can be relatively inexpensive and cost effective, but if they are to work most effectively, they must successfully enlist "high-risk" individuals—those in greatest need of the program. Unfortunately, most employees who participate in wellness programs exhibit fewer risk factors to

begin with, while employees at high-risk tend to stay away. Because at-risk individuals do not seek help, many employee wellness programs fail to meet their objectives. As human-resources consultant Bob Brady noted in *HR Daily Advisor* in 2007, "people with the most severe problems have little interest in lifestyle changes, and even those that are interested find making the changes very difficult."

Employers must, then, find some way to motivate high-risk individuals to participate. Some companies offer incentives such as cash bonuses to individuals who participate, while others impose certain penalties on non-participants. Examples of penalties include higher insurance premiums and deductibles. Other motivational approaches include involving family, bringing initiatives directly to employees in their workplaces, and focusing on high-level management who can model best practices for their employees.

Even with the potential obstacles, human resource managers recognize that wellness programs not only pay their own way, they can be extremely effective tools for improving the workplace, employee morale, productivity, and profits.

EMPLOYEE BENEFITS

Employee benefits, sometimes called fringe benefits, are indirect forms of compensation provided to employees as part of an employment relationship. To compete for quality employees in today's marketplace, employers must do more than offer a "fair day's pay." Workers also want a good benefits package. In fact, employees have grown accustomed to generous benefits programs, and have come to expect them.

Employee benefits exist in companies worldwide, but the types and levels of benefits vary greatly from country to country. Generally speaking, companies in industrialized countries in Europe and North America offer employees the most generous benefit packages. Even within the industrialized world, however, employee benefits can vary significantly. For example, employees in Germany and other European countries receive more vacation days than the average U.S. employee. Conversely, most employers in the United States offer some form of medical/health insurance to employees. But most companies in European countries don't offer this employee benefit, because it is provided through government-sponsored socialized medicine programs.

HISTORICAL OVERVIEW

Employee benefits were not a significant part of most employees' compensation packages until the mid-twentieth century. In the United States, for example, benefits comprised only about 3 percent of total payroll costs for companies in 1929. According to the U.S. Chamber of Commerce, however, employee benefits in the United States now comprise approximately 42 percent of total payroll costs. Several things account for the tremendous increase in the importance of employee benefits in the United States. In the 1930s, the Wagner Act significantly increased the ability of labor unions to organize workers and bargain for better wages, benefits, and working conditions. Labor unions from the 1930s to 1950s took advantage of the favorable legal climate and negotiated for new employee benefits that have since become common in both unionized and non-union companies. Federal and state legislation requires companies to offer certain benefits to employees. Finally, employers may find themselves at a disadvantage in the labor market if they do not offer competitive benefit packages.

LEGALLY REQUIRED BENEFITS

In the United States, legislation requires almost all employers to offer the social security benefit, unemployment insurance, and workers' compensation insurance. Larger companies (those with fifty or more employees) are also required to offer employees an unpaid family and medical leave benefit. Each of these legally required benefits is discussed briefly below.

Social Security. The Social Security Act of 1935, as amended, provides monthly benefits to retired workers who are at least sixty-two years of age, disabled workers, and their eligible spouses and dependents. Social Security is financed by contributions made by the employee and matched by the employer, computed as a percentage of the employee's earnings. Monthly benefits are based on a worker's earnings, which are adjusted to account for wage inflation. The Social Security Act also provides Medicare health insurance coverage for anyone who is entitled to retirement benefits. Medicare is funded by a tax paid by the employer and employee. The tax rate for Medicare is a combined 2.9 percent of the employee's total wage or salary income.

Unemployment Insurance. Unemployment compensation provides income to unemployed individuals who lose a job through no fault of their own. Eligible workers receive weekly stipends for twenty-six weeks. The specific amount of the stipend is determined by the wages the claimant was paid during the previous year. Unemployment compensation laws in most states disqualify workers from receiving benefits under the following conditions:

1. Quitting one's job without good cause
2. Being discharged for misconduct connected with work
3. Refusing suitable work while unemployed

Workers' Compensation Insurance. Millions of workers are hurt or become sick for job-related reasons each year. All fifty states have workers compensation insurance laws that are designed to provide financial protection for such individuals. Specifically, these laws require the creation of a no-fault insurance system, paid for by employers. When workers suffer job-related injuries or illnesses, the insurance system provides compensation for medical expenses; lost wages from the time of injury until their return to the job (employees are given a percentage of their income, the size of which varies from state to state); and death (paid to family members), dismemberment, or permanent disability resulting from job-related injuries.

Nationwide, payouts for workers' compensation are relatively high and curbing costs is a priority for many U.S. companies. The increase in costs is primarily due to rising medical costs that now account for as much as 60 percent of total workers' compensation costs in some states. Fraudulent claims also increase costs.

PARENTAL LEAVE
Maternal and paternal leave are both popular topics in today's business world. Currently, federal law requires up to twelve weeks of unpaid leave for new parents, although legislation has been considered to raise the time limit. Globally, this is a very low amount of time, and many other nations, including Canada, offer a longer leave and pay their employees.

While some American employers use the national minimum, other companies recognize the global imbalance and offer their employees paid parental leave, or a contribution plan that will allow them to take more time off with their newborn child. Only California and Washington require paid leave for employees, but recent trends are encouraging more generous behavior in the private sector. One popular method companies are currently practicing is the inclusion of maternal benefits other than parental leave. This can include compensation plans for medical visits, extended health coverage for pregnant workers, or on-site facilities to make newborn and childcare easier for the employee.

OPTIONAL EMPLOYEE BENEFITS
Other employee benefits are quite common, but are not required by federal law in the United States. Some of the more significant optional benefits are summarized below.

Health Insurance. Basic health-care plans cover hospitalization, physician care, and surgery. Traditional fee-for-service health care coverage became increasingly expensive in the late twentieth century. As a result, many U.S. companies adopted "managed care" health care plans. In general, managed care plans cut health care costs for employers by requiring them to contract with health care providers to perform medical services for their employees at an agreed upon fee schedule, in exchange for the employer encouraging (sometimes requiring) the employees to receive their medical care within the approved network of health care providers.

Health Maintenance Organizations (HMOs) are one type of managed care plan. HMOs are organizations of physicians and other health care professionals who provide a wide range of services for a fixed fee. When participants need medical services, they pay a nominal per-visit charge of $5 or $10. Because members visit their health care facility more frequently, potential problems can be discovered and eliminated before they can become major health threats. Thus, HMOs can save money through preventative medicine. However, employees have a limited number of doctors from which to choose and must get approval from a primary care physician for specialized treatment.

Preferred Provider Organizations (PPOs) provide services at a discounted fee in return for the company's participation, which creates increased business for the health facility. Employees may choose the member facility of their choice. PPOs are somewhat less restrictive of patient choice than HMOs, since they allow employees

to receive health care outside the approved network if the employee is willing to shoulder a higher percentage of their health care expenses.

Point of Service (POS) plans are more flexible versions of PPO plans. In a point of service plan, there is a company-authorized network of medical centers and physicians that the employees can choose from, but the employee can also go outside the network for particular medical needs. Some sort of discount usually applies to the medical network the company offers, to encourage employees to stay within the plan, but the choice is theirs.

Employers are not legally required to offer health insurance to employees. If they do, however, the Consolidated Omnibus Budget Reconciliation Act (COBRA) provides for a continuation of health insurance coverage for a period of up to three years for employees who leave a company through no fault of their own. Such employees are required to pay the premiums themselves, but at the company's group rate.

CDHPs and FSAs. Due to rising health costs, many companies are choosing to repeal their health care benefits or offer alternative plans for their employees to find health insurance. In 2004 alone, the average cost of health premiums rose 7.5 percent, and companies continued to raise copayments and deductibles to follow the market. This has resulted in high costs all around for employees seeking competent health insurance, especially for those working in small to mid-sized companies. The smaller companies cannot handle the higher premiums very easily, so they must move the cost onto their employees. Larger companies are able to shoulder more of the cost, but they, too, are struggling under the rising costs.

In response to these issues, several alternative employee benefit plans have gained popularity. One of these options is the Consumer Directed Health Plan, or CDHP, which has gained more support in recent years. In CDHPs, employees work with companies to choose their own health coverage plan, tailored for them specifically. Companies offer CDHPs because analysis has shown employees often chose more streamlined, simpler plans that result in less cost for the companies. Many organizations also give employees the necessary resources to research health coverage so that they can choose the best components for themselves.

According to a 2008 study by Watson Wyatt and the National Business Group on Health (NBGH), more than half of United States companies are expected to offer some kind of CDHP by 2009, and the number is expected to increase even more. In 2006, a similar study found that only 33 percent of companies offered consumer-directed health plans. This increased to 39 percent in 2007, and then to 47 percent in 2008.

Nearly a third of American companies offering CDHP also offer a health savings account, or HSA. Deposits in an HSA account can be used by the employee in the event of a medical crisis, and provide yet another supplement to CDHPs.

Another form of the HSA is the flexible spending account (FSA), an option some companies are offering instead of—or in addition to—the CDHP. At the beginning of each year, employees are able to select specific health benefits and the amount they are willing to pay for the insurance. The cost is then deducted from their pre-tax salary, giving better benefits to both the company and the employee than they would receive.

Voluntary Leave. Voluntary leave includes all the leave companies offer employees for extraneous reasons (vacations, holidays, emergencies, etc). Paid sick leave is especially common for companies to establish and can be offered in a variety of ways. Employers can offer sick days based on how long an employee has been with a company and what position the employee has, or they can offer a flat number of sick days for all employees alike. Other companies use a paid-time-off plan that incorporates sick days, vacation days, and other types of voluntary leave into one cache of days that an employee can draw from when needed. Some states are considering making a certain amount of paid sick leave mandatory.

Long-Term Disability (LTD) Insurance. This benefit provides replacement income for an employee who cannot return to work for an extended period of time due to illness or injury. An LTD program may be temporary or permanent. The benefits paid to employees are customarily set between 50 and 67 percent of that person's income.

Pensions. Pensions, or retirement incomes, may be the largest single benefit most employees receive. In most instances, employees become eligible to participate in company pension plans when they reach 21 years of age and have completed one year of service. After they have satisfied certain age and time requirements, employees become vested, meaning that the pension benefits they have earned are theirs and cannot be revoked. If they leave their jobs after vesting, but before retirement, employees may receive these benefits immediately or may have to wait until retirement age to collect them, depending on the provisions of their specific pension plan.

Employers may choose from two types of pension plans—defined benefit plans or defined contribution plans. Defined benefit plans specify the amount of pension a worker will receive on retirement. Defined contribution plans specify the rate of employer and employee contributions, but not the ultimate pension benefit received by the employee. If a defined benefit plan is

chosen, an employer is committing itself to an unknown cost that can be affected by rates of return on investments, changes in regulations, and future pay levels. Consequently, most employers have adopted defined contribution plans.

Companies establish pension plans voluntarily, but once established, the Employee Retirement Income Security Act of 1974 (ERISA) requires that employers follow certain rules. ERISA ensures that employees will receive the pension benefits due them, even if the company goes bankrupt or merges with another firm. Employers must pay annual insurance premiums to a government agency in order to provide funds from which guaranteed pensions can be paid. Additionally, ERISA requires that employers inform workers what their pension-related benefits include.

Stock Options. A publicly traded company has the ability to offer its employees stock option benefits, if it chooses. If an employee takes part in a stock option plan, then part of their annual income will be invested in the company's own stock, usually at a lower than market price. This allows the company to gain extra investment from willing employees, if so needed, and also to bolster employee interest in the success of the company.

The company must come to an agreement on several factors before offering a stock option benefit plan to employees. First, the company must decide how many shares to set aside for stock option possibilities; this is usually somewhere between 5 percent and 20 percent of outstanding stocks. Many companies also choose to create a vesting time, a period that the employee must stay with the company before his shares become exercisable. This period differs for all companies.

Of course, companies should have full approval of the stockholders before installing an employee stock option plan. If they are too careless, the company can lose a controlling interest through overselling their stock. Along with shareholder approval, the corporate board should create applicable caveats for employee termination, options to exercise stock by employees, and refusal rights to limit the number of shareholders.

401(k) Plans. A 401(k) plan is a retirement plan offered by many companies. Essentially, it offers employees a possible contribution of their income into several different investment opportunities. Some companies offer a limited list of investment plans, while others work with the customer to form an investment plan including stocks the employee is interested in. A portion of the employee's income is then automatically contributed to that investment, with the employer acting as fiduciary. 401(k) plans are protected from creditors under national legislation and have an annual contribution limit of $15,000.

The money withdrawn for 401(k) plans is not taxed as an investment, but only as earned income. If an employee withdraws investment money before retirement, then a fee is taken, usually 10 percent, payable to the IRS. Some employees are allowed to take loans from their 401(k) plans. Such investment opportunities are becoming more commonly considered necessary for a successful retirement in the United States. It is a helpful benefit to offer employees who are not part of a public company, so that they can still participate in a company-contribution stock plan.

Life Insurance Plans. These employee benefits are very common. The premiums for basic life insurance plans are usually paid by the employer. Employee contributions, if required, are typically a set amount per $1,000 in coverage based on age. Employees are often given the opportunity to expand their coverage by purchasing additional insurance.

BENEFITS ADMINISTRATION

Two issues that are crucial to the management of employee benefits are flexible benefit plans and cost containment. Many employers now offer flexible benefit plans, also known as cafeteria plans. These plans allow employees to choose among various benefits and levels of coverage. Under a cafeteria plan, employees may choose to receive cash or purchase benefits from among the options provided under the plan. Flexible benefit plans present a number of advantages:

- Such plans enable employees to choose options that best fit their own needs. New workers, for example, may prefer cash; parents may prefer to invest their benefit dollars in employer-sponsored childcare programs; and older workers may decide to increase their pension and health care coverage.

- Deciding among the various options makes employees more aware of the cost of the benefits, giving them a real sense of the value of the benefits their employers provide.

- Flexible benefit plans can lower compensation costs because employers no longer have to pay for unwanted benefits.

- Employers and employees can save on taxes. Many of the premiums may be paid with pretax dollars, thus lowering the amount of taxes to be paid by both the employee and the employer.

Because of these advantages, flexible benefit plans have become quite popular: such plans are now being offered by many U.S. companies. However, some companies are shying away from cafeteria plans because they create such an administrative burden. Moreover, the use

of such plans can lead to increased insurance premiums because of adverse selection. Adverse selection means that people at high risk are more inclined than others to choose a particular insurance option. For instance, a dental plan option would be chosen primarily by employees with a history of dental problems. Consequently, insurance rates would increase because the number of low-risk individuals enrolled in the programs would be insufficient to offset the claims of high-risk individuals.

Companies can contain costs in several ways. Because an employer's workers' compensation premiums increase with each payout, firms can prevent unnecessary costs by scrutinizing the validity of each claim. Some employers cut costs by deleting or reducing some of the benefits they offer employees. This approach, however, can negatively affect both recruitment and retention. A more viable approach is to offer benefits that are less costly, but equally desirable. Companies can continue to offer attractive benefits by implementing some of the cost-containment strategies discussed next.

Many companies implement utilization review programs in order to cut health care costs by ensuring that each medical treatment is necessary before authorizing payment, and ensuring that the medical services have been rendered appropriately at a reasonable cost. These programs require hospital pre-admission certification, continued stay review, hospital discharge planning, and comprehensive medical case management for catastrophic injuries or illnesses.

Some employers have been able to increase the attractiveness of their benefit programs while holding costs constant, allowing an organization to get more of a "bang for its buck" from these programs.

CURRENT TRENDS IN EMPLOYEE BENEFITS

According to a 2008 article in the *Insurance Journal*, employee benefits are likely to remain balanced in the coming years, despite rising health care costs. Alternatives such as FSAs and other flexible plans are allowing employees to have more choice in health coverage and giving employers ways to save money. In addition to the new forms of coverage, employers are offering more subtle benefits at a lesser cost—benefits such as telecommuting options, stipends for gas, childcare options, and cross-training for skill development.

While some of the more traditional forms of employee benefits have declined in the past few years, other more innovative forms are on the rise. Personal use of company-sponsored cell phones is one of the growing benefit fields, as are fitness-center memberships and on-site vaccinations for employees. Companies are also becoming more family conscious, offering more long-distance calling for business trips, compressing work weeks, and providing legal assistance and other personal benefits.

EMPLOYEE COMPENSATION

Employees receive compensation from a company in return for work performed. While most people think compensation and pay are the same, the fact is that compensation is much more than just the monetary rewards provided by an employer. According to Milkovitch and Newman in their 2005 book, *Compensation,* it is "all forms of financial returns and tangible services and benefits employees receive as part of an employment relationship." The phrase "financial returns" refers to an individual's base salary, as well as short- and long-term incentives. "Tangible services and

benefits" are such things as insurance, paid vacation and sick days, pension plans, and employee discounts.

An organization's compensation practices can have far-reaching effects on its competitive advantage. As compensation expert Richard Henderson notes, "To develop a competitive advantage in a global economy, the compensation program of the organization must support totally the strategic plans and actions of the organization." Labor costs greatly affect competitive advantage because they represent a large portion of a company's operating budget. By effectively controlling these costs, a firm can achieve cost leadership. The impact of labor costs on competitive advantage is particularly strong in service and other labor-intensive organizations, where employers spend between 40 and 80 cents of each revenue dollar on such costs. This means that for each dollar of revenue generated, as much as 80 cents may go to employee pay and benefits.

EXEMPT AND NONEXEMPT JOBS

In terms of compensation, employee payment is divided into different subcategories based on what sort of job the employee has and what payment plan the organization follows for that particular job.

Jobs generally have two classifications, exempt and non-exempt, based on the qualities and position of the employment. Management positions, professional jobs, and many other higher-level positions within an organization are exempt, meaning that they are paid by salary instead of wage. Exempt positions are salary positions, where the employee is paid not by the hour but by a certain interval of time, upon which the employee receives a predetermined amount of payment. Most exempt positions receive higher compensation and benefits than non-exempt jobs but do not receive any added payment for overtime; indeed, people in exempt positions are expected to fulfill expectations often requiring more effort and longer hours than non-exempt positions.

Non-exempt jobs are paid with a wage, an hourly amount. Nearly all entry-level positions and "unskilled" jobs fall in this category, with the employee receiving payment based on a predetermined, hourly wage. This wage, like the salary, is subject to change based on performance reviews. A different wage is usually available for the employee when working overtime, over 40 hours a week, or on holidays. This wage is higher than the normal hourly rate.

Payment systems are also divided according to two different classifications. First, payment can include a base pay, or set amount that the employee will receive. This is the amount that defines the salary or wage; it is set by the organization through the study of many factors, including the market rate and the history of payment for that position. The base pay and the definition of the job are closely connected. The other type of employee compensation is variable pay, or payment based on some type of performance by the employee. Variable pay can take many forms, including incentives and commissions. Most American jobs are a combination of base and variable pay, the ratio changing for different positions, although American jobs tend to have a higher variable pay component than other nations previously did, an organizational decision that is now being adopted globally.

LEGISLATION

Several important forms of national legislation have had a significant effect on employee compensation over the last hundred years of United States business. State legislation has often added onto national legislation, increasing compensation for wages or creating additional requirements for organizations, but federal law has led the way in changing compensation practices.

The Fair Labor Standards Act of 1938 (FLSA) applied to all commercial jobs and set the foundation of regulation of employee compensation. Among other things, the act established the first national minimum wage, set restrictions against the employment of minors by defining oppressive child labor, and enforced time-and-a-half policies for overtime work (the law stating that, for certain positions, employees must be paid 50 percent more per hour for overtime). Several other acts throughout American history have affected the FLSA. The Portal-to-Portal Act, enacted in the 1940s, defined work time and what sort of work had to be paid. Other amendments defined more specifically what businesses were covered by the FLSA, made coverage a requirement for care facilities, public establishments, and all government positions, and raised the federal minimum wage several times.

Also important to the history of employee compensation is the Equal Pay Act of 1963, which was created in order to prevent discrimination in pay, especially sexual discrimination. This act included several reasons Congress had for enforcing equal payment for the sexes, citing economic gain and living standards. The act also focused on requiring payment systems to be based solely on skills and experience, rather than gender.

The Employee Retirement Income Security Act of 1974 required a minimum pension plan amount for businesses, and established a series of tax laws to govern the use of pension plan payments.

In 2004, the government enacted several changes to the FLSA, called FairPay. FairPay dealt mostly with reclassifying job positions and their definitions. This caused many jobs to be switched between the categories of exempt and non-exempt. Some supervisors who had previously been on wages were required to switch to salaries, losing their overtime benefits. Other employees,

especially in supportive roles of business administration, were moved from wages to exempt status. These changes were made in order to classify jobs more according to their functions and responsibilities than to their titles.

Most recently, the *Fair Minimum Wage Act of 2007* again raised the federal wage level, from $5.25 to $7.25 an hour, to better represent state and private wages across the nation. This act will reach completion in 2009.

INFLUENCE OF PAY ON EMPLOYEE ATTITUDES AND BEHAVIOR

Since compensation practices heavily influence recruitment, turnover, and employee productivity, it is important that applicants and employees view these practices in a favorable light. In the following section, we discuss how people form perceptions about a firm's compensation system and how these perceptions ultimately affect their behavior.

Equity is an important concern, so individuals responsible for developing a firm's compensation system need to understand how perceptions of equity are formed. Equity theory, formulated by J. Stacy Adams, attempts to provide such an understanding. The theory states that people form equity beliefs based on two factors: inputs and outcomes. Inputs (I) refer to the perceptions that people have concerning what they contribute to the job (e.g., skill and effort). Outcomes (O) refer to the perceptions that people have regarding the returns they get (e.g., pay) for the work they perform. People judge the equity of their pay by comparing their outcome-to-input ratio (O/I) with another person's ratio. This comparison person is referred to as one's "referent other." People feel equity when the O/I ratios of the individual and his or her referent other are perceived as being equal. A feeling of inequity occurs when the two ratios are perceived as being unequal. For example, inequity occurs if a person feels that he or she contributes the same input as a referent other, but earns a lower salary.

A person's referent other could be any one of several people. People may compare themselves to others:

- Doing the same job within the same organization
- Working in the same organization, but performing different jobs
- Doing the same job in other organizations

For example, an assistant manager at a Wal-Mart department store might compare her pay to other assistant managers at Wal-Mart, to Wal-Mart employees in other positions (either above or below her in the organizational hierarchy), or to assistant managers at Kmart department stores.

While the mechanism for choosing a referent other is largely unknown, one study found that people do not limit their comparisons to just one person; they have several referent others. Thus, people make several com-

parisons when they assess the fairness of their pay; perceived fairness is achieved only when all comparisons are viewed as equitable. When employees' O/I ratios are less than that of their referent others, they feel they are being underpaid; when greater, they feel they are being overpaid. According to equity theory, both conditions produce feelings of tension that employees will attempt to reduce in one of the following ways:

1. Decrease inputs by reducing effort or performance.

2. Attempt to increase outcomes by seeking a raise in salary.

3. Distort perceptions of inputs and/or outcomes by convincing themselves that their O/I ratio already is equal to that of their referent other.

4. Attempt to change the inputs and/or outcomes of their referent other(s). For example, they may try to convince their referent other(s) to increase inputs (e.g., work harder for their pay).

5. Choose a new referent other whose O/I ratio already is equal to their own.

6. Escape the situation. This response may be manifested by a variety of behaviors, such as absenteeism, tardiness, excessive work-breaks, or quitting.

While equity theory poses six possible responses to inequity, only two of them typically occur (namely, numbers 1 and 6). Research findings, for example, have linked underpayment to increases in absenteeism and turnover, and to decreases in the amount of effort exerted on the job. These linkages are especially strong among individuals earning low salaries.

Contrary to equity theory's predictions, these responses occur only when employees believe they are underpaid. Overpaid individuals do not respond because they feel little, if any tension, and thus have no need to reduce it. (The research findings on the issue of overpayment find overpayment to be either just as satisfying as equity, or somewhat dissatisfying but not nearly as dissatisfying as underpayment.) When feeling underpaid, why do some people choose to decrease their inputs, while others choose to escape the situation? A study found that reaction to inequity depends on the source of the comparison; people react differently depending on whether they judge equity on the basis of external (referents outside of the organization) or internal (referents employed by the individual's own organization) comparisons. When perceptions of inequity are based on external comparisons, people are more likely to quit their jobs. For instance, a nurse working for Hospital A may move to Hospital B if the latter pays a higher salary. When based on internal comparisons, people are more likely to remain at work, but reduce their inputs (e.g., become less willing to help others with problems, meet deadlines, and/or take initiative).

From the previous discussion, one may conclude that employees will believe their pay is equitable when they perceive that it:

- Is fair relative to the pay received by coworkers in the same organization (internal consistency).

- Is fair relative to the pay received by workers in other organizations who hold similar positions (external competitiveness).

- Fairly reflects their input to the organization (employee contributions).

ACHIEVING INTERNAL CONSISTENCY

To achieve internal consistency, a firm's employees must believe that all jobs are paid what they are "worth." In other words, they must be confident that company pay rates reflect the overall importance of each person's job to the success of the organization. Because some jobs afford a greater opportunity than others to contribute, those holding such jobs should receive greater pay. For instance, most would agree that nurses should be paid more than orderlies because their work is more important; that is, it contributes more to patient care, which is a primary goal of hospitals.

For pay rates to be internally consistent, an organization first must determine the overall importance or worth of each job. A job's worth typically is assessed through a systematic process known as job evaluation. In general, the evaluation is based on "informed judgments" regarding such things as the amount of skill and effort required to perform the job, the difficulty of the job, and the amount of responsibility assumed by the jobholder.

Job evaluation judgments must be accurate and fair, given that the pay each employee receives is so heavily influenced by them. Most firms create a committee of individuals, called a job evaluation committee, for the purpose of making the evaluations. Because those serving on the committee represent the organization's various functional areas, collectively they are familiar with all the jobs being evaluated. Such individuals typically include department managers, vice presidents, plant managers, and HR professionals (e.g., employee relations specialists and compensation managers). The committee chair usually is an HR professional or an outside consultant.

Perhaps the two most serious problems with job evaluation ratings are subjectivity and the rapidity with which jobs fundamentally change, both of which can cause inaccurate and unreliable ratings. In order to minimize subjectivity, the rating scales used to evaluate jobs must be clearly defined, and evaluators should be thoroughly trained on how to use them. Moreover, the evaluators should be provided with complete, accurate, and up-to-date job descriptions. The second issue is more difficult to address. Due largely to changes in technology,

---

Exhibit 1

Compensable Factors Used in the Point-Factor Method of Job Evaluation

Compensable Factor	Rating Criteria
Skill/know-how	Education Experience Knowledge
Effort	Physical effort Mental effort
Responsibility	Judgement/decision-making Internal business contacts Consequence of error Degree of influence Supervisory responsibilities Responsibility for independent action Responsibility for machinery/equipment Fiscal responsibility Responsibility for confidential information
Working conditions	Risks Comfort Physical demands Personal demands

---

jobs now change so rapidly and so fundamentally that evaluation results quickly become out of date.

Job evaluation process is analogous to performance appraisal in that evaluators are asked to provide certain ratings on a form. Job evaluation ratings, however, focus on the requirements of the job rather than on the performance of the individual jobholder. Although several methods may be used to evaluate jobs, the most common approach is the point-factor method. Using this method, jobs are evaluated separately on several criteria, called compensable factors. These factors represent the most important determinants of a job's worth. A list of some commonly used factors and the criteria upon which they are judged appear in Exhibit 1.

The development of a point-factor rating scale consists of the following steps:

1. Select and carefully define the compensable factors that will be used to determine job worth.

2. Determine the number of levels or degrees for each factor. The only rule for establishing the number of degrees is that some jobs should fall at each level.

3. Carefully define each degree level. Each adjacent level must be clearly distinguishable.

4. Weight each compensable factor in terms of its relative importance for determining job worth.

5. Assign point values to the degrees associated with each compensable factor. Factors assigned greater weights in Step 4 would be allotted a greater number of possible points for each degree level.

When completing the job evaluation ratings, the evaluators use job descriptions to rate each job, one factor at a time until all jobs have been evaluated on all factors. They then calculate a total point value for a job by summing the points earned on each compensable factor.

This approach to job evaluation is difficult and time-consuming. However, most organizations believe that it is well worth the effort. If properly conducted, the overall score for each job should reflect its relative worth to the organization, thus enabling the firm to establish internal consistency.

When job evaluations have been completed, jobs are grouped into pay grades based on the total number of points received. Jobs with the same or similar point values are placed in the same grade. For example, consider jobs that are rated on a scale from 1 to 1,000. All jobs earning up to 100 points could be assigned to pay grade one, jobs earning 101 to 200 to pay grade two, and so forth.

Administrators use pay grades because, without them, firms would need to establish separate pay rates for each job evaluation point score. Once jobs are classified into grades, all jobs within the same grade are treated alike for pay purposes; that is, the same range of pay applies to each job in a grade.

As companies develop pay grade systems, they must decide how many pay grades to establish. Most firms use thirty to fifty pay grades. However, some use as many as one hundred or more, while others use as few as five or six. The practice of limiting the number of pay grades eases the firm's administrative burdens. However, using a limited number of grades creates a situation in which jobs of significantly different worth fall into the same grade and receive the same pay. This outcome could lead to equity problems. For instance, registered nurses may feel underpaid if classified in the same pay grade as nursing aides.

ACHIEVING EXTERNAL COMPETITIVENESS

A firm achieves external competitiveness when employees perceive that their pay is fair in relation to what their counterparts in other organizations earn. To become externally competitive, organizations must first learn what other employers are paying and then make a decision regarding just how competitive they want to be. They then establish pay rates consistent with this decision. Following is an examination of how these steps are carried out.

The firm begins by conducting or acquiring a salary survey. This survey provides information on pay rates offered by a firm's competitors for certain benchmark jobs (i.e., jobs that are performed in a similar manner in all companies and can thus serve as a basis for making meaningful comparisons). Some firms gather this information from existing surveys already conducted by others, such as those produced by the Bureau of Labor Statistics. Trade associations also conduct surveys routinely for their members, or companies may hire consulting firms to gather such information. Salary surveys conducted by others should be used when they contain all the information needed by the company in question. When no such surveys exist, companies generally conduct their own.

After the pay practices of other companies have been identified, the organization must determine how competitive it wants to be (or can afford to be). Specifically, it must set a pay policy stipulating how well it will pay its employees relative to the market (i.e., what competitors pay for similar jobs). The determination of a pay policy is a crucial step in the design of a pay system. If pay rates are set too low, the organization is likely to experience recruitment and turnover problems. If set too high, however, the organization is likely to experience budget problems that ultimately may lead to higher prices, pay freezes, and layoffs.

Once market rates for jobs are determined and a pay policy is established, an organization must price each of its jobs. Since market rates identified by a salary survey usually are restricted to benchmark jobs, how do organizations determine these rates for their non-benchmark jobs? Using the data collected on the benchmark jobs, an organization would determine the statistical relationship (i.e., simple linear regression) between job evaluation points and prevailing market rates. This regression line is referred to as the pay policy line. The appropriate pay rates for non-benchmark jobs are set based on this line.

EXECUTIVE COMPENSATION

Recently, the payment plans and benefits for the top executives in American business have been questioned. The national attention that the tax and fraud scandals of 2000–2002 brought to companies also shed light on the profits chief executives were making, especially their bonus and benefit packages, which many felt to be unfairly inflated based on the returns investors were receiving and the compensation of other employees in the companies. Amendments to the Sarbanes-Oxley Act, carried out in 2006, require that executive compensation pertaining directly to investor information must be disclosed in a separate section of financial reports. This led to a wider knowledge of executive payment practices among the public than had previously been seen before, and began a series of critical examinations of companies and their treatment of top management.

These questionable compensation plans applied to many in top management, including chief executive officers, mergers and acquisitions executives, top tax executives, top sales executives, and top diversity executives. According to a Watson Wyatt analysis, people in these positions received a

2007 pay increase of 11.4 percent or more, with merger and acquisition officers receiving the highest average pay increase. Recent legislation pertaining to executive payment includes the Office of Federal Procurement Policy's 2008 compensation cap establishing a maximum yearly salary for contracted companies and certain management positions within them. The maximum amount for government contract management positions—which combines salaries, benefits, and other extra executive profits—is $612,196.

In response to the continuing criticism, companies are taking a closer look at how they pay executives and how much payment is financially responsible, healthy for their business, and encouraging to their stockholders. According to a 2008 *Wall Street Journal* article by Phred Dvorak, approximately 15 percent of Fortune 500 companies took a closer look at their payment systems when paying executives the 2007 salary, taking into account such factors as accumulated wealth. This number is nearly double the amount of firms who accounted for such factors in 2006.

As an example, in 2007 Waddell & Reed Financial Inc. decided to halt further contributions to the retirement fund of the CEO Henry Herrmann. Their review of his accumulated wealth showed that, during his thirty-six-year career, he had amassed roughly $70 million in stocks, deferred compensation, bonuses, and other benefits. The company decided he had sufficient funds to retire and stopped the retirement contribution plan. Although companies' reactions are varied, Waddell & Reed may not be alone in their compensation dilemmas—compensation tracker Equilar has found the average stock owned by a large-company CEO in 2007 was worth about 56.7 million dollars. While some companies are declaring such stock gains to be prohibitive, others argue that such stock investments give executives incentives to perform well.

Performance Plans for Executives. There are many forms of performance plans for executives, but most involve the company reaching certain goals under the executive's supervision. Often, a third-party compensation committee is created solely to supervise the compensation plans for top executives, and avoid public criticism or unfair payment practices.

Some performance plans divide compensation requirements into two different areas. First, the compensation committee looks at what accomplishments the company intended to make in the past year under the executive's guidance, and how far the company has progressed in reaching those goals. Second, the committee takes into account leadership qualities and judgment decisions made by the executive, a more flexible factor including personal skills and management talent. A ratio can be formed for these two areas, assigning each a percentage of overall importance.

Other plans divide the executive's accomplishments down even further, taking into account vision, team-building, and accountability. Often, such plans are either long-term or short-term. Short-term plans will evaluate recent goals and decisions made by the executive, while long-term analysis extends throughout the past year. Benefits are awarded based on similar plans, which can factor in growth of company stock and evaluation by other board members.

According to revenue laws established in 1993 to help create fair practice in executive compensation, there are limitations to how much overall tax deductions a company can take from the benefits and payment of its five top executives, *unless the payment is performance based*. The tax deduction limit was $1 million, which was intended to be the cap for executive salaries for commercial companies, all other benefits being limited to stock options. Performance plans have since evolved to include other benefit forms, but the key component remains stock options.

Deferred Compensation. Most executive retirement plans, granted in the form of a salary percentage or stock options, are considered deferred compensation. It is deferred because the money is set aside in some type of savings account or investment for the executive, until such time as it can be accessed. This is different from the retirement package an executive often receives when stepping down.

Deferred compensation can be of two different types, qualified and nonqualified, as pertaining to taxes. Qualified deferred compensations are those which are subject to tax laws, including the million dollar limit deductable for the company granting the compensation. These are the more traditional, common sort of deferred compensation plan. Some companies, however, choose to grant their executives unqualified deferred compensation, which is not subject to the same tax laws and usually results in a larger retirement package for the executive. The company accomplishes unqualified compensation by setting the money aside within the organization, not legally granting it to the executive but retaining it in a separate account. Any money earned by the fund is reinvested, until the executive retires. The deferred compensation, however, is based upon the success of the company, and if the company becomes insolvent, the fund—and the retirement package—are at risk.

Legislation is currently being debated in Congress on increasing taxes and restrictions for nonqualified deferred compensation, since it is seen by some as a loophole in the current laws.

Intermediate Sanctions. Intermediate sanctions are used by the IRS to administer excise taxes to individuals who are believed to have improperly or illegally benefited from a commercial company transaction. Although this is a broad definition, it is meant to apply primarily to family

members, organizations, and company executives who receive benefits from their company greater than the IRS considers reasonable. The sanctions can be applied to the individual receiving the benefits and to anyone who has given permission for such benefits, such as other members of the corporate board.

While these sanctions limit the amount of payment and extra benefits executives can be granted, they also function on more subtle levels. Intermediate sanctions are most often applied by the IRS in cases where the individual profits indirectly from the company's actions. For instance, the executive might receive a certain amount of stock as part of a deferred compensation plan, but also receives a second amount of stock from a dummy organization as a "gift" or "bonus." Overall, the executive has profited more from the exchange than the company could have, and is open to intermediate sanctions. Other arrangements can also lead to sanction penalties by the IRS.

Usually, the money from such activities, plus interest, is returned to the company, and the individual is penalized, usually at 25 percent of the excess benefit as decided by the IRS. If the individual does not return the profits to the organization, or pay the penalty fee within the taxable period, the required tax shoots up to 200 percent of the excess benefit received. A tax of 10 percent might also be imposed on any manager or board member who took part in the decision to impart the excess benefit.

Shareholder Voting. There is a current push for legislation requiring some sort of shareholder vote authorizing executive compensation, known as the "Say on Pay" law. This would require an annual vote by all shareholders in the company on compensation methods and amounts. Although this legislation has not yet been passed by Congress, it has been submitted numerous times in 2007–2008. Many organizations are against the "Say on Pay" law, fearing it would turn compensation plans in a lengthy bureaucratic bargaining system.

FORMS OF COMPENSATION

As stated before, American companies often used a mixture of base and variable pay to determine an employee's compensation. The amount of variable pay is usually larger in American than internationally, where the term "compensation" most often means extra benefits and "remuneration" means the wages or salaries received.

Globally, there are several considerations that must be made when creating a compensation (or remuneration) plan for outsourced workers or international plants. A company should understand what counts as a healthy standard of living for the nation they are working with, as well as knowing what forms of benefits are acceptable. Some changes might be needed for incentive plans in different cultures that put a stronger emphasis on different values or company qualities than the United States does in its incentives. Also, tax laws and data security may be different in other countries, leading to necessary changes in compensation plans.

When creating forms of compensation, whether at home or internationally, there are several factors companies should take into consideration. For instance, any changes in employee compensation will affect the value propositions made to potential employees, Skilled employees will naturally be more attracted to companies that offer above-market rates.

EMPLOYEE EVALUATION AND PERFORMANCE APPRAISALS

Most companies have a formal performance appraisal system in which employee job performance is rated on a regular basis, usually once a year. A good performance appraisal system can greatly benefit an organization. It helps direct employee behavior toward organizational goals by letting employees know what is expected of them, and it yields information for making employment decisions, such as those regarding pay raises, promotions, and discharges.

Developing and implementing an effective system is no easy task, however. For instance, one study found that a majority of companies—65 percent—are dissatisfied with their performance appraisal systems. Analysts have found that a fairly low degree of reliability and validity remains a major bug in most appraisal systems. Many such systems are met with considerable resistance by those whose performance is being appraised, thus hampering the possibilities for effectiveness. While accurate and informative appraisal systems can be a major asset to a business, they are too often an unrealized goal.

There are three major steps in the performance appraisal process: identification, measurement, and management. With identification, the behaviors necessary for successful performance are determined. Measurement involves choosing the appropriate instrument for appraisal and assessing performance. Management, which is the ultimate goal, is the reinforcing of good performance and the correction of poor performance. Each step is described below. Additionally, management by objectives, which involves evaluating performance without a traditional performance appraisal, is described.

IDENTIFICATION

The organization must determine for each job family the skills and behaviors that are necessary to achieve effective performance. The organization should identify dimensions, which are broad aspects of performance. For instance, "quality of work" is a dimension required in many jobs. To determine which dimensions are important to job performance, the organization should rely on an accurate and up-to-date job analysis. Job descriptions written from job analyses should offer a detailed and valid picture of which job behaviors are necessary for successful performance.

In the identification stage, the company must also choose who will rate employee performance. Supervisors, peers, and the employees themselves may provide performance ratings. In most instances, performance appraisals are the responsibility of the immediate supervisor of an employee. Supervisors rate performance because they are usually the ones most familiar with the employee's work. Additionally, appraisals serve as management tools for supervisors, giving them a means to direct and monitor employee behavior. Indeed, if supervisors are not allowed to make the appraisals, their authority and control over their subordinates could be diminished.

While supervisory ratings can be quite valuable, some companies have added peer appraisals to replace or supplement those given by the supervisor. Naturally, peers and supervisors each view an individual's performance from different perspectives. Supervisors usually possess greater information about job requirements and performance outcomes. On the other hand, peers often see a different, more realistic view of the employee's job performance because people often behave differently when the boss is present. Using peer ratings to supplement supervisory ratings may thus help to develop a consensus about an individual's performance. It may also help eliminate biases and lead to greater employee acceptance of appraisal systems.

Potential problems may limit the usefulness of peer ratings, however, especially if they are used in lieu of supervisory ratings. First, the company must consider the nature of its reward system. If the system is highly competitive, peers may perceive a conflict of interest. High ratings given to a peer may be perceived as harming an individual's own chances for advancement. Second, friendships may influence peer ratings. A peer may fear that low ratings given to a colleague will harm their friendship or hurt the cohesiveness of the work group. On the other hand, some peer ratings may be influenced by a dislike for the employee being rated.

Some organizations use self-ratings to supplement supervisory ratings. As one might expect, self-ratings are generally more favorable than those made by supervisors and peers and therefore may not be effective as an evaluative tool. However, self-ratings may be used for employee development. Their use may uncover areas of subordinate-supervisor disagreement, encourage employees to reflect on their strengths and weaknesses, lead to more constructive appraisal interviews, and make employees more receptive to suggestions.

With 360-degree feedback, employee performance appraisals are a group effort. The employee receives performance feedback from his or her supervisor and four to eight peers, reporting staff members, coworkers and customers. Most 360-degree feedback tools also include a self-assessment. Using 360-degree feedback, each employee understands how his effectiveness—as an employee, coworker, or staff member—is viewed by others. The most effective 360-degree feedback processes provide feedback based on behaviors that other employees can see. The feedback provides insight about the skills and behaviors

desired in the organization to accomplish the mission, vision, and goals, and live the values.

Companies using 360-degree feedback have high expectations of the process, yet these often are not realized. Using this system, appraisers fail to connect the employee's work to the corporate goals. The anonymity of the process leaves employees with insufficient information and it is difficult for employees to attain follow-up information. Inexperienced raters (a problem in itself) tend to spend too much time focusing on employees' negative attributes. Finally, the 360-degree process is a daunting administrative task that creates paper and data entry overload.

MEASUREMENT

Once the appropriate performance dimensions have been established for jobs, the organization must determine how best to measure the performance of employees. This raises the critical issue of which rating form to use. In the vast majority of organizations, managers rate employee job performance on a standardized form. A variety of forms exist, but they are not equally effective. To be effective, the form must be relevant and the rating standards must be clear. Relevance refers to the degree to which the rating form includes necessary information, that is, information that indicates the level or merit of a person's job performance. To be relevant, the form must include all the pertinent criteria for evaluating performance and exclude criteria that are irrelevant to job performance.

The omission of pertinent performance criteria is referred to as criterion deficiency. For example, an appraisal form that rates the performance of police officers solely on the basis of the number of arrests made is deficient because it fails to include other aspects of job performance, such as conviction record, court perform-ance, number of commendations, and so on. Such a deficient form may steer employee behavior away from organizational goals; imagine if police officers focused only on arrests and neglected their other important duties.

When irrelevant criteria are included on the rating form, criterion contamination occurs, causing employees to be unfairly evaluated on factors that are irrelevant to the job. For example, criterion contamination would occur if an auto mechanic were evaluated on the basis of personal cleanliness, despite the fact that this characteristic has nothing to do with effective job performance.

Performance standards indicate the level of performance an employee is expected to achieve. Such standards should be clearly defined so that employees know exactly what the company expects of them. For instance, the standard "load a truck within one hour" is much clearer than "work quickly." Not only does the use of clear performance standards help direct employee behavior, it also helps supervisors provide more accurate ratings; two supervisors may disagree on what the term "quickly" means, but both attribute the same meaning to "one hour."

To meet the standards described in the previous section, a firm must use an effective rating form. The form provides the basis for the appraisal, indicating the aspects or dimensions of performance that are to be evaluated and the rating scale for judging that performance. Human resources (HR) experts have developed a variety of instruments for appraising performance. A description of the most commonly used instruments, along with their strengths and weaknesses, is given in the following paragraphs. A summary of these instruments appears in Exhibit 1. It should be noted, however, that companies can create additional types of instruments. For instance, they can rate employees on job task performance using graphic or behavior rating scales.

Exhibit 1

Rating Errors and their Likely Causes

Errors	Causes					
	A	B	C	D	E	F
Leniency		X		X		X
Severity		X		X		
Central tendency	X	X				
Halo		X				X
Implicit personality theory					X	
Recency			X			

Key:
A   administrative procedures
B   poorly defined rating standards
C   memory decay
D   political considerations
E   incomplete information
F   rater's lack of conscientiousness

Employee Comparison Systems. Most appraisal instruments require raters to evaluate employees in relation to some standard of excellence. With employee comparison systems, however, employee performance is evaluated relative to the performance of other employees. In other words, employee comparison systems use rankings, rather than ratings. A number of formats can be used to rank employees, such as simple rankings, paired comparisons, or forced distributions. Simple rankings require raters to rank-order their employees from best to worst, according to their job performance. When using the paired comparison approach, a rater compares each possible pair of employees. For example, Employee 1 is compared to Employees 2 and 3, and Employee 2 is compared to Employee 3. The employee winning the most "contests" receives the highest ranking. A forced distribution approach requires a rater to assign a certain percentage of employees to each category of excellence, such as best, average, or worst. Forced distribution is analogous to grading on a curve, where a certain percentage of students get As, a certain percentage get Bs, and so forth.

Employee comparison systems are low cost and practical; the ratings take very little time and effort. Moreover, this approach to performance appraisal effectively eliminates some of the rating errors discussed earlier. Leniency is eliminated, for instance, because the rater cannot give every employee an outstanding rating. In fact, by definition, only 50 percent can be rated as being above average. By forcing raters to specify their best and worst performers, employment decisions such as pay raises and promotions become much easier to make.

Employee comparison systems are plagued with several weaknesses. Because the rating standards for judging performance are vague or nonexistent, the accuracy and fairness of the ratings can be seriously questioned. Moreover, employee comparison systems do not specify what a worker must do to receive a good rating and, thus, they fail to adequately direct or monitor employee behavior. Finally, companies using such systems cannot compare the performance of people from different departments fairly. For example, the sixth-ranked employee in Department A may be a better performer than the top-ranked employee in Department B.

Graphic Rating Scale. A graphic rating scale (GRS) presents appraisers with a list of dimensions, which are aspects of performance that determine an employee's effectiveness. Examples of performance dimensions are cooperativeness, adaptability, maturity, and motivation. Each dimension is accompanied by a multi-point (e.g., 3, 5, or 7) rating scale. The points along the scale are defined by numbers and/or descriptive words or phrases that indicate the level of performance. The midpoint of the scale is usually anchored by such words as "average," "adequate," "satisfactory," or "meets standards."

Many organizations use graphic rating scales because they are easy to use and cost little to develop. HR professionals can develop such forms quickly, and because the dimensions and anchors are written at a general level, a single form is applicable to all or most jobs within an organization. Graphic rating scales do present a number of problems, however. Such scales may not effectively direct behavior; that is, the rating scale does not clearly indicate what a person must do to achieve a given rating, thus employees are left in the dark as to what is expected of them. For instance, an employee given a rating of 2 on "attitude" may have a difficult time figuring out how to improve.

Graphic rating scales also fail to provide a good mechanism for providing specific, non-threatening feedback. Negative feedback should focus on specific behaviors rather than on the vaguely defined dimensions the GRSs describe. For example, if told that they are not dependable, most employees would become angered and defensive; they would become less angry and defensive if such feedback were given in behavioral terms: "Six customers complained to me last week that you did not return their phone calls."

Another problem with GRSs concerns rating accuracy. Accurate ratings are not likely to be achieved because the points on the rating scale are not clearly defined. For instance, two raters may interpret the standard of "average" in very different ways. The failure to clearly define performance standards can lead to a multitude of rating errors (as noted earlier) and provides a ready mechanism for the occurrence of bias. U.S. courts consequently frown on the use of GRSs. One court noted that ratings made on a graphic rating scale amounted to no more than a "subjective judgment call," and ruled that such rating scales should not be used for promotion decisions because of the potential bias inherent in such a subjective process.

Behaviorally Anchored Rating Scales. A behaviorally anchored rating scale (BARS), like a graphic rating scale, requires appraisers to rate employees on different performance dimensions. The typical BARS includes seven or eight performance dimensions, each anchored by a multi-point scale. But the rating scales used on BARS are constructed differently than those used on graphic rating scales. Rather than using numbers or adjectives, a BARS anchors each dimension with examples of specific job behaviors that reflect varying levels of performance.

The process for developing a BARS is rather complex. Briefly, it starts with a job analysis, using the critical incident technique. This involves having experts generate a list of critical incidents—or specific examples of poor, average, and excellent behaviors—that are related to a certain job. The incidents are then categorized by dimension. Finally, a

rating scale is developed for each dimension, using these behaviors as "anchors" to define points along the scale.

When initially formulated, BARS were expected to be vastly superior to graphic rating scales. HR experts thought the behavioral anchors would lead to more accurate ratings because they enabled appraisers to better interpret the meaning of the various points along the rating scale. That is, rather than having the rater try to pinpoint the meaning of a vague anchor such as "excellent," the rater would have improved accuracy by having a critical incident as an anchor. As we shall see, however, this expectation has not been met. Perhaps the greatest strength of BARS is its ability to direct and monitor behavior. The behavioral anchors let employees know which types of behavior are expected of them and gives appraisers the opportunity to provide behaviorally-based feedback.

The superiority of BARS over graphic rating scales has not been substantiated by research. In fact, the great majority of studies on this topic have failed to provide evidence that justifies the tremendous amount of time and effort involved in developing and implementing BARS. The failures of BARS may lie in the difficulty raters experience when trying to select the one behavior on the scale that is most indicative of the employee's performance level. Sometimes an employee may exhibit behaviors at both ends of the scale, so the rater does not know which rating to assign.

Behavior Observation Scales. A behavior observation scale (BOS) contains a list of desired behaviors required for the successful performance of specific jobs, which are assessed based on the frequency with which they occur. The development of BOS, like BARS, also begins with experts generating critical incidents for the jobs in the organization and categorizing these incidents into dimensions. One major difference between BARS and BOS is that, with BOS, each behavior is rated by the appraiser.

When using BOS, an appraiser rates job performance by indicating the frequency with which the employee engages in each behavior. A multi-point scale is used ranging from "almost never" to "almost always." An overall rating is derived by adding the employee's score on each behavioral item. A high score means that an individual frequently engages in desired behaviors, and a low score means that an individual does not often engage in desired behaviors.

Because it was developed more recently, the research on BOS is far less extensive than that on BARS. The available evidence, however, is favorable. One study found that both managers and subordinates preferred appraisals based on BOS to both BARS and graphic rating scales. The same study found that equal employment opportunity attorneys believed BOS is more legally defensible than the other two approaches.

Because raters do not have to choose one behavior most descriptive of an employee's performance level, the problem noted earlier regarding BARS does not arise. Moreover, like BARS, BOS is effective in directing employees' behavior because it specifies what they need to do in order to receive high performance ratings. Managers can also effectively use BOS to monitor behavior and give feedback in specific behavioral terms so that the employees know what they are doing right and which behavior needs to be corrected. Like BARS, however, a BOS instrument takes a great deal of time to develop. Moreover, a separate instrument is needed for each job (since different jobs call for different behaviors), so the method is not always practical. Developing a BOS for a particular job would not be cost-efficient unless the job had many incumbents.

Accuracy of the Ratings. Accurate ratings reflect the employees' actual job performance levels. Employment decisions that are based on inaccurate ratings are not valid and would thus be difficult to justify if legally challenged. Moreover, employees tend to lose their trust in the system when ratings do not accurately reflect their performance levels, and this causes morale and turnover problems. Unfortunately, accurate ratings seem to be rare. Inaccuracy is most often attributable to the presence of rater errors, such as leniency, severity, central tendency, halo, and recency errors. These rating errors occur because of problems with human judgment. Typically, raters do not consciously choose to make these errors, and they may not even recognize when they do make them.

Leniency error occurs when individuals are given ratings that are higher than actual performance warrants. Leniency errors most often occur when performance standards are vaguely defined. That is, an individual who has not earned an excellent rating is most likely to receive one when "excellent" is not clearly defined. Why do appraisers distort their ratings in an upward or downward direction? Some do it for political reasons; that is, they manipulate the ratings to enhance or protect their self-interests. In other instances, leniency and severity come about from a rater's lack of conscientiousness. Raters may allow personal feelings to affect their judgments; a lenient rating may be given simply because the rater likes the employee.

Severity error occurs when individuals are given ratings that are lower than actual performance warrants. Severe ratings may be assigned out of a dislike for an individual, perhaps due to personal bias. A male appraiser may, for example, underrate a highly-performing female employee because she threatens his self-esteem; a disabled employee may receive an unduly low rating because the

employee's presence makes the appraiser feel embarrassed and tense; or an appraiser may provide harsh ratings to minorities out of a fear and distrust of people with different nationalities or skin color. Alternately, a severe rating may be due to the very high standards of a rater, or to "send a message" to motivate employees to improve.

When raters make leniency and severity errors, a firm is unable to provide its employees with useful feedback regarding their performance. An employee who receives a lenient rating may be lulled into thinking that performance improvement is unnecessary. Severity errors, on the other hand, can create morale and motivation problems and possibly lead to discrimination lawsuits.

Central tendency error occurs when appraisers purposely avoid giving extreme ratings even when such ratings are warranted. For example, when rating subordinates on a scale that ranges from one to five, an appraiser would avoid giving any ones or fives. When this error occurs, all employees end up being rated as average or near average, and the employer is thus unable to discern who its best and worst performers are. Central tendency error is likely the result of administrative procedures. That is, it frequently occurs when an organization requires appraisers to provide extensive documentation to support extreme ratings. The extra paperwork often discourages appraisers from assigning high or low ratings. Central tendency errors also occur when the end points of the rating scale are unrealistically defined (i.e., a five effectively means "the employee can walk on water" and a one means "the employee would drown in a puddle").

Appraisals are also subject to the halo effect, which occurs when an appraiser's overall impression of an employee is based on a particular characteristic, such as intelligence or appearance. When rating each aspect of an employee's work, the rater may be unduly influenced by his or her overall impression. For example, a rater who is impressed by an employee's intelligence may overlook some deficiencies and give that employee all fives on a one-to-five scale; an employee perceived to be of average intelligence may be given all threes. The halo effect acts as a barrier to accurate appraisals because those guilty of it fail to identify the specific strengths and weaknesses of their employees. It occurs most often when the rating standards are vague and the rater fails to conscientiously complete the rating form. For instance, the rater may simply go down the form checking all fives or all threes.

Most organizations require that employee performance be assessed once a year. When rating an employee on a particular characteristic, a rater may be unable to recall all of the employee's pertinent job behaviors that took place during that rating period. The failure to recall such information is called memory decay. The usual consequence of memory decay is the occurrence of recency error; that is, ratings are heavily influenced by recent events that are more easily remembered. Ratings that unduly reflect recent events can present a false picture of the individual's job performance during the entire rating period. For instance, the employee may have received a poor rating because he or she performed poorly during the most recent month, despite an excellent performance during the preceding eleven months.

MANAGEMENT

In the management phase of performance appraisal, employees are given feedback about their performance and that performance is either reinforced or modified. The feedback is typically given in an appraisal interview, in which a manager formally addresses the results of the performance appraisal with the employee. Ideally, the employee will be able to understand his or her performance deficiencies and can ask questions about the appraisal and his or her future performance. The manager should give feedback in a way that it will be heard and accepted by the employee; otherwise, the appraisal interview may not be effective.

The appraisal interview may also have an appeals process, in which an employee can rebut or challenge the appraisal if he or she feels that it is inaccurate or unfair. Such a system is beneficial because it:

- Allows employees to voice their concerns
- Fosters more accurate ratings—the fear of a possible challenge may discourage raters from assigning arbitrary or biased ratings
- Often prevents the involvement of outside third parties (e.g., unions, courts)

The downside of using an appeals system is that it tends to undermine the authority of the supervisor and may encourage leniency error. For example, a supervisor may give lenient ratings to avoid going through the hassle of an appeal.

MANAGEMENT BY OBJECTIVES

Management by objectives (MBO) is a management system designed to achieve organizational effectiveness by steering each employee's behavior toward the organization's mission. MBO is often used in place of traditional performance appraisals. The MBO process includes goal setting, planning, and evaluation. Goal setting starts at the top of the organization with the establishment of the organization's mission statement and strategic goals. The goal-setting process then cascades down through the organizational hierarchy to the level of the individual employee. An individual's goals should represent outcomes that, if achieved, would most contribute to the

attainment of the organization's strategic goals. In most instances, individual goals are mutually set by employees and their supervisors, at which time they also set specific performance standards and determine how goal attainment will be measured.

As they plan, employees and supervisors work together to identify potential obstacles to reaching goals and devise strategies to overcome these obstacles. The two parties periodically meet to discuss the employee's progress to date and to identify any changes in goals necessitated by organizational circumstances. In the evaluation phase, the employee's success at meeting goals is evaluated against the agreed-on performance standards. The final evaluation, occurring annually in most cases, serves as a measure of the employee's performance effectiveness.

MBO is widely practiced throughout the United States. The research evaluating its effectiveness as a performance appraisal tool has been quite favorable. These findings suggest that the MBO improves job performance by monitoring and directing behavior; that is, it serves as an effective feedback device, and it lets people know what is expected of them so that they can spend their time and energy in ways that maximize the attainment of important organizational objectives. Research further suggests that employees perform best when goals are specific and challenging, when workers are provided with feedback on goal attainment, and when they are rewarded for accomplishing the goal.

MBO presents several potential problems, however, five of which are addressed here.

1. Although it focuses an employee's attention on goals, it does not specify the behaviors required to reach them. This may be a problem for some employees, especially new ones, who may require more guidance. Such employees should be provided with action steps specifying what they need to do to successfully reach their goals.

2. MBO also tends to focus on short-term goals, goals that can be measured by year's end. As a result, workers may be tempted to achieve short-term goals at the expense of long-term ones. For example, a manager of a baseball team who is faced with the goal of winning a pennant this year may trade all of the team's promising young players for proven veterans who can win now. This action may jeopardize the team's future success (i.e., its achievement of long-term goals).

3. The successful achievement of MBO goals may be partly a function of factors outside the worker's control. For instance, the baseball manager just described may fail to win the pennant because of injuries to key players, which is a factor beyond his control. Should individuals be held responsible for outcomes influenced by such outside factors? For instance, should the team owner fire the manager for failing to win the pennant? While some HRM experts (and baseball team owners) would say "yes," because winning is ultimately the responsibility of the manager, others would disagree. The dissenters would claim that the team's poor showing is not indicative of poor management and, therefore, the manager should not be penalized.

4. Performance standards vary from employee to employee, and thus MBO provides no common basis for comparison. For instance, the goals set for an "average" employee may be less challenging than those set for a "superior" employee. How can the two be compared? Because of this problem, the instrument's usefulness as a decision-making tool is limited.

5. MBO systems often fail to gain user acceptance. Managers often dislike the amount of paperwork these systems require and may also be concerned that employee participation in goal setting robs them of their authority. Managers who feel this way may not properly follow the procedures. Moreover, employees often dislike the performance pressure that MBO places on them and the stress that it creates.

EMPLOYEE HANDBOOK AND ORIENTATION

The employee handbook is a document an organization compiles in order to inform employees of rules, regulations, and policies. It is a consistent, formalized way for organizations to communicate with employees, and it is one of the most important forms of information that the company can provide its employees. Employees can refer to the handbook to answer basic questions throughout their tenure with the organization. Additionally, managers in the organization can use the handbook to help them make uniform and consistent decisions regarding employees. By avoiding arbitrary or uninformed decisions by managers, the company may prevent problems that stem from the unfair or even illegal treatment of employees, problems that can result in reduced worker motivation, lower performance, or even litigation.

Orientation is a training program that introduces new employees to the company, their work units, and their particular jobs; it is used to familiarize employees with the organization's rules, policies, and procedures. Often the employee handbook is used as a reference during a company's orientation sessions. The typical elements of both the employee handbook and orientation are described in detail below.

THE EMPLOYEE HANDBOOK

Employee handbooks are likely to include information on the following topics: employee compensation and benefits, performance appraisal procedures, smoking restrictions, drug-testing procedures, leave policies, dress code, sexual harassment, workplace dating, disciplinary procedures, and safety rules.

Compensation and Benefits. An employee handbook should provide information about compensation and benefits, and in particular, fringe benefits. Employees need to know how often they will receive paychecks and when and if pay raises will be given. Any variable pay (e.g., merit pay or incentive pay) should also be explained, since this pay is dependent upon employee performance. Employees should also be informed about who is eligible for which fringe benefits, what options they have, and when they are allowed to make changes to their benefits package. Additionally, detailed information about the benefits that are available is often included in employee handbooks.

Performance Appraisal Procedures. Employee handbooks should inform the employee about the procedure for performance appraisal. In addition to providing details about the instruments and required documentation in general, several questions should be answered. First, when will the appraisals be conducted? Some organizations conduct appraisals annually, while others do so more often (e.g., every six months). Additionally, will appraisals take place on a common date for everyone in a work unit (or company-wide), or are they conducted on the anniversary of an employee's hire date? Second, who will conduct the appraisal? Third, when and how will results be communicated to the employee? That is, will there be an appraisal meeting in which the employee is told the results of the performance appraisal? Fourth, what options are available to employees who disagree with their appraisal? These questions and any other details about the procedure should be addressed in this section of the handbook.

Smoking Restrictions. Most organizations have a policy on smoking that indicates whether smoking is allowed in the physical facility, outside of the physical facility (and how far away from the building smokers must be), or outside of work altogether. Any restrictions on smoking should be detailed in the employee handbook. In some organizations, smoking inside or around physical facilities may be hazardous, such as when flammable substances are present. In other organizations, smoking may be prohibited within a building for the comfort of non-smokers. In America, twenty-two states as well as the District of Columbia and Puerto Rico have laws forbidding smoking in nearly all workplaces as well as public spaces. Some employers have gone so far as to prohibit smoking even when employees are not on the job, a reaction to increased health care costs for smokers. In 2005, Michigan employee benefits firm Weyco instituted mandatory nicotine testing for its employees, and eventually required the employees' spouses to submit to testing as well. The company was acquired the next year, but the impact of the experiment lives on: in 2008 Michigan passed a bill protecting workers from off-hours restrictions on their personal behavior.

Drug Testing Procedures. If a company tests its employees for illegal drug use, then the policies and procedures associated with the tests should be included in the employee handbook. The organization should inform employees of the type of test—urinalysis, hair analysis, or blood analysis—and of the specific sample collection procedures. Additionally, the handbook should indicate when tests will be used. Testing may occur before employment begins, or it may occur randomly, for a cause, or after an accident. Finally, details about possible actions associated with positive test results, and procedures to appeal test results, should be provided.

Leave Policies. Paid leave (such as sick leave, vacation days, and personal days) requires rules for administration. The employee handbook should detail the number of sick or personal days available to each employee, the reasons

for which this leave may be taken, any documentation or verification that may be required to take a sick day, and who to contact in the event of an illness.

Employees must also be informed as to how and when vacations can be scheduled, how the time can be taken (e.g., intermittently or all at once), and whether days not taken in one year are carried over into the next year, or lost, or paid back to the employee in the form of cash. Additionally, the handbook should inform employees about the number of vacation days they have, particularly if the number increases with an employee's tenure.

The handbook should also detail information about who is eligible for unpaid leave under the Family and Medical Leave Act (FMLA), and what the procedure is for requesting such leave. Some organizations may not be covered by this act because of their size, but for those that are, informing employees of their rights under this law is important. Some employers require that employees exhaust their other paid leave (e.g., sick days and vacation days) before taking FMLA leave, and if this is the case, it should be detailed in the employee handbook.

Dress Code. Many employee handbooks include a dress code that informs employees which type of clothing is appropriate for the office. This is particularly important if an employer has a "casual Friday" policy that allows employees to dress less formally on Fridays. Employees are often confused or unsure as to what is appropriate for casual Friday, so a detailed dress code is important. A dress code should provide specific detailed information about what employees may and may not wear in the workplace. See Exhibit 1 for a sample, casual Friday dress code.

Sexual Harassment Policy. A typical sexual harassment policy includes definitions as to what constitutes sexual harassment, a procedure for reporting claims of sexual harassment within the company, the process the organization follows for investigating a sexual harassment claim, and the penalties for engaging in sexual harassment. First, the policy should explain the two types of sexual harassment: quid pro quo and hostile environment. This will help employees to understand which behaviors are acceptable or unacceptable in the workplace. Second, the policy should indicate reporting procedures, or how an employee should go about reporting a claim of sexual harassment. Typically, employees are encouraged to report to their direct supervisor and to present evidence of the alleged harassment. However, the organization should have an exception in the policy for those employees who are being harassed by their supervisor and therefore do not want to report to that person. Third, the details of the investigation of sexual harassment claims should be included in the policy: what evidence is necessary, which parties will be involved, the steps taken to resolve the problem. Finally, the policy should detail the disciplinary procedures for sexual harassment violations as some types of sexual harassment may be punishable by immediate dismissal.

Workplace Dating. Many organizations are creating workplace dating policies that may restrict personal relationships between employees. Workplace dating has increased dramatically due to a number of factors, including the presence of more women in the workforce, an older average age for first marriage in the U.S., and the longer working hours of many employees. Companies often choose to limit workplace romance because of concerns of favoritism and/or sexual harassment. Despite their legality, many workplace dating policies have come under fire because some employees feel that these policies

---

Exhibit 1

Sample Casual Friday Dress Code

Although professional dress is required at the workplace Monday through Thursday, on Fridays employees may wear more casual clothing. Please follow these guidelines when deciding how to dress on Fridays.

All casual Friday clothing should be clean, unwrinkled, and conservative in nature. Men may wear slacks, khaki pants, or high quality blue jeans. Men's shirts must have a collar, but may be short- or long-sleeved. Men may wear loafers, but may not wear athletic shoes or sandals. As with the professional dress code, men may not wear earrings.

Women may wear slacks, khaki pants, high quality jeans, skirts (high quality denim skirts are acceptable), or dresses. Women may wear sleeveless tops, but may not wear spaghetti straps, halter tops, or strapless tops. Women may wear open-toed shoes, but may not wear flip-flop sandals or athletic shoes.

No employees, male or female, may wear the following items: shorts, athletic clothing (e.g., track pants, sweat pants, sweatshirts), t-shirts, hats, flip-flop sandals, or athletic shoes.

Even on Fridays, clothing should still be office appropriate. It should not be dirty, stained, have tears or holes, or be threadbare. Additionally, clothes should not have unprofessional prints (e.g., animal prints, neon colors) or advertisements on them. Finally, clothing should not be too revealing. Women's skirts must not be too short, and no employee's clothing should be too tightly fitted to their body.

If you are unsure about whether a clothing item is appropriate for this office, please consult with your manager or with a member of the human resources management department before you wear it.

---

are an invasion of privacy. Additionally, because some couples may keep their relationship secret while other couples do not, there are concerns that such policies may be enforced inconsistently.

There are many different forms of workplace dating policies; they range in degree of restrictiveness. The least restrictive allows dating between anyone at any level of the organization. A slightly more strict policy would require that, if a relationship is established, a manager must be informed of such a relationship. Some policies allow for dating employees in other work units or at the same level of hierarchy, but prohibit relationships between supervisors and subordinates. The most restrictive policies prohibit any dating relationships whatsoever between any employees of the company.

Disciplinary Procedures. The employee handbook should include information about the disciplinary procedures that will be used if work rules are broken. This means that specific work rules will need to be listed, if they are not presented elsewhere in the employee handbook. Then, the company must identify actions that result in immediate termination, such as proof of theft, drug use on the job, quid pro quo sexual harassment, violence toward an employee or customer, or other types of extreme behavior. Additionally, the company must detail the procedures by which it will discipline less severe rule infractions.

Many organizations use progressive discipline, in which harsher punishments are given for each subsequent rule violation. The typical progression of punishments is a verbal warning, a written warning, a short suspension, and then termination of employment. Progressive disciplinary procedures allow the employee to change his or her behavior on minor issues before they result in termination; thus, this type of discipline provides appropriate due process for employees. Managers find the prescribed steps of a progressive discipline procedure easy to follow, particularly because they do not have to determine the punishment to give.

One element of a successful disciplinary procedure, which should be documented in the employee handbook, is the right to appeal disciplinary decisions. If an employee feels that he or she has been unfairly disciplined, the organization should have a procedure by which the employee can have others examine the process to make sure that it is free from bias. Two of the most useful procedures for an appeals process are an open-door management policy and the use of an employee relations representative.

Safety Rules. Any rules related to safety and security need to be detailed in the employee handbook, not only to inform employees of proper procedures but also to protect the company from liability. This section of the handbook should identify any required safety clothing or equipment, proper use of machinery and other equipment, and any necessary security measures (e.g., locking exterior doors of the building).

LEGAL CONCERNS WITH EMPLOYEE HANDBOOKS

There are two major legal concerns associated with the employee handbook: (1) when organizations do not follow their own documented policies and procedures, and (2) a possible implied contract exception to employment-at-will. When an employee handbook details procedures for discipline, for investigation of sexual harassment or other topics on which improper procedures may result in litigation from employees, it is crucial that managers closely follow the handbook procedures. If managers deviate from procedures, they may be susceptible to claims of wrongful discharge or sexual harassment. For instance, if an employee is fired after only one minor rule violation, yet the handbook indicates that the first step with such a violation is a verbal warning, the employee is likely to have a viable claim for wrongful discharge. Similarly, if managers do not follow their own printed policies for the investigation of sexual harassment claims and an employee suffers continued harassment, the organization is likely to be found liable for that harassment. Thus, it is critical that managers be aware of the policies and procedures documented in the employee handbook particularly if there has been a recent change to them.

The second major legal issue associated with employee handbooks is the possibility that they may be seen as implied contracts and thus exempt employees from employment-at-will. Employment-at-will is a common employment agreement that allows employers to release an employee from the organization at any time for any non-discriminatory reason, and allows the employee to quit at any time. Most U.S. workers are at-will employees; those who are not have employment contracts that specify job duties, the length of employment, and possible reasons for termination of employment.

There are three major exceptions to the employment-at-will doctrine for which the employer is not legally able to terminate employment at their discretion. One is the implied contract exception in which an employee is led to believe that he or she has an employment contract with the employer and is therefore not an at-will employee. This issue comes into play with the employee handbook because the handbook details specific, possible rule violations and because many employers now ask employees to sign a document indicating that they have read and understand the information provided in the employee handbook. By requiring a signature, the company can indicate at a later date that the employee was aware of certain rules and

regulations that they violated, thus protecting the company from employee claims of ignorance. However, while requiring a signature on the employee handbook has become very popular in many organizations, the company must make evident that the signature does not create an employment contract. That is, an employee may perceive their signature to indicate that he or she is no longer an at-will employee and will only be terminated if the rules in the handbook are violated. If the employer does not intend that an employment contract exist, then a statement such as "I understand that I am an at-will employee and can be terminated for any reason at any time" can be useful to protect the employer from claims of wrongful discharge.

ORIENTATION

Orientation is a training session intended to familiarize an employee with the workplace and its rules. An orientation session typically takes place within the first few working days that an employee is on the job, although it may occur before the job begins. A typical orientation program includes information about the company, the work unit, and other miscellaneous areas. To be effective, the orientation program should provide key information without overwhelming individuals and prepare them for their first work experience with the company. The employee handbook is a key supporting document throughout orientation.

Company-Level Orientation Information. Orientation programs often include information about the company as a whole. This information may be a company overview, such as the origination and history of the company, its mission, and its values. This allows the employee to put the information about the current organization into its historical context.

Policies and procedures (regarding work rules, disciplinary procedures, etc.) should be reviewed in the orientation session so that employees are sure to be aware of them and so that they can ask questions if necessary.

Compensation and benefits should be reviewed, from the basics of when paychecks are issued to more detailed information about incentives and benefits. Many organizations provide detailed information about fringe benefits because new employees often need guidance in understanding their benefits or in selecting from a list of benefit options.

Safety and accident prevention should be addressed in orientation and depending on the type of work done in the company, further safety training programs may also be required. In many office settings, safety regulations are brief and easy to cover. However, in manufacturing settings, a great deal of time may need to be spent on educating employees about safe behaviors and the proper use of equipment. In such circumstances, orientation is likely to provide only an overview of safety issues before further training is offered.

Employee relations information should cover any employee assistance programs or wellness plans. It should also review employee rights, such as the right to appeal disciplinary actions or other managerial decisions related to human resources.

Orientation often includes an overview of the company's physical facilities and may include a tour of those facilities. New employees need to know which entrances and exits to use, how to maintain building security, where to park vehicles, where different work units are located, and even where the restrooms are. Such information will reduce new employees' anxiety and may prevent other problems such as having a car towed, leaving an exterior door unlocked, or getting lost in a large building.

Work Unit Orientation Information. In orientation, employees need to know specific information about the particular work unit in which they will be employed. This portion of the orientation may begin with an overview of the departmental functions and continue with information about the new employee's specific job duties and responsibilities, and the performance expectations of that position. Employees should then be told of any policies or procedures that may be specific to the work unit. Finally, work unit orientation should include a tour of the department (where offices are, where supplies are kept, etc.), and an introduction to other employees and managers.

Miscellaneous Information. Many orientation programs go beyond company and work unit information to provide new employees with details about the community, housing options, or other issues associated with adjusting to a new location. This is particularly important if the organization hires employees who relocate from a distance, especially if new employees arrive from overseas.

NEWCOMER SOCIALIZATION

Both the employee handbook and the orientation session aid the organization in socializing newcomers. Socialization is the process by which new employees learn the values, norms, and necessary behaviors to effectively participate as members of the organization. Socialization may begin even before a person is hired and may continue for weeks, or even months, after the person is on the job. Formal socialization occurs when employees review the employee handbook and attend new employee orientation. Socialization continues informally through advice from co-workers, the employee's observation of the workplace, and by trial-and-error.

Socialization involves three phases: anticipatory socialization, encounter phase, and settling in. Anticipatory

socialization occurs before an individual begins work at an organization. Through interactions with representatives of the company during the recruitment and selection process, the job applicant learns a lot about an organization. The encounter phase of socialization starts when an employee begins the new job, and typically the employee learns a great deal of new information. Regardless of how well-prepared an employee may feel to begin a new job with a new employer, there is likely to be something unexpected or even shocking that occurs when the employee is actually on the job. Finally, when the employee reaches the settling in stage of socialization, he or she begins to feel comfortable with both the job demands and the interpersonal relationships with others in the workplace.

The employee handbook and new employee orientation training are critical elements in preparing employees to be effective members of an organization. Thus, it is important that the handbook and orientation sessions include information that employees need to know about workplace policies and procedures. In addition, attention to the stages of newcomer socialization will help managers to ease the difficulties in transition that new employees may face.

EMPLOYEE RECRUITMENT PLANNING

STEP 1: IDENTIFY THE JOB OPENING

Ideally, organizations should attempt to identify job openings well in advance of an announced resignation. The human resource (HR) department should plan for future openings in both the short and long term. The projection of future openings provides organizations with the time needed to plan and implement recruitment strategies so that they do not fall prey to the "must-hire-by-last-week" syndrome. The HR plan should answer at least the following questions:

- Are any newly budgeted positions opening soon?

- Is a contract under negotiation that may result in the need for additional hires?

- What is the amount of expected turnover in the next several months?

STEP 2: DECIDE HOW TO FILL THE JOB OPENING

The first question to ask after determining that an opening exists is "Do we need to find a new person to fill the vacant position?" Sometimes it is unnecessary to staff a vacant position because the firm can rely on other alternatives. For instance, it may be more prudent to provide overtime opportunities to current workers to complete the needed work. Other alternatives include job elimination and job redesign (i.e., incorporating the tasks of the vacant position into currently existing positions). If the firm chooses to fill the vacancy, it must address two issues: (1) whether to outsource, and (2) in the absence of outsourcing, whether to recruit candidates internally or externally.

STEP 3: IDENTIFY THE TARGET POPULATION

Now the organization must determine what types of individuals it is looking for to fill the vacant positions. To address this question, an organization must define its target population. Two issues arise here: (1) specifying worker requirements and (2) deciding whether to target a certain segment of the applicant population.

An organization must identify specific requirements of the job: the duties, reporting relationships, salary range for hiring, and competencies required of a new worker (e.g., education, experience, knowledge, skills, and abilities). Ideally, much of this information will have been gathered during a job analysis and thus will be contained in the job description. If not, the recruiter should gather it from the hiring manager. An organization must also decide at this point whether to target all qualified applicants or to focus its recruitment efforts on certain segments of the qualified applicant population.

When recruiting internally, the issue is this: Should the company post the job so that all qualified employees can be considered? Or should the company select certain high-potential employees and groom them for the position? When recruiting externally, the company must decide whether to inform all potential applicants or target certain types. Companies may reap advantages when they target members of certain groups. Another strategy is to target graduates of specific schools that have exceptionally strong programs in the functional areas of concern. Additionally, some companies target top-performing employees working for other companies. Recruitment of such individuals poses some unique problems, however; these individuals may be difficult to reach because they are not actively seeking a new job. Moreover, the practice of pirating employees from other firms raises some serious ethical questions.

STEP 4: NOTIFY THE TARGET POPULATION

Once an applicant population has been targeted, the company must determine how to notify these individuals of the vacant position. A variety of recruitment methods may be used for communicating vacancies. A firm can benefit from both low-involvement and high-involvement strategies at this stage of the recruitment process. Low-involvement strategies are things such as corporate sponsorship or advertisements of the company's product or service may influence applicants' positive perceptions of that firm and therefore increase applicant attraction, but do not specifically identify a job opening. High-involvement recruitment strategies involve things such as detailed recruitment advertisements or employee endorsements, which occur when potential applicants meet with current employees to hear more about their experiences with that company. Both low-involvement and high-involvement strategies have a positive effect on the number of applicants who apply for jobs with an organization and on the quality of the applicants who apply.

When choosing a specific way to notify the target population, different recruitment methods may be used. Some popular options are internal job postings; newspaper, radio, and television advertisements; trade magazine advertisements; Internet job sites; college campus interviews; and current employee referrals. The choice of which to use depends on the number of positions to be filled, the cost of each recruitment method, the characteristics of the target audience, and economic conditions.

The more positions to be filled, the more widely the firm may choose to advertise, perhaps using a newspaper or radio advertisement. Costs differ for recruitment methods and a firm may be willing to invest more in recruitment when suitable applicants are difficult to find or when poor hiring decisions may be costly. The characteristics of the target audience influence recruitment method; for example, using an Internet posting would be fruitless if most of the applicant pool is unlikely to have access to a computer. Poor economic conditions, where unemployment is high, will result in higher numbers of job applicants and possibly a lower average level of quality of applicants. In this situation, to avoid spending an inordinate amount of time weeding through applications, firms must discourage all but the best applicants from applying.

STEP 5: MEET WITH THE CANDIDATES

Finally, the most qualified candidates are brought in for interviews and other assessment procedures. These serve both selection and recruitment purposes. From a selection perspective, they give the firm a chance to further assess the candidates' qualifications. From a recruitment perspective, they provide the candidates with an opportunity to learn more about the employment opportunity.

Candidates should be provided with information about the company and the job. Failure to provide a sufficient amount of information could be detrimental to the recruiting process. For example, it may be interpreted by the candidates as an attempt to evade discussion of unattractive job attributes, or it may be viewed as an indication of the recruiter's disinterest in them. Without specific information, applicants might accept a job offer without knowing about aspects of it that might affect their long-term job satisfaction, or they may refuse an offer without knowing about some of the job's attractive attributes.

KASH SYSTEM

Bea Quirk, in a 2008 article for the *Charlotte Business Journal*, spotlights a system of recruitment called KASH, which stands for knowledge, attitudes, skills, and habits. These are four of the most important qualities to know about potential employees before hiring. Recruitment policies, according to Quirk, should focus on discovering the KASH qualities of potential employees. Résumés often help to identity the knowledge and skills job seekers have in the form of experience. Attitudes and habits are

harder to define, but employers should seek for those in interviews, using in-depth questions to help find the more ingrained practices of employees.

ONLINE RECRUITMENT

According to a 2008 NORAS report, online job seekers in the United Kingdom have grown by 50 percent within the last year alone. In America, many companies are looking to change the way they use online job boards, giving more attention to using the Internet as a chief recruitment tool. Companies are seeking to cut costs and increase the effectiveness of their recruiting efforts, which means the increase in seeking employees online will continue to grow as a cheap, efficient way to contact a skilled workforce. With online job ads producing quick results at very little cost, companies are seeking new ways to use online tools for recruitment purposes.

Job boards are the most common way to advertise for positions online, whether a company chooses to use a specialty job board to fill a particular position, or a general job board to attract a wide range of job seekers. There are other electronic recruitment methods as well; many companies are using their corporate Web sites as an outreach to job seekers, while others are making use of mass emailing and intranet, in-company recruitment. Companies can also use online recruitment techniques to spread their name and improve their brand–every internet post for job seekers is an ability for companies to advertise themselves.

Social networks are also becoming an important recruitment tool for businesses. Sites such as MySpace and Facebook draw a great number of job seekers, many with newly developed skills. This is a new market for recruitment endeavors, and businesses are still exploring how to use social networks effectively. Employers can set up personalized recruitment pages on MySpace to communicate their messages and seek to fill specific positions. Other applications for networks such as Facebook allow for the creation of résumés and job-seeking profiles. Some companies use social networks as a tool to review potential employees before hiring.

RECRUITMENT OPTIONS

A 2008 article by Penelope Trunk, "Advantage, Employees," suggests that the new wave of recruitment tools, including online advertising and social networking, will make more traditional methods, such as résumés, increasingly obsolete. Job listings, currently overloaded with information, may eventually become inefficient, background noise to the talented job seekers who are looking for more than a detailed report on job functions. As Trunk advises, there may be other ways to appeal to the most skilled employees, different recruiting methods that focus more on value-propositions and personal advance-

ment than time-consuming lists of job qualifications and necessary experience.

Encouraging employee advancement—both within and outside of the company—is an excellent way to attract ambitious and talented job seekers. For instance, when an employee leaves the company, their manager can send out a public notice thanking them for a job well done. If they are moving to a different organization or a better position, the note can include congratulations for the employee's success as well as appreciation for the mark they left on the company. Employers can also use the opportunity for advancement and experience as a company advantage, advertising themselves as a "stepping stone" to reach higher positions or more prestigious businesses.

Many potential employees are concerned with who they will be working with and for. A thoughtful manager can put in a good word for the employee when they move on, give them important and necessary skills for their jobs, and coach them into better emotional intelligence and stronger values. Employees will be looking for these sorts of opportunities, so Trunk suggests companies advertise the qualities of their managers and employees as well the functions of the job. Outlining the advantages of working under a particular supervisor or executive is a great way to attract serious and skilled workers who are looking for a strong relationship with their company.

Recruiters also play a large role in the employment process, often working closely with job seekers to find them the best positions available. Job seekers will even spend a large amount of time working with recruitment agencies or online boards looking for suitable jobs. Because of this time spent with recruiters, employees will often have loyalty to their connectors. In the rapid transitions common today among workers, employees can be more comfortable with their recruiters than with the companies they currently work for. For this reason, employers should be sure to have an equally friendly relationship with recruiters. If recruiters know and respect organizations, they will be more likely to recommend suitable employees for the right positions.

Job seekers also belong to many communities outside of the business world. Companies can capitalize on these small communities by advertising opportunities and services meant specifically for them. For instance, managers and recruitment officers can become parts of blog networks specializing in computer software or engineering, where they can keep up on technological advancements and find the talent they need for their positions. Other communities with blogs and activities that companies can become a part of include working mothers, sports enthusiasts, and environmental activists.

RECRUITMENT MISTAKES

There are a number of methods companies should avoid when putting their recruitment plans into practice. For

instance, many businesses have the necessary talent within their organizations, but are too busy looking outside to recruit the skilled employees they already have. Others try to look for a mirror-replacement to the employee they have lost, duplicates with the same attitudes and skills, when companies can benefit more from employees with new experience and outlooks on the position. Some employers forget to include their employees in the recruitment process, or attempt to find the "perfect" employee without noticing the talents of the job seekers they interview.

EMPLOYEE SCREENING AND SELECTION

Effective employee selection is a critical component of a successful organization. How employees perform their jobs is a major factor in determining how successful an organization will be. Job performance is essentially determined by the ability of an individual to do a particular job and the effort the individual is willing to put forth in performing the job. Through effective selection, the organization can maximize the probability that its new employees will have the necessary knowledge, skills, and abilities (referred to collectively as "KSAs") to do the jobs they were hired to do. Employee selection is one of the two major ways, along with orientation and training, to make sure that new employees have the abilities required to do their jobs.

THE STAFFING PROCESS

Employee screening and selection is one part of the overall staffing process of the organization. This process also includes human resource (HR) planning, recruitment, evaluation, and retention activities. By doing human resource planning, the organization projects its likely demand for personnel with particular KSAs, and compares that to the anticipated availability of such personnel in the internal or external labor markets. During the recruitment phase of staffing, the organization attempts to establish contact with potential job applicants by job postings within the organization, advertising to attract external applicants, employee referrals, and many other methods, depending on the type of organization and the nature of the job in question. Employee selection begins when a pool of applicants is generated by the organization's recruitment efforts.

During the employee selection process, a firm decides which of the recruited candidates will be offered a position based on the use of available information and employer-generated criteria. As Gatewood, Field, and Barrick put it, employee selection is the "process of collecting and evaluating information about an individual in order to extend an offer of employment." This process lays the groundwork for future HR activities, such as evaluation and retention. As employment offers are generated by the screening and selection process, this process also provides the basis for other essential HR practices—such as effective job design, goal setting and performance evaluation, and promotion and compensation—that motivate workers to exert the effort needed to do their jobs effectively.

THE SCREENING AND SELECTION PROCESS

Job applicants differ along many dimensions, such as educational and work experience, personality characteristics, and innate ability and motivation levels. The logic of employee selection begins with the assumption that at least some of these individual differences are relevant to a person's suitability for a particular job. Thus, in employee selection the organization has two distinct but interrelated tasks: first, to determine the relevant individual differences needed to do the job—that is, the KSAs associated with the position; and second, to identify and utilize selection methods that will reliably and validly assess the extent to which job applicants possess the needed KSAs. The organization must achieve these tasks in a way that does not illegally discriminate against any job applicants on the basis of race, color, religion, sex, national origin, disability, or veteran's status.

The employee screening and selection process consists of several important stages, as shown in Exhibit 1. Since the organization must determine the individual KSAs needed to perform a job, the selection process begins with job analysis, which is the systematic study of the content of jobs in an organization. Effective job analysis tells the organization what people occupying particular jobs "do" in the course of performing their jobs. It also helps the organization determine the major duties and responsibilities of the job, as well as aspects of the job that are of minor or tangential importance to job performance. The job analysis often results in a document called the job description, which is a comprehensive document that details the duties, responsibilities, and tasks that make up a job. Because job analysis can be complex, time-consuming, and expensive, standardized job descriptions have been developed that can be adapted to thousands of jobs in organizations across the world. Two examples of such databases are the U.S. government's *Standard Occupational Classification* (SOC), which has information on at least 821 occupations, and the Occupational Information Network, which is also known as O*NET. O*NET provides job descriptions for thousands of jobs.

An understanding of the content of a job assists an organization in specifying the knowledge, skills, and abilities needed to do the job. These KSAs can be expressed in terms of a job specification, which is an organizational document that details what is required to successfully perform a given job. The necessary KSAs are called job requirements, which simply means they are thought to be necessary to perform the job. Job requirements are expressed in terms of desired education or training, work experience, specific aptitudes or abilities, and in many other ways. Care must be taken to ensure that the job requirements are based on the actual duties and responsibilities of the job and that they do not include irrelevant requirements that may discriminate against some applicants; in recent years, many organizations have revamped their job descriptions and specifications to ensure that these documents contain only job-relevant content in order to comply with the Americans with Disabilities Act. Furthermore, because the job description is frequently used as a recruitment tool, care is taken to ensure that the description will draw an applicant pool with an appropriate level of knowledge, skills, and abilities.

SELECTION METHODS

Once the necessary KSAs are identified, the organization must either develop a selection method to accurately assess whether applicants possess the needed KSAs, or adapt selection methods developed by others. There are many selection methods available to organizations. The most common is the job interview, but organizations also use some or all of the following:

- Reference and background checks
- Personality testing
- Cognitive ability testing
- Aptitude testing
- Assessment centers
- Drug tests

These and many other methods are used in an attempt to assess accurately the extent to which applicants possess the required KSAs and whether they have unfavorable characteristics that would prevent them from successfully performing the job. For both legal and practical reasons, it is important that the selection methods used are relevant to the job in question and that the methods are as accurate as possible in the information they provide. Selection methods cannot be accurate unless they possess reliability and validity.

VALIDITY OF SELECTION METHODS

Validity refers to the quality of a measure that exists when the measure assesses a construct. In the selection context, validity refers to the appropriateness, meaningfulness, and

---

Exhibit 1

Selection Process

1. Job Analysis
The systematic study of job content in order to determine the major duties and responsibilities of the job. Allows the organization to determine the important dimensions of job performance. The major duties and responsibilities of a job are often detailed in the job description.

2. The Identification of KSAs or Job Requirements
Drawing upon the information obtained through job analysis or from secondary sources such as O*NET, the organization identifies the knowledge, skills, and abilities necessary to perform the job. The job requirements are often detailed in a document called the job specification.

3. The Identification of Selection Methods to Assess KSAs
Once the organization knows the KSAs needed by job applicants, it must be able to determine the degree to which job applicants possess them. The organization must develop its own selection methods or adapt methods developed by others. Selection methods include, but are not limited to, reference and background checks, interviews, cognitive testing, personality testing, aptitude testing, drug testing, and assessment centers.

4. The Assessment of the Reliability and Validity of Selection Methods
The organization should be sure that the selection methods they use are reliable and valid. In terms of validity, selection methods should actually assess the knowledge, skill, or ability they purport to measure and should distinguish between job applicants who will be successful on the job and those who will not.

5. The Use of Selection Methods to Process Job Applicants
The organization should use its selection methods to make selection decisions. Typically, the organization will first try to determine which applicants possess the minimum KSAs required. Once unqualified applicants are screened, other selection methods are used to make distinctions among the remaining job candidates and to decide which applicants will receive offers.

Exhibit 2

**A Menu of Possible Qualities
Needed for Job Success**

A. Technical KSAs or aptitude for learning them

B. Nontechnical skills, such as

    1. Communication

    2. Interpersonal

    3. Reasoning ability

    4. Ability to handle stress

    5. Assertiveness

C. Work habits

    1. Conscientiousness

    2. Motivation

    3. Organizational citizenship

    4. Initiative

    5. Self-discipline

D. Absence of dysfunctional behavior, such as

    1. Substance abuse

    2. Theft

    3. Violent tendencies

E. Job-person fit; the applicant

    1. is motivated by the organization's reward system

    2. fits the organization's culture regarding such things as risk-taking and innovation

    3. would enjoy performing the job

    4. has ambitions that are congruent with the promotional opportunities available at the firm

---

usefulness of the inferences made about applicants during the selection process. It is concerned with the issue of whether applicants will actually perform the job as well as expected based on the inferences made during the selection process. For example, when a personality test such as the Myers-Briggs Type Indicator (MBTI) is used, the organization should have a clear idea of what personality type(s) will fit in with the identified KSAs, and more importantly, whether or not personality type is in fact an important dimension of job performance. The closer the applicants' actual job performances match their expected performances, the greater the validity of the measures used in the selection process.

In order to achieve validity, the organization must have a clear notion of the job requirements and use selection methods that reliably and accurately measure these qualifications. A list of typical job requirements is shown in Exhibit 2. Some qualifications—such as technical KSAs and nontechnical skills—are job-specific, meaning that each job has a unique set. The other qualifications listed in the exhibit are universal in that nearly all employers consider these qualities important, regardless of the job. For instance, employers want all their employees to be motivated and have good work habits.

The job specification derived from job analysis should describe the KSAs needed to perform each important task of a job. By basing qualifications on job analysis information, a company ensures that the qualities being assessed are important for the job. Job analyses are also needed for legal reasons. In discrimination suits, courts often judge the job-relatedness of a selection practice on whether or not the selection criteria was based on job analysis information. For instance, if someone lodges a complaint that a particular test discriminates against a protected group, the court would (1) determine whether the qualities measured by the test were selected on the basis of job analysis findings and (2) scrutinize the job analysis study itself to determine whether it had been properly conducted.

The attainment of validity depends heavily on the appropriateness of the particular selection technique used. Organizations should pay close attention to how reliable and accurate their selection methods are in order to ensure that effective employment choices are made.

Reliability. The reliability of a measure refers to its consistency. It is defined as "the degree of self-consistency among the scores earned by an individual." Reliable evaluations are consistent across both people and time. Reliability is maximized when two people evaluating the same candidate provide the same or very similar ratings, and when the ratings of a candidate taken at two different times are the same or very similar. When selection scores vary widely, they should be considered unreliable, which diminishes their validity.

Various factors can affect the reliability of a selection method. These include the following:

- *Emotional and physical state of the candidate*. Reliability suffers if candidates are particularly nervous during the assessment process.

- *Lack of rapport with the administrator of the measure.* Reliability suffers if candidates are "turned off" by the interviewer and thus do not "show their stuff" during the interview.

- *Inadequate knowledge of how to respond to a measure.* Reliability suffers if candidates are asked questions that are vague or confusing.

- *Individual differences among respondents.* If the range or differences in scores on the attribute measured by a selection device is large, that means the device can reliably distinguish among people.

- *Question difficulty.* Questions of moderate difficulty produce the most reliable measures. If questions are too easy, many applicants will give the correct answer and individual differences are lessened; if questions are too difficult, few applicants will give the correct answer and, again, individual differences are lessened.

- *Length of measure.* As the length of a measure increases, its reliability also increases. For example, an interviewer can better gauge an applicant's level of interpersonal skills by asking several questions, rather than just one or two.

Accuracy. In addition to providing reliable assessments, the firm's assessments should accurately measure the required worker attributes. Many selection techniques are available for assessing candidates. How does a company decide which ones to use? A particularly effective approach to follow when making this decision is known as the behavior consistency model. This model specifies that the best predictor of future job behavior is past behavior performed under similar circumstances. The model implies that the most effective selection procedures are those that focus on the candidates' past or present behaviors in situations that closely match those they will encounter on the job. The closer the selection procedure simulates actual work behaviors, the greater its validity.

In implementing the behavioral consistency model, employers should thoroughly assess each applicant's previous work experience to determine if the candidate has exhibited relevant behaviors in the past. If such behaviors are found, evaluate the applicant's past success on each behavior based on carefully developed rating scales. If the applicant has not had an opportunity to exhibit such behaviors, employers must estimate the future likelihood of these behaviors by administering various types of assessments (listed above). The more closely an assessment simulates actual job behaviors, the better the prediction.

ASSESSING AND DOCUMENTING VALIDITY

Validity, reliability, and accuracy are essential features of the criteria employed during the screening and selection process. Due to their importance, an effective selection process must itself undergo a process of evaluation. This evaluation process should focus on determining the validity of the selection methods used.

Three strategies can be used to determine the validity of a selection method:

1. **Content-oriented strategy:** Demonstrates that the company followed proper procedures in the development and use of its selection devices.

2. **Criterion-related strategy:** Provides statistical evidence showing a relationship between applicant selection scores and subsequent job performance levels.

3. **Validity generalization strategy:** Demonstrates that other companies have already established the validity of the selection practice.

Content-oriented strategy. When using a content-oriented strategy to document validity, a firm gathers evidence that it followed appropriate procedures in developing its selection program. The evidence should show that the selection devices were properly designed and were accurate measures of the worker requirements. Most importantly,

the employer must demonstrate that the selection devices were chosen on the basis of an acceptable job analysis and that they measured a representative sample of the KSAs identified. The sole use of a content-oriented strategy for demonstrating validity is most appropriate for selection devices that directly assess job behavior. For example, one could safely infer that a candidate who performs well on a properly-developed typing test would type well on the job because the test directly measures the actual behavior required on the job.

When the connection between the selection device and job behavior is less direct, content-oriented evidence alone is insufficient. Consider, for example, an item once found on a civil service exam for police officers: "In the Northern Hemisphere, what direction does water circulate when going down the drain?" The aim of the question is to measure mental alertness, which is an important trait for good police officers. However, can one really be sure that the ability to answer this question is a measure of mental alertness? Perhaps, but the inferential leap is a rather large one. Whether or not there is an indirect relationship, it should be clear that there is not a direct relationship between this assessment item and the specific tasks required to perform the job.

Criteria-related strategy. A criterion-related strategy is needed when employers must make such large inferential leaps; a content-oriented strategy, by itself, is insufficient to document validity. The use of this strategy is an attempt to demonstrate statistically that someone who does well on a selection instrument is more likely to be a good job performer than someone who does poorly on the selection instrument. To gather criterion-related evidence, the HR professional needs to collect two pieces of information on each person: a predictor score and a criterion score. Predictor scores represent how well the individual fared during the selection process as indicated by a test score, an interview rating, or an overall selection score. Criterion scores represent the job performance level achieved by the individual and are usually based on supervisor evaluations.

Validity is calculated by statistically correlating predictor scores with criterion scores (statistical formulas for computing correlation can be found in most introductory statistical texts). This correlation coefficient (designated as r) is called a validity coefficient. To be considered valid, r must be statistically significant and its magnitude must be sufficiently large to be of practical value. When a suitable correlation is obtained ($r > 0.3$, as a rule of thumb), the firm can conclude that the inferences made during the selection process have been confirmed. That is, it can conclude that, in general, applicants who score well during selection turn out to be good performers, while those who do not score as well become poor performers.

Exhibit 3

Steps in the Predictive and Concurrent Validation Processes

Predictive Validation

1. Perform a job analysis to identify needed competencies.
2. Develop/choose selection procedures to assess needed competencies.
3. Administer the selection procedures to a group of applicants.
4. Randomly select applicants or select all applicants.
5. Obtain measures of the job performance for the applicant after they have been employed for a sufficient amount of time. For most jobs, this would be six months to a year.
6. Correlate job performance scores of this group with the scores they received on the selection procedures.

Concurrent Validation

1 and 2. These steps are identical to those taken in a predictive validation study.
3. Administer the selection procedures to a representative group of job incumbents.
4. Obtain measures of the current job performance level of the job incumbents who have been assessed in step 3.
5. Identical to step 6 in a predictive study.

A criterion-related validation study may be conducted in one of two ways: a predictive validation study or a concurrent validation study. The two approaches differ primarily in terms of the individuals assessed. In a predictive validation study, information is gathered on actual job applicants; in a concurrent study, current employees are used. The steps to each approach are shown in Exhibit 3.

Concurrent studies are more commonly used than predictive ones because they can be conducted more quickly; the assessed individuals are already on the job and performance measures can thus be more quickly obtained. (In a predictive study, the criterion scores cannot be gathered until the applicants have been hired and have been on the job for several months.) Although concurrent validity studies have certain disadvantages compared to predictive ones, available research indicates that the two types of studies seem to yield approximately the same results.

Validity generalization strategy. The discussion of content-oriented and criteria-related strategies assumes that an employer needs to validate each of its selection practices. But many organizations employ selection methods that have been used and properly validated by other companies. This raises the question of whether or not this organization can rely on the validity evidence gathered by others, and thus avoid having to conduct its own study. This can be done by using a validity generalization strategy. Validity generalization is established by demonstrating that a selection device has been consistently found to be valid in many other similar settings. An impressive amount of evidence points to the validity generalization of

many specific devices. For example, some mental aptitude tests have been found to be valid predictors for nearly all jobs and thus can be justified without performing a new validation study to demonstrate job relatedness. To use validity generalization evidence, an organization must present the following data:

- Studies summarizing a selection measure's validity for similar jobs in other settings.

- Data showing the similarity between the jobs for which the validity evidence is reported and the job in the new employment setting.

- Data showing the similarity between the selection measures in the other studies composing the validity evidence and those measures to be used in the new employment setting.

MAKING A FINAL SELECTION

The extensiveness and complexity of selection processes vary greatly depending on factors such as the nature of the job, the number of applicants for each opening, and the size of the organization. A typical way of applying selection methods to a large number of applicants for a job requiring relatively high levels of KSAs would be the following:

1. Use application blanks, resumes, and short interviews to determine which job applicants meet the minimum requirements for the job. If the number of applicants is not too large, the information provided by applicants can be verified with reference and/or background checks.

2. Use extensive interviews and appropriate testing to determine which of the minimally qualified job candidates have the highest degree of the KSAs required by the job.

3. Make contingent offers to one or more job finalists as identified by step 2. Job offers may be contingent upon successful completion of a drug test or other forms of background checks. General medical exams can only be given after a contingent offer is made.

One viable strategy for arriving at a sound selection decision is to first evaluate the applicants on each individual attribute needed for the job. That is, at the conclusion of the selection process, each applicant could be rated on a scale for each important attribute based on all the information collected during the selection process. For example, one could arrive at an overall rating of a candidate's dependability by combining information derived from references, interviews, and tests that relate to this attribute.

Decision-making is often facilitated by statistically combining applicants' ratings on different attributes to form a ranking or rating of each applicant. The applicant

with the highest score is then selected. This approach is appropriate when a compensatory model is operating, that is, when it is correct to assume that a high score on one attribute can compensate for a low score on another. For example, a baseball player may compensate for a lack of power in hitting by being a fast base runner.

In some selection situations, however, proficiency in one area cannot compensate for deficiencies in another. When such a non-compensatory model is operating, a deficiency in any one area would eliminate the candidate from further consideration. Lack of honesty or an inability to get along with people, for example, may serve to eliminate candidates for some jobs, regardless of their other abilities.

When a non-compensatory model is operating, the "successive hurdles" approach may be most appropriate. Under this approach, candidates are eliminated during various stages of the selection process as their non-compensable deficiencies are discovered. For example, some applicants may be eliminated during the first stage if they do not meet the minimum education and experience requirements. Additional candidates may be eliminated at later points after failing a drug test or honesty test or after demonstrating poor interpersonal skills during an interview. The use of successive hurdles lowers selection costs by requiring fewer assessments to be made as the list of viable candidates shrinks.

EMPLOYMENT LAW AND COMPLIANCE

Employment law and compliance concerns the legal framework within which organizations must operate in their treatment of employees. Laws and regulations exist covering a wide range of human resource practices, including recruiting, hiring and firing, performance appraisal, compensation, health and safety, and labor relations. Employers must comply with a myriad of federal and state laws and regulations.

This article will focus on identifying and summarizing the major federal laws that comprise employment law. Exhibit 1 shows some of the more important federal employment laws. The exhibit is divided into four sections: anti-discrimination law, compensation law, health and safety law, and labor relations law. The sections that follow provide additional information on each of these areas, with special emphasis on anti-discrimination laws, which probably have a broad impact on the activities of employers.

ANTI-DISCRIMINATION LAWS

Anti-discrimination law has had a growing impact on U.S. businesses over the past five decades. The body of federal law has increased in size and complexity and developed into new areas since passage of the Civil Rights Act of 1964. Additionally, developments in Supreme Court doctrine have had an important impact on anti-discrimination law, prompting changes in judicial interpretation as well as responses from Congress that have led to further developments in anti-discrimination policy. Throughout this ongoing process, employers have been required to keep up with the current status of the laws, a task that is often complicated not only by the sheer size of the body of anti-discrimination law, but by uncertainties about court rulings and future legislative actions.

Title VII. Without a doubt, the most important anti-discrimination law is Title VII of the Civil Rights Act of 1964. Title VII was initially motivated by the U.S. government's desire to end workplace discrimination against African Americans, which was brought to national attention by the civil rights movement of the 1950s and 1960s. However, by the time the law was passed and signed into law in 1964, it had become a comprehensive workplace anti-discrimination law.

Title VII prohibits workplace discrimination on the basis of race, color, religion, national origin, and sex. Affected organizations must not discriminate in any employment decision or in regard to any term or condition of employment. Title VII applies to all U.S. organizations with fifteen or more employees, as well as labor unions and public sector employers. Only a few U.S. employers with more than fifteen employees are exempt from Title VII.

Exhibit 1
Sampling of Major Federal Employment Laws

Anti-Discrimination Laws	Major Provisions
Title VII of the Civil Rights Act 1964	Prohibits employment discrimination based on race, color, religion, national origin, and sex.
Age Discrimination in Employment Act 1967	Prohibits employment discrimination against applicants or employees aged 40 and older.
Americans with Disabilities Act 1990	Prohibits employment discrimination against qualified applicants or employees with a physical or mental disability.
Civil Rights Act 1991	Codifies the "adverse impact" theory of discrimination. Clarifies and strengthens rules for enforcement of the anti-discrimination provisions in Title VII.
Compensation Laws	
Fair Labor Standards Act 1938	Requires employers to pay a federal minimum wage to non-exempt workers. Requires employers to pay overtime pay to non-exempt workers.
Equal Pay Act 1963	Requires employers to pay men and women equally for doing substantially the same work, unless differences in pay are based on merit, quantity or quality of production, or any other factor other than sex.
Labor Laws	
Wagner Act 1935	Establishes the National Labor Relation Board. Lays out the framework for union organizing activities. Identifies and bans unfair management practices in regard to unionization.
Taft Hartley Act 1947	Identifies and bans unfair labor union practices in regard to union organizing efforts. Bans the closed shop and allows states to pass "right-to-work" laws that give workers the right to refuse to join a union. Allows the president to temporarily stop strikes that imperil the national interest.
Health and Safety Laws	
Occupational Safety and Health Act	Establishes general safety standards and standards for specific industries. Requires employers to record and report accidents that occur in the workplace. Lays out rules for federal workplace inspections and penalties for violations of the act.

Title VII was amended in 1972 by the Equal Employment Opportunity Act. This law strengthened the enforcement of Title VII, which up to that time had been largely ineffective in changing workplace practices. The Equal Employment Opportunity Commission, a quasi-independent federal government agency, is in charge of enforcing Title VII, as well as many other anti-discrimination laws.

Employees alleging workplace discrimination that falls under the purview of the EEOC must report the alleged discrimination to the EEOC or one of the state-level fair employment offices that exists in every state. The EEOC has the right to investigate claims of discrimination or to initiate investigations itself. Many times the EEOC will attempt to work out a solution with the affected organization, which may or may not involve an admission of guilt by the employer. If conciliation fails, the EEOC also has the right to bring class-action discrimination lawsuits against organizations on behalf of a "class" of employees who have allegedly suffered from discrimination.

If the EEOC's investigation does not reveal a strong case of discrimination, the agency can still issue a "right-to-sue" letter to a plaintiff, which gives that person the right to bring their charges of discrimination against an employer to state or federal court, whichever is appropriate in a given case. Some claims of discrimination filed with the EEOC do not have merit and the EEOC often issues findings to that effect—but such findings still do not prevent the individual plaintiff from filing his or her own lawsuit against an employer.

Civil Rights Act of 1991. In the late 1980s, the Supreme Court decided several employment discrimination cases that made it more difficult for employees to prove discrimination cases in court. Concerned about these cases, the U.S. Congress addressed several issues by passing the 1991 Civil Rights Act. This act modified some of the procedures and rights in discrimination cases and strengthened Title VII protections.

One of the major changes made by this act was the codification of the "disparate impact" theory of discrimination, which makes it easier for employees alleging discrimination to prove their case. Instead of requiring plaintiffs to prove discriminatory intent, the theory means that plaintiffs only have to show that there was a discriminatory effect. This act also allowed plaintiffs to have jury trials under some circumstances, instead of "bench" trials decided by a federal judge. Juries tend to be sympathetic to plaintiffs, particularly those suing large corporations, so this was a major victory for employees. Another major change was that Title VII protections were extended to certain types of organizations that had not been covered before (for example, the law extended the reach of Title VII to the federal government, which prior to passage had been exempt). Finally, the law banned the "race norming" of employment test scores.

Sexual Harassment. For many years, most discrimination claims filed under Title VII were race discrimination cases. However, with the advent of sexual harassment lawsuits in the late 1970s and 1980s, sex discrimination cases became quite common. Sexual harassment at the workplace is a long-standing problem, affecting working women, as well as many men. Sexual harassment came to light during the mid-1970s and has since gained a great

deal of national attention. The growing attention to the topic stems from a number of well-publicized events in the 1990s—the Clarence Thomas hearings, the 1991 Tailhook Convention where several women were severely harassed by naval pilots, and the accusations made by Arkansas state employee Paula Jones about then-governor Bill Clinton.

Sexual harassment is a form of sex discrimination and therefore violates Title VII of the Civil Rights Act. The number of sexual harassment complaints filed with the Equal Employment Opportunity Commission (EEOC) rose significantly throughout the 1990s, going from about 6,000 in 1991 to a peak of over 15,000 in 1997. That number held steady throughout the late 1990s and early 2000s, but it began to decline in the mid 2000s, and by 2007 was down to just over 12,000. However, this is still more than double the number in 1991. The majority of these complaints involve claims of unwanted physical contact, offensive language, sexual propositions, and socialization or date requests.

An employer should establish a written sexual harassment policy. The policy should specify grievance procedures by which employees can bring claims of harassment to management's attention. These procedures should provide employees with opportunities to bypass their supervisor if the supervisor is the one being accused. The company should also provide supervisory training that focuses on the legal definition of sexual harassment.

In addition to holding formal training sessions, top management should also meet with employees to emphasize management's strong commitment to keep the workplace free of harassment. The employer should also have investigative guidelines that maintain employee confidentiality. The EEOC recommends that a committee that consists of both men and women should investigate sexual harassment claims. Committee members should receive investigative training.

Age Discrimination in Employment Act. The federal government added to employment law with the passage of the Age Discrimination in Employment Act (ADEA) of 1967. This law prohibited discrimination in employment decisions on the basis of age, provided the person affected was between 40 and 70 years old. Initially, the law allowed mandatory retirement policies, but later amendments phased out and eventually prohibited mandatory retirement. The ADEA also contains specific guidelines for the operation of benefit, pension, and retirement plans.

The heart of the ADEA is the prohibition of discrimination in employment decisions on the basis of age. For many years, age discrimination suits have been more difficult to prove against organizations because the person alleging discrimination had to show that the employer had a specific intent to discriminate on the basis of age, that there was no other explanation for the employment decision other than age, and that there was a specific employer policy or procedures that was discriminatory. In short, the person had to prove what is called "disparate treatment" under employment law.

However, the Supreme Court decision in *Smith v. City of Jackson*, handed down in 2005, changed the interpretation of this law, allowing those alleging age discrimination to proceed under what is called the "disparate impact" theory of discrimination. This means that the person or persons alleging age discrimination would not have to prove discriminatory intent. Instead, the person would only have to show that some action by the employer had a disproportionately negative effect on workers age 40 and older. Once this was done, the employer would have the burden to show that the discriminatory action was job-related or consistent with business necessity. After the ruling was handed down, commentators remarked that this new interpretation would increase the instance of age discrimination suits and make it more likely for these suits to be successful; however, some legal scholars pointed out that this was not the case, and it has turned out that age discrimination suits have not significantly increased in number or success since the *Smith* ruling.

Americans with Disabilities Act. The Americans with Disabilities Act of 1990 (ADA) prohibits discrimination in any employment decision against qualified applicants or employees with a disability. It also requires employers to reasonably accommodate the disabilities of applicants and employees. The ADA applies to the same set of companies covered by Title VII.

Three definitions are key to understanding the ADA. First, is the definition of disability, which is any physical or mental impairment that prevents the person from engaging in a major life activity. Covered disabilities include both physical and mental impairments. The extent of the disabilities covered is one of the more controversial aspects of the law. Some conditions are specifically excluded from coverage, including pyromania and kleptomania.

A second key definition is that of qualification. Under the ADA, a person with a disability is qualified for a job if he or she can perform the essential functions of the job with or without accommodation. This means that the person does not have to be able to do every single duty of the job, if they are very minor, but that he or she must be able to perform the major responsibilities of the job.

A third important definition under the law is reasonable accommodation. A reasonable accommodation is one that does not cause an undue hardship on the employer. Undue hardship would be determined on a case-by-case

basis and would consider the cost and inconvenience to the employer of accommodating the disability.

The ADA has resulted in many disability discrimination complaints with the EEOC, as well as many lawsuits against employers. Although the law, like most, has had unintended consequences, its net effect appears to have been a positive one, as it seems to have increased opportunities for qualified, disabled workers.

The ADA has been a frequent target of criticism for allowing claims by people with only minor disabilities (such as chronic neck or back pain), for creating a group of professional plaintiffs who make a living out of suing non-compliant businesses, and for placing undue financial burdens on businesses to accommodate persons with disabilities. The Supreme Court has signaled its support of the ADA by ruling in a number of cases to uphold its provisions or apply them in challenged areas. One example, *Barden v. The City of Sacramento* (1999), involved applying the ADA to the construction of city sidewalks. The Supreme Court let stand a lower court ruling that sidewalks must be made accessible to persons with disabilities. In a 2005 case, the Supreme Court ruled that the ADA applied to employment on ships flying foreign flags if the businesses had headquarters in the United States. Given the direction of case law in this area, it seems likely that the Court will continue to take a supportive stand on the ADA.

COMPENSATION LAWS

Since the first minimum wage law was passed in 1938, the federal government has enacted a wide variety of compensation laws.

Fair Labor Standards Act. The most important compensation law is the Fair Labor Standards Act (FLSA), passed in 1938. This law provides the basic framework within which millions of U.S. workers are paid. These workers are called "non-exempt" workers. These workers are those who, by virtue of the type of jobs they hold, must be paid in accordance with the FLSA. Exempt workers, who are not covered by the law, are primarily executive, managerial, professional, and highly-paid technical workers.

Perhaps the most important provision of this law is the federal minimum wage provision. Because of this law, non-exempt workers must be paid a basic minimum wage. This wage has periodically been raised to higher levels. Non-exempt workers must also be paid overtime for hours worked in excess of a standard workweek, which in most industries is forty hours per week. The current federal minimum wage law is the Fair Minimum Wage Act of 2007, which gradually raises the minimum wage from its 1997 level of $5.15 per hour to $7.25 per hour by the middle of 2009; the 2007 increase to $5.85 was the first increase in the minimum wage in ten years.

A final provision of the act does not involve compensation directly, but the employment of minors. The law prevents the employment of minors in almost all jobs before the age of fourteen, and places fairly stringent restrictions on the employment of children between the ages of fourteen and eighteen.

Equal Pay Act. The Equal Pay Act (EPA) was passed in 1963 as an amendment to the FLSA. The Equal Pay Act requires a single employer to pay men and women equally for doing "substantially" the same job for the employer. An employer is allowed to pay men and women differently if the difference is based on merit, quantity of production, quality of production, or any other factor other than gender. Thus, the law does not mean that men and women doing the same work can't be paid differently, only that the difference must not be based on the sex of the worker.

Since the passage of the EPA, women's pay as a percentage of men's pay has risen significantly, from 62 percent in 1970 to 80 percent in 2004. Because the EPA's goals have not been fully achieved, Senator Hillary Clinton introduced the "Paycheck Fairness Act" in 2007. This proposed law would expand damages under the EPA, amend one of the very broad defenses of unequal pay available to employers, and call on the EEOC to propose guidelines for employers to evaluate jobs in order to eliminate unfair gender disparities.

LABOR RELATIONS LAWS

The National Labor Relations Act of 1935, known popularly as the Wagner Act, was the first law to provide a full framework within which labor union and management would interact in the United States. This act guaranteed workers' basic right to organize and created the National Labor Relations Board to oversee union-management relations. It also provided for an election process for unionization efforts in U.S. businesses, and it prohibited five major "unfair labor practices" on the part of U.S. employers.

The Wagner Act was amended and reduced in power in 1947, when Congress enacted the Taft-Hartley Act over President Harry Truman's veto. This act is still in effect. Whereas the Wagner Act was "pro-labor" in its effect, the Taft-Hartley Act was most decidedly "pro-business" in its provisions. Most significantly, Taft-Hartley laid out several "unfair practices" of labor unions and banned them. It also gave the president authority to issue an injunction temporarily stopping a strike, if the strike is deemed to be causing a threat to national security or creates an emergency detrimental to the national interest.

Another important provision banned the union security arrangement known as the closed shop. In a closed shop, individuals must belong to the appropriate union before they can be hired by a company. This arrangement is now

banned in all but a handful of situations. The act also gave the states the right to pass what are called "right-to-work" laws, which create "open shops." An open shop exists when no individual can be compelled to join a union before or after they are hired, even if the employer's workforce is organized. Labor unions typically object to open shops, as they make it difficult for unionization efforts to succeed. Twenty-two states, mostly located in the South, Southwest, and Great Plains regions, are "right-to-work" states.

HEALTH AND SAFETY LAWS

The primary law relating to the health and safety of U.S. workers is the Occupational Safety and Health Act, passed in 1970. This law is controversial because it imposes very complex and detailed safety standards on thousands of U.S. businesses. The Occupational Safety and Health Administration (OSHA) was created to administer and enforce the law.

OSHA has general safety standards for almost all employers and specific standards for certain industries. It has workplace inspectors who have the right to, with a search warrant, inspect the conditions in almost any business in the United States. OSHA has the right to respond to employee complaints of unsafe conditions and in fact, the highest priority for OSHA inspections are those situations that pose an imminent threat to the health and safety of workers.

OSHA has the power to impose penalties on employers who violate its provisions. The severity of the penalties will vary based on the seriousness of the violation, a first or repeat offense, the cooperation of the business, and the size of the business. Although many U.S. companies do not like dealing with OSHA, it does appear that the law and its enforcement has resulted in improvements in the health and safety conditions in U.S. businesses.

OTHER MAJOR LAWS

The Family and Medical Leave Act. The Family and Medical Leave Act (FMLA) of 1993 requires all employers with fifty or more employees to grant workers up to twelve weeks of unpaid leave per year for the care of a newborn child, an ill family member, or their own illness. Employees may take the leave all at once or in increments.

While it helps employees, the FMLA can be quite costly to employers when they must replace workers on leave. Because women are more likely to use these leaves, companies that employ a majority of women are especially hard-hit. Consider the case of Sibley Memorial Hospital of Washington, D.C.: The hospital ran into difficulty when trying to replace an employee on leave. Because she worked in an extremely specialized position, the hospital could not find a replacement locally. In addition to paying the on-leave employee's medical benefits, Sibley had to pay for the replacement worker's round-trip airfare, weekly housing, car rental, and salary. At the end of the original employee's leave, she informed the hospital that she would not be returning to work.

The FMLA protects employers from this type of problem in two ways: (1) it allows employers to exempt workers with highest earnings, and (2) it requires employees to reimburse the employer for insurance premiums paid during the leave if they are able to return to work, yet choose not to do so. While Sibley Memorial Hospital was not able to utilize the first protection (the employee's salary was not among the top 10 percent), it was reimbursed for its insurance payments.

Employee Privacy Laws. Privacy has become one of the most important workplace issues of the twenty-first century. Privacy concerns surface at the workplace when organizations attempt to collect and/or disseminate information about employees in ways that intrude upon their privacy. Privacy issues also surface when employee behavior is constrained by certain workplace rules and policies, denying employees the right to be "let alone," or to do as they please.

Employees may justifiably lodge an invasion of privacy claim if the information collected by an employer is irrelevant to the employer's business needs. A company should have a clear business reason for each piece of information collected and maintained on an individual. For example, a company should not collect information about an employee's spouse unless that information is needed for benefits administration or some other useful purpose.

As a general rule, information pertaining to such personal issues as home ownership, previous marriages, sexual orientation, parents' occupations, and previous arrest records are usually of no concern to employers, and efforts to collect such information could pose legal threats to the company.

Privacy Act. Should employees have access to data kept on them? According to the Privacy Act of 1974, public-sector employees must be given access to any information in their files. Specifically, the act states that employees have the right to:

- Determine what information is being kept on them by their employers.

- Review that information.

- Correct erroneous information.

- Prevent the information from being used for a purpose other than that for which it was collected.

An important limitation to the Privacy Act was enacted in 2007, when President Bush exempted the Department of

Homeland Security and the Arrival and Departure System from the provisions of the act. While the Privacy Act does not cover private-sector employees or non-U.S. citizens, most companies do allow employees to access to their own records as a good employee-relations gesture. Prohibiting employees from seeing their own files may create doubts and suspicions regarding the company's good faith efforts to create business-relevant personnel files.

EMPOWERMENT

The primary goal of employee empowerment is to give workers a greater voice in decisions about work-related matters. Their decision-making authority can range from offering suggestions to exercising veto power over management decisions. Although the range of decisions that employees may be involved in depends on the organization, possible areas include: how jobs are to be performed, working conditions, company policies, work hours, peer review, and how supervisors are evaluated.

Many experts believe that effective use of employee empowerment can allow organizations to increase productivity. This occurs in two ways. First, empowerment can strengthen motivation by providing employees with the opportunity to attain intrinsic rewards from their work, such as a greater sense of accomplishment and a feeling of importance. In some cases, intrinsic rewards such as job satisfaction and a sense of purposeful work can be more powerful than extrinsic rewards such as higher wages or bonuses. Motivated employees clearly tend to put forth more effort than those who are less motivated. Second, employee empowerment can increase productivity through encouraging better decision-making skills. Especially when decisions require task-specific knowledge,

those on the front line can often better identify problems, particularly when they are empowered to do so.

Empowering employees to identify problems, combined with higher-level management involvement in coordinating solutions across departmental boundaries within the firm, can enhance the overall decision-making process and increase organizational learning. For example, Toyota Motor Company empowers some of its employees to identify and help remedy problems occurring during product assembly. An automobile coming off Toyota's assembly line with a paint defect is seen as an opportunity to delve into the root cause of the defect, as opposed to merely fixing the defect and passing it on to distributors for resale. Solutions resulting from employee involvement tend to have more employee buy-in when it comes to implementation. Because such solutions are generated from the front lines, this further enhances the potential for productivity improvements by reducing the attitude that solutions are "passed down from above."

A number of different human resource management programs are available that grant employee empowerment to some extent. A number of these are discussed in the following sections, including informal participative decision-making programs, job enrichment, continuous improvement, and self-managed work teams.

INFORMAL PARTICIPATIVE DECISION-MAKING PROGRAMS

Informal participative decision-making programs involve managers and subordinates making joint decisions on a daily basis. Employees do not enjoy blanket authority to make all work-related decisions; managers decide just how much decision-making authority employees should have in each instance. The amount of authority varies depending on such situational factors as decision complexity and the importance of employee acceptance of the decision. While it may seem obvious, one key to empowerment is choosing under what conditions to empower employees. Employees should be empowered in situations where they can make decisions that are as good as, or better than, those made by their managers.

One possible problem with these types of programs is that the interests of workers may not align with those of the organization. For example, at one university a department head delegated the task of determining job performance standards to the faculty. Because the faculty believed that it was not in their own best interest to develop challenging standards, the standards they eventually developed were easily attainable. The success of empowerment also often hinges on whether employees want to participate in decision making. Some employees, for instance, have no desire to make work-related decisions. Suggestions for increasing employee participation levels include work situations where:

1. All possible solutions are equally effective. For example, consider employee vacation schedules. If one solution is as good as another, employee groups can be empowered to work out the scheduling.

2. Managers do not possess sufficient information or expertise to make a quality decision without employee input. Managers should at least consult their employees before a decision is reached to prevent overlooking solutions that may appear obvious to front-line employees, but which may be more evasive for higher-level managers who are unfamiliar with front-line practices.

3. Managers do not know exactly what information is needed or how to find it. Again, managers should at least consult their employees before a decision is reached to determine whether employees have the information required to make an effective decision.

4. The group's acceptance of, or commitment to, effective implementation is crucial and the group is unlikely to accept a manager's unilateral decision. If employees' acceptance is crucial, participative decision-making should be used. As alluded to previously, employees tend to accept decisions more willingly if they have had a voice in the decision-making process. One caveat is that the participation should be genuine; managers should not ask for employee input simply to give the appearance of participation. Employees can usually recognize this ploy and, if they do, feelings of distrust will likely develop.

5. Employees' goals are aligned with those of management. If employees do not share management's goals, participative decision-making would be inappropriate, because the two parties would be at odds.

Several studies have examined the effects of informal participative decision-making programs. While the results have been mixed and thus cannot be considered definitive, most studies have found that informal participative decision-making programs do, in fact, have a positive impact on productivity.

JOB ENRICHMENT

Sometimes, employees are not motivated because of the way their jobs are designed. For example, consider the job of an assembly-line worker who does nothing but place a screw in a hole as the product passes by on the production line. Such a job provides little opportunity for workers to gain intrinsic rewards. Job enrichment aims to redesign jobs to be more intrinsically rewarding. Certain job characteristics help managers to build enrichment into jobs. These characteristics (summarized in Exhibit 1) include:

Exhibit 1

Job Characteristics That Enhance Intrinsic Motivation

1. Skill Variety: The degree to which a job requires a variety of different activities to carry out the work. A job has high skill variety if it requires a number of different skills and talents.

2. Task Identity: The degree to which a job requires completion of the whole and identifiable piece of work. A job has high task identity if the worker does the job from the beginning to end with a visible outcome.

3. Task Significance: The degree to which the job has a substantial impact on the lives of other people, whether these people are in the immediate organization or in the world at large. A job has a task significance if people benefit greatly from results of the job.

4. Autonomy: The degree to which the job provides the workers with autonomy. A job has high autonomy if workers are given substantial freedom, independence, and discretion in scheduling the work and determining the procedures to be used in carrying it out.

5. Job Feedback: The degree to which the job provides the worker with knowledge of results. A job has high job feedback if carrying out the work activities required by the job provides the individual with direct and clear information about the effectiveness of his or her performance.

- **Skill variety.** The various skills needed to perform a given task, where increased skill requirements are associated with increased motivation.

- **Task identity.** The degree to which employees perceive how their job impacts the overall production of a product or service.

- **Task significance.** Whether the task is meaningful beyond the task itself.

- **Autonomy.** Employee discretion over how to perform a task.

- **Feedback.** Input from peers and supervisors regarding the quality of an employee's work.

When these characteristics are present in a job, employees tend to be more motivated than when these characteristics are not present. However, there is not a "silver bullet" for motivating employees through empowerment; there is considerable variation in the degree to which each of these empowerment factors motivates individuals. On the other hand, it is a mistake to think that because certain individuals do not respond equally to such job designs that overall productivity will not increase as a result of empowerment through proper job design and enrichment. In general, productivity tends to increase despite the inherent variation of specific effects.

Once a job has been identified as needing enrichment, the organization must redesign it to incorporate these characteristics: skill variety, task identity, task significance, autonomy, and feedback. Some specific job enrichment techniques include:

- **Combine tasks.** This involves assigning tasks performed by different workers to a single individual. For example, in a furniture factory, rather than working on just one part of the production process, each person could assemble, sand, and stain an entire table or chair. This change would increase skill variety, as well as task identity, as each worker would be responsible for the job from start to finish.

- **Establish client relationships.** Client relationships could be established by putting the worker in touch with customers. For example, an auto dealership service department could allow its mechanics to discuss service problems directly with customers, rather than going through the service manager. By establishing client relationships, skill variety is increased because workers have a chance to develop interpersonal skills. It also provides them with a chance to do a larger part of the job (task identity), to see how their work impacts customers (task significance), and to have more decision-making authority (autonomy).

- **Reduce direct supervision.** Workers gain autonomy when they are given responsibility for doing things previously done by supervisors. For instance, clerks could be allowed to check for their own errors or be allowed to order supplies directly.

A variation of this type of employee empowerment is illustrated by freight transportation company Con-way Inc. In May 2008, Con-way launched a "driver career choice" program, in which drivers were informed of open positions at sister companies before the jobs were officially advertised to the public. Thus the employee experience was enriched via a reduction of direct supervision, i.e., access to information that would have normally been handled solely by the management. While this program benefited the drivers by giving them greater autonomy to direct their careers, it also benefited the management by automatically creating a pool of experienced job candidates.

Many organizations have successfully enriched otherwise dull jobs, thereby empowering employees to have greater control over their work and the decisions affecting them. In addition to increased productivity, empowerment also may lead to improvements in product or service quality, reduced absenteeism rates, and increased employee retention. In situations where enriched jobs become less automated, however, production may become less efficient. Job enrichment would thus be ill-advised in situations where the loss in efficiency cannot be offset by productivity gains stemming from increased motivation. Moreover, employees preferring highly automated, easy jobs are likely to oppose job enrichment efforts.

CONTINUOUS IMPROVEMENT

Companies adopting continuous improvement attempt to build quality into all phases of product or service design, production, and delivery. Often referred to as total quality management, these programs empower workers to trace product or service problems to their root causes and redesign production processes to eliminate them using various problem-solving and statistical techniques. In these situations, empowerment arises from the need to involve employees at nearly all organizational levels in continuous improvement efforts. The use of continuous improvement programs have grown rapidly, built on the successful experiences of numerous companies. Xerox, for example, was able to decrease the number of customer complaints it received by 38 percent after implementing continuous improvement methods, and Motorola reduced the number of defects in its products by 80 percent. Proponents of self-managed work teams claim they succeed because they are customer-focused and promote sound management practices like teamwork, continuous learning, and continuous improvement.

SELF-MANAGED WORK TEAMS

Self-managed work teams have the authority to manage themselves. Rather than having managers control their work, self-managed work teams incorporate group norms to regulate activities. They plan, organize, coordinate, and take corrective actions. Some can hire, fire, and discipline team members with little intervention from higher levels of management. In short, self-managed work teams are given responsibilities usually held by managers, but control comes from the concerted influence of the team rather than from more formal means. Not surprisingly, managers' jobs are minimized and group norms are maximized when self-managed work teams are used. Self-managed work teams are not for all organizations; characteristics needed for success include:

- **Technical skills.** Cross-training, which allows team members to move from job to job within the team, is essential. Thus, team members should receive training in the specific skills that will broaden their personal contributions to the overall effort.

- **Interpersonal skills.** Team members must communicate effectively, both one-on-one and in groups. Cooperative decision-making within and among teams demands the skills of group problem solving, influencing others, and resolving conflicts. Team members must learn problem-solving skills that assist in zeroing in on problem areas, gathering facts, analyzing causes, generating alternatives, selecting solutions, and other related facets.

- **Administrative skills.** Self-managed work teams must perform tasks formerly handled by supervisors. The team must learn how to keep records, report procedures, budget, schedule, monitor, and appraise the performance of team members.

Research findings concerning self-managing teams have been largely positive. Proponents claim that self-managed work teams are effective because they empower employees to make decisions that affect their day-to-day business lives. Thus, these teams radically change the way that employees value and think about their jobs. Other benefits associated with self-managed teams include greater flexibility to respond to market changes and competitive pressures.

However, there are a number of drawbacks. As noted previously, self-managed teams are not for every organization. Some may be better served by other ways of empowerment, rather than the dramatic empowerment seen with self-managed teams. Drawbacks can include:

- Rivalry within and across teams.

- A shortage of time and skills on the team to deal with conventional management concerns like hiring, training, and resolving interpersonal disputes.

- Difficulty appraising employees in the absence of a traditional management figure.

In addition to these concerns, one of the most difficult issues companies face with self-directed work teams is deciding how to effectively implement them. A number of obstacles must be overcome. Sometimes, managers are reluctant to relinquish control and employees are reluctant to accept new responsibilities. To prepare team members for self-management, the organization must provide a considerable amount of training. Without proper training, teams are likely to become bogged down permanently in mid-process.

As the previous discussion suggests, empowerment is not a single event or process, but rather takes a variety of forms. The degree of empowerment ranges from asking employees for input to allowing total discretion. Informal participative decision-making programs, job enrichment, continuous improvement, and self-managed work teams are some of the ways that organizations empower employees, giving them more control, but at the same time increasing overall organizational productivity.

ENTERPRISE RESOURCE PLANNING

Enterprise resource planning (ERP) refers to a computer information system that integrates all the business activities and processes throughout an entire organization. ERP systems incorporate many of the features available in other types of manufacturing programs, such as project management, supplier management, product data management, and scheduling. The objective of ERP is to provide seamless, real-time information to all employees throughout the enterprise. Companies commonly use ERP systems to communicate the progress of orders and projects throughout the supply chain, and to track the costs and availability of value-added services.

ERP systems offer companies the potential to streamline operations, eliminate overlap and bottlenecks, and save money and resources. However, ERP systems are very expensive and time-consuming to implement, and surveys have shown that not all companies achieve the desired benefits. According to the online business resource *Darwin Executive Guides*, it is "a tall order, building a single software program that serves the needs of people in finance as well as it does the people in human resources and the warehouse...To do ERP right, the ways you do business will need to change and the ways people do their jobs will need to change too. And that kind of change doesn't come without pain."

EVOLUTION OF ERP

ERP is a part of an evolutionary process that began with material requirements planning (MRP). MRP is a computer-based, time-phased system for planning and controlling the production and inventory function of a firm—from the purchase of materials to the shipment of

finished goods. It begins with the aggregation of demand for finished goods from a number of sources (orders, forecasts, and safety stock). This results in a master production schedule (MPS) for finished goods. Using this MPS and a bill-of-material (a listing for all component parts that make up the finished goods), the MRP logic determines the gross requirements for all component parts and subassemblies. From an inventory status file, the MRP logic deducts the on-hand inventory balance and all open orders to yield the net requirements for all parts. Then all requirements are offset by their lead times to provide a date by which an order must be released in order to avoid delaying the production of finished goods.

From this MRP logic evolved manufacturing resource planning (MRP II). Before MRP II, many firms maintained a separate computer system within each functional department, which led to the overlap in storage of much of the firm's information in several different databases. In some cases, the firm did not even know how many different databases held certain information, making it difficult, if not impossible, to update it. This could also cause confusion throughout the firm if different units (such as engineering, production, sales, and accounting) held different values for the same variables. MRP II expands the role of MRP by linking together such functions as business planning, sales and operations planning, capacity requirements planning, and all related support functions. The output from these MRP II functions can be integrated into financial reports, such as the business plan, purchase-commitment report, shipping budget, and inventory projections. MRP II is capable of addressing operational planning in units or financial planning in dollars, and has a simulation capacity that allows its users to analyze the potential consequences of alternative decisions.

The next step in the evolutionary process was enterprise resource planning (ERP), a term coined by the Gartner Group of Stamford, Connecticut. ERP extends the concept of the shared database to all functions within the firm. Like MRP II systems, ERP systems rely on a common database throughout the company with the additional use of a modular software design that allows new programs to be added to improve the efficiency of specific aspects of the business. By entering information only once at the source and making it available to all employees, ERP enables each function to interact with one centralized database and server. This eliminates not only the need for different departments within the firm to reenter the same information over and over again into separate computer systems, but also the incompatibility that was created by past practice.

FEATURES OF ERP

ERP is a hybrid of many different types of software, incorporating many of the features available in other programs. ERP provides a way to keep track of materials, inventory, human resources, billing, and purchase orders. It is also useful for managing various types of orders, from mass-customized orders where daily or weekly shifts occur within the plant or multiple plants, to products that are made-to-stock, made-to-order, or assembled-to-order.

Higher-level ERPs employ design engineering and engineering change control modules. These modules facilitate the development of new product-engineering information and provide for modification of existing bills of material, allowing engineers to support working models of items and bills of material prior to their production releases.

It is important to understand that ERPs are not cheap to implement and operate, nor can they be implemented overnight. Owens-Corning spent more than $100 million over the course of two years installing one of the most popular ERP systems, SAP AG's R/3 system. Microsoft spent $25 million over 10 months installing R/3. Chevron also spent $100 million on installation. Apparently, however, the benefits of ERP implementation and use can be enormous. Microsoft used its ERP system to replace thirty-three different financial tracking systems used in twenty-six of its subsidiaries, with an expected savings of $18 million annually. In the same respect, Chevron expected to recoup its $100 million investment within two years.

Owens-Corning's aim was to offer buyers one-stop shopping for insulation, pipes, and roofing material. Use of the R/3 facilitated this goal by allowing sales representatives to quickly see what products were available at any plant or warehouse. Analog Devices use the R/3 to consolidate the products stored at its warehouse, thereby creating an international order-processing system that can calculate exchange rates automatically.

ERP AND SUPPLY CHAIN MANAGEMENT

When ERP systems first appeared, they acted as the connection between front-office operations (e.g., sales and forecasting) and the day-to-day functions of manufacturing. As ERP technology has advanced, the systems have increasingly incorporated logistics and warehousing capabilities, further connecting them with the supply chain. Some ERP systems offer Internet functionality, which can provide real-time connectivity from suppliers to the end customer.

The result of ERP use is more than an automation of existing processes—it is a significantly new way of doing business that enables a firm to respond to market changes more rapidly and efficiently. This can apply to service firms as well as manufacturers. Many ERP packages also let the user track and cost service products in the same way they compute the cost of making, storing, and shipping physical products.

RECENT DEVELOPMENTS

The same technological advances that made MRP, MRP II, and ERP more useable and powerful have led to the improvement of other systems with similar purposes, such as lean manufacturing and just-in-time (JIT) production. ERP has been challenged in recent years by improvements in these other areas, with some firms coming to see ERP systems as obsolete. However, research has found that in certain environments with advance demand information, ERP systems yield better performance than their competitors. In 2007, author Phil Robinson noted that "when properly implemented, an ERP package can be the most cost-effective project a company has ever seen."

Others note that MRP and EPR systems are so entrenched in businesses that they no longer provide a source of competitive advantage, necessitating further advances in these systems' use. In 2005, the authors of *Manufacturing Planning and Control for Supply Chain Management* pointed out that sustaining competitive advantage would require that manufacturing planning and control (MPC) systems cross organizational boundaries to coordinate company units that have traditionally worked independently. Calling this the "next frontier" for manufacturing planning and control systems, they recommended that organizations should begin working in pairs or dyads to develop jointly new MPC systems that would allow integrated operations. This approach would allow organizations to learn as much as possible from each dyad and then leverage what they have learned into other dyads.

ENTREPRENEURSHIP

Entrepreneurship is the process of identifying opportunities, marshalling the resources needed to take advantage of the opportunities, and creating a new venture for the purposes of providing needed products or services to customers and achieving a profit. The word "entrepreneurship" is taken from the French word *entreprendre*, which means "to undertake." A person who engages in entrepreneurship is called an entrepreneur. Entrepreneurship occurs all over the world, but it is a particular characteristic of free-market economies. Countries with the highest rates of entrepreneurship include the United States, Canada, Israel, Italy, and Great Britain.

Entrepreneurship involves considerable risk, as the failure rate for new ventures is very high. Thus, to be successful, an entrepreneur must be able to tolerate and even thrive under conditions of risk and uncertainty. Successful entrepreneurship also requires innovativeness and creativity, as well as self-confidence, high levels of energy, and a strong need for achievement. Interest in entrepreneurship is at an all-time high. Most colleges and universities offer courses or even entire programs of study in entrepreneurship.

The process of entrepreneurship is complex and requires the aspiring entrepreneur to make many decisions. It begins with recognizing an opportunity and applying innovativeness and creativity to exploit the opportunity. The entrepreneur must engage in strategic thinking and identify a competitive advantage that will set the small business apart and provide customers a unique reason to patronize the business.

The outcomes of this strategic thinking should be a business plan, which is a written statement that provides a comprehensive blueprint for the new venture. Although every business plan should reflect the unique characteristics of the entrepreneur and the proposed new business, there are common elements that exist in most business plans. Typically, the business plan includes some or all of the following components:

- Executive Summary
- Description of the Firm's Product/Service
- Business Strategy
- Forecasted Financial Statement
- Loan or Investment Proposal

The executive summary provides a concise one to two page overview of the entire business plan. The description of the product or service should identify the key features and benefits of the product or service. The business strategy is the most detailed part of the business plan. Here, the plan provides the entrepreneur's vision and what he or she sees as the mission of the new venture.

This section must also lay out key strategies in the areas of operations, marketing, and finance. The forecasted financial statements should include monthly and/or quarterly projected cash budgets, income statements, balance sheets, and capital expenditures. The loan or investment proposal should identify the type of financing required and a plan for repayment.

Entrepreneurship is an important, if not the most important, component of a successful market-based economy. Free economies require individuals who are willing to take risks by creating, organizing, and successfully running new businesses. Most entrepreneurs operate in the areas of small business and/or family-owned business. These are the engines of economic growth. If small businesses are defined as those having fewer than 100 employees, 99 percent of businesses in the U.S. are small. Ninety percent of these small businesses employ fewer than twenty employees. Yet, it is estimated that small businesses have created 85 percent of the new jobs in the U.S. since the early 1990s. Further, most of these small businesses are family-owned. Family-owned businesses employ more than 50 million people and generate more than 50 percent of the nation's GDP. Thus, much emphasis is placed on public policies that will encourage entrepreneurial activity and nurture and sustain new ventures, small businesses, and family-owned businesses.

STARTING A BUSINESS

Once the business plan has been formed, the entrepreneur must find investors, form a business structure both legally and economically, and bring together employees with the necessary skills and tenacity to run a successful business around a common goal. These steps, especially those requiring financial backing, can be difficult for entrepreneurs. Professor Scott Shane, author of the 2008 article "Top Ten Myths of Entrepreneurship," writes about some of these difficulties and few of the common misconceptions among those trying to start businesses.

First, it does not take a large amount of money to begin a business. The average amount is about $25,000, and successful entrepreneurs will have the skills necessary to run a company with a low amount of funding. Some of the tricks include paying beginning employees on commission, renting premises for the first couple of years, and offering conditional benefits. There are rarely large investors willing to fund starter businesses, unless they are promising computer or science companies. Most investors are not million dollar venture capitalists, and good entrepreneurs know how to work with limited resources.

Other entrepreneurs are hesitant to begin their businesses with debt, afraid that it will impede success. Actually, most entrepreneurial businesses are financed primarily by debt, with a little less than half their money coming from equity (approximately 47%). Conventional wisdom also insists that entrepreneurs search for loans among their friends, families, interested investors, and government entities, using banks only as a last resort. Banks, however, are the most common provider of loans toward entrepreneurial activities, and they are often willing to consider promising business plans.

The business an entrepreneur picks has an enormous effect on the success of his or her idea. Most entrepreneurs have difficulty spotting and entering industries that have potential. Those who began businesses in the tech industry several years ago had a far better chance of succeeding than those who chose other industries. What will be the industries of the future? What markets will open? A good entrepreneur will be able to choose an industry with potential, which will take a continuing commitment. Professor Shane's article says that only the top 10 percent of entrepreneurs make more money than their employees. The key is to defy the odds with superior innovation and work.

INTERNATIONAL ENTREPRENEURSHIP

International entrepreneurship refers to the practice of using technology and insight to develop an overseas company by highlighting a need in foreign nations that the entrepreneur can fulfill. Foreign markets have particular resources that an entrepreneur can capitalize on, making use of differing cultures, financial regulations, economies, and desires to create a successful global business. Most international entrepreneurship is conducted by well-established companies that have sufficient funds or backers to attempt expanding into foreign markets. Fortunately, more investors are becoming willing to support a global endeavor, especially if a company has clear plans to fill a specific niche in international business. Like local entrepreneurship, international business-building is a matter of opportunities and design.

Once a new element is introduced into a foreign market, there is a period of adaption that takes place in increments. An international market might at first be unwilling to admit a new entrepreneurial business, requiring more time for trial and acceptance of products or services. The number of other businesses trying to sell the same new ideas and the type of international market being entered will also affect the trial period for the entrepreneurial endeavor. Generally, entrepreneurs will encounter three different types of markets globally, as described by Jones and Dimitratos in their 2004 book *Emerging Paradigms in International Entrepreneurship*:

- **Bazaar economies.** Bazaar economies function on a flexible, personal level. Prices are usually negotiated, and competition involves cooperating with others in the same industry to form a reliable network of businesses. Loyalty is often based on personal treatment, customer to customer.

- **Firm-type economies.** In these markets, similar to many of the markets in America, firms have much more control over goods and services. Prices are usually set by the firms or the industry. They are based on customer demand but are not negotiable, and transactions are impersonal, resembling legal contracts more than personal connections. Since relationships are not so important, competition is generally more vigorous and direct. Complex strategy and business plans are commonplace in firm-type economies. Loyalty is generally directed toward a product or a name brand, and not the companies creating or selling the product. Decision-making power, instead of being displaced on a person-to-person basis, is centrally located at a main office.

- **Multi-polar network economies.** These markets are systems that incorporate both personal and transactional styles in their business. Relationship marketing is conducted, where companies form lasting connections with customers. Prices are usually negotiated in these markets, but not always. Relationship networks affect competition and decision-making, but at a wider scale than person-to-person. Power is not held by any main office, but is distributed along the relationship network of the business.

SOCIAL ENTREPRENEURSHIP

Social entrepreneurship, like international entrepreneurship, has risen in popularity over recent years. It involves developing unique ideas, usually from a business standpoint, to solve social problems. Often social entrepreneurs can create practices that revolutionize industries and create very successful companies, but the goal is always social welfare. Social entrepreneurs tend to judge success in terms of "social value" rather than the income generated by a business. They look for ways in which their society needs aid or needs a particular problem solved, then work to solve the problem in the same way a traditional entrepreneur does. A social entrepreneur deals with social potential, and seeks to create lasting change for the better.

Examples of social entrepreneurship abound. Medical practices centering around helping the patient achieve responsibility for their own health and treatment by teaching them about their ailments is a successful form of entrepreneurship begun in World War II by doctors like Byrnes Shouldice. Another good example is strategies for police departments to deal with criminal behavior with new, results-oriented methods. Community programs designed to bring out talents in at-risk youth or help senior citizens become more independent function in the same way.

When considering a social enterprise, an entrepreneur must first decide what sort of business to create—nonprofit or for-profit. Nonprofit businesses find it easier to focus on the social endeavor, attract the right-minded employees, and effectively market their purpose without sounding pretentious. Nonprofit organizations also receive more donations, especially from taxpayers who can write off the donation. For-profit businesses, on the other hand, can often make a better profit, raise more money through investors and stockholders who are willing to keep the business focused on its social goals, and create more opportunity for growth than nonprofit organizations. Which type of business to construct is one of the first questions a social entrepreneur should ask when sitting down to outline the plan.

ELEVATOR PITCH

Many entrepreneurial businesses can hinge on very brief—even chance—proposals to investors, ventures capitalists, and banks. These short proposals have become so useful and widespread that they are referred to as *elevator pitches*, the name drawn from a scenario in which an entrepreneur encounters a high-ranking business executive or capitalist in an elevator, and has only the time both are in the elevator to make the pitch and win the necessary investment.

So, how does an entrepreneur form a perfect elevator speech? Professor Jack Raiton, in his 2007 article, "Mastering the Elevator Pitch," has several good pieces of advice:

- An elevator pitch should not be directed at making a sale. That is a lot to shoot for in a very short amount of time. Instead, the pitch should be designed to pique interest, to give valuable tidbits of information, and to secure some sort of return communication. A successful entrepreneur will win an e-mail, phone call, or interview after an elevator pitch.

- The problem or need the entrepreneur intends to solve should be presented in the elevator pitch. This should be explained in concise, vivid language.

- Since attention spans are not notably long, an elevator pitch should sound interesting—about 30 seconds of spontaneous, memorable conversation. "Spontaneity" can be achieved through extensive practice, rehearsing the speech until it flows naturally and sounds unstilted. A script and a mirror both help prepare for a good elevator pitch.

- The pitch should include the particular advantages the entrepreneur can offer, wrapped up in a nutshell. The title to a book is a good metaphor to apply. The title should be clear, explain the abilities and status of the book, and not run on all over the cover—neither should the elevator speech.

- Nothing complex should be included in an elevator pitch. If it can be simplified, simplify it. Otherwise, do not include it. An idea that is too complex can ruin the entire pitch.

The structure of the elevator speech can be formed using the guidelines above. There are many other tips entrepreneurs may find useful as well. It is a good idea, for instance, to begin by giving a statistic or other arresting fact concerning the pertinent industry, introducing the problem or general situation immediately. Technical or scientific language, in any form, should be avoided in the pitch; even though it may impress, the use of unfamiliar terms ultimately confuses and bores any investor listening. Contacts can also be used in elevator pitches to catch attention, whether it be the dropping of a significant name or previous work experience at a prestigious company. The most important thing is that the entrepreneur feels comfortable and excited giving the pitch under any circumstances.

ANGELS

Business angels are resourceful investors who have a medium amount of capital available to contribute to starting businesses and are known to save or start entrepreneurial endeavors. They are not as difficult to find or win over as the major-investment venture capitalists, and so much of an entrepreneur's selling efforts are directed toward angels. Angels can exist individually and as part of sponsoring networks.

As a way of life, entrepreneurship has several advantages. It offers individuals the chance to be their own boss and to enjoy an independent lifestyle. It provides individuals the opportunity to develop and grow a new business that makes an impact on their community. And, of course, successful new ventures offer the tantalizing prospect of almost unlimited profit potential. However, as a lifestyle, entrepreneurship also has its downside. It requires a tremendous amount of personal commitment and long work hours, particularly in the early stages of new business startup. Uncertainty of income and the potential for financial loss are also potential negatives.

ENVIRONMENTALISM AND SUSTAINABILITY

The importance of the environment and how to preserve it have become as much a priority for corporations as for individual citizens. "Going green" is not only the socially accountable thing to do, it is also one of the most progressive new ways that companies are winning over new clients and saving more money than ever before. Interestingly, doing the right thing for the environment is now, more than ever, a win-win game for stakeholders, business owners, and consumers alike.

Environmentalism on the corporate scale has become a good deal more organized as its importance to the future and sustainability of the planet becomes paramount. Learning how to manage entire corporations and all aspects of their operation in a manner that will be eco-friendly is no longer the exception but the rule. How to manufacture goods and offer services using greener methodologies is the future of business on all fronts and will shape the future of commerce as much as any other crucial marketplace variables.

FINANCIAL BENEFITS OF GOING GREEN

For many corporate entities, the idea of changing practices to become a more environmentally friendly operation isn't enough to commit the resources and time to change practices or completely revamp company policies that are often decades old. But as "greening up" becomes the lasting trend, it shapes the climate of the commercial world; companies that live up to a higher environmental standard will attract a new majority of consumers who

care. Saving money and creating larger profit margins are an added benefit to new, more ecologically sound business and manufacturing practices.

Revenue is increased by simple increase of value. Both consumers and stakeholders see the value of a corporation increase as their practices become more in line with current and future trends and move away from antiquated methods and practices that give a company a reputation for being old-fashioned or behind the times. When consumers and shareholders believe a corporation is moving in a positive direction on a consistent basis, they are more likely to buy more, invest more, and become vigilant about spreading the word—there is no more powerful marketing tool than consumers telling friends and family about the good conduct and quality products or services being provided by a company.

Corporations also increase revenue and lower their cost of production when they act in environmentally friendly ways that save energy. Reducing carbon footprints by making operations more sustainable also bodes well for corporate reputations. Something as simple as reducing the output of greenhouse gases by switching to alternative fuel and energy sources or reducing energy output by reinsulating an old factory can save millions of dollars over a short period of time. Many companies have started to save money by offering customers e-mailed versions of billing statements or access to an online account where bills can be paid, merchandise and services can be purchased, and customers can communicate virtually with company representatives. In this way, metric tons of paper are saved, trees are spared, and dramatically less energy is used. To spread the word, companies incorporate information about new, greener practices in their marketing strategies.

GREEN MANAGEMENT

A joint study by firms Jones Lang Lasalle and CFO Research showed that more than 50 percent of seasoned executives and corporate officers believe that green practices will increase revenue, and more than 45 percent believe that a main environmental concern of corporations should be reducing the impact of manufacturing and other operations on the environment. With these kinds of values intact at the head of large corporations, it is clear that learning and knowing how to manage a company from an environmentally responsible standpoint is crucial to the future of today's successful enterprises.

Because of the rising importance of ecologically sound practices in the corporate sphere, more and more schools of management and business colleges are offering degrees in green management or programs pertaining to green management as part of their curriculums. The Dominican University of California is home to green business degree pioneer Professor John Stayton, and many

other colleges and universities across the United States and the world now offer "green degrees" in several disciplines. Across Asia, especially in Hong Kong, green management practices have become extremely popular— the governments of some Asian countries now offer incentives to corporations that practice green management and manufacturing. These polities also strongly urge companies of all sizes and in many industries to have green committees and managers trained in eco-friendly practices that they can hand down to their subordinates.

The rising importance of proactive and ecologically responsible corporate conduct varies in popularity from one country and region to another. The best way for new and growing enterprises to hedge their bets is to simply practice the highest standards of green management and manufacturing to ensure that their standards are, at the very least, as high as those in use in any region where future business could be headed. Companies that understand this are always researching and putting into practice the newest ways of "greening up" any processes they undertake to create products or offer services. Ensuring that transitions to greener practices go smoothly and that the highest level of efficiency is attained is the job of managers—hence the rising importance of a strong environmentally conscious education from a management school.

An important part of green management has been the ISO 9000 and ISO 14000 standards. These two international standards of quality are motivated to show they want to lessen waste, wish to be greener, and wish to be perceived as a proponent for ecologically friendly business and manufacturing practices. ISO 9000 and ISO 14000 are standards put forth by the International Organization for Standardization that effect both quality and environmental management. The two standards do this by encouraging companies to improve processes that may have harmful effects on the environment, and to improve the quality of products and services for consumers in a manner that lessens the carbon footprint of both the consumer and the purveyor of the product or service.

Green managers are responsible for giving their company the competitive edge against other industry names by constantly creating new ways of saving energy, lessening the company's carbon footprint in any way possible, and saving money through the use of measures that meet those needs. A qualified green manager will make it possible for a corporation to meet its production needs and deadlines using less energy and output a higher quality product that is friendlier to the planet for consumers. A green manager will also keep up with changing laws, regulations, and trends to ensure that his or her enterprise stays ahead of the curve. In addition to these roles, a green manager must also create ways to market the business so that consumers can appreciate the good the company is doing for the

environment. Research indicates that consumers who believe company A is greener than company B will gladly spend the few extra dollars or drive the few extra miles to buy the product or service from company A. A qualified green manager knows this about consumers and creates a way to commercialize and publicize the company's efforts at environmentalism.

GREEN MANUFACTURING

Green manufacturing is the practice of lessening the output of any type of pollution, waste, or byproduct of manufacturing any product. The greater aim of green manufacturing, beyond saving money and increasing corporate profits, is to conserve energy and natural resources and make an effort to leave the environment better—rather than worse—than it was found. Green manufacturing is not always the easiest route for all companies in all industries, but even those firms that won't make up for the cost in terms of overhead will almost always pick up the difference in profit margins and popularity with consumers. Additionally, when companies have to pick up the extra cost of doing business in a more ecologically sound manner, there will often be the impetus for further research and development that uncovers groundbreaking new methods for manufacturing that cut costs for all parties involved, including the consumer.

Recycling and reusing are important aspects of green manufacturing, and consumers are happy to support corporations that actively make use of recycled materials. In addition to making use of materials that have already been processed, reusing when it is a viable option also keeps overall cost down by reducing the need to process new materials, which saves on both raw materials and energy.

Everyday, more advanced methods of green manufacturing become more cost effective and realistic for more companies across more industries. As the popularity of green manufacturing grows, so does the likelihood of more expeditious development of progressively more innovative systems and processes of manufacturing. Of course, there is a cost associated with training existing employees on green manufacturing methods, which may include learning how to operate new machines and other technologies. However, the financial undertaking of training laborers is better spent on ecologically sound methods than on training that would likely be done at some point anyway on equipment that may or may not be so environmentally friendly.

Types of Green Manufacturing. Just in time (JIT) manufacturing is a type of supply chain management that helps reduce the cost and waste output of manufacturing. JIT accomplishes this by more closely following market and consumer trends to know how much of which product to create based on demand. Additionally, components used to create products are not housed by the manufacturing company, thus reducing energy needed to operate, heat, cool, and otherwise maintain warehouse space.

Zero emission manufacturing is a highly green methodology that calls for absolutely no output of hazardous materials that could harm the environment. While this type of green manufacturing is not possible for all entities in all industries, it certainly sets the bar high and creates an atmosphere of high corporate responsibility, one in which companies are competitively urged to hold themselves to a higher standard of production.

EXISTING GREEN COMPANIES

There are many companies, even very large corporations that have been environmentally friendly for many years, some since their conception. Some companies have gone green intentionally while others are green as a natural offshoot of how or where they do business. According to a 2007 article about "green giants" in *Fortune* magazine, Goldman Sachs, Hewlett-Packard, Continental Airlines, Pacific Gas and Electricity (PG&E), and S.C. Johnson are American-based corporations leading the pack. All of these are large corporate entities that are changing the way business is done globally by creating and following a higher standard of green management and manufacturing.

ETHICS

Ethics, also commonly referred to as morality, is the broad discipline that deals with determining what is right and what is wrong. There are various approaches to ethics and a wide variety of ethical rules and principles put forward by different ethicists. Making moral decisions is something

that people do on a regular basis. Ethics assists individuals in deciding what to do when faced with various situations.

Ethics is also a crucial component of social life, as individuals' actions usually have an impact on others. Ethical systems are necessary for ordered human existence, but there is and has always been deep disagreement about the proper rules and principles to put in place. Ethics can be grounded in natural law, religious tenets, parental and family influence, educational experiences, life experiences, and cultural and societal expectations.

BUSINESS ETHICS

Ethics in business, or business ethics as it is often called, is the application of the discipline, principles, and theories of ethics to the organizational context. Business ethics have been defined as "principles and standards that guide behavior in the world of business." Business ethics is also a descriptive term for the field of academic study in which many scholars conduct research and in which undergraduate and graduate students are exposed to ethics theory and practice, usually through the case method of analysis.

Ethical behavior in business is critical. When business firms are charged with infractions, and when employees of those firms come under legal investigation, there is a concern raised about moral behavior in business. Hence, the level of mutual trust, which is the foundation of our free-market economy, is threatened.

Although ethics in business has been an issue for academics, practitioners, and governmental regulators for decades, some believe that unethical, immoral, and/or illegal behavior is widespread in the business world. Numerous scandals in the late 1990s and early 2000s seemed to add credence to the criticism of business ethics. Corporate executives of WorldCom, a giant in the telecommunications field, admitted fraud and misrepresentation in financial statements. A similar scandal engulfed Enron at around the same time. Other notable ethical lapses were publicized involving ImClone, a biotechnological firm; Arthur Andersen, one of the largest and oldest public accounting firms; and HealthSouth, a large healthcare firm located in the southeast United States. These companies eventually suffered public humiliation, huge financial losses, and in some cases, bankruptcy or dissolution. The ethical and legal problems resulted in some corporate officials going to prison, many employees losing their jobs, and thousands of stockholders losing some or all of their savings invested in the firms' stock.

Although the examples mentioned involved top management, huge sums of money, and thousands of stakeholders, business ethics is also concerned with the day-to-day ethical dilemmas faced by millions of workers at all levels of business enterprise. It is the awareness of and judgments made in ethical dilemmas by all that determines the overall level of ethics in business. Thus, the field of business ethics is concerned not only with financial and accounting irregularities involving billions of dollars, but all kinds of moral and ethical questions, large and small, faced by those who work in business organizations.

APPROACHES TO ETHICAL DECISION-MAKING

Philosophers have studied and written about ethics for thousands of years, and there continues to be vigorous investigation into and debate about the best ethical principles. Although many different ethical theories have been developed through the ages, there are several broad categories that are commonly used to group different theories by their major traits. These groupings are: teleology, deontology, and virtue. A fourth category, relativism, may be added, although relativism is less an ethical theory than it is a broad claim about the nature of ethics.

Each of the three major types of theories is prescriptive— that is, they purport to determine what conduct is right and wrong, or to prescribe what people *should* (and should not) do. The prescriptions put forward by the theories in each category stem from different fundamental principles. For teleological theories, the fundamental principles focus on the consequences caused by human actions, while deontological theories of ethics focus on (1) the rights of all individuals and (2) the intentions of the person(s) performing an action. Deontological theories differ substantially from teleological views because they do not allow, for instance, harming some individuals in order to help (a greater number of) others. To the deontologist, each person must be treated with the same level of respect, and no one should be treated as a means to an end. Virtue ethics, unlike both teleology and deontology, emphasizes the virtues, or moral character, behind a certain action or set of actions instead of looking at duties or rules, as deontology does, or the outcomes of actions, as teleology does. Thus, an action is evaluated in terms of whether or not a "good person" would perform that action.

Teleological, deontological, and virtue theories are all "universal" theories, in that they purport to advance principles of morality that are permanent and applicable to everyone. In contrast, relativism states that there are no universal principles of ethics and that right and wrong are by different individuals and groups. The relativist does not accept that some ethical standards or values are superior to others and believes that standards of right and wrong change over time and are different across cultures.

CONSEQUENTIALISM

Teleological theories of ethics, often referred to as "consequentialist" theories, focus, as the name indicates, on the consequences or outcomes of ethical decisions. For instance,

when evaluating whether or not it is ethical to use company time to deal with personal business, the relevant question would center on whether any harm came from the action. The consequentialist would look at what happened as a result of that choice. If, say, there were no loss of productivity as a result of conducting a piece of personal business while at work, then consequentialism theories would likely make no adverse ethical judgment about that choice. A commonly heard phrase justifying such choices—"It's not hurting anyone"—is practically the consequentialist motto.

Consequentialist theories are very popular, largely because they are more concrete than deontological or virtue-based ones. It is much easier to determine the consequences of an action—they can be seen—than it is to determine a person's intentions or their moral character. Consequentialism is widely used in the field of business ethics, most likely because businesses are about results, not intentions or character. The most common consequentialist theories are egoism and utilitarianism. These two theories differ in their focus on where the consequences of actions are evaluated. For egoism, the relevant consequences concern one's self; for utilitarianism, the overall impact on society is considered.

Egoism. Egoism is defined by self-interest, and defines right and wrong in terms of the consequences to one's self. An egoist would weigh an ethical dilemma or issue in terms of how different courses of action would affect his or her physical, mental, or emotional well-being. Egoists, when faced with business decisions, will choose the course of action that they believe will best serve their own interests.

Although it seems likely that egoism would potentially lead to unethical and/or illegal behavior, this philosophy of ethics is, to some degree, at the heart of a free-market economy. Since the time of political economist Adam Smith, advocates of a free market unencumbered by governmental regulation have argued that individuals, each pursuing their own self-interest, would actually benefit society at large.

This point of view is notably espoused by the famous economist Milton Friedman, who suggested that the only moral obligation of business is to make a profit and obey the law. However, it should be noted that Smith, Friedman, and most others who advocate unregulated commerce, acknowledge that some restraints on individuals' selfish impulses are required.

Utilitarianism. In the utilitarian approach to ethical reasoning, one emphasizes the utility, or the overall amount of good, that might be produced by an action or a decision. For example, companies decide to move their production facilities from one country to another. How much good is

Table 1
Approaches to Ethics in Business

Teleological	Actions are judged as ethical or unethical based on their results.
Egoism	Actions are judged as ethical or unethical based on the consequences to one's self. Actions that maximize self-interest are preferred.
Utilitarianism	Actions are judged as ethical or unethical based on the consequences to "others." Actions that maximize the "good" (create the greatest good for the greatest number) are preferred.
Deontological	Actions are judged as ethical or unethical based on the inherent rights of the individual and the intentions of the actor. Individuals are to be treated as means and not ends. It is the action itself that must be judged and not its consequences.
Justice	Actions are judged as ethical or unethical based on the fairness shown to those affected. Fairness may be determined by distributive, procedural, and/or interactional means.
Relativism	Actions are judged as ethical or unethical based on subjective factors that may vary from individual to individual, group to group, and culture to culture.

Adapted from: Ferrell, Fraedrich, and Ferrell, 2002, p. 57.

expected from the move? How much harm? If the good appears to outweigh the harm, the decision to move may be deemed an ethical one, by the utilitarian yardstick.

This approach also encompasses what has been referred to as cost-benefit analysis. In this, the costs and benefits of a decision, a policy, or an action are compared. Sometimes these can be measured in economic, social, human, or even emotional terms. When all the costs are added and compared with the results, if the benefits outweigh the costs, then the action may be considered ethical.

One fair criticism of this approach is that it is difficult to accurately measure costs and benefits. Another criticism is that the rights of those in the minority may be overlooked or even intentionally trampled if doing so provides an overall benefit to society as a whole.

Utilitarianism is like egoism in that it advocates judging actions by their consequences, but unlike egoism, utilitarianism focuses on determining the course of action that will produce the greatest good for the greatest number of people. Thus, it is the ends that determine the morality of an action and not the action itself (or the intent of the actor).

Utilitarianism is probably the dominant moral philosophy in business ethics. Utilitarianism is attractive to many business people, since the philosophy acknowledges that many actions result in good consequences for some, but bad consequences for others. This is certainly true of many decisions in business.

INDIVIDUAL ETHICAL DECISION-MAKING

In addition to ethical theories about right and wrong—prescriptive theories, sometimes also called "normative"—the field of business ethics consists of theories about how people make ethical decisions. This area of business ethics is more descriptive than prescriptive. There are many approaches to the individual ethical decision-making process in business. However, one of the more common was developed by James Rest and has been called the four-step or four-stage model of individual ethical decision-making. Numerous scholars have applied this theory in the business context. The four steps include: ethical issue recognition, ethical (moral) judgment, ethical (moral) intent, and ethical (moral) behavior.

Ethical Issue Recognition. Before a person can apply any standards of ethical philosophy to an issue, he or she must first comprehend that the issue has an ethical component. This means that the ethical decision-making process must be "triggered" or set in motion by the awareness of an ethical dilemma. Some individuals are likely to be more sensitive to potential ethical problems than others. Numerous factors can affect whether someone recognizes an ethical issue; some of these factors are discussed in the next section.

Ethical (Moral) Judgment. If an individual is confronted with a situation or issue that he or she recognizes as having an ethical component or posing an ethical dilemma, the individual will probably form some overall impression or judgment about the rightness or wrongness of the issue. The individual may reach this judgment in a variety of ways, following a particular ethical theory or a mixture of theories, as noted in the previous section on approaches to ethical decision-making.

Ethical (Moral) Intent. Once an individual reaches an ethical judgment about a situation or issue, the next stage in the decision-making process is to form a behavioral intent. That is, the individual decides what he or she will do (or not do) with regard to the perceived ethical dilemma.

According to research, ethical judgments are a strong predictor of behavioral intent. However, individuals do not always form intentions to behave that are in accord with their judgments, as various situational factors may act to influence the individual otherwise.

Ethical (Moral) Behavior. The final stage in the four-step model of ethical decision-making is to engage in some behavior with regard to the ethical dilemma. Research shows that behavioral intentions are the strongest predictor of actual behavior in general and ethical behavior in particular. However, individuals do not always behave consistent with either their judgments or intentions with

regard to ethical issues. This is particularly a problem in the business context, as peer group members, supervisors, and organizational culture may influence individuals to act in ways that are inconsistent with their own moral judgments and behavioral intentions.

FACTORS AFFECTING ETHICAL DECISION-MAKING

In general, there are three types of influences on ethical decision-making in business: (1) individual difference factors, (2) situational (organizational) factors, and (3) issue-related factors.

Individual Difference Factors. Individual difference factors are personal factors about an individual that may influence their sensitivity to ethical issues, their judgment about such issues, and their related behavior. Research has identified many personal characteristics that impact ethical decision-making. The individual difference factor that has received the most research support is "cognitive moral development."

This framework, developed by Lawrence Kohlberg in the 1960s and extended by Kohlberg and other researchers in the subsequent years, helps to explain why different people make different evaluations when confronted with the same ethical issue. It posits that an individual's level of "moral development" affects their ethical issue recognition, judgment, behavioral intentions, and behavior.

According to the theory, individuals' level of moral development passes through stages as they mature. Theoretically, there are three major levels of development. The lowest level of moral development is termed the "pre-conventional" level. At the two stages of this level, the individual typically will evaluate ethical issues in light of a desire to avoid punishment and/or seek personal reward. The pre-conventional level of moral development is usually associated with small children or adolescents.

The middle level of development is called the "conventional" level. At the stages of the conventional level, the individual assesses ethical issues on the basis of the fairness to others and a desire to conform to societal rules and expectations. Thus, the individual looks outside him or herself to determine right and wrong. According to Kohlberg, most adults operate at the conventional level of moral reasoning.

The highest stage of moral development is the "principled" level. The principled level, the individual is likely to apply principles (which may be utilitarian, deontological, or justice) to ethical issues in an attempt to resolve them. According to Kohlberg, a principled person looks inside him or herself and is less likely to be influenced by situational (organizational) expectations.

The cognitive moral development framework is relevant to business ethics because it offers a powerful explanation of individual differences in ethical reasoning. Individuals at different levels of moral development are likely to think differently about ethical issues and resolve them differently.

Situational (Organizational) Factors. Individuals' ethical issue recognition, judgment, and behavior are affected by contextual factors. In the business ethics context, the organizational factors that affect ethical decision-making include the work group, the supervisor, organizational policies and procedures, organizational codes of conduct, and the overall organizational culture. Each of these factors, individually and collectively, can cause individuals to reach different conclusions about ethical issues than they would have on their own. This section looks at one of these organizational factors, codes of conduct, in more detail.

Codes of conduct are formal policies, procedures, and enforcement mechanisms that spell out the moral and ethical expectations of the organization. A key part of organizational codes of conduct are written ethics codes. Ethics codes are statements of the norms and beliefs of an organization. These norms and beliefs are generally proposed, discussed, and defined by the senior executives in the firm. Whatever process is used for their determination, the norms and beliefs are then disseminated throughout the firm.

An example of a code item would be, "Employees of this company will not accept personal gifts with a monetary value over $25 in total from any business friend or associate, and they are expected to pay their full share of the costs for meals or other entertainment (concerts, the theater, sporting events, etc.) that have a value above $25 per person." Hosmer points out that the norms in an ethical code are generally expressed as a series of negative statements, for it is easier to list the things a person should not do than to be precise about the things a person should.

Almost all large companies and many small companies have ethics codes. However, in and of themselves ethics codes are unlikely to influence individuals to be more ethical in the conduct of business. To be effective, ethics codes must be part of a value system that permeates the culture of the organization. Executives must display genuine commitment to the ideals expressed in the written code—if their behavior is inconsistent with the formal code, the code's effectiveness will be reduced considerably.

At a minimum, the code of conduct must be specific to the ethical issues confronted in the particular industry or company. It should be the subject of ethics training that focuses on actual dilemmas likely to be faced by employees in the organization. The conduct code must contain communication mechanisms for the dissemination of the organizational ethical standards and for the reporting of perceived wrongdoing within the organization by employees.

Organizations must also ensure that perceived ethical violations are adequately investigated and that wrongdoing is punished. Research suggests that unless ethical behavior is rewarded and unethical behavior punished, that written codes of conduct are unlikely to be effective.

Issue-Related Factors. Conceptual research by Thomas Jones in the 1990s and subsequent empirical studies suggest that ethical issues in business must have a certain level of "moral intensity" before they will trigger ethical decision-making processes. Thus, individual and situational factors are unlikely to influence decision-making for issues considered by the individual to be minor.

Certain characteristics of issues determine their moral intensity. In general, the research suggests that issues with more serious consequences are more likely to reach the threshold level of intensity. Likewise, issues that are deemed by a societal consensus to be ethical or unethical are more likely to trigger ethical decision-making processes.

BUSINESS ETHICS TODAY

Ethics has been an important dimension of business and management practice for several decades, but in recent years, largely due to high-profile scandals, ethics has been placed on the center stage. Since the corporate scandals of the early-2000s, there has been vigorous debate about which ethical principles should prevail in the business world and about the proper role of government in enforcing morality in the marketplace. While there is no universal agreement on ethical principles or underlying theories, there has been wider agreement that the government has to take a more aggressive role in defining and enforcing ethical practice in the business world.

Congress passed the Sarbanes-Oxley Act of 2002 to reform American business practices in response to corporate scandals. This act establishes new or enhanced standards for publicly-traded companies (it does not apply to privately-held companies). Following passage of the Sarbanes-Oxley Act, the Federal Sentencing Guidelines for Organizations were updated in 2005 to strengthen the standards for corporate compliance and ethics programs.

Business ethics is an exceedingly complicated area, one that has contemporary significance for all business practitioners. There are, however, guidelines in place for effective ethical decision making, and there is continued attention paid to developing and maintaining these guidelines. These all have their positive and negative sides, but taken together, they may assist the businessperson to steer toward the most ethical decision possible under a particular set of circumstances.

EUROPEAN UNION

The European Union (EU) is an economic and political federation consisting of twenty-seven member countries that make common policy in several areas. The EU was created in 1993 with the signing of the Treaty on European Union, commonly referred to as the Maastricht Treaty, but it was preceded by various European organizations that contributed to the development of the EU. The EU represents the latest and most successful in a series of efforts to unify Europe, including many attempts to achieve unity through force of arms, such as those seen in the campaigns of Napoleon Bonaparte and World War II.

STEPS TOWARDS THE MAASTRICHT TREATY

In the wake of the Second World War, which devastated the European infrastructure and economies, efforts began to forge political union through increasing economic interdependence. In 1951 the European Coal and Steel Community (ECSC) was formed to coordinate the production and trading of coal and steel within Europe. In 1957 the member states of the ECSC ratified two treaties creating the European Atomic Energy Community (Euratom) for the collaborative development of commercial nuclear power and the European Economic Community (EEC), an international trade body whose role was to gradually eliminate national tariffs and other barriers to international trade involving member countries. Initially the EEC, or, as it was more frequently referred to at the time, the Common Market, called for a twelve- to fifteen-year period for the institution of a common external tariff among its members, but the timetable was accelerated and a common tariff was instituted in 1967.

Despite this initial success, participation in the EEC was limited to Belgium, France, Germany, Italy, Luxembourg, and the Netherlands. Immediately following the creation of the EEC a rival trade confederation known as the European Free Trade Association (EFTA) was created by Austria, Britain, Denmark, Finland, Norway, Portugal, Sweden, and Switzerland. Although its goals were less comprehensive than those of the EEC, the existence of the EFTA delayed European economic and political unity.

By 1961 the United Kingdom indicated its willingness to join the Common Market if allowed to retain certain tariff structures which favored trade between Britain and its Commonwealth. Negotiations between the EEC and the United Kingdom began, but insurmountable differences arose and Britain was denied access to the Common Market in 1963. Following this setback, however, the Common Market countries worked to strengthen the ties between themselves, culminating in the merger of the ECSC, EEC, and Euratom to form the European Community (EC) in 1967. In the interim the importance of the Commonwealth to the British economy waned considerably and by 1973 Britain, Denmark, and the Republic of Ireland had joined the EC. Greece followed suit in 1981, followed by Portugal and Spain in 1986 and Austria, Finland, and Sweden in 1995.

Even as it expanded, the EC worked to strengthen the economic integration of its membership, establishing a European Monetary System (EMS) featuring the European Currency Unit (ECU, later known as the Euro) in 1979. The EC then passed the Single European Act, which strengthened the EC's ability to regulate the economic, social, and foreign policies of its members, in 1987. The EC took its largest step to date toward true economic integration among its members with the 1992 ratification of the Maastricht Treaty, after which the EC changed its name to the European Union (EU). The Maastricht Treaty also created a central banking system for EU members, established the mechanisms and timetable for the adoption of the Euro as the common currency among members, and further strengthened the EU's ability to influence the public and foreign policies of its members.

EXPANSION SINCE 1993

The EU originally had twelve member nations: Belgium, Denmark, France, Germany, Greece, Italy, Luxembourg, the Netherlands, Portugal, the Republic of Ireland, Spain, and the United Kingdom. In 1993, the European Council, meeting in Copenhagen, Denmark, determined the criteria for joining the EU. These requirements, known as the Copenhagen criteria, included: (1) a stable democracy which respects human rights and the rule of law; (2) a functioning market economy capable of competition within the EU; and (3) the acceptance of the obligations of membership, including EU law. The European Council has the responsibility for evaluating a country's fulfillment of these criteria.

The EU has enlarged three times since its creation. In 1995, three new members were added: Austria, Finland, and Sweden. In 2004, ten new members were added, mostly from the former Soviet bloc: Czech Republic, Cyprus, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Slovakia, and Slovenia. In 2007, Romania and Bulgaria, who were not ready to join in 2004, were admitted. As of 2008, there were three official candidates for membership—Croatia, Macedonia, and Turkey—and five nations officially recognized as potential candidates—Albania, Bosnia and Herzegovina, Kosovo, Montenegro, and Serbia.

THE EURO

One of the goals of the EU is economic integration and a common European currency. EU leaders expect great benefits from the adoption of a single currency. International trade within the single currency area will be greatly facilitated by the establishment of what amounts to a single market, complete with uniform pricing and regulation, in place of separate national markets. The creation of a single market is also expected to spur increased competition and the development of more niche products, and ease the acquisition of corporate financing, particularly in what would formerly have been international trade among members of the single currency area. Finally, in the long term, the establishment of the single currency area should simplify European corporate structures, since in time nearly all regulatory statutes within the single currency area should become uniform.

The Maastricht Treaty established conditions that EU member nations would be expected to meet before they would be allowed to participate in the introduction of the single European currency. These conditions were designed to create a "convergence" among the various national economies of Europe to ease the transition to a single currency and ensure that no single country would benefit or be harmed unduly by its introduction. Such a convergence would also create greater uniformity among the various national economies of the EU, making admin-

istration of economic activity within the single-currency area more feasible. The conditions set for participation in the introduction of the Euro and inclusion in the single-currency area included the following:

- Maintaining international currency exchange rates within a specified range (called the Exchange Rate Mechanism or ERM) for at least two years prior to the introduction of the Euro.

- Maintaining long-term interest rates within 2 percent of the national inflation rate and within 1.5 percent of the three best-performing EU member states in terms of price stability.

- Maintaining public debt at no more than 3 percent of the gross domestic product.

- Maintaining total government debt at no more than 60 percent of gross domestic product.

Despite difficulties faced by some members in meeting these conditions, implementation of the Euro went ahead on schedule through the three phases set forth at Maastricht. Phase one began in 1998 with an EU summit in Brussels, Belgium, that determined which of the fifteen member states had achieved sufficient convergence to participate in the introduction of the Euro. The selected participants were Austria, Belgium, Finland, France, Germany, Ireland, Italy, Luxembourg, the Netherlands, Portugal, and Spain (exceptions were Demark, Greece, Sweden and the UK). Phase two, which commenced on 1 January 1999, introduced the Euro as legal tender within the eleven selected countries, referred to as the single-currency area, although the new currency would only exist as a "currency of account," that is, it would exist only on paper or for electronic transactions, as no Euro notes or coins were yet in circulation. Instead, the existing currencies of the participating countries functioned as fixed denominations of the Euro. Phase two also included the subordination of the eleven national banks in the single-currency area to the European Central Bank.

Phase three, which began on 1 January 2002, set the Euro banknotes and coins into circulation and by July 2002, it became the legal tender of the countries, replacing their national currencies. At the time of introduction there were twelve countries in the area using the Euro, known as the Eurozone: Austria, Belgium, Finland, France, Germany, Ireland, Italy, Luxembourg, Netherlands, Portugal, Spain, and Greece. Denmark, Sweden and the UK chose not to use the Euro. By the beginning of 2008, the Eurozone had expanded to include fifteen member nations, with Cyprus, Malta, and Slovenia having joined the original members. Nine of the new EU member states were still operating with a currency other than the Euro. The Accession Treaties signed by all of

these countries requires them to join the Euro; some have already joined the ERM and others have set themselves the goal of joining the Euro as follows:

- Slovakia: January 1, 2009

- Lithuania: January 1, 2010

- Estonia: January 1, 2011

- Bulgaria, Czech Republic, Hungary, Latvia, Poland, and Romania: January 1, 2012 or later.

The initial introduction of the Euro as a currency of account began with a resounding success, as the new currency rose immediately to an exchange rate of 1.17 U.S. dollars to the Euro. Uncertainties about the further progress of European Union raised by conflicts in the Balkans in 1999 soon dampened investor interest in the Euro, however, and its value fell to 1.04 U.S. dollars per Euro by the summer of that year. The Euro continued to slip, and by late 2000, it had fallen to a record low of $0.83. Since 2003, however, the Euro has steadily risen against the dollar, gaining strength in 2007 as the U.S. economy began slipping towards recession; by mid 2008, the Euro was holding steady in the mid $1.50s.

STRUCTURE

The EU maintains four administrative bodies dealing with specific areas of economic and political activity.

Council of Ministers. The Council of Ministers comprises representatives, usually the foreign ministers, of member states. The presidency of the council rotates between the members on a semiannual basis. When issues of particular concern arise, members may send their heads of state to sit on the council. At such times the council is known as the European Council, and has final authority on all issues not specifically covered in the various treaties creating the EU and its predecessor organizations. The Council of Ministers also maintains the Committee of Permanent Representatives (COREPER), with permanent headquarters in Brussels, Belgium, to sit during the intervals between the council's meetings; and operates an extensive secretariat monitoring economic and political activities within the EU. The Council of Ministers and European Council decide matters involving relations between member states in areas including administration, agriculture and fisheries, internal market and industrial policy, research, energy, transportation, environmental protection, and economic and social affairs. Members of the Council of Ministers or European Council are expected to represent the particular interests of their home country before the EU as a whole.

European Commission. The European Commission serves as the executive organization of the EU. Currently each country has one commissioner except for the five largest countries that have two. The Commission enlarges as more countries join. The European Commission seeks to serve the interests of Europe as a whole in matters including external relations, economic affairs, finance, industrial affairs, and agricultural policies. The European Commission maintains twenty-three directorates general to oversee specific areas of administration and commerce within the EU. It also retains a large staff to translate all EU documents into each of the EU's twenty official languages. Representatives sitting on the European Commission are expected to remain impartial and view the interests of the EU as a whole rather than the particular interests of their home countries.

European Parliament. The European Parliament comprises representatives of the EU member nations who are selected by direct election in their home countries. Although it serves as a forum for the discussion of issues of interest to the individual member states and the EU as a whole, the European Parliament has no power to create or implement legislation. It does, however, have some control over the EU budget, and can pose questions for the consideration of either the Council of Ministers or the European Commission.

Court of Justice. The Court of Justice comprises thirteen judges and six advocates general appointed by EU member governments. Its function is to interpret EU laws and regulations, and its decisions are binding on the EU, its member governments, and firms and individuals in EU member states.

IMPORTANT PROGRAMS

From its creation the EU has maintained the Economic and Social Committee (ESC), an appointed advisory body representing the interests of employers, labor, and consumers before the EU as a whole. Although many of the ESC's responsibilities are now duplicated by the European Parliament, the committee still serves as an advocacy forum for labor unions, industrial and commercial agricultural organizations, and other interest groups.

One ongoing area of contention among the members of the EU is agricultural policy. Each European nation has in place a series of incentives and subsidies designed to benefit its own farmers and ensure a domestically grown food supply. Often these policies are decidedly not beneficial to the EU as a whole, and lead to conflict between rival national organizations representing agricultural and fisheries industries. The degree of contention on agricultural and fisheries issues within the EU can be seen in the

fact that nearly 70 percent of EU expenditures are made to address agricultural issues, even though agriculture employs less than 8 percent of the EU workforce. In an attempt to reduce conflict between national agricultural industries while still supporting European farmers, the EU adopted a Common Agricultural Policy (CAP) as part of the Treaty on European Union.

The CAP seeks to increase agricultural productivity, ensure livable wages for agricultural workers, stabilize agricultural markets, and assure availability of affordable produce throughout the EU. Although the CAP has reduced conflicts within the EU, it has also led to the overproduction of many commodities, including butter, wine, and sugar, and has led to disagreements involving the EU and agricultural exporting nations including the United States and Australia.

The European Social Fund (ESF) and the European Regional Development Fund (ERDF) were established to facilitate the harmonization of social policies within EU member states. The ESF focuses on training and retraining workers to ensure their employability in a changing economic environment, while the ERDF concentrates on building economic infrastructure in the less-developed countries of the EU.

The European Investment Bank (EIB) receives capital contributions from the EU member states, and borrows from international capital markets to fund approved projects. EIB funding may be granted only to those projects of common interest to EU members that are designed to improve the overall international competitiveness of EU industries. EIB loans are also sometimes given to infrastructure development programs operating in less-developed areas of the EU.

OBSTACLES FACING THE EU

Although the EU has accomplished a great deal in its first two decades, many hurdles must still be crossed before true European unity can be achieved. Many EU nations experienced great difficulty in meeting the provisions required by the EU for joining the EMS, although eleven countries met them by the 1 January 1999 deadline. Meeting these provisions forced several EU members, including Italy and Spain, to adopt politically unpopular domestic economic policies. Others, such as the United Kingdom, chose not to take politically unpopular action and thus failed to qualify for participation. Even though the Euro was introduced according to schedule, economic unity has far outstripped political cooperation among EU members to date and real and potential political disagreements within the EU remain a threat to its further development. Although the Eurozone represents a formidable force in international trade, the EU faces several grave challenges as it strives to form an ever closer linkage of its national constituents.

Despite the fact that the Treaty on European Union created a central bank to supercede the national banks of its members, responsibility for the creation of fiscal policies remains in the hands of each national government. As such, there is great potential for the central authority and national economic policy making agencies to adopt conflicting programs. Furthermore, national political institutions within the EU are likely to be more responsive to the desires of their national constituencies than to the well being of the Eurozone as a whole, especially in times of economic instability. It is difficult to see how voters in the nations of the EU will be able to put the good of Europe ahead of their own particular interests.

This difficulty is particularly troublesome as political integration has progressed much more slowly than economic integration, and further political integration has recently suffered several potentially insurmountable setbacks. In 2004, the Treaty establishing a European Constitution (TCE) was signed by the representatives of all twenty-seven member nations, but the treaty failed to be ratified by all of the members. Most members did in fact ratify the TCE by parliamentary measure or popular referendum, but France and the Netherlands both rejected it in referendums. These failures led other members to postpone or call off their ratification procedures. As a result, the European Council called for a "period of reflection," which subsequently led to negotiations over a new constitutional treaty, known as the Lisbon Treaty. The Treaty of Lisbon, signed on 13 December 2007, was in the process of being ratified by member nations when the Irish electorate rejected the treaty in June 2008, creating uncertainty as to the future ratification of this version of a European constitution.

Another problem also arises out of the composition of the Eurozone. According to the optimal currency theory first posed by American Robert Mundell in 1961, in order for a single currency to succeed in a multinational area several conditions must be met. There should be no barriers to the movement of labor forces across national, cultural, or linguistic borders within the single-currency area; there should be wage stability throughout the single currency area; and an area-wide system should exist to stabilize imbalanced transfers of labor, goods, or capital within the single-currency area. These conditions do not exist in present-day Europe, where labor mobility is small, largely because of language barriers, and wages vary widely among EU member countries, particularly between those in the West and in the East. Furthermore, the present administrative structure of the EU is not powerful enough to redress imbalanced transfers, which are bound to occur periodically. Such imbalances would engage the sort of

political response discussed previously, to the detriment of the EU as a whole.

Optimal currency theory also holds that for a single currency area to be viable it must not be prone to asymmetric shocks, that is, economic events that lead to imbalanced transfers. Ideally, a single-currency area should comprise similar economies that are likely to be on similar cycles, thus minimizing imbalances. Similarly, the need for a freely transferable labor force within the single-currency area is also necessary to minimize imbalances, since each national member of the area must be able to respond flexibly to changes in wage and price structures.

ANALYSIS AND PROSPECTS

The EU has made remarkable progress during its first two decades. Although there are significant obstacles in the way of further strengthening of the EU, especially in political matters, the continued enhancement of economic ties binding members is likely to increase the political unity of EU members over time. That this is feasible is evidenced by the efforts of EU nations to conform to the stipulations of the Maastricht Agreement. Maintaining stable currency exchange rates, reducing public and overall government debt, and controlling long-term interest rates are all areas in which national governments and fiscal agencies had exercised complete autonomy in the past. Before the implementation of the Euro's second phase, many doubted that the EU member states could put aside their own internal interests to meet the Maastricht provisions; however, eleven of the fifteen managed to do so, and currently over half of the EU members belong to the Eurozone. Significantly, many had to experience economic slowdowns and increased unemployment in order to do so. Such resolve bodes well for continued strengthening of European unification in both political and economic areas. In fact, the history of the EU to date has been one of overcoming obstacles similar to those faced during the first two phases of the introduction of the Euro, and a unified Europe is and will remain a fact of international economic life for the foreseeable future.

EXECUTIVE COMPENSATION

Executive employees, such as chief executive officers (CEOs), chief financial officers (CFOs), company presidents, and other upper level managers are often compensated differently than those at lower levels of an organization. Executive compensation consists of base salary, bonuses, long-term incentives, benefits, and perquisites. Total executive compensation has increased dramatically during the past decade, leading to concerns about pay equity and ethics. As the gap between pay at lower and higher levels of corporations widens, CEOs and other executives are increasingly perceived as overcompensated.

TYPES OF EXECUTIVE COMPENSATION

There are several different types of executive compensation that are used to reward corporate executives for their job performance. The underlying purpose of executive compensation is to increase the corporation's profits by motivating executives to make good decisions about the direction of the company; however, compensation packages are determined by a variety of factors, both internal and external.

Base Salary of Executives. Base salary is the regular annual salary of the executive. While job evaluation is typically used to set employee pay in organizations, executive base salary levels are often more influenced by the opinion of the compensation committee (which consists of some or all of the members of the company's board of directors), which is often dependent on information from salary surveys of similar companies. Typically, pay of CEOs and other executives is set to be competitive with other executive salaries in the market and thus may be very high in comparison to the pay of employees in their own company. According to the *Mercer Human Resource Consulting 2006 CEO Compensation Survey*, the median CEO base salary was $995,000 in 2006. However, that same study also

noted that CEO salary is typically only about one-sixth (15% to 16%) of a CEO's total compensation.

Recent data also shows that salaries for executives typically rise more quickly than salaries for other employees. According to the Mercer survey, CEO compensation increased by 7.1 percent in both 2005 and 2006 while exempt employee salaries increased by only 3.6 percent and 3.7 percent respectively; in 2004, CEO compensation increased 14.5 percent while salaries rose only 3.4 percent.

Executive Bonuses. In addition to a base salary, most executives receive variable pay, a compensation that fluctuates according to some level of performance. The use of compensation beyond base salary is intended to motivate executives to reach certain organizational performance goals, for example, specific profit levels, and reward them for reaching these goals. One very popular type of variable pay is the executive bonus, which is a one-time payment tied to some short-term performance goal. The bonus may be based on any number of performance outcomes, ranging from judgments of executive performance by the board of directors, to levels of company profits or market share. Nearly all executives now receive some sort of bonus as a part of their compensation package. The Mercer survey cited above notes that in 2006, CEO bonuses were 26 percent of a CEO's total compensation, an increase from 16 percent in 2002.

Long-term Incentives. In recent decades, long-term incentives (LTIs) have become important for rewarding the performance of executives, and they now make up over half of total executive compensation. Incentives are rewards that are linked to specific long-term goals of the organization. The most common long-term incentive is the stock option, which either gives the executive free company stock or allows him or her to purchase company stock at a reduced price for a period of time. These stocks become more valuable as the company improves financially; therefore, ownership of stock is intended to encourage the executive to make the organization more profitable. Executives can then sell these stocks at a later time when they have appreciated in value, therefore providing compensation beyond the employee's tenure with the organization. However, company failures—in which unethical accounting practices and artificial inflation of stock prices caused lower-level employees to lose investments in company stock—have raised concerns about the ethics of granting large numbers of stock options to executives.

Executive Benefits and Perquisites. Benefits for executive-level employees are also likely to be different than those offered to lower-level employees. Executives will often receive high levels of typical company fringe benefits, like health insurance, life insurance, and pension plans. Addi-

tionally, some executives may also have a contract for large severance packages, paying cash and stock options to a CEO fired from a company. Many executives negotiate generous severance packages at the time of hire, so that even if they are unable to deliver upon promises to the company, they can collect compensation upon exit.

Executive perquisites, or "perks," are special benefits and services for executives and other top employees of companies. Perks may be things such as a car service, an executive dining room, special parking, membership in clubs, and other such amenities. It is customary for many U.S. executives to receive perks as a part of their total compensation. Some of these perks, like car service or a company airplane, may serve to improve an executive's ability to do his or her job. Additionally, some perks bring with them a certain level of status (for example, company-paid membership to an exclusive country club that is appealing to executive employees).

PAY EQUITY

High-profile media reports on executive compensation that followed in the wake of the corporate scandals throughout the 2000s raised consciousness about the issue of pay equity. Both employees and stockholders became increasingly aware of the wide disparity between executive compensation and pay for all other employees, particularly when CEOs of corporations involved in scandals or financial distress were reported to have received millions of dollars in bonuses, stock options, and pensions. (For example, Freddie Mac CEO, Richard Syron, received $14.5 million in 2007; $2.2 million of this amount was a "performance bonus.") Many critics argue that executive pay is far too high, and that these pay rates invite ethical problems.

Pay equity, or the fairness of pay, can be evaluated both internally and externally. These ideas are based on equity theory, a theory of motivation. Equity theory, briefly, indicates that a person examines what he brings to a job (inputs) and what he receives from a job (outcomes) and compares that to a reference person, evaluating the other person's inputs and outcomes. An employee might determine that she brings a certain level of education, experience, and effort to her job and that those inputs result in a certain level of salary and benefits. She would then compare this relationship to the education, experience, and effort, and the subsequent salary and benefits of another person. If these ratios are not equal, then the employee will feel unfairly treated. If this employee determines that her inputs are far greater than her counterpart's inputs, but their pay is the same, this employee will feel unfairly compensated.

External equity is the assessment of the fairness of pay in similar jobs in different organizations. Executives

who compare their pay to executives in other similar firms are making an assessment of external equity. External equity can be determined through market pay surveys, in which companies share information about the pay and benefits in their jobs. Additionally, the pay levels of executives may be public knowledge, either in company publications to shareholders or in trade organizations. If an executive is compensated highly as compared to others in similar companies, he or she is likely to feel positively about this situation; however, executives who are compensated at a lower rate than comparable executives in other companies may attempt to have their salary raised or may look for another position.

Internal equity is an assessment of the fairness of pay in different jobs within the same organization. Executives and employees compare their inputs and their pay to one another's to determine if they are fairly treated. Internal equity is often referred to as pay structure, and there are two types of pay structure: egalitarian and hierarchical. In egalitarian pay structures, the range of pay from the lowest paid employee to the highest paid employee is not very big; there are not large differences in pay. Egalitarian structures tend to be preferred by the lower-paid employees, because they feel that executive pay is not too high. However, executives may become dissatisfied in organizations with egalitarian pay structures, because they feel that their pay may not be commensurate with their skills or job duties. Hierarchical pay structures, conversely, have a fairly wide range of pay between the lowest and highest paid employees. In hierarchical pay structures, upper-level employees are likely to be paid very high salaries, which they are likely to find satisfying. However, in hierarchical structures, employees in low-level jobs may feel unfairly treated because of their relatively lower pay rate.

The pay level of U.S. executives is very high as compared to the pay of executives in other countries, as compared to pay of U.S. executives in the past, and as compared to U.S. employees at lower levels of the organization. Currently, U.S. executives earn about 400 times the pay of the lowest paid workers in their own companies. In Europe and Asia, the pay of executives is about 10 times that of the lowest paid worker. Additionally, many U.S. executives have generous stock option or severance packages that increase the value of their compensation.

EVALUATING PAY EQUITY

With increasing attention focused on the issue of pay equity, corporate boards and stockholders are more concerned than ever about evaluating pay equity. To examine the fairness of executive pay, several factors must be assessed. First, the executive pay package should be responsible to shareholders, which means that it is not so high that it detracts from company profits or that its incentives discourage unethical influence of stock prices. One result of recent attention to issues of pay equity has been an increase in the linkage between long-term incentives and performance. The Mercer Survey cited above indicates that LTIs for CEOs are increasingly performance-based, with performance-shares making up 31 percent of the LTI mix in 2006 (up from 21% in 2005) and stock options dropping from 52 percent to 46 percent of the total. This marks a drastic change from 2002, when stock options made up 76 percent of CEO LTI pay.

Another factor in evaluating pay equity concerns the competitiveness of pay packages with those of other similar organizations so that executives can be recruited, rewarded, and retained successfully. If a pay package is not competitive, there may be motivation problems or turnover. Additionally, executive pay should fit with the company's strategy so that it encourages overall company success. This is particularly relevant in regards to short-term bonuses and long-term incentives which can be used to steer the performance of the executive and the organization. Finally, compensation for executives must be in compliance with regulations. There are a number of laws regarding retirement plans, stock options, and other compensation components that must be followed when designing executive pay plans.

ETHICAL CONCERNS WITH EXECUTIVE COMPENSATION

The base salary, bonuses, incentives, and benefits for executives have raised serious questions about the ethical implications of such pay. One concern about the high pay level for American executives is that they may encourage executives to make business decisions that benefit themselves rather than the organization in order to meet performance goals necessary to receive incentive pay. This is particularly likely if incentives are short-term in nature. For example, an executive may drive up short-term profits that cannot be sustained, only to collect a large bonus and leave the company before long-term financial problems are revealed.

A second concern with the ethics of high executive pay is the use of stock options as an incentive. Recent evidence of illegal practices in some high-profile American companies has prompted the enactment of the Sarbanes-Oxley Act of 2002. This act prevents executives of companies from keeping profits or bonuses acquired from selling company stock if they have misled the public about the financial health of the company to increase stock price.

Finally, some question the ethics of the high level of executive pay when lower-level employee pay has not risen at the same rate. There is a continually widening gap in compensation in different levels of organizations;

for instance, the Mercer study determined that CEOs enjoyed bonuses of 162 percent of salary in 2006, while other studies indicate that typical clerical and technical staff earn approximately 5 percent of salary as an annual bonus. Although some argue that executive level positions deserve high rates of pay due to the nature of the job and the high level of responsibility involved, others argue that the gap in executive versus typical employee pay has widened so dramatically that employees are under-compensated and may even be tempted to engage in unethical behavior, such as stealing from the company.

RESPONSIBLE EXECUTIVE COMPENSATION

The post-Sarbanes-Oxley world has seen an increasing push for responsible executive pay. This trend continues to gain momentum with new rules requiring companies to make disclosures about the nature and value of executive compensation packages. Stockholders have been particularly concerned with ensuring that executive compensation grows only as shareholder returns grow. Recent data indicates that this has in fact been happening. As the Mercer Survey notes, "While the median change in CEO total direct compensation (salary, bonus and long-term incentives) was 8.9 percent, corporate net income increased by 14.4 percent, up from 13 percent in 2005, and total shareholder return was 15.1 percent, more than double the 6.8 percent return in 2005. Companies heard the message that pay has to be linked to performance." It remains to be seen whether there will be sustained attention on this issue.

EXIT STRATEGY

An exit strategy in the business world can refer to how a person or entity will leave a firm or part of a firm behind; this can mean selling, liquidating, or in some cases, the complete demolition of an entire corporation (or a branch thereof). An exit strategy is a plan devised by a person or team within the firm—or by a consultant group—that will end the life of a product, service, or sector of a business venture. In some cases, an exit strategy refers to a plan that will enable an entrepreneur to part with a business in a variety of ways for the sake of profit and nothing else.

Ultimately, the goal of an exit strategy is to keep a firm from losing money on a product or branch that is no longer lucrative. When it no longer makes financial sense to keep an item or branch of business going, a clear-cut exit strategy must be established. Creating a good exit strategy is the responsible choice when an item is costing more than it is profiting. Experienced strategic managers will know when this time has come by looking at the numbers and making choices based on fiscal results; stakeholder input can also factor into the decision. In many cases, however, the point of an exit strategy is to sell a business for a profit and simply walk away. This type of exit strategy usually involves liquidation, acquisition, or sale to an employee or other interested, invested party.

ENDING A BRAND OR PRODUCT TYPE

Ending the life of a product or brand within a company can also mean the end of jobs or an entire division of a company. Therefore, as much consideration and planning should be done for the end as was done to begin the operation in question. In this case, providing different jobs or job training to employees who will be displaced by the cancellation of the product or division are important parts of an exit strategy. Other considerations may concern what to do with unnecessary equipment and space, and how to put together a campaign for public notice that a brand or product type will be discontinued.

ENDING OWNERSHIP

Perhaps the most popular reason for calling for an exit strategy is selling a business for profit. Most entrepreneurs sell for a profit or sell at a time when maintaining the business no longer makes financial sense. When the time comes to sell, having a well-thought-out exit strategy is important; unloading a business hastily or without a plan can cost thousands or millions of dollars or can create legal issues. The strategy used should always be approved or even drafted by legal counsel that specializes in business law. Regardless of how the entrepreneur leaves, thinking about the future and what the sale will mean should be on the top of a short list.

A business owner can leave his or her business behind in just a few ways: by sale to an employee or interested party, by liquidation, or by acquisition. Other strategies—like staying on with an extravagant salary or massive stock benefits—are not really exit strategies, as they don't cause an immediate, well-planned or even guaranteed exit. In fact, it's altogether possible to bankrupt the company this way, causing major financial upset for the owner and employees. An exit strategy should include a plan for the best future for everyone, simply bleeding the corporate coffers is not considered a strategy.

Selling Versus Acquisition. Of the exit strategies for the sale of a business, the best option for the life of the business is to sell to an employee, family, or customer. In this way the business will be preserved, for the buyer typically has a vested interest in what is best for its future. Additionally, selling to someone who already knows the business well, and who the buyer knows, will create an atmosphere of trust during the sale and will expedite the process.

Selling the business in an acquisition can mean a good deal more profit for the entrepreneur, which is a good choice if the life of the business is not a concern. Selling to an acquirer is often more lucrative because the acquirer is often a larger company and not an individual. Additionally, when negotiating price with an acquiring company, it may be easier to negotiate upward because as the process moves forward, others interested in acquisition may come along, stirring up an interest and therefore increasing the value of the company for sale. Conversely, selling to an acquiring company can lock the entrepreneur out of a specific industry (noncompete agreement) and the best interest of the company and its history are likely not major concerns for the acquirer. Selling the company becomes a question of what is more important to stakeholders: the legacy or the profit.

Emergency Exit. Sometimes a business must be sold due to a death, divorce, or other event that makes keeping it no longer possible or sensible. In this case, liquidation may be the best bet. While liquidation almost never adds up to the kind of benefit that selling outright does, it offers a fast exit with some profit for the entrepreneur. One way to avoid having to liquidate in the event of a divorce or death is to incorporate. In this way, a business is seen as its own "self," an entity other than the person(s) who own it. A good exit strategy will include plans for what to do and who gets what in the event of a tragedy or emergency. Part of any exit strategy should include a formula for determining the company's worth, a plan for the surviving partner(s), and who will receive what in the event of a divorce.

An exit strategy should be a part of every business plan at the onset. "Begin with the end in mind," says Steven Covey in *The Seven Habits of Successful Living*. Without this kind of forethought, little can be done when the end approaches. An exit strategy should always consider stakeholders, family, and employees first, as protecting them during a transition is always essential to the end goal.

EXPATRIATES

An expatriate is an employee sent by his or her employer to work in a foreign country. The firm is normally referred to as the parent company, while the country of employment is known as the host country. If General Motors sent one of its U.S. executives to oversee a new development in Brazil, the executive would be an expatriate, General Motors would be the parent company, and Brazil would be the host country. Equally, if an employee from Brazil was sent to the U.S. or an employee from Canada was sent to the People's Republic of China, they would be expatriates.

Many corporations are sending expatriates to their overseas operations, particularly as more firms face global competition and require internationally competent managers. Organizations need to understand the dynamic relationships between staffing and outcomes, and how these relationships change over time.

Expatriates provide a number of benefits for companies, including greater parent control and particular expertise. International experience is also seen as providing opportunities for personal and professional development and career advancement. Expatriates are very expensive, however, and this can discourage extensive use of expatriates. Many companies have also experienced relatively high failure rates, with failure often being attributed to the family's inability to adapt.

Surprisingly, given the high costs and potential for failure, companies often make these expensive commitments without preparing their employee for a cross-cultural transition. Expatriate success and job performance is closely related to intercultural adjustment and the same is true of families.

Given this, it is critical that companies use a rigorous selection process to identify which employees would likely succeed as expatriates. The selection process should also include consideration of the family.

istrative competencies. Strong relationships with the host country and headquarters' operations also make the expatriate's assignment more productive. Conflict resolution skills are also important to the expatriate. Expatriates must also have a strong belief in the assignment if it is to be a success, and they must believe that the assignment will be advantageous to their careers.

Motivation is likely to be higher if the person has an interest in the specific host country culture as well as in an overseas experience. To be successful the expatriate must be willing to acquire new behavior patterns and attitudes. The most successful expatriates enjoy the challenge of forging their way through new situations and are comfortable networking and initiating new social contacts. These are also critical for the families of expatriates. Training for expatriates and their families is therefore as important as proper selection.

To reduce the likelihood of premature termination of the assignment, companies should choose expatriates who have well-developed relationship skills. Some characteristics are crucial for a successful expatriate: tolerance for ambiguity, behavioral flexibility, strong interpersonal skills, and a nonjudgmental disposition. In addition, an effective expatriate would have high cultural empathy. Ethnocentrism is the belief that one's culture is superior. Ethnocentric expatriates are likely to have problems adjusting to a new culture, and the local people are likely to perceive them negatively. Communication is also key.

The expatriate needs to have some working knowledge of the host language, but it may be more important that the expatriate have outstanding nonverbal communication skills and an understanding that nonverbal communication varies between cultures. He or she should become familiar with common nonverbal protocol in the new culture.

Most expatriates take their families with them to the foreign country, and their family situation is one of the most critical factors in the successful completion of an overseas assignment. Family transition must be taken very seriously. An expatriate must be comfortable on a personal level. Major stress can be caused for the entire family by something as seemingly trivial as the transportation of a family pet. An expatriate's spouse must have a very strong willingness to live abroad. The spouse must be supportive as well as adaptive. Many firms have had expatriates' assignments terminated early because the spouse was unwilling or unable to make the necessary adjustments to the host country.

Predeparture training for the expatriate greatly increases the likelihood of success. The extent of training can depend on a variety of variables: previous overseas experience (if applicable), time until departure, and novelty of the new country. Cross-cultural training must be meaningful for the expatriate and family. Training should, at the minimum,

---

Exhibit 1

Types of Allowances Given to Expatriates

Foreign Service Premiums-This is a sum of money that is simply a reward for being willing to move one's family to a new country. The sum is generally a percentage of one's base salary—usually between 10 to 25 percent.

Hardship Allowance-The hardship allowance is actually another foreign service premium added to the original one. It is based on not just having to go overseas, but where you go overseas. Hardship allowances are greatest when the expatriate is sent to places having poor living conditions, a vastly different culture, less access to good health care, etc.

Cost of Living Allowances-Cost of living allowances (COLAs) enable expatriates to maintain their standard of living. COLAs are given when the cost of living in the host country is greater than that in the United States.

Housing Allowances-The cost of housing in various parts of the world is much higher than it is in the United States. Large apartments in Tokyo or Hong Kong, for instance, can go for upwards of $10,000 a month. Housing allowances compensate expatriates for these higher costs.

Utility Allowances-Some companies give expatriates a fixed sum of money above their base salary to pay their utilities bills; other companies try to ascertain the difference in utility bills between the home and the host countries, and give an allowance based on that difference.

Furnishing Allowances-Some companies offer to ship all of the expatriate's furnishings overseas. A second approach is to pay for the lease or purchase of furnishings overseas by expatriates. A third approach is to just give the expatriate a fixed sum of money (usually between $8,000 to $10,000) to buy furnishings.

Education Allowances-Most expatriates send their children to private school overseas. Companies often pay the full cost of tuition, books, and supplies.

Home Leave Allowances-Companies usually provide expatriates and their families with round-trip, business-class airfare to visit the home country at least once a year.

Relocation Allowances-The allowance makes up for any mistakes made in any of the other allowances for unforeseen complications. Expatriates receive about one month's salary.

Medical Allowances-Companies usually pay for all medical expenses. In hardship countries where medical facilities are inadequate, this includes emergency trips to other countries to receive medical care.

Car and Driver Allowances-Most companies offer expatriate managers a car allowance. This enables the expatriate to lease, buy, or rent a car in the host country. In some cases, the expatriate is given funds to hire a chauffeur.

Club Membership Allowances-In some countries the only way an expatriate can gain access to recreational facilities (e.g., tennis courts, swimming pools, country clubs) is by joining clubs. Also, in many cultures these facilities are important places in which to develop contacts and conduct business. This type of allowance is usually made on a case-by-case basis.

Taxes-Many companies reimburse expatriates for taxes they pay in excess of what they would have paid had they remained in the United States.

Several characteristics determine an expatriate's expected level of success: job skills, motivational state, language skills, relationship skills, and family situation. Technical competency is most often used as the selection criteria for expatriates, but that is rarely the best selection technique. An expatriate is likely to make more progress at the overseas location if he or she has effective managerial skills and admin-

inform the expatriate about the new country, and at the best, it would immerse the expatriate into the new culture.

Low-interaction training is focused on information distribution. It generally takes the form of lectures, videos, and readings. The material should include general area studies and a company operational overview. Low-intensity training would be appropriate for someone who has been on an expatriate assignment before or someone familiar with the host country. Unfortunately, this is often the only training received by most expatriates whether they have previous experience or not. This lack of training is usually due to last-minute selection or no training budget.

Medium- to high-intensity training should have a duration of one to two months. This training provides affective learning and cultural immersion. Medium-intensity training takes the intercultural experience workshop approach, offering cultural simulations, role plays, and case studies. Skill development can be culture-general or culture-specific. High-intensity training, most necessary for inexperienced expatriates entering a very different culture, provides sensitivity training and includes communication workshops and field exercises that focus on self awareness, listening skills, open-mindedness, and communication skills.

Prior to 2001, there were relatively few female expatriates (Stroh, Varma, Valy-Durbin, 2000), but a 2006 study by Mercer Human Resource Consulting showed an enormous increase in women being sent out on international assignments. This was particularly true for the Asia-Pacific region, which saw a sixteen-fold increase in female expatriates. The female expatriates in this study were far less likely than their male counterparts to be accompanied by a partner on the assignment. Although the companies surveyed did not have different policies for male and female assignees, it was clear that male and female expatriates were treated differently in certain respects. For example, 15 percent of the companies surveyed said they would not send a female employee to high-risk locations such as the Middle East.

Given that expatriates are very expensive, it is in a firm's interest to make sure the assignment is successful. Proper expatriate selection and training, as well as attention to the needs of the family, can be a productive investment.

EXPERIENCE AND LEARNING CURVES

Experience and learning curve models are developed from the basic premise that individuals and organizations acquire knowledge by doing work. By gaining experience through repetition, organizations and individuals develop relatively permanent changes in behavior or learning. As additional transactions occur in a service, or more products are produced by a manufacturer, the per-unit cost often decreases at a decreasing rate. This phenomenon follows an exponential curve. The organization thus gains competitive advantage by converting this cost reduction into productivity gains. This learning competitive advantage is known as the experience curve, the learning curve, or the progress curve.

It is common for the terms *experience curve* and *learning curve* to be used interchangeably. They do, however, have different meanings. According to definitions by Hall and Starr, the experience curve is an analytical tool designed to quantify the rate at which experience of accumulated output, to date, affects total lifetime costs. Melnyk defined the learning curve as an analytical tool designed to quantify the rate at which cumulative experience of labor

hours or cost allows an organization to reduce the amount of resources it must expend to accomplish a task. Experience curve is broader than learning curve with respect to the costs covered, the range of output during which the reductions in costs take place, and the causes of reduction.

Organizational learning is complex in that people learn at many levels simultaneously. In organizations, procedures, norms, rules, and forms store knowledge. March states that managers of competitive organizations often find themselves in situations where relative position with regard to a competitor matters. This possible competitive advantage through enhanced learning is the essence of the study of experience and learning curves.

The analytical use of the concept for business purposes first surfaced in 1936 during airplane construction, when Wright observed that as the quantity of manufactured units doubled, the number of direct labor hours needed to produce each individual unit decreased at a uniform rate. The variation of labor cost with production quantity is illustrated by the following formula:

$$F = \log\ F/\log N$$

where *F* equals a factor of cost variation proportional to the quantity *N*. The reciprocal of *F* represents a direct percent variation of cost versus quantity.

This insight shows that experience-based learning is closely correlated with cumulative output, extending beyond changes in design and tooling. Wright found empirical evidence that as unit volume increases there are predictable corresponding reductions in cost. These data become central concepts for strategic and operational planning. There has been much discussion on the role of learning in business organizations. A seminal work in learning theory is the 1963 *A Behavioral Theory of the Firm* by Cyert and March. These authors viewed firms as adaptively-rational systems. This means that the firm learns from its experience. In its basic form, an adaptive system selects preferred states for use in the future. With experience, management uses decision variables that lead to goals and shuns those that do not lead to goals.

The learning curve model was expanded by Adler and Clark into a learning process model. A key conceptual difference from the prior model is that "a significant part of the effect of experience on productivity (captured in the learning curve model) might be due to the influence of identifiable managerial actions." The authors present two orders of learning. First-order learning refers to the classic learning curve model where productivity is an exponential function of experience. Second-order learning denotes that which is driven by changes in technology or human capital that lead to goal attainment.

FUNDAMENTALS OF EXPERIENCE AND LEARNING CURVES

Following a strategy of increasing market share, the experience curve focuses on cost leadership. Management attempts to increase market share while simultaneously reducing costs. This is a detriment to market entry as the firm can lower its price, which may further increase its market share and place added pressure on potential competitors, as found in a study by Lieberman. Learning through experience becomes an important component of the increased market share strategy.

Quality learning is enhanced through the shared experience at the worker and organizational levels. Quality increases as the firm moves further along the experience curve, thus increasing productivity and efficiency. As the individual employees and organization become more efficient, there should be a corresponding increase in productivity. More output for less input effectively increases capacity; taken together with the increased efficiency and productivity, this should lead to a reduction in unit cost. The business is investing in a cost-leadership posture based on the assumption that price is a basis for competition. If the firm is able to produce quality units and reduce market price, there is the opportunity for increased market share (the business strategy). Increased market share via reduced price may lead to the global goal of improving profits.

Use of a cost-leadership strategy based on the experience curve implies several assumptions, according to Amit:

1. Price is a basis for competition.
2. If per unit cost is reduced, price may be reduced, which may lead to increased market share.
3. As cumulative output increases, the firm's average cost is reduced. Therefore, for any production rate, there is a reduction in the per-unit cost.
4. If market share is increased, profits will increase.

Another critical assumption of the experience curve, noted by Lieberman, is that learning can be kept within the organization. Where industry-wide dissemination of process technology is rapid, the benefits of organizational learning through the experience curve may be short-lived. The cost benefits, therefore, may not lead to increased market share even though industry costs are declining because all participants are learning at approximately the same rate.

LEARNING CURVE FORMULATION

The formula for the learning curve model is commonly shown either as a margin-cost model or as a direct-labor-hours model. The direct-labor-hours formula is more useful, as hourly compensation typically changes over time and there may be inflation considerations as well. However,

both derivations will be presented here for clarity. Also, direct-labor hours may be easily converted into costs if necessary, according to Yelle. By convention, we refer to experience curves by the complement of the improvement rate. For example, a 90 percent learning curve indicates a 10 percent decrease in per-unit (or mean) time or cost, with each doubling of productive output. Experience and learning curves normally apply only to cost of direct labor hours.

Marginal Cost Model. The cumulative-average learning curve formulation is:

$$Y_{cx} = ax^b$$

where Y_{cx} = average cost of the first x units,
   a = the first unit cost,
   x = the cumulative unit number output,
and
   b = the learning elasticity, which defines the slope of the learning curve.

This learning curve model indicates that as the quantity of units produced doubles, the average cost per unit decreases at a uniform rate.

Direct-Labor-Hours Model. The direct-labor-hours model of the learning curve is:

$$Y = KX^n$$

where Y = the number of direct labor hours required to produce the Xth unit,
   K = the number of direct labor hours required to produce the first unit,
   X = the cumulative unit number,
   n = log ϕ/log 2,
   ϕ = the learning rate, and
   $1 - \phi$ = the progress ratio.

These empirical models have been shown to fit many production situations very well. One criticism is that many other undocumented variables may be behind the benefits attributed to the experience curve. There are intermingling variables that also may account for cost reductions. Some of these variables might be economies of scale, product design decisions, tooling and equipment selections, methods analysis and layout, improved organizational and individual skills training, more effective production scheduling and control procedures, and improved motivation of employees. All of these variables play a role in decreasing cost and increasing capacity.

APPLICATIONS AND USES

There are three general areas for the application and use of experience curves: strategic, internal, and external to the organization. Strategic uses include determining volume-cost changes, estimating new product start-up costs, and pricing of new products. Internal applications include developing labor standards, scheduling, budgeting, and make-or-buy decisions. External uses are supplier scheduling, cash flow budgeting, and estimating purchase costs. The usefulness of experience and learning curves depends on a number of factors: the frequency of product innovation, the amount of direct labor versus machine-paced output, and the amount of advanced planning of methods and tooling. All lead to a predictable rate of reduction in throughput time.

Knowledge on the practical application of experience curves and learning curves has increased greatly since 1936. Interest was renewed in the early 1990s with the publication of *The Fifth Discipline* by Peter Senge. Senge melded theories on mental models, the systems approach, and learning curves in a way that made sense for executives.

These curves offer potential competitive advantage to managers who can capitalize on the cost reductions they offer. The experience and learning curves rely, however, on keeping the knowledge gained *within* their organization. Given rapid communication, high manager and engineer turnover, and skills in reverse engineering, this is harder to accomplish with each passing year. However, Hatch and Dyer found that in the case of the semiconductor manufacturing industry, in particular, skills acquired in one firm are not necessarily effectively transferable to another firm since knowledge is specific to the original work environment. Therefore, even if the employee is hired away, there is limited threat to the original firm.

Hatch and Dyer conclude that to truly maintain an advantage over the competition, firms must employ effective human resource selection, training, and deployment processes that facilitate learning by doing. Those firms that meet this challenge may enjoy the only truly sustainable advantage—the ability to learn (and improve) faster than competitors. As manufacturing and service product lives become shorter, management must be keenly on top of experience and learning curves to continue to enjoy the advantages.

EXPERT SYSTEMS

Expert systems are artificial intelligence (AI) tools that capture the expertise of knowledge workers and provide advice to (usually) non-experts in a given domain. Expert systems use computer programs that contain a knowledge database for a particular area along with an inference mechanism—usually a set of rules of deduction—that enables the program to solve problems that would normally be handled by humans. The outcome of expert system calculations are recommendations of one or more courses of action.

KNOWLEDGE REPRESENTATION SYSTEMS

Expert systems, also known as knowledge representation systems, utilize computerized models that capture the knowledge of one or more subject matter experts (SMEs) and store it in the framework that is most appropriately suited to the reasoning processes that the SMEs use in their problem-solving behavior. Such systems are created by a specialized systems analyst called a knowledge engineer, whose task is to interview the expert and/or observe his problem-solving behavior, then determine the most appropriate form(s) of knowledge representation to model the expert's problem-solving techniques. This process, called knowledge acquisition, is perhaps the most difficult and time-consuming aspect of expert systems development. It requires both technical and people skills on the part of the knowledge engineer, who must establish rapport with the domain expert, maintain a productive relationship during the interviewing process, and recognize the required mapping from the expert's explanations to the appropriate knowledge representation. The knowledge engineer then encodes the expert's knowledge into a knowledge base, which is a repository of the expert's knowledge in a particular representational structure. Some of the most common knowledge representations are described below.

In addition to the knowledge base, an expert system includes an automated reasoning mechanism called an inference engine that performs calculations and/or logical processes to produce the results of a particular problem-solving session. The explanation facility of an expert system provides the user with an explanation of the reasoning process that was used to achieve the conclusion or recommendation. Each knowledge representation has a corresponding inference technique. Three very common knowledge representations are rule-based systems, frame-based systems, and case-based systems.

UNCERTAINTY IN ARTIFICIAL INTELLIGENCE

The types of problems that AI systems try to solve are often fraught with uncertainties. Sometimes SMEs are uncertain

about the conclusions they may draw based on the facts that are presented to them. In addition, the facts themselves may not be clear-cut; they may be in error, incomplete, or ambiguous. Thus, AI systems must have the ability to reason and draw some inference even in the face of such uncertainties. AI systems do this in many ways. Two common approaches are described below.

Rules with Confidence Factors. This approach to uncertainty combines probability with logic. It enhances rule-based systems with probability-like numbers that represent the confidence in either a fact or an inferred conclusion. For example, consider this rule:

If the engine will not start but it will turn over, then the injection system is bad.

In some cases the facts are uncertain. Suppose the user is uncertain whether the engine starts or whether it turns over. If the user is 70 percent sure that the engine does not start and 80 percent sure that the engine turns over, then the conclusion of a bad injection system will be uncertain as well. A typical inference with this uncertainty is to multiply the two probabilities. In this case, 70 percent times 80 percent results in 56 percent confidence that the injection system is bad.

Furthermore, the rule itself may be uncertain. An expert may be only 60 percent sure that an engine that does not start and turns over implies a bad injection system. In this case, even if the user were 100 percent sure that the engine does not start but does turn over, the confidence in the conclusion of a bad injection system would be only 60 percent.

The inference process propagates the uncertainties through to the conclusions, so that the expert system tells the user not only what its recommendation is, but also the level of confidence in the recommendation.

An example of an expert system using rules can be found in the Department of Veterans Affairs within their OneVA initiative, which seeks to improve service by implementing improved information technology. A component of this initiative is the creation of an "expert system for the determination of potential benefits." This expert system utilizes a rule-based approach that analyzes customer data to determine proper eligibility levels.

Fuzzy Logic Systems. One of the most difficult obstacles facing the construction of expert systems is the inherent fuzziness of much human communication. Consider the question "Is this item expensive?" Here, "expensive" implies that the item costs a good deal of money. But how, even with data about prices, does one determine if an item is *expensive*? What is expensive to one person may be quite inexpensive to another. This is a case of linguistic ambiguity, where one word may have different meanings depending on context.

Fuzzy logic deals with linguistic ambiguity by mapping precise values (e.g., price, temperature, age in years) onto imprecise concepts (e.g., expensive, cold, young) via a membership function. The imprecise concept is called a fuzzy set, and the membership function measures the degree to which a precise value belongs in the fuzzy set.

Consider Figure 1, which shows three fuzzy sets related to the price of a product: inexpensive, moderate, and expensive. The membership functions are the solid and dashed lines in the graph. The X-axis shows the crisp value (actual price) and the Y-axis shows the degree of membership of a particular crisp value in each of the fuzzy sets. The price of $10 has 100 percent membership in the inexpensive set and 0 percent membership in each of the others. By contrast, the $100 price has 100 percent membership in the expensive set and 0 percent in the others. The $50 price has some degree of membership in all of the sets; it has 100 percent membership in the moderate set, but also some small degree of membership in both the others.

Figure 1
Artificial Intelligence & Expert Systems
Consider this rule:

**If the price is expensive then do not buy
the product**.

Such a rule will not fire at all if the price is $10. It will fire with 100 percent strength if the price is $100. It will fire with a much lower strength if the price is $50. This is the main idea behind fuzzy logic systems.

Fuzzy logic systems are used in many applications. They are commonly embedded in control systems, such as regulating automatic braking systems in cars and auto focusing in cameras.

COMPUTATIONAL INTELLIGENCE

In theory, expert systems can be applied to any domain of human knowledge. Researchers have focused on improving and expanding the kind of human thinking that can be imitated by computer systems. During the 1990s, developments in expert systems focused on applying computer models to banking and finance, forecasting, security, manufacturing, marketing, and many other business areas and industries. Specifically, areas such as loan applications, fraud detection, inventory management, enterprise resource planning, and supply-chain management found useful applications of expert systems.

With the success of these systems, there was an explosion of work on expert systems during the late 1990s and early 2000s, primarily focused on attempting to refine decision-making algorithms. This research led to the creation of a field known as computational intelligence, which is the current successor to artificial intelligence. Computational intelligence represents an evolution of expert-systems thinking, improving decision-making procedures by incorporating techniques such as neural networks, Swarm intelligence, fractals, and chaos theory. The field of computational intelligence is fairly new, and its techniques, tools, and goals are not as yet fully solidified. Researchers within this field expect exciting breakthroughs in intelligence-modeling and expert-systems developments during the early part of the twenty-first century, but the full power and potential of developing expert systems remains unclear.

EXPORTING AND IMPORTING

Exporting is the act of producing goods or services in one country and selling or trading them to another country. The term *export* originates from the Latin words *ex* and *portare*, meaning "to carry out." The counterpart to exporting is importing: acquiring goods from one country and selling them in another country. Although it is common to speak of a nation's exports or imports in the aggregate, the company that produces the good or service—as opposed to a nation's government—usually conducts exporting in terms of logistics and sales transactions. However, export and import levels may be highly influenced by government policies, such as offering subsidies that either restrict or encourage the sale of particular goods and services abroad. Certain exports, such as military technology, may be banned entirely, at least for certain recipients, in cases of trade embargoes or other government regulations (e.g., U.S. companies generally cannot export to or import from Cuba). Exporting is just one method that companies use to establish their presence in economies outside their home country. Importing is the method used to acquire products not readily available from within a country or to acquire products at a less expensive cost than if they were produced in that country.

A country may be in a favorable position to export for several reasons. A nation may export if it is the world's sole supplier of a certain good, such as when it has access to natural resources others lack. Some countries are also able to manufacture products at a relatively lower cost than other countries, for example, when labor costs less. Other factors include the ability to produce superior quality goods or the ability to produce the goods in a season of the year when other countries need them (Branch, 1990).

BALANCE OF TRADE

A country's international trade consists of both importing and exporting goods and services. The difference between the amount exported and the amount imported equals the balance of trade. A trade surplus consists of exporting more than importing while a trade deficit consists of importing more than exporting.

Figure 1

U.S. International Trade in Goods and Services (in billions of US dollars)

BRIEF HISTORY OF U.S. EXPORTS AND IMPORTS

The United States has been heavily dependent upon exporting throughout its history. It has played an important role in global trade as well. Even before its Declaration of Independence, the United States relied heavily on the exportation of cotton, tobacco, and other agricultural products to Europe for much of its commerce. After the Revolutionary War, the United States endured English duties and restrictions in Europe and the West Indies. This caused the United States to form new trade ties with overseas buyers in Africa, India and East Asia, helping to form a legacy of U.S. trading overseas.

Although the United States thrived in exporting during its first one hundred years, it was not until the Industrial Revolution gained momentum in the late nineteenth century that exporting began to significantly increase. This occurred mainly due to the technological advancements in communications, manufacturing, transportation, and food preservation techniques. It was during this time that the United States made the transition from being a supplier of agricultural products to a manufacturer of industrial goods, such as ships, railroads, clothes, and cars.

However, in the first decades of the twentieth century there was an increase in protective trade barriers and restrictions created by counties to further their own trade interests.

As a result, many laws were created to protect domestic industries and give local firms an advantage in trade. The Sherman Antitrust Act of 1890, the Federal Trade Commission Act of 1914, the Trading with the Enemy Act of 1917, and the Smoot-Hawley Tariff Act of 1930 were some of the laws passed in the United States at this time. While not all of these were intended to reduce trade, and probably none were intended to devastate U.S. exports, the general pattern internationally was to raise protectionist trade barriers and tariffs in kind, creating an unfavorable climate for U.S. exports. This repressive trade environment is considered one of the causes of the Great Depression.

During the mid- and late 1930s, the United States and other nations cooperated to reduce trade barriers and create a smoother world trade climate. The U.S. Reciprocal Trade Agreements Act of 1934 helped to introduce lower tariffs and duties imposed on imports. Additionally, the most-favored-nation (MFN) trading program extended the benefits of any bilateral tariff reductions negotiated by the United States to all MFNs.

World War II helped to increase United States exports, as did reduced trade barriers. At this time, countries turned to the United States for supplies and it was increasingly perceived as an industrial power and a source of high-quality goods. In the postwar years, the United States emerged as the most powerful international trade

leader, while the European and Japanese manufacturing sectors concentrated on rebuilding. From the 1940s through the 1960s, the U.S. trade surplus—the value of exports out of the country less the value of imports into the country—increased at a rate of 20 percent annually. U.S. exports continued to increase throughout the 1970s, growing from about $43 billion in 1970 to nearly $225 billion by 1980.

In the 1970s, however, increased competition from Western Europe and Japan wrested international market share from the United States. In the 1980s U.S. exports were outweighed by imports, as the national trade deficit grew to more than $160 billion annually by the late 1980s. Much of this deficit was due to oil imports; however, Japan's success at manufacturing quality goods for export, particularly autos and electronics, also contributed.

Despite this, increasing globalization of markets and an ongoing effort to lower trade barriers greatly expanded global trading. From 1986 to 1990, U.S. merchandise exports contributed more than 40 percent of the rise in gross national product (GNP). In 1990, almost 84 percent of U.S. GNP growth was due to exports, which totaled a record high of $394 billion. The increase of U.S. exports in the late 1980s and early 1990s led to a significantly lower trade deficit and two million new jobs attributed to exports. The U.S. Department of Commerce estimates that for every $45,000 in export sales, one job is created, more than double the rate of jobs created by domestic sales. By 2004, annual U.S. exports of goods and services were around $1.147 trillion, leaving a $617 billion trade deficit, based on U.S. Census Bureau, Foreign Trade Statistics figures. According to World Trade Organization estimates, in 2004 the United States supplied about 9.6 percent of the world's merchandise exports by value. The United States was the world leader in imports claiming a 16.8 percent share of world total imports.

CHARACTERISTICS OF EXPORTERS

Exports remain an important growth vehicle for U.S. companies, as many domestic product and service markets are saturated and offer only limited growth prospects. Many smaller firms export occasionally and seek to develop permanent, recurring business in foreign countries. Other companies only export to a few countries and want to increase the number of countries in which they do business.

In 2004, 15 percent of U.S. exporters accounted for 84 percent of the value of U.S. manufactured exports. Half of all exporters sell in only one foreign market. Fewer than 20 percent of exporters and fewer than three percent of U.S. companies overall export to more than five markets. From January of 2007 to January of 2008, U.S. exports increased by 16.56 percent, the most growth in one fiscal year since 2004. From 1993 to 2008, the largest single dip

in U.S. exports was in 2001, and this was largely due to the events and aftermath of September 11, 2001.

METHODS OF EXPORTING

Direct Exporting. The typical exporting system is a company-owned export department in which a manufacturer sells directly to companies or consumers in foreign countries. In this arrangement, the company has complete control over the marketing and distribution of its goods and services, distribution, sales, pricing, and other business choices. Most U.S. exporters, however, don't utilize this system. Many companies depend on one or several specialized export channels outside their organizations. Most companies choose direct and indirect routes. Direct exports are sold through foreign-based parties. Indirect exports are sold through home-based proxies or resellers. Both methods can be implemented through either merchants or agents. In these cases, merchants actually assume ownership of the goods, as opposed to agents, who only represent the manufacturer or owner. Bartering is another method that manufacturers may use to sell their goods abroad.

A direct merchant is an organization that buys goods abroad, then sells the goods in their own country. The merchants usually offer complementary services to their buyers such as maintenance, parts sales and technical support. A direct merchant often has a close relationship with the exporter, giving the merchant exclusive rights to sell and service the goods.

There are several different types of direct agents. Some direct agents, for example, are paid by U.S. firms on commission, have a contract, and usually do not sell competing products. The exporter trains a representative on the product and provides them with collateral material. Purchasing agents are similar to commission agents in that they are sent abroad by their company or country to purchase products. Purchasing agents are only in the target country long enough to broker a purchase.

Indirect Exporting. Indirect exporting is using a home-based merchant or agent to find and deliver goods to foreign buyers. This method of exporting poses the least amount of risk and expense because it is relatively easy to start up and has a moderate up-front capital investment. Indirect agents act as intermediaries between the exporter and buyer and facilitate the flow of goods.

There are several different types of indirect agents. One is an export management company (EMC). EMCs usually represent several companies in one or more industries. The agent charges the domestic company a fee or commission and in return provides the manufacturer with access to foreign channels of distribution and knowledge of foreign markets. Another type of indirect agent is a Webb-Pomerene Association. There are about forty such associations in

the United States. These associations are composed of competing manufacturers for the purpose of exporting. The associations are exempt from U.S. antitrust laws relating to price setting, discounting, and customer information. Export trading companies (ETCs) are another type of indirect agent. These were created in 1982 by the U.S. government to help U.S. manufacturers compete with powerful Japanese conglomerates. These companies are similar to but larger than EMCs and Webb-Pomerene Associations. Export commission houses are another indirect agency. In this case, commission agents represent buyers in foreign markets. The foreign buyer places an order and the commission agent solicits bids from domestic manufacturers. The lowest bidder usually receives the order and is compensated by the foreign buyer with a commission. This is an advantage for the exporter because the payment is usually received immediately and it takes little effort to complete the sale. Other indirect trading methods include foreign freight forwarding, which manage overseas shipments for a fee; brokering, which brings buyers and sellers together, but do not handle or distribute the goods; and export agents, who represent the manufacturer, and act under their own name.

EXPORTING GUIDELINES

The international market is more than four times larger than the U.S. market. The growth rates in foreign countries are also much greater than domestic market growth. For the first time in recent history, countries other than the United States are economically stronger due to their importing and exporting savvy. This is largely due to the fact that international exports are no longer just traveling West to serve the United States; much exchange (between even third world countries) now makes up overall global exports.

By exporting, companies can keep ahead of competition. Before starting to export, a company should measure the benefits against the costs and risks associated with it. The following are eleven keys to keep in mind when exporting.

1. Obtain export counseling and create an international marketing plan before beginning to export. The plan should include goals, objectives, and expected challenges.

2. Get a statement of financial commitment from executive management. Take a long-range view of exporting and ensure that management is ready and willing to troubleshoot and work to resolve any issues that may arise.

3. Carefully select foreign distributors. Due to global communication and transportation difficulties, international distributors must act independently.

4. Establish and agree unanimously to a foundation for a profitable operation and growth.

5. Continue dedication to export effort even when the U.S. market is booming. Many companies ignore their exporting plan when the U.S. economy picks up and subsequently lose a good share of the market.

6. Foreign distributors should be treated like domestic counterparts. Many companies implement advertising campaigns, discount offers, sales incentive programs, and so on to the U.S. market but don't make similar offers to their international distributors.

7. Do not assume that a marketing technique that works in one market will automatically work in others. Each market has to be treated separately to ensure success.

8. Research target demographics anywhere a presence is desired; not doing so will result in creating costly campaigns that may not work.

9. Be willing to make modifications to products to meet foreign regulations. Suppliers must take into account cultural preferences in other countries.

10. Messages pertaining to sale and warranties should be printed in local languages. Keep in mind that a foreign distributor may speak English, but it is unlikely that all sales and service personnel have this capability.

11. Readily available servicing for products should be provided. A company can earn a bad reputation when service support is not provided.

IMPORTING

Importing products into countries is often dependent on what product, commodity, or service is being imported. In the United States the Harmonized Tariff Schedule is the directory for determining which tariff is imposed on a given product. Importing will involve communicating with customs agencies to determine the necessary licensing and logistics issues of each nation. Often a customs broker is necessary to facilitate the smooth transfer of goods and services between countries. Inherently, importing involves exporting from one country; thus many of the issues involved in exporting are relevant and necessary for importing goods and services as well.

BARRIERS TO EXPORTS

Barriers to the export and import of goods have been widely established by governments. These barriers serve a number of purposes, including protecting industries, national employment levels, and improving trade balances. The United States and many other nations have made efforts to lower trade barriers, although many countries

still have an intricate network of barriers that greatly impact the world export market.

The two major classes of trade restrictions are tariff and nontariff. Tariffs are duties imposed on goods coming or going into a country. Among other uses, tariffs are used to penalize other countries for trade or political actions. Nontariff barriers include quotas, taxes, and exchange rate controls. These can be broken down into six major categories that include specific trade limitations, customs and administrative entry restrictions, standards, government participation, import charges, and miscellaneous categories. Many governments offer various global export initiatives to encourage free trade. The General Agreement on Tariffs and Trade (GATT), which was signed by the United States and the majority of developed and developing countries, calls for a decrease of both tariff and nontariff barriers worldwide. Other important developments include the North American Free Trade Agreement of 1993 and the European Union's gradual evolution toward economic unity. These agreements significantly reduce trade barriers within the affected regions. In the United States, most governments support specific industries or companies through financial aid, lower tax rates, loans, and grants.

REASONS TO EXPORT

The most important reason a company begins exporting is to maximize profits by exploiting opportunities in foreign markets that are not available in domestic markets. A product may become obsolete in one country, but may perform well abroad. When this happens, a manufacturer can reduce new product development costs and take advantage of learned efficiencies related to the product dealing with production, distribution, and marketing. When markets for products in the United States begin to mature and become saturated, producers can continue to receive continuous sales and profit gains through exporting. International markets are often less saturated

and less competitive, allowing manufacturers to gain faster sales growth and higher profit margins. Foreign markets can provide shelter not only from maturing domestic markets, but also from increased competition in the home market. As manufacturing volume increases, benefits related to economies of scale aid the exporter's competitiveness in both foreign and domestic markets. Market risk diversification is another benefit of exporting. A supplier can usually decrease its exposure to cyclical economic downswings or regional issues by increasing its geographic presence. Exporting also decreases risks associated with seasonality of some products, e.g., warm-weather-related products might be marketed in the Southern Hemisphere when it is winter in the Northern Hemisphere.

As trade barriers continue to dissolve due to the efforts of the World Trade Organization, exporting will become much more lucrative. The significant consumer buying power of industrialized nations, including the United States, is creating an ever expanding market for the exporting and importing of goods and services.

F

FACILITATOR

A facilitator is a person who helps a group identify and solve problems by structuring the discussion and intervening when necessary to improve the effectiveness of the group's processes and outcomes. Facilitators, sometimes called moderators, maintain a neutral approach to topics and issues and serve the whole group in an unbiased manner.

The word *facilitator* is derived from the French word *faciliter*, which means to make easy or to simplify. Indeed, the goal of the facilitator is to make a group's decision-making process easy, efficient, and effective.

In the mid-1970s, Doyle and Strauss, authors of *How to Make Meetings Work*, argued that facilitators were "neutral servants" responsible for making sure participants were using the most effective approaches to problem solving and decision making while reaching consensus efficiently. The role of facilitators in business has grown dramatically in the past few years, and multiple books on the topic describe the responsibilities of a facilitator as well as approaches for developing facilitation skills. The distinction is often made between facilitators who are external to the organization or the group and facilitators who are internal. Both external and internal facilitators focus primarily on a group's process. In fact, some facilitators have minimal subject matter expertise.

Certain organizations (such as the International Association of Facilitators) offer certification programs for individuals who want to become "professional" facilitators. According to the IAF's Web site, certification as a professional facilitator requires competency in the following areas: creating collaborative client relationships, planning appropriate group processes, creating and sustaining a participatory environment, guiding the group to appropriate and useful outcomes, building and maintaining professional knowledge, and modeling positive professional attitude. Candidates for certification complete an application, pay a fee, and undergo assessment by other members of the organization.

THE ROLE OF THE FACILITATOR

Facilitators set the agenda for a group meeting or discussion, monitor the group's process in discussing agenda items, and help the group reach consensus, make decisions, and set action plans. Effective facilitators bring out a variety of opinions and ideas, at the same time ensuring that all participants feel they are valued contributors to the discussion. Facilitators monitor how the group works together by encouraging participation, protecting individuals from attack, and minimizing dominance by one or two participants.

Facilitators begin by clearly defining the role they will play and the strategies they will use. In addition, facilitators help set ground rules for how group members will interact with each other, how long and when group members will speak, and how the group will make decisions.

Facilitators use a number of strategies to help groups achieve their goals. Focusing on consensus building, facilitators help participants discuss issues so that the end result is an outcome that all participants can support. Voting might be used to assess the depth of agreement or disagreement, but final group decisions are reached by consensus.

Facilitators can be most effective when groups are discussing future-oriented tasks such as developing mission statements, vision and value statements, or conducting strategic planning. Facilitation is also useful when groups

are discussing complex or controversial issues that require an outsider's unbiased attention to structure and process.

Typically, facilitators use flip charts, electronic boards, and web conferencing tools to capture ideas generated by group participants as well as the flow of the discussion. This visual reminder of the group's ideas, decisions, and action plans provide a "recorded" memory for the group during the discussion and the notes following the group meeting.

ADVANTAGES AND DISADVANTAGES OF USING FACILITATORS

Advantages for groups that use facilitators include a well-structured meeting, focus on a common goal and a common process, record of the group's discussion and decisions, and an efficient way to reach consensus and productive outcomes. Facilitators provide strategies to handle conflicts between members as well as other nonproductive participant behaviors that impede the group's process. They also absolve group participants from the responsibility of handling the discussion or staying neutral.

Disadvantages can occur when facilitators are not effective. If a facilitator loses objectivity, the group may feel manipulated by the facilitator's approach. Also, if the facilitator does not manage the group's process effectively, the group will either waste time reaching consensus or in some cases may not meet their goals at all. Finally, groups can become overly dependent on a facilitator and may not learn the skills and strategies necessary to make decisions.

MANAGERS AS FACILITATORS

While facilitators are usually not members of the group since they are required to remain neutral, there is a trend toward managers and team members developing facilitation skills that they can use in meetings and discussions. Managers who assume the role of a facilitator, by definition, are not neutral. Yet, through facilitation managers can lead teams in managing change and achieving work-related outcomes. Specifically, managers as facilitators provide clear expectations of the work to be done, monitor the team's process to increase team productivity, and manage the boundaries that can affect the work of the team. The manager as a facilitator empowers team members to make decisions and resolve problems.

For frequent, regular meetings, groups may rotate responsibility for acting as facilitator among team members or meeting participants. This spares any one person from always bearing the responsibility for focusing discussions, following the agenda, and enforcing time limits.

In a business world marked by rapid change, the role of facilitators will continue to expand as the need for managers and teams to solve complex problems also grows.

FEEDBACK

Feedback is the return of information about the result of a process, activity, or experience, usually relating to an individual's performance within a company. Feedback can be upward or downward in the organizational structure. Upward feedback is the process by which superiors or management are rated by employees or subordinates, while downward feedback is the flow of information from superiors or management to employees or subordinates.

In the past, feedback has been gathered from sources such as subordinates, peers, and internal or external customers. This is referred to as multi-source feedback when evaluations are collected from more than one source. In recent years, the majority of feedback has been collected for developmental purposes, but it seems that feedback is being used increasingly more in administrative decisions, including compensation and promotion. Such feedback is also being employed as a component of executive appraisals.

The impact of upward feedback is debatable, as is whether managers' responses to feedback are related to performance improvements over time. The major limitation of much research concerning feedback was that no one had examined whether managers' responses to such

Exhibit 1
Types of Feedback

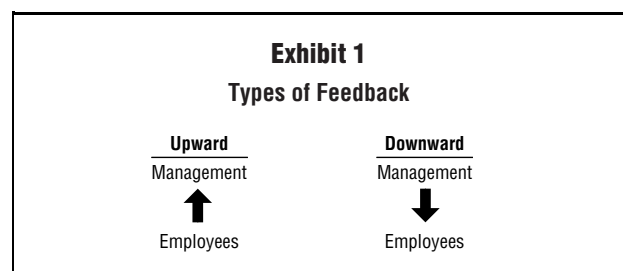
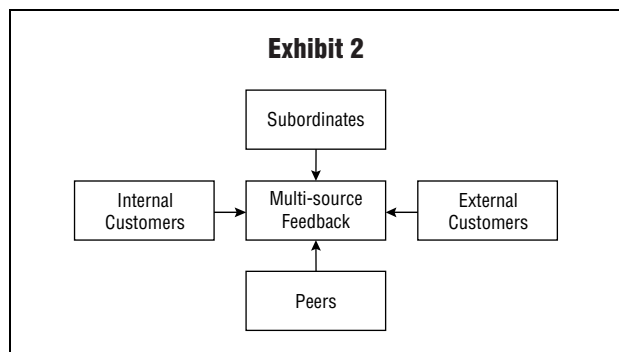
Management	Management
↑	↓
Employees	Employees

Exhibit 2

Subordinates → Multi-source Feedback ← External Customers

Internal Customers → Multi-source Feedback ← Peers




feedback were associated with performance improvement. It had been shown in the past that feedback alone was not the cause of behavior change; instead it was the goals that people set in response to feedback. A recent five-year study of upward feedback was conducted to answer some of these questions. The research covered more than 250 managers who received upward feedback annually over the five years. The results show that managers who were initially rated as being poor or moderate registered significant improvements in upward feedback ratings over the next five-year period. The results also show that managers who participated in discussions about their upward feedback improved more than managers who did not. It further showed that managers improved more in years when they discussed the previous year's feedback than in years when they did not. This study is important because it shows that what managers do with upward feedback is related to its benefits.

One alternative to upward feedback is a process known as "360-degree feedback." In this appraisal process, feedback about a particular employee is collected from that employee's supervisors, subordinates, peers, and sometimes customers, as well as through a self-evaluation. As a result, the employee receives a more comprehensive analysis as to how they are viewed by others, and the company can carefully tailor that employee's development program. A 2006 study showed that this type of feedback results in improved leadership behavior, often as a result of improved employee attitudes.

In the past, it has been assumed that discrepancies between self-ratings and subordinate ratings raise self-awareness, highlight gaps between goals and job performance, and suggest areas of needed improvement. According to the self-consistency theory, when managers receive feedback showing that subordinates ratings are lower than self-ratings, the managers may question whether their behavior is consistent with their self-image. This should, in theory, motivate the managers to improve their performance and reduce discrepancies between how they look at themselves and how subordinates perceive them. However, if the feedback is consistent with self-ratings, man-

agers may be satisfied and may not be motivated to improve their work ethic, even if their current performance level is low. Accordingly, the theory suggests that managers whose subordinate ratings exceed their self-rating have little incentive to improve their performance.

One study investigated whether performance improvement following upward feedback is related to self-other rating discrepancies. It also investigated how self-ratings change after feedback and whether agreement among raters influences performance improvement. The study determined that managers who overrated themselves compared to how others rated them tended to improve their performance from one year to the next, while the underraters tended to decline. These results are consistent with the self-consistency theory. Self-ratings tended to decrease for overraters and increase for underraters, but this was not constant throughout the range of self-ratings. Agreement with subordinate ratings was found to be negatively related to performance improvement.

An issue related to self-ratings of performance is the degree to which employees proactively seek feedback about their own performance from supervisors and/or coworkers. Some studies have linked employees' feedback-seeking to increases in job performance. By asking more often how they are doing, employees tend to know how to perform better. Employees seek feedback in order to reduce their uncertainty, to manage impressions of themselves in the workplace, and to protect their own egos. They are more likely to seek feedback when they have a positive relationship with the manager from whom they seek feedback, when they feel that their manager has expertise, and if they feel that their manager is supportive of them. Additionally, employees may be more likely to seek feedback in private, rather than when others are present.

Beyond its uses in performance appraisal, feedback may also be seen as a more general tool for communication within organizations. Many companies all over the world now use e-mail and toll-free numbers to solicit feedback from their employees. Many of these companies reward employees for their good ideas. In some instances, employees are paid for ideas that turn into new products and technologies, while other companies reward with job opportunities. By implementing a suggestion system, there is a direct link between an employee's suggestion and the rewards that the employee receives for it. The majority of employee ideas focus on improving safety and operations within the company.

FINANCIAL ISSUES FOR MANAGERS

One of the most critical aspects of management pertains to the finances of running a firm. Although there are numerous issues facing modern managers with respect to financial management, the following sections will address three of the most ubiquitous: acquisition of outside capital for start-up and growth, management of working capital and cash flow, and the construction and implementation of a capital budgeting process. Accessing the capital markets is fundamental for procuring funds that allow the firm to grow. Working capital involves managing the current assets and liabilities of the firm. Capital budgeting is the process of making long-term fixed asset investments.

ACCESSING THE FINANCIAL MARKETS

In the initial start-up of any firm, management must procure the funds needed to get the business off the ground. These funds may come from a variety of sources, but managers should be aware that all assets are initially financed with either of two sources of capital—equity and debt. The capital markets represent the method by which external funds are made available to firms requiring outside capital infusions.

Equity Markets. The equity markets are the means by which managers may raise capital by selling portions of the firm's ownership. The most common method is selling common stock in the firm. Outside investors provide the firm with new investment capital in exchange for ownership rights in the firm. As owners, stockholders receive voting rights and may participate in the financial success of the firm. In corporations, stockholders are protected by limited liability, meaning they are liable only for losses limited to the amount invested in the firm's stock; personal assets are protected against liability. Other sources of equity capital include contributions by the individual owner or owners from their own resources, and those made by family and friends of originators of the business.

Another method of raising equity capital involves the sale of preferred stock in the firm. Preferred stock promises to pay investors a stated dividend amount, and may also offer the opportunity for eventual conversion into common shares, commonly called convertible preferred stock. Preferred stock is particularly important for larger corporations as a source of funds because current tax law subsidizes the investment by one corporation in another corporation's preferred stock by exempting a portion of dividend income from taxation.

Other methods of equity capital attainment include the selling of warrants and rights. Warrants are securities that grant the holder the right to purchase a fixed number of common shares in the firm at a specified price for a specified period of time. Because warrants are stand-alone securities that may be traded among investors, the firm may raise new capital immediately through the sale of warrants while delaying the dilution of existing stockholders's interests until the warrants are exercised.

Rights are similar to warrants in that firms issue rights as a method of raising new equity capital. In a rights offering, the firm issues additional common stock to raise new capital. Rights are then issued to all outstanding shareholders, giving them the right to purchase shares in the new offering to avoid dilution of their pro-rata ownership in the firm. Through the use of rights, the firm is able to directly access the group of investors who are already interested in the firm's financial success, namely existing shareholders. Because rights have value in that they allow the purchase of new shares at a set subscription price, they are desired by shareholders and may be sold to others if the shareholder decides not to use the rights.

Debt Markets. The other major market for outside capital is the debt market. The debt market is often vital to the financial success of a firm and managers must be familiar with, and have access to, outside sources of debt capital to ensure the survival of the firm. A common method of debt financing is borrowing from financial institutions. Banks, finance companies, and other lenders offer loans of varying terms that are critical for financial management, particularly short-term debt to alleviate temporary cash flow problems. Venture debt firms are also experiencing a resurgence in popularity as managers seek ways to raise capital without further diluting the ownership of the firm. A firm that experiences seasonal sales or uneven production schedules will sometimes utilize an established line of credit to borrow during times of capital needs and repay during times of cash surplus. By arranging credit lines prior to the capital need, managers assure that the firm will not experience sales or production interruptions due to cash shortages. Company infrastructure expenditures like servers or lab equipment are common short-term investments for this type of debt. For longer-term needs,

negotiated notes from lenders serve as an intermediate source of debt financing.

For longer-term capital, the bond markets represent the primary source of debt financing. Bonds are debt securities in which investors become creditors of the firm in exchange for the right to receive payments of interest at regular intervals. For firms desiring to grow beyond local or regional status, access to the bond markets is critical for long-term capital needs, especially when firms do not desire to dilute existing ownership by offering additional equity financing.

SHORT-TERM FINANCIAL ISSUES

Short-term financial issues for managers revolve around two primary areas: the management of current assets and current liabilities. Together, they constitute the overall management of cash flow for the firm. Cash flow management is absolutely critical to the financial survival of a firm, since a shortage of cash may result in a firm that shows a profit on its income statement actually going bankrupt by being unable to meet its financial obligations.

Current Assets. Management of a firm's current assets starts with the management of cash. Cash provides the liquidity needed to meet everyday obligations owed to creditors and suppliers and the flexibility to take advantage of new opportunities that may arise. Managing cash is a tricky issue for many firms; cash is a necessary component of daily operations, yet cash is a non-earning asset. Dollars tied up in cash (checking accounts) could be earning higher rates of return if invested in other areas. Larger corporations spend considerable time and resources in cash management, whereby dollars are transferred back and forth between cash accounts and marketable securities that earn a higher rate of return. As previously mentioned, negotiated credit lines serve to supplement depleted cash during periods of shortage.

Another critical issue is the management of accounts receivable. Receivables are money owed to the firm that has not yet been collected. They represent an important investment for the firm, since dollars not yet received cannot earn a positive return. The management of accounts receivable involves the determination and implementation of the firm's credit policy such as how long customers are allowed to pay for merchandise or services received and cash discounts for immediate rather than deferred payment. These are important financial issues for any manager: to whom does the company extend credit, for how much, and for how long? A tight credit policy may result in missed sales opportunities, since fewer potential customers will qualify for credit sales. Conversely, liberal credit terms may result in longer average collection periods and greater uncollected accounts. There are real costs associated with these issues, and managers must work to find appropriate trade-offs that

result not only in higher sales, but also in the greatest profitability.

A third aspect of current asset management involves the management of inventories. Like receivables, inventory represents an investment of resources by the firm that has yet to pay off. On one hand, adequate inventory levels are necessary to ensure uninterrupted production schedules and to meet unexpected sales demand. However, too much inventory means dollars tied up in non-earning assets that could be devoted to more profitable investments. Managers must decide whether to attempt to coordinate production with sales patterns, or maintain level production regardless of current demand. These decisions spill over into other areas such as employee morale, since uneven or random production scheduling may result in temporary layoffs or overtime requirements. Again, managers utilize negotiated credit lines to access capital to maintain needed inventory materials when production and sales patterns differ.

Current Liabilities. Management of current liabilities involves accounts payable, short-term bank loans, lines of credit, and, for larger corporations, commercial paper. While the importance of short-term credit lines has already been discussed, accounts payable management is a critical issue, particularly for smaller firms. The longer a firm takes to pay its creditors, the longer it maintains access to and has the use of the funds. Thus, managers have every incentive to pay outstanding bills as slowly as possible. However, taking too long to pay may result in suppliers declining to offer future credit. Trade credit offered by suppliers is one of the most important sources of short-term financing for small firms that have limited access to other capital market sources. It is incumbent on managers to seek and negotiate the most favorable trade credit terms possible, since longer payment periods reduce potential cash flow problems and provide greater financial flexibility.

Larger corporations are able to issue commercial paper to provide short-term financial liquidity. Commercial paper is a short-term, unsecured note backed only by the firm's ability to repay. As such, only large, established firms find a market for their commercial paper. Firms such as General Motors use commercial paper as a regular source of short-term debt financing to cover cash flow shortages and provide the firm with ready liquidity.

Cash Budget. Pulling together the management of current assets and liabilities results in the development of a cash budget. A cash budget is a schedule of expected cash inflows and outflows by a period that allows managers the ability to plan for and cover cash shortfalls and surpluses. A successful cash budget prevents the types of surprises or shortages that can result in financial crises such as the inability to pay creditors or purchase additional inventory to meet production needs.

Likewise, managers should work to monitor and manage the firm's cash conversion cycle. The cash conversion cycle consists, primarily, of three elements: the inventory conversion period, the receivable collections period, and the payables deferral period. The goal of effective cash management is to minimize the inventory conversion and receivables collection periods, and to maximize the payables deferral period. Through the successful management of current assets and liabilities, managers can maintain a cash conversion cycle that provides the firm with liquidity and profitability while avoiding the cash flow problems that so often result in financial distress.

CAPITAL BUDGETING ANALYSIS

The third major financial issue for managers involves long-term investments. This area, collectively known as capital budgeting, involves investment in fixed assets such as plant and equipment, new product and business analysis, and expansion and merger analysis. Capital budgeting is extremely important, because the decisions made involve the direction and opportunities for the future growth of the firm. The goal of corporate management is to maximize shareholder wealth; profitable capital projects result in increased firm value.

Discounted Cash Flow. This process is also known as discounted cash flow analysis. The first step in evaluating a long-term investment opportunity is to estimate the net cash flows that would accrue to the firm. Managers should take care to use economically-sound techniques in cash flow analysis. All cash flows should be incremental (i.e., those that would otherwise not accrue to the firm unless this project or investment is undertaken). They should be on an after-tax basis; the only relevant cash flows are those that the firm will actually receive after all expenses and taxes are paid. Finally, sunk costs should not be included in the net cash flows associated with the project or investment. Only those cash flows associated with the future profitability of the investment should be included in the decision analysis. The proper economic decision is whether or not to invest today, and that decision is based on how the future cash flows will affect the present value of the firm. Past expenditures are not part of the analysis.

Once the project's net cash flows are determined, the timing of the cash flows should be considered. This is the discounted portion of discounted cash flow analysis. The decision of whether or not to invest is made in the present, so all dollars associated with the investment should be converted into present-value dollars. Managers must determine the proper interest rate at which to discount future cash flows. The discount rate should represent the opportunity cost of capital (also referred to as the Weighted Average Cost of Capital, or WACC), the rate of return that could be earned on alternative investment projects of similar risk. Many firms set an internal "hurdle rate" for capital budgeting analysis, in effect saying no long-term investments will be undertaken that offer an expected rate of return lower than the hurdle rate. Normally, this rate is the weighted average cost of capital, which incorporates the firm's capital structure in determining the required rate of return on investment.

Net Present Value Analysis. Once the net cash flows are determined and the discount rate has been established, managers should utilize a discounted cash flow method to evaluate and rank investment alternatives. The most economically-sound technique is net present value analysis (NPV), which involves discounting all future project cash flows back to the present using the firm's discount rate, then subtracting the net cost of the investment project. If the present value of the future cash-flow stream exceeds the present cost, then undertaking the project would add value to the firm today. The NPV method is congruent with the idea of management's goal to maximize the present value, which represents shareholder wealth, of the firm.

Internal Rate of Return. Another popular technique is the internal rate of return (IRR) method. The IRR is actually a special case of the NPV method. The internal rate of return is the unique discount rate that equates the present value of the future cash flow stream to the net cost of the project. If the IRR of the project is greater than the firm's hurdle rate, then the project offers a chance to earn a profitable return on investment and should be undertaken.

Payback Method. Finally, a third technique often used is the payback method. The payback method attempts to determine how long it will take for the project to recoup the total investment costs. Unlike the NPV and the IRR methods, the payback method is not a measure of profitability. Instead, it is a measure of time. Firms and managers often set a (subjective) hurdle period, such as no projects will be undertaken which do not recoup their initial costs in less than five years. The analysis then involves comparing the payback of the proposed investment to the firm's hurdle period. The payback method is popular because it provides an answer to a frequently asked question: "how long before this investment pays for itself?" However, it is a flawed method because it does not consider all of the project's cash flows and does not consider the time value of money. Managers should employ the payback technique only in tandem with at least one of either the NPV or IRR discounted cash-flow methods.

Financial management is an integral aspect of managing a company. Accessing the capital markets to provide investment dollars, managing the working capital of the firm to ensure liquidity and flexibility, and making long-

term investment decisions are all important issues that managers should address to allow the firm to grow and prosper.

FINANCIAL RATIOS

Financial ratios are one of the most common tools of managerial decision making. A ratio is the comparison of one number to another—mathematically, a simple division problem. Financial ratios involve the comparison of various figures from financial statements in order to gain information about a company's performance. It is the interpretation, rather than the calculation, that makes financial ratios a useful tool for business managers. Ratios may serve as indicators, clues, or red flags regarding noteworthy relationships between variables used to measure the firm's performance in terms of profitability, asset utilization, liquidity, leverage, or market valuation.

USE AND USERS OF RATIO ANALYSIS

There are basically two uses of financial ratio analysis: to track individual firm performance over time, and to make comparative judgments regarding firm performance. Firm performance is evaluated using trend analysis—calculating individual ratios on a per-period basis, and tracking their values over time. This analysis can be used to spot trends that may be cause for concern, such as an increasing average collection period for outstanding receivables or a decline in the firm's liquidity status. In this role, ratios serve as red flags for troublesome issues, or as benchmarks for performance measurement.

Another common usage of ratios is to make relative performance comparisons. For example, comparing a firm's profitability to that of a major competitor or observing how the firm stacks up versus industry averages enables the user to form judgments concerning key areas such as profitability or management effectiveness. Financial ratios are used by parties both internal and external to the firm. External users include security analysts, current and potential investors, creditors, competitors, and other industry observers. Internally, managers use ratio analysis to monitor performance and pinpoint strengths and weaknesses from which specific goals, objectives, and policy initiatives may be formed.

PROFITABILITY RATIOS

Perhaps the type of ratios most often used and considered by those outside a firm are profitability ratios. Profitability ratios provide measures of profit performance that serve to evaluate the periodic financial success of a firm. One of the most widely-used financial ratios is net profit margin, also known as return on sales.

$$\text{Net profit margin } = \frac{\text{net income}}{\text{net sales}}$$

Return on sales provides a measure of bottom-line profitability. For example, a net profit margin of 6 percent means that for every dollar in sales, the firm generated six cents in net income.

Two other margin measures are gross profit margin and operating margin.

$$\text{Gross profit margin } = \frac{\text{gross profit}}{\text{net sales}}$$

Gross margin measures the direct production costs of the firm. A gross profit margin of 30 percent would indicate that for each dollar in sales, the firm spent seventy cents in direct costs to produce the good or service that the firm sold.

$$\text{Operating margin } = \frac{\text{operating profit}}{\text{net sales}}$$

Operating margin goes one step further, incorporating nonproduction costs such as selling, general, and administrative expenses of the firm. Operating profit is also commonly referred to as earnings before interest and taxes, or EBIT. An operating margin of 15 percent would indicate that the firm spent an additional fifteen cents out of every dollar in sales on nonproduction expenses, such as sales commissions paid to the firm's sales force or administrative labor expenses.

Two very important measures of the firm's profitability are return on assets and return on equity.

$$\text{Return on assets } = \frac{\text{net income}}{\text{total assets}}$$

Return on assets (ROA) measures how effectively the firm's assets are used to generate profits net of expenses. An ROA of 7 percent would mean that for each dollar in assets, the firm generated seven cents in profits. This is an extremely useful measurement for any firm's management

---

Table 1

Profitability Ratios

Gross profit margin	Return on assets
Operating margin	Return on equity
Net profit margin	

---

performance as it is the job of managers to utilize the assets of the firm to produce profits.

$$\text{Return on equity } = \frac{\text{net income}}{\text{common shareholders equity}}$$

Return on equity (ROE) measures the net return per dollar invested in the firm by the owners, the common shareholders. An ROE of 11 percent means the firm is generating an eleven-cent return per dollar of net worth.

In each of the profitability ratios mentioned above, the numerator in the ratio comes from the firm's income statement. Hence, these are measures of periodic performance, covering the specific period reported in the firm's income statement. Therefore, the proper interpretation for a profitability ratio such as an ROA of 11 percent would be that, over the specific period (such as fiscal year 2004), the firm returned eleven cents on each dollar of asset investment.

ASSET UTILIZATION RATIOS

Asset utilization ratios provide measures of management effectiveness. These ratios serve as a guide to critical factors concerning the use of the firm's assets, inventory, and accounts receivable collections in day-to-day operations. Asset utilization ratios are especially important for internal monitoring concerning performance over multiple periods, serving as warning signals or benchmarks from which meaningful conclusions may be reached on operational issues. An example is the total asset turnover (TAT) ratio.

$$\text{Total asset turnover } = \frac{\text{net sales}}{\text{total assets}}$$

This ratio offers managers a measure of how well the firm is utilizing its assets in order to generate sales revenue. An increasing TAT would be an indication that the firm is using its assets more productively. For example, if the TAT for 2003 was 2.2×, and for 2004 it was 3×, the interpretation would follow that in 2004, the firm generated three dollars in sales for each dollar of assets, and an additional eighty cents in sales per dollar of asset investment over the previous year. Such change may be an indication of increased managerial effectiveness.

A similar measure is the fixed asset turnover (FAT) ratio.

$$\text{Fixed asset turnover } = \frac{\text{net sales}}{\text{net fixed assets}}$$

Fixed assets (such as plant and equipment) are often more closely associated with direct production than are current assets (such as cash and accounts receivable), so many analysts prefer this measure of effectiveness. A FAT of 1.6× would be interpreted as the firm generating $1.60 in sales for every $1.00 it had in fixed assets.

Two other asset utilization ratios concern the effectiveness of a firm's asset management. Inventory is an important economic variable for management to monitor since dollars invested in inventory have not yet resulted in any return. Inventory is an investment, and it is important for the firm to maximize its inventory turnover. The inventory turnover ratio is used to measure this aspect of performance.

$$\text{Inventory turnover ratio} = \frac{\text{cost of goods sold}}{\text{average inventory}}$$

Cost of goods sold (COGS) derives from the income statement and indicates the expense dollars attributed to the actual production of goods sold during a specified period. Inventory is an asset on the balance sheet. Because the balance sheet represents the firm's assets and liabilities at one point in time, an average figure is often used from two successive balance sheets. Managers attempt to increase this ratio, since a higher turnover ratio indicates that the firm is going through its inventory more often due to higher sales. A turnover ratio of 4.75×, or 475 percent, means the firm sold and replaced its inventory stock more than four and one-half times during the period measured on the income statement.

One of the most critical ratios that management must monitor is days sales outstanding (DSO), also known as average collection period.

$$\text{DSO } = \frac{\text{accounts receivable}}{\text{net sales}} \times 360 \text{ days}$$

This represents a prime example of the use of a ratio as an internal monitoring tool. Managers strive to minimize the firm's average collection period, since dollars received from customers become immediately available for reinvestment. Periodic measurement of the DSO will "red flag" a lengthening of the firm's time to collect outstanding accounts before customers get used to taking longer to pay. A DSO of 36 means that, on average, it takes 36 days to collect on the firm's outstanding

Table 2
Asset Utilization Ratios

Total asset turnover	Days sales outstanding
Inventory turnover	Fixed asset turnover

accounts. This is an especially critical measure for firms in industries where extensive trade credit is offered, but any company that extends credit on sales should be aware of the DSO on a regular basis.

LEVERAGE RATIOS

Leverage ratios, also known as capitalization ratios, measure the firm's use of debt financing. These are extremely important for potential creditors who are concerned with the firm's ability to generate the cash flow necessary to make interest payments on outstanding debt. Thus, these ratios are used extensively by analysts outside the firm to make decisions concerning the provision of new credit or the extension of existing credit. It is also important for management to monitor the firm's use of debt financing. The commitment to service outstanding debt is a fixed cost to a firm, resulting in decreased flexibility and higher break-even production rates. Therefore, the use of debt financing increases the risk associated with the firm. Managers and creditors must constantly monitor the trade-off between the additional risk that comes with borrowing money and the increased opportunities that new capital provides. Leverage ratios provide a means of such monitoring.

Perhaps the most straightforward measure of a firm's use of debt financing is the total-debt ratio.

$$\text{Total debt ratio} = \frac{\text{total debt}}{\text{total assets}}$$

There are only two ways to finance the acquisition of any asset: debt (using borrowed funds) and equity (using funds from internal operations or selling stock in the company); total debt ratio covers both. A debt ratio of 35 percent means that, for every dollar of assets the firm has, thirty-five cents were financed with borrowed money. The natural corollary is that the other sixty-five cents came from equity financing. This is known as the firm's capital structure—35 percent debt and 65 percent equity. Greater debt means greater leverage, and more leverage means more risk. How much debt is too much is highly subjective, and opinions vary from one manager to another. To a large extent, the nature of the business will determine debt risk. Large manufacturers, who require heavy investment in fixed plant and equipment, will require higher levels of debt financing than will service firms such as insurance or advertising agencies.

The total debt of a firm consists of both long- and short-term liabilities. Short-term (or current) liabilities are often a necessary part of daily operations and may fluctuate regularly depending on factors such as seasonal sales. Many creditors prefer to focus their attention on the firm's use of long-term debt. Thus, a common variation on the total debt ratio is the long-term debt ratio, which does not incorporate current liabilities in the numerator.

$$\text{Long-term debt ratio} = \frac{\text{long-term debt}}{\text{total assets}}$$

Similarly, many analysts prefer a direct comparison of the firm's capital structure. Such a measure is provided by the debt-to-equity ratio.

$$\text{Debt-to-equity ratio} = \frac{\text{total debt}}{\text{total equity}}$$

This is perhaps one of the most misunderstood financial ratios, as many confuse it with the total debt ratio. A debt-to-equity ratio of 45 percent would mean that for each dollar of equity financing, the firm has 45 cents in debt financing. This does not mean that the firm has 45 percent of its total financing as debt; debt and equity percentages, together, must sum to one (100 percent of the firm's total financing). A little algebra will illustrate this point. Let x = the percent of equity financing (in decimal form), so $0.45x$ is the percent of debt financing. Then $x + 0.45\ x = 1$, and $x = 0.69$. So, a debt to equity ratio of 45 percent indicates that each dollar of the firm's assets is financed with sixty-nine cents of equity and thirty-one cents of debt. The point here is to caution against confusing the interpretation of the debt-to-equity ratio with that of the total debt ratio.

Two other leverage ratios that are particularly important to the firm's creditors are the times-interest-earned and the fixed-charge coverage ratios. These measure the firm's ability to meet its on-going commitment to service debt previously borrowed. The times-interest-earned (TIE) ratio, also known as the EBIT (earnings before interest and tax) coverage ratio, provides a measure of the firm's ability to meet its interest expenses with operating profits.

$$\text{Times interest earned} = \frac{\text{EBIT}}{\text{interest charges}}$$

For example, a TIE of 3.6× indicates that the firm's operating profits from a recent period exceeded the total interest expenses it was required to pay by 360 percent. The higher this ratio, the more financially stable the firm and the greater the safety margin in the case of fluctuations

Table 3
Leverage Ratios

Total debt ratio	Times interest earned
Long-term debt ratio	Fixed charge coverage
Debt-to-equity ratio	

in sales and operating expenses. This ratio is particularly important for lenders of short-term debt to the firm, since short-term debt is usually paid out of current operating revenue.

Similarly, the fixed charge coverage ratio, also known as the debt service coverage ratio, takes into account all regular periodic obligations of the firm.

$$\text{Fixed charge coverage} = \frac{\text{EBIT}}{(\text{Interest expense} + \frac{\text{Principal repayment}}{1 - \text{tax rate}})}$$

The adjustment to the principal repayment reflects the fact that this portion of the debt repayment is not tax deductible. By including the payment of both principal and interest, the fixed charge coverage ratio provides a more conservative measure of the firm's ability to meet fixed obligations.

LIQUIDITY RATIOS

Managers and creditors must closely monitor the firm's ability to meet short-term obligations. The liquidity ratios are measures that indicate a firm's ability to repay short-term debt. Current liabilities represent obligations that are typically due in one year or less. The current and quick ratios are used to gauge a firm's liquidity.

$$\text{Current ratio} = \frac{\text{current assets}}{\text{current liabilities}}$$

A current ratio of $1.5\times$ indicates that for every dollar in current liabilities, the firm has \$1.50 in current assets. Such assets could, theoretically, be sold and the proceeds used to satisfy the liabilities if the firm ran short of cash. However, some current assets are more liquid than others. Obviously, the most liquid current asset is cash. Accounts receivable are usually collected within

Table 4
Liquidity Ratios

Current ratio	Quick ratio

one to three months, but this varies by firm and industry. The least liquid of current assets is often inventory. Depending on the type of industry or product, some inventory has no ready market. Since the economic definition of liquidity is the ability to turn an asset into cash at or near fair market value, inventory that is not easily sold will not be helpful in meeting short-term obligations. The quick (or acid test) ratio incorporates this concern.

$$\text{Quick ratio} = \frac{\text{current assets} - \text{inventories}}{\text{current liabilities}}$$

By excluding inventories, the quick ratio is a more strident liquidity measure than the current ratio. It is a more appropriate measure for industries that involve long product production cycles, such as manufacturing.

MARKET VALUE RATIOS

Managers and investors are interested in market ratios, which are used in valuing the firm's stock. The price-earnings ratio and the market-to-book value ratio are often used in the valuation analysis. The price/earnings ratio, universally known as the PE ratio, is one of the most heavily-quoted statistics concerning a firm's common stock. It is reported in the financial pages of newspapers, along with the current value of the firm's stock price.

$$\text{Price/earnings ratio} = \frac{\text{market price per share}}{\text{earnings per share}}$$

Caution is warranted in the calculation of PE ratios. Analysts use two different components in the denominator: trailing earnings and forecast earnings. Trailing earnings refer to the firm's reported earnings, per share, over the last twelve months of operation. Forecast earnings are based on security analyst forecasts of what they expect the firm to earn in the coming twelve-month period. Neither definition is more correct than the other; one should simply pay attention to which measure is used when consulting published PE ratios. A PE ratio of 16 means investors are willing to pay \$16 for \$1 worth of earnings. PE ratios are used extensively, on a comparative basis, to analyze investment alternatives. In investment lingo, the PE ratio is often referred to as the firm's "multiple." A high PE is often indicative of investors' belief that the firm has very promising growth prospects, while firms in more mature industries often trade at lower multiples.

A related measure used for valuation purposes is the market-to-book value ratio. The book value of a firm is defined as:

Table 5
Market Value Ratios

Price/earnings ratio	Market-to-book ratio

$$\text{Book value per share} = \frac{\text{total shareholders equity}}{\text{common shares outstanding}}$$

Technically, the book value represents the value of the firm if all the assets were sold off, and the proceeds used to retire all outstanding debt. The remainder would represent the equity that would be divided, proportionally, among the firm's shareholders. Many investors like to compare the current price of the firm's common stock with its book, or break-up, value.

$$\text{Market-to-book ratio} = \frac{\text{market price per share}}{\text{book value per share}}$$

This is also known as the price/book ratio. If the ratio is greater than one, which is often the case, then the firm is trading at a premium to book value. Many investors regard a market-to-book ratio of less than one an indication of an undervalued firm. Interpretation of market ratios—high PEs versus low PEs—is highly subjective. Nonetheless, these measures provide information that is valued both by managers and investors regarding the market price of a firm's stock.

COMMON SIZE RATIOS

Common size ratios are used to contrast and compare the financial statements of large and small enterprises. Using the common size ratio, an analyst can determine which variables and which trends are affecting businesses of all sizes, and which of these is affecting small business more than larger business (and vice versa). Common size ratios are used to compare data about inventory, total assets, cost of goods sold, gross profit, overhead and production costs, and overall yearly revenue from one firm to another, usually one significantly larger than the other.

The comparison of one company to another company using common size ratios is sometimes called a *cross-sectional analysis*, and will include industry averages to draw a comparison for both entities. Often the common size ratio will use comparative data about an industry's leader by which to compare another smaller, more modest operation to see how it might be progressing.

CAUTIONS ON THE USE AND INTERPRETATION OF FINANCIAL RATIOS

Financial ratios represent tools for insight into the performance, efficiency, and profitability of a firm. Ratio calculation and interpretation can be confusing. For example, if someone refers to a firm's profit margin, are they referring to gross profit margin, operating margin, or net profit margin? Is debt ratio a reference to total debt ratio, long-term debt ratio, or debt-to-equity ratio? Confusing these can make the use of ratio analysis a frustrating experience.

Financial ratios should be interpreted with care. A net profit margin of 12 percent may be outstanding for one type of industry and mediocre to poor for another. This highlights the fact that individual ratios should not be interpreted in isolation. Trend analyses should include a series of identical calculations, such as following the current ratio on a quarterly basis for two consecutive years. Ratios used for performance evaluation should always be compared to some benchmark, either an industry average or the identical ratio for the industry leader.

Another factor in ratio interpretation is identifying whether individual components, such as net income or current assets, originate from the firm's income statement or balance sheet. The income statement reports performance over a specified time period, while the balance sheet gives static measurement at a single point in time. These issues should be recognized when interpreting the results of ratio calculations.

Despite these issues, financial ratios are useful for internal and external evaluations of a firm's performance. A working knowledge and ability to use and interpret ratios remains a fundamental aspect of effective financial management. Financial ratios were widely used and highly valued during the stock market decline of 2000, when the bottom dropped out of the soaring "dot.com" economy. Throughout the long run-up, some financial analysts warned that the stock prices of many technology companies—particularly Internet start-up businesses—were overvalued based on the traditional rules of ratio analysis. Yet investors largely ignored such warnings and continued to flock to these companies in hopes of making a quick return.

Conversely, the 2008 crossroads in energy and fuel management—and China's growing need for oil and other raw materials—has been largely forecasted and interpreted using financial ratios. Investors and analysts alike have weathered rough parts of this supply and demand crisis by evaluating market circumstances with ratios and facing the truth rather than ignoring it.

In the end, it becomes clear that the old rules still apply, and that financial ratios remain an important means of measuring, comparing, and predicting a firm's performance.

FIRST-MOVER ADVANTAGE

The idea of first-mover advantage is similar to the old adage, "the early bird gets the worm." In business, being the first company to sell a new product may provide long-lasting benefits or competitive advantages. Most researchers use the term "first-mover" to refer to the first company to enter a market, not the first company to develop a product (the inventor). First movers are also called market pioneers. The benefits of pioneering may result in market dominance and higher-than-average profitability over time. There are several reasons why these benefits may develop, but research has shown that being the first mover does not always provide advantages. Sometimes there are even first-mover disadvantages, where companies that enter a market later can achieve superior results to those attained by the first-mover firm.

For example, Amazon.com was the first major online bookstore, seizing a head start on later entrants. Established book retailers Barnes & Noble and Borders were quick to develop their own Web sites. Amazon maintained their first-mover advantage in two ways: by partnering with Borders and by extending their product offerings into apparel, electronics, toys, and housewares. This negated any customer preference for purchasing from Barnes & Noble because Amazon became a much larger and more versatile one-stop-shopping destination. Company strategists need to decide if they are likely to benefit from being first, or whether it would be better to wait and follow the leader.

There are two stages to developing first-mover advantages. First, a company must have an opportunity to be first at something, either through skill or luck. Second, the firm must be able to capture the benefits of being first.

In their award-winning article, professors Marvin Lieberman and David Montgomery of Stanford University described three benefits of being first: technology leadership, control of resources, and buyer-switching costs.

TECHNOLOGY LEADERSHIP

First, early entrants can lead other companies in their understanding and use of technology in ways that are hard for later entrants to copy. One way this can happen is that the early entrant learns how to reduce the costs of producing a product through accumulated experience in producing it. This is called a "learning" or "experience" curve effect. Unless later entrants can learn how to produce at these lower costs faster than the first entrant did, the first entrant will have a cost advantage. Harvard University Professor Michael Porter discusses how Procter & Gamble developed an advantage in disposable diapers in the United States. However, researchers have found that in most industries it is relatively easy for later entrants to learn new technology quickly and overcome the lead held by the first-mover firm.

Another way that a first mover may benefit from technology leadership is by applying for patents for their technology to try to prevent other companies from copying it. Patents appear to protect first-mover advantages in some industries, such as pharmaceuticals. In many industries, though, later entrants can invent their own technology quickly enough so that the first-mover's patent protection does not matter. A stronger advantage from technology leadership arises when the first mover can establish their product as the industry standard, making it more difficult for followers to gain customer acceptance. An example of this is the RIM BlackBerry. While there are other mobile devices that offer as much or more in terms of Internet and communications technology, BlackBerry—the first mover in this category—is the industry standard, making BlackBerry the "it" handheld device by which all others are compared.

CONTROL OF RESOURCES

The second type of first-mover benefit is the ability to control a resource necessary for the business that is better than resources later entrants must use. For example, the first company to open a new type of restaurant in town may obtain the best location. This is considered to be one of the advantages exploited by Wal-Mart (and later by Starbucks) when they were the first to scout and secure store locations in small towns. Other resources that a first entrant may be able to control include a supply of raw materials needed to make the product, or access to shelf space at the supermarket. First-mover firms also have the opportunity to build resources that may discourage entry by other companies. For example, the first mover may

increase production capacity or broaden their product line, signaling that there is not enough room for followers to enter and profit.

BUYER-SWITCHING COSTS

The final benefit that first movers may enjoy comes from buyer-switching costs. If it is costly or inconvenient for a customer to switch to a new brand, the first company to gain the customer will have an advantage. Switching costs includes adapting to a new product (e.g., employee training), and penalties associated with breaking a long-term contract. Especially for consumer products, the first mover has the opportunity to shape consumer preferences. The first company to offer a product of acceptable quality may earn brand loyalty. Satisfied consumers tend not to spend time seeking information about other products, and tend to avoid the risk of being dissatisfied if they switch. The pioneering brands in many product categories, such as Coca-Cola soft drinks and Kleenex facial tissues, often dominate their markets for a long time. These brand preferences appear to be more important for products purchased by consumers than for products purchased by businesses. Businesses buy products in larger volume and have more incentive to search for information about lower-cost options.

UNCERTAINTY OF FIRST-MOVER ADVANTAGE

Three types of benefits—technology leadership, control of resources, and buyer-switching costs—can provide long-lasting first-mover advantages. However, researchers believe that in many industries, companies entering later can overcome these advantages. Sometimes there are even first-mover disadvantages, or advantages enjoyed by companies who enter later. For example, the first entrant may invest heavily in enticing customers to try a new type of product. Later entrants would benefit from informed buyers without having to spend as much on educational marketing. Later entrants may be able to avoid mistakes made by the first movers. If first movers become complacent, later entrants may take advantage of changing customer needs. As the Internet continues to develop, technology companies find themselves especially susceptible to second- or later-mover success. Follower companies are reverse-engineering many new products to develop competing products either faster or cheaper—negating much of the first-mover advantage.

Given the uncertainty about when first-mover advantages occur, companies need to carefully consider their strategy. Does the firm want to invest in seeking opportunities to be first? If opportunities arise, what is the best approach to market timing? Which of the three types of benefits are likely to be available to the first entrant in this market and to what degree? Does the firm have the resour-

ces to sustain any initial benefits they gain from being first? If someone else enters first, how difficult will it be to follow? What advantages might a later entry provide in better or lower-cost technology, or better adaptation to customer needs? Although first-mover advantages may be attractive, there are also advantages to being a follower. Company strategists need to decide which approach has the highest potential for long-term profits given their resources and viable market characteristics.

FIVE S FRAMEWORK

The 5S framework was originally developed by just-in-time expert and international consultant Hiroyuki Hirano. The 5S framework is an extension of Hirano's earlier works on just-in-time production systems. The 5Ss represent a simple "good housekeeping" approach to improving the work environment consistent with the tenets of lean manufacturing systems. The focus on the concept is how the visual

workplace can be utilized to drive inefficiencies out of the manufacturing process.

This framework also improves workplace safety, which makes it attractive to businesses. According to Hirano, without the organization and discipline provided by successfully implementing the 5Ss, other lean manufacturing tools and methods are likely to fail. The 5Ss stand for the Japanese words *seiri, seiton, seiso, seiketsu,* and *shitsuke.* These Japanese "S" words roughly translate into the English words organization, orderliness, cleanliness, standardized cleanup, and discipline. Alternative corresponding "Ss" have also been developed for the English language: sort, set in order, shine, standardize, and sustain.

Seiri, or sort, focuses upon reducing the amount of rarely used material or tools that tend to create clutter. Only those things required for immediate production should be retained in the work area. *Seiton,* or orderliness, facilitates the reduction of clutter and efficient access to material or tools by following the old adage "a place for everything and everything in its place." Workers readily know when a tool is missing because of visual signals (e.g., empty space on a signboard).

Seiso, or cleanliness, focuses upon keeping the workplace, machinery, and tools clean. This includes keeping tools and machinery calibrated, performing preventive maintenance, and the use of visual cues to signal when maintenance is needed. *Seiketsu,* or standardized cleanup, is essentially the condition that occurs when the first three pillars—the first 3Ss—are implemented well. However, it also includes institutionalizing the first three pillars. This includes developing rules, processes, and procedures to ensure that the continuity and uniformity of achievements accrued by the first three pillars do not erode over time.

Finally, *shitsuke,* or discipline, focuses upon putting procedures into place that sustain the psychological meaningfulness of the payoffs achieved by the overall framework. This may include periodic rewards for workers who excel in some facet of the framework or other visual signals that communicate the commitment of management to the continued implementation of 5S.

Use of color is a primary tool of the visual workplace. Examples include color-coded connections to mistake-proof and speed connections of all sorts of parts, and colored boundary markers on shop floors. Information sharing is also an important aspect of the visual workplace. For example, processes can be designed to provide visual signals indicating that certain activities need to occur (e.g., empty inventory space on the floor) or to communicate productivity standards and output.

5S framework guidelines can be tailored by managers to suit the routine workplace environment of their particular organizations. Moreover, training of new employees (to ensure that they understand the organization-specific workplace environment guidelines) is a very important formality in the orientation process. This is primarily because different organizations observe different procedures for implementing the 5S framework model. For example, training of new employees at McDonald's begins with an immediate one-hour orientation program on the general structures and operation procedures of the company.

Many companies have utilized the simple guidelines provided by the 5S framework. However, implementing the framework is not always a simple task. It may require redesigning processes or buying new, more reliable machinery. This difficulty has given rise to a burgeoning consulting business designed to help firms implement the 5S system, including process design as well as employee training. Interestingly, while there appears to be a wide variety of firms utilizing the 5S framework, there is no published empirical research supporting its utility. There does, however, appear to be some anecdotal evidence supporting the efficacy of the 5S framework.

FLEXIBLE BENEFITS

SEE *Cafeteria Plan—Flexible Benefits*

FLEXIBLE MANUFACTURING

Business firms generally choose to compete within one or two areas of strength. These areas of strength are often referred to as distinctive competencies, core competencies, or competitive priorities. Among the options for competition are price (cost), quality, delivery, service, and flexibility. An ever-increasing number of firms are choosing to compete in the area of flexibility. Generally, this has meant that the firm's major strength is flexibility of product (able to easily make changes in the product) or flexibility of volume (able to easily absorb large shifts in demand). Firms that are able to do this are said to have flexible capacity—the ability to operate manufacturing equipment at different production rates by varying staffing levels and operating hours, or starting and stopping at will. Specifically, manufacturing flexibility consists of three components: (1) the flexibility to produce a variety of products using the same machines and produce the same products on different machines; (2) the flexibility to produce new products on existing machines; and (3) the flexibility of machines to accommodate changes in the design of products.

FLEXIBLE MANUFACTURING SYSTEMS

A flexible manufacturing system (FMS) is a group of numerically-controlled machine tools, interconnected by a central control system. The various machining cells are interconnected, via loading and unloading stations, by an automated transport system. Operational flexibility is enhanced by the ability to execute all manufacturing tasks on numerous product designs in small quantities and with faster delivery. It has been described as an automated job shop and as a miniature automated factory. Simply stated, it is an automated production system that produces one or more families of parts in a flexible manner. Today, this prospect of automation and flexibility presents the possibility of producing nonstandard parts to create a competitive advantage.

The concept of flexible manufacturing systems evolved during the 1960s when robots, programmable controllers, and computerized numerical controls brought a controlled environment to the factory floor in the form of numerically-controlled and direct-numerically-controlled machines.

FMS is generally limited to firms involved in batch production or job shop environments. Normally, batch producers have two kinds of equipment from which to choose: dedicated machinery or non-automated, general-purpose tools. Dedicated machines save cost but lack flexibility. More flexible general purpose machines such as lathes, milling machines, or drill presses are all costly, and may not reach full capacity. Flexible manufacturing systems provide the batch manufacturer with another option—one that can make batch manufacturing just as efficient and productive as mass production.

OBJECTIVES OF FMS

The general objectives of an FMS are to approach the efficiencies and economies of scale normally associated with mass production, and to maintain the flexibility required for small- and medium-lot-size production of a variety of parts. Two kinds of manufacturing systems fall within the FMS spectrum. These are assembly systems, which assemble components into final products, and forming systems, which actually form components or final products. A generic FMS is said to consist of the following components:

1. A set of work stations containing machine tools that do not require significant set-up time or change-over between successive jobs. Typically, these machines perform milling, boring, drilling, tapping, reaming, turning, and grooving operations.

2. A material-handling system that is automated and flexible in that it permits jobs to move between any pair of machines so that any job routing can be followed.

3. A network of supervisory computers and microprocessors that perform some or all of the following tasks: (1) directs the routing of jobs through the system; (2) tracks the status of all jobs in progress so it is known where each job is to go next; (3) passes the instructions for the processing of each operation to each station and ensures that the right tools are available for the job; and (4) provides essential monitoring of the correct performance of operations and signals problems requiring attention.

4. Storage, locally at the work stations, and/or centrally at the system level.

5. The jobs to be processed by the system. In operating an FMS, the worker enters the job to be run at the supervisory computer, which then downloads the part programs to the cell control or NC controller.

BENEFITS OF FMS

The potential benefits from the implementation and utilization of a flexible manufacturing system have been detailed by numerous researchers on the subject. A review of the literature reveals many tangible and intangible benefits that FMS users extol. These benefits include:

- Less waste
- Fewer workstations
- Quicker changes of tools, dies, and stamping machinery

- Reduced downtime

- Better control over quality

- Reduced labor

- More efficient use of machinery

- Work-in-process inventory reduced

- Increased capacity

- Increased production flexibility

LIMITATIONS OF FMS

Despite these benefits, FMS does have certain limitations. In particular, this type of system can only handle a relatively-narrow range of part varieties, so it must be used for similar parts (family of parts) that require similar processing. Due to increased complexity and cost, an FMS also requires a longer planning and development period than traditional manufacturing equipment.

Equipment utilization for the FMS is not always as high as one would expect. Japanese firms tend to have a much higher equipment utilization rate than U.S. manufacturers utilizing FMS. This is probably a result of U.S. users' attempt to utilize FMS for high-volume production of a few parts rather than for a high-variety production of many parts at a low cost per unit. U.S. firms average ten types of parts per machine, compared to ninety-three types of parts per machine in Japan.

Other problems can result from a lack of technical literacy, management incompetence, and poor implementation of the FMS process. If the firm misidentifies its objectives and manufacturing mission, and does not maintain a manufacturing strategy that is consistent with the firm's overall strategy, problems are inevitable. It is crucial that a firm's technology acquisition decisions be consistent with its manufacturing strategy.

If a firm chooses to compete on the basis of flexibility rather than cost or quality, it may be a candidate for flexible manufacturing, especially if it is suited for low- to mid-volume production. This is particularly true if the firm is in an industry where products change rapidly, and the ability to introduce new products may be more important than minimizing cost. In this scenario, scale is no longer the main concern and size is no longer a barrier to entry.

However, an FMS may not be appropriate for some firms. Since new technology is costly and requires several years to install and become productive, it requires a supportive infrastructure and the allocation of scarce resources for implementation. Frankly, many firms do not possess the necessary resources. Economically justifying an FMS can be a difficult task, especially since cost accounting tends to be designed for mass production of a mature product, with known characteristics, and a stable technology. Therefore, it is difficult to give an accurate indication of whether flexible manufacturing is justified in many cases.

Rapidly-changing technology and shortened product life cycles can cause capital equipment to quickly become obsolete. Conversely, however, it is important to understand that when it is financially possible, flexible manufacturing is an option that creates synergy among existing machines, making it possible to create massive batches of products in a span of time previously thought impossible. With today's fast moving trends and constant inventory turnover on all marketplaces, flexibility is truly the key in manufacturing almost anything.

For other firms, their products may not require processes at the technological level of an FMS. IBM found that a redesigned printer was simple enough for high-quality manual assembly and that the manual assembly could be achieved at a lower cost than automated assembly. Potential FMS users should also consider that some of the costs traditionally incurred in manufacturing may actually be higher in a flexible automated system than in conventional manufacturing. Although the system is continually self-monitoring, maintenance costs are expected to be higher and energy costs are likely to be higher despite more efficient use of energy. Increased machine utilization can result in faster deterioration of equipment, providing a shorter than average economic life. Finally, personnel training costs may prove to be relatively high in comparison.

For some firms, worker resistance is a problem. Workers tend to perceive automation as an effort to replace them with a tireless piece of metal that does not eat, take breaks, or require benefits. To combat this perception, many firms stress that workers are upgraded as a result of FMS installation, and that no loss of jobs ensues.

Despite any problems, use of flexible manufacturing systems should continue to grow as more firms are forced to compete on a flexibility basis and as technology advances. It has shown many advantages in low- to mid-volume, high-mix production applications. Future systems will probably see lower and lower quantities per batch. FMS can somewhat shift emphasis in manufacturing from large-scale, repetitive production of standard products to highly-automated job shops featuring the manufacture of items in small batches for specific customers. The increased availability of flexible manufacturing technology will also give multi-product firms more choices of how to design production facilities, how to assign products to facilities, and how to share capacity among products.

BEYOND FLEXIBLE MANUFACTURING: AGILE MANUFACTURING

Fliedner and Vokurka, in their *Production and Inventory Management Journal* article on agile manufacturing, define

agile manufacturing as the ability to successfully market low-cost, high-quality products with short lead times (and in varying volumes) that provide enhanced customer value through customization. An agile firm manages change as a matter of routine. The difference between agility and flexibility is whether or not the change in market demand has been predicted. Flexibility refers to the capability of rapidly changing from one task to another when changing conditions are defined ahead of time. Agility refers to the ability to respond quickly to unanticipated marketplace changes. Fliedner and Vokurka present four key dimensions of agile competition:

1. **Enriching the customer:** This requires a quick understanding of the unique requirements of individual customers and rapidly meeting those requirements.

2. **Cooperating to enhance competitiveness:** This includes better intra-organizational cooperation and may extend to inter-organizational cooperation, such as supplier partnerships and virtual relationships.

3. **Organizing to master change and uncertainty:** This involves utilizing new organizational structures provided by such techniques as concurrent engineering and cross-functional teams.

4. **Leveraging the impact of people and information:** This places great emphasis on the development of employees through education, training, and empowerment.

IMPLEMENTING AGILE MANUFACTURING

Finally, the two authors prescribe a series of internal and external initiatives for successful implementation of agile manufacturing. The internal initiatives include the following:

1. **Business process reengineering:** This is the rethinking and radical redesign of business processes so that dramatic improvements in critical areas can be achieved.

2. **Management planning and execution tools:** This involves the use of such techniques as manufacturing resource planning, real-time manufacturing execution systems, production planning configurators, and real-time threaded scheduling.

3. **Design for manufacturability/assembly:** The results include modular products that allow for future upgrades, fewer parts for enhanced reliability, and recycling.

4. **Reorganization processes:** Process reorganization could include the use of flexible manufacturing systems or cellular manufacturing.

5. **Intraorganizational cooperation.** This form of cooperation calls for the use of employee empowerment/involvement techniques and employee education and training.

External initiatives include:

1. **Interorganizational cooperation:** This means early supplier involvement in product and process designs, training suppliers in such activities as vendor-managed inventories, and joint research efforts.

2. **Supply chain practices:** The use of outsourcing, schedule sharing, and postponement of product design are included.

3. **Information technology:** Some companies are using technology to improve supply chain efficiency. For example, the move from centralized mainframe computing to decentralized client and server computing.

4. **Point-of-sale data collection:** Reductions in order entry time are being achieved with electronic data interchange (EDI), radio frequency communications tools, bar coding, and electronic commerce.

The authors propose that flexibility provided by agility may emerge as the most important competitive priority of the early twenty-first century, as competition is expected to ensure that manufacturers will increasingly need to adapt readily to market shifts.

FLEXIBLE SPENDING ACCOUNTS

Flexible spending accounts (FSAs), sometimes called reimbursement accounts, are accounts set up by employers. These accounts allow employees to make annual, pre-tax contributions that can be used to pay for certain health care and dependent care expenses that are not paid for by insurance companies. FSAs are offered under the umbrella of cafeteria benefit plans and are sometimes called cafeteria plans. FSAs must comply with all applicable rules and regulations governing benefits under cafeteria plans. FSAs are commonly associated with health savings accounts, or HSAs. Health savings accounts are a specific type of account made available to employees, usually a type of FSA. They are permanent and tax exempt, and are used specifically for medical insurance purposes.

Employers must establish flexible spending accounts so that they comply with all applicable federal legislation. Once an FSA is established, employees have the opportunity to sign up for the plan during the annual "open enrollment" period. During the sign-up period that precedes the plan year, employees must estimate the relevant costs they are likely to incur during the year and indicate the amount of money they want set aside in the FSA for the year. Usually, the money is set aside using regular payroll deductions from the employee's paychecks. The deductions from employees' wages are pre-tax, thus reducing the employee's tax liability. Employees must carefully consider the amount they elect to contribute to the FSA, because amounts unused at the end of the plan year cannot be carried over to the next year and are forfeited by the employee if a balance remains at the end of the year. There is no legal limit to the annual amount that can be set aside, but employers can set their own limit if they wish.

As employees incur eligible expenses throughout the plan year, they must obtain and retain all receipts and documentation. Employees then provide required documentation that they have incurred eligible expenses (usually by providing receipts for the expenditures) and are reimbursed from the accumulated money in their account. Employees can turn in requests for reimbursement throughout the plan year or save all their documentation and turn in their request at the end of the plan year. Recent innovations in FSAs include the introduction of debit cards by some employers. These debit cards allow employees to obtain immediate reimbursement for eligible expenses rather than compiling receipts and documentation, submitting the paperwork, and waiting for the employer to cut them a check.

EXPENSES ELIGIBLE FOR COVERAGE UNDER FSAS

Flexible spending accounts can be used to pay for eligible costs related to health care and dependent care for children

or elderly parents. FSAs cover insurance premiums, deductibles, co-payments, prescription drugs, and many health-related expenses not covered by an employee's health insurance. For example, employees can pay for procedures and items such as laser eye surgery, orthodontia, hearing aids, and contact lenses with their FSAs. Flexible spending accounts can also be used to pay for certain expenses related to child and elder care. In 2003, the government expanded the drug coverage under FSAs to include certain types of over-the-counter drugs, such as pain relievers, cold medicines, nicotine patches, and allergy medications.

HEALTH CARE AND DEPENDENT DAY CARE ACCOUNTS

FSAs are commonly divided into two different categories, the health care account and the dependent day care account. The health care account is an FSA used for various health expenses, especially those not covered by a normal health care plan.

Dependent day-care accounts are used to set aside pre-tax funds for medical aid to any eligible dependents the employee may have, such as children.

ORIGINATION OF FLEXIBLE SPENDING ACCOUNTS

Although flexible spending accounts have been available since the enactment of Section 125 in the late 1970s, for many years employers didn't offer them and only a small percentage of eligible employees utilized them. There were various reasons for their lack of popularity. Employers were initially put off by what they perceived as the complexity and administrative costs associated with cafeteria plans in general, and flexible spending accounts in particular. Employees were reluctant to participate because of the forfeiture rule, which requires a participating employee to "use or lose" the funds set aside in the FSA each year. The advent and spread of managed care plans, such as health maintenance organizations (HMOs) and preferred provider organizations (PPOs) in the 1980s and 1990s also hampered the growth of flexible spending accounts. Managed care plans often included a low (or no) deductible, low co-payments, and coverage for preventive care. Employees' "out-of-pocket" health care expenses were often reduced; thus there was less incentive for employees to set aside money to cover non-reimbursed medical or dependent care expenses.

However, rising health care costs and dissatisfaction with managed care plans in the 1990s and early 2000s caused many organizations to look for ways to cut health care costs. Many found it necessary to raise the premiums employees pay for health insurance, the deductible employees pay before health expenditures are covered, and the copayments that employees pay once deductibles are met.

Thus, employees' out-of-pocket expenses rose. The flexible spending account offers a way for employees to cover some of these extra expenses with pre-tax dollars, which lowers their out-of-pocket expenses.

A 2004 survey by the Society for Human Resource Management found that over 70 percent of member organizations offer flexible spending accounts as part of a cafeteria benefits plan. Small employers, however, are much less likely to offer such plans. For example, one Bureau of Labor Statistics report estimated that only 4 percent of employers with fewer than 100 employees offer flexible spending accounts.

HEALTH REIMBURSEMENT ARRANGEMENT

An HRA, or health reimbursement arrangement, is an extra account that can be used with nearly any health plan, and it is most commonly established with high-deductible health plans. HRAs are employer-funded accounts that reimburse employees for certain medical expenses. Where some flexible spending accounts, such as HSAs, do not need employer contribution or can be made with a combination of employer and employee dollars, HRAs are made only of employer contributions, and cannot be taken by employees when they leave their company. However, HRAs tend to be more flexible than HSAs, since many employers allow employees to rollover unused funds in HRAs for the next year or move them to a different account.

HIGH-DEDUCTIBLE HEALTH PLANS

Some companies have also begun to use high-deductible health plans, or HDHPs. These plans have a minimum deductible of $1,000 dollars for individuals and $2,000 for families. They are used in conjunction with the other plans discussed and are intended to create more awareness of health insurance choices. Employees, forced to pay higher deductibles, become more conscious of the form of health care they use, and make better choices in what kind of accounts they want, which benefits the company overall.

FORECASTING

Forecasting involves the generation of a number, set of numbers, or scenario that corresponds to a future occurrence. It is absolutely essential to short-range and long-range planning. By definition, a forecast is based on past data, as opposed to a prediction, which is more subjective and based on instinct, gut feel, or guess. For example, the evening news gives the weather "forecast," not the weather "prediction." Therefore, forecasts should not be mistaken for predictions because forecasting is based on traceable and observable data and trends as opposed to mere assumptions. Properly prepared forecasts should be able to address blips that arise from one-off spread factors as well as other major seasonal factors. Spreadsheets can be used for analyzing past trends and determining forecasts.

Forecasting is based on a number of assumptions:

1. The past will repeat itself. In other words, what has happened in the past will happen again in the future.

2. As the forecast horizon shortens, forecast accuracy increases. For instance, a forecast for tomorrow will be more accurate than a forecast for next month; a forecast for next month will be more accurate than a forecast for next year; and a forecast for next year will be more accurate than a forecast for ten years in the future.

3. Forecasting in the aggregate is more accurate than forecasting individual items. This means that a company will be able to forecast total demand over its entire spectrum of products more accurately than it will be able to forecast individual stock-keeping units. For example, General Motors can more accurately forecast the total number of cars needed for next year than the total number of white Chevrolet Impalas with a certain option package.

4. Forecasts are seldom accurate and almost never totally accurate, although some are very close. Therefore, it is wise to offer a forecast "range." If one were to forecast a demand of 100,000 units for the next month, it is extremely unlikely that demand would equal exactly 100,000. However, a forecast of 90,000

to 110,000 would provide a much larger target for planning.

William J. Stevenson lists a number of characteristics that are common to a good forecast:

- Accurate—some degree of accuracy should be determined and stated so that comparison can be made to alternative forecasts.

- Reliable—the forecast method should consistently provide a good forecast if the user is to establish some degree of confidence.

- Timely—a certain amount of time is needed to respond to the forecast so the forecasting horizon must allow for the time necessary to make changes.

- Easy to use and understand—users of the forecast must be confident and comfortable working with it.

- Cost-effective—the cost of making the forecast should not outweigh the benefits obtained from the forecast.

Forecasting techniques range from the simple to the extremely complex. These techniques are usually classified as being qualitative or quantitative.

QUALITATIVE TECHNIQUES

Qualitative forecasting techniques are generally more subjective than quantitative forecasting techniques. Qualitative techniques are more useful in the earlier stages of the product life cycle, when less past data exists for use in quantitative methods. Qualitative methods include the Delphi technique, Nominal Group Technique (NGT), sales force opinions, executive opinions, and market research.

The Delphi Technique. The Delphi technique uses a panel of experts to produce a forecast. Each expert is asked to provide a forecast specific to the need at hand. After the initial forecasts are made, each expert reads what every other expert wrote and is influenced by their views. A subsequent forecast is then made by each expert. Each expert then reads again what every other expert wrote and is again influenced by the perceptions of the others. This process repeats itself until each expert nears agreement on the needed scenario or numbers.

Nominal Group Technique. The Nominal Group technique is similar to the Delphi technique in that it utilizes a group of participants, usually experts. After the participants respond to forecast-related questions, they rank their responses in order of perceived relative importance. Then the rankings are collected and aggregated. Eventually, the group should reach a consensus regarding the priorities of the ranked issues.

Sales Force Opinions. The sales staff is often a good source of information regarding future demand. The sales manager may ask for input from each salesperson and aggregate their responses into a sales force composite forecast. Caution should be exercised when using this technique as the members of the sales force may not be able to distinguish between what customers say and what they actually do. Also, if the forecasts will be used to establish sales quotas, the sales force may be tempted to provide lower estimates.

Executive Opinions. Sometimes upper-level managers meet and develop forecasts based on their knowledge of their areas of responsibility. This is sometimes referred to as a jury of executive opinion.

Market Research. In market research, consumer surveys are used to establish potential demand. Such market research usually involves constructing a questionnaire that solicits personal, demographic, economic, and marketing information. On occasion, market researchers collect such information in person at retail outlets and malls, where the consumer can experience—taste, feel, smell, and see—a particular product. The researcher must be careful that the sample of people surveyed is representative of the desired consumer target.

QUANTITATIVE TECHNIQUES

Quantitative forecasting techniques are generally more objective than qualitative forecasting methods. Quantitative forecasts can be time-series forecasts (i.e., a projection of the past into the future) or forecasts based on associative models (i.e., based on one or more explanatory variables). Time-series data may have underlying behaviors that need to be identified by the forecaster. In addition, the forecast may need to identify the causes of the behavior. Some of these behaviors may be patterns or simply random variations. Among the patterns are:

- Trends, which are long-term movements (up or down) in the data.

- Seasonality, which produces short-term variations that are usually related to the time of year, month, or even a particular day, as witnessed by retail sales at Christmas or the spikes in banking activity on the first of the month and on Fridays.

- Cycles, which are wavelike variations lasting more than a year that are usually tied to economic or political conditions.

- Irregular variations that do not reflect typical behavior, such as a period of extreme weather or a union strike.

- Random variations, which encompass all non-typical behaviors not accounted for by the other classifications.

Table 1

Naïve Forecasting

Period	Actual Demand (000's)	Forecast (000's)
January	45	
February	60	45
March	72	60
April	58	72
May	40	58
June		40

Among the time-series models, the simplest is the naïve forecast. A naïve forecast simply uses the actual demand for the past period as the forecasted demand for the next period. This makes the assumption that the past will repeat. It also assumes that any trends, seasonality, or cycles are either reflected in the previous period's demand or do not exist. An example of naïve forecasting is presented in Table 1.

Another simple technique is the use of averaging. To make a forecast using averaging, one simply takes the average of some number of periods of past data by summing each period and dividing the result by the number of periods. This technique has been found to be very effective for short-range forecasting.

Variations of averaging include the moving average, the weighted average, and the weighted moving average. A moving average takes a predetermined number of periods, sums their actual demand, and divides by the number of periods to reach a forecast. For each subsequent period, the oldest period of data drops off and the latest period is added. Assuming a three-month moving average and using the data from Table 1, add 45 (January), 60 (February), and 72 (March) and divide by three to arrive at a forecast for April:

$$45 + 60 + 72 = 177 \div 3 = 59$$

To arrive at a forecast for May, drop January's demand from the equation and add the demand from April. Table 2

Table 2

Three Month Moving Average Forecast

Period	Actual Demand (000's)	Forecast (000's)
January	45	
February	60	
March	72	
April	58	59
May	40	63
June		57

presents an example of a three-month moving average forecast.

A weighted average applies a predetermined weight to each month of past data, sums the past data from each period, and divides by the total of the weights. If the forecaster adjusts the weights so that their sum is equal to 1, then the weights are multiplied by the actual demand of each applicable period. The results are then summed to achieve a weighted forecast. Generally, the more recent the data is, the higher the weight, and the older the data the smaller the weight. Using the demand example, a weighted average using weights of .4, .3, .2, and .1 would yield the forecast for June as:

$$60(.1) + 72(.2) + 58(.3) + 40(.4) = 53.8$$

Forecasters may also use a combination of the weighted average and moving average forecasts. A weighted moving average forecast assigns weights to a predetermined number of periods of actual data and computes the forecast the same way as described above. As with all moving forecasts, as each new period is added, the data from the oldest period is discarded. Table 3 shows a three-month weighted moving average forecast utilizing the weights .5, .3, and .2.

A more complex form of weighted moving average is exponential smoothing, so named because the weight falls off exponentially as the data ages. Exponential smoothing takes the previous period's forecast and adjusts it by a predetermined smoothing constant, α (called alpha; the value for alpha is less than one) multiplied by the difference in the previous forecast and the demand that actually occurred during the previously forecasted period (called forecast error). Exponential smoothing is expressed formulaically as such:

New forecast = previous forecast +
alpha (actual demand – previous forecast)

$$F = F + \acute{\alpha}(A–F)$$

Exponential smoothing requires the forecaster to begin the forecast in a past period and work forward to the period for which a current forecast is needed. A substantial amount of past data and a beginning or initial forecast are also necessary. The initial forecast can be an actual forecast from a previous period, the actual demand from a previous period, or it can be estimated by averaging all or part of the past data. Some heuristics exist for computing an initial forecast. For example, the heuristic $N = (2 \div \alpha) - 1$ and an alpha of .5 would yield an N of 3, indicating the user would average the first three periods of data to get an initial forecast. However, the accuracy of the initial forecast is not critical if one is using large amounts of data, since exponential smoothing is "self-correcting."

Table 3
Three–Month Weighted Moving Average Forecast

Period	Actual Demand (000's)	Forecast (000's)
January	45	
February	60	
March	72	
April	58	55
May	40	63
June		61

Given enough periods of past data, exponential smoothing will eventually make enough corrections to compensate for a reasonably inaccurate initial forecast. Using the data used in other examples, an initial forecast of 50, and an alpha of .7, a forecast for February is computed as such:

New forecast (February) = 50 + .7(45 –50) = 41.5

Next, the forecast for March:

New forecast (March) = 41.5 + .7(60 – 41.5) = 54.45

This process continues until the forecaster reaches the desired period. In Table 4 this would be for the month of June, since the actual demand for June is not known.

An extension of exponential smoothing can be used when time-series data exhibits a linear trend. This method is known by several names: double smoothing; trend-adjusted exponential smoothing; forecast including trend; and Holt's Model. Without adjustment, simple exponential smoothing results will lag the trend; that is, the forecast will always be low if the trend is increasing, or high if the trend is decreasing. With this model there are two smoothing constants, α and β with β representing the trend component.

An extension of Holt's Model, called Holt-Winter's Method, takes into account both trend and seasonality.

Table 4

Period	Actual Demand (000's)	Forecast (000's)
January	45	50
February	60	41.5
March	72	54.45
April	58	66.74
May	40	60.62
June		46.19

There are two versions, multiplicative and additive, with the multiplicative being the most widely used. In the additive model, seasonality is expressed as a quantity to be added to or subtracted from the series average. The multiplicative model expresses seasonality as a percentage—known as seasonal relatives or seasonal indexes—of the average (or trend). These are then multiplied times values in order to incorporate seasonality. A relative of 0.8 would indicate demand that is 80 percent of the average, while 1.10 would indicate demand that is 10 percent above the average. Detailed information regarding this method can be found in most operations management textbooks or one of a number of books on forecasting.

Associative or causal techniques involve the identification of variables that can be used to predict another variable of interest. For example, interest rates may be used to forecast the demand for home refinancing. Typically, this involves the use of linear regression, where the objective is to develop an equation that summarizes the effects of the predictor (independent) variables upon the forecasted (dependent) variable. If the predictor variable were plotted, the object would be to obtain an equation of a straight line that minimizes the sum of the squared deviations from the line (with deviation being the distance from each point to the line). The equation would appear as: $y = a + bx$, where y is the predicted (dependent) variable, x is the predictor (independent) variable, b is the slope of the line, and a is equal to the height of the line at the y-intercept. Once the equation is determined, the user can insert current values for the predictor (independent) variable to arrive at a forecast (dependent variable).

If there is more than one predictor variable or if the relationship between predictor and forecast is not linear, simple linear regression will be inadequate. For situations with multiple predictors, multiple regression should be employed, while non-linear relationships call for the use of curvilinear regression.

ECONOMETRIC FORECASTING

Econometric methods, such as autoregressive integrated moving-average model (ARIMA), use complex mathematical equations to show past relationships between demand and variables that influence the demand. An equation is derived and then tested and fine-tuned to ensure that it is as reliable a representation of the past relationship as possible. Once this is done, projected values of the influencing variables (income, prices, etc.) are inserted into the equation to make a forecast.

EVALUATING FORECASTS

Forecast accuracy can be determined by computing the bias, mean absolute deviation (MAD), mean square error

(MSE), or mean absolute percent error (MAPE) for the forecast using different values for alpha. Bias is the sum of the forecast errors [$\sum$(FE)]. For the exponential smoothing example above, the computed bias would be:

$$(60 - 41.5) + (72 - 54.45) + (58 - 66.74) +$$
$$(40 - 60.62) = 6.69$$

If one assumes that a low bias indicates an overall low forecast error, one could compute the bias for a number of potential values of alpha and assume that the one with the lowest bias would be the most accurate. However, caution must be observed in that wildly inaccurate forecasts may yield a low bias if they tend to be both over forecast and under forecast (negative and positive). For example, over three periods a firm may use a particular value of alpha to over forecast by 75,000 units (-75,000), under forecast by 100,000 units (+100,000), and then over forecast by 25,000 units (-25,000), yielding a bias of zero (-75,000 + 100,000 − 25,000 = 0). By comparison, another alpha yielding over forecasts of 2,000 units, 1,000 units, and 3,000 units would result in a bias of 5,000 units. If normal demand was 100,000 units per period, the first alpha would yield forecasts that were off by as much as 100 percent while the second alpha would be off by a maximum of only 3 percent, even though the bias in the first forecast was zero.

A safer measure of forecast accuracy is the mean absolute deviation (MAD). To compute the MAD, the forecaster sums the absolute value of the forecast errors and then divides by the number of forecasts ($\sum$ |FE| ÷ N). By taking the absolute value of the forecast errors, the offsetting of positive and negative values are avoided. This means that both an over forecast of 50 and an under forecast of 50 are off by 50. Using the data from the exponential smoothing example, MAD can be computed as follows:

$$(|60 - 41.5| + |72 - 54.45| + |58 - 66.74| +$$
$$|40 - 60.62|) \div 4 = 16.35$$

Therefore, the forecaster is off an average of 16.35 units per forecast. When compared to the result of other alphas, the forecaster will know that the alpha with the lowest MAD is yielding the most accurate forecast.

Mean square error (MSE) can also be utilized in the same fashion. MSE is the sum of the forecast errors squared divided by N-1 [($\sum$(FE)) ÷ (N-1)]. Squaring the forecast errors eliminates the possibility of offsetting negative numbers, since none of the results can be negative. Utilizing the same data as above, the MSE would be:

$$[(18.5) + (17.55) + (-8.74) + (-20.62)] \div 3$$
$$= 383.94$$

As with MAD, the forecaster may compare the MSE of forecasts derived using various values of alpha and assume the alpha with the lowest MSE is yielding the most accurate forecast.

The mean absolute percent error (MAPE) is the average absolute percent error. To arrive at the MAPE one must take the sum of the ratios between forecast error and actual demand times 100 (to get the percentage) and divide by N [($\sum$ | Actual demand − forecast | ÷ Actual demand) × 100 ÷ N]. Using the data from the exponential smoothing example, MAPE can be computed as follows:

$$[(18.5/60) + 17.55/72 + 8.74/58 + 20.62/48) \times$$
$$100] \div 4 = 28.33\%$$

As with MAD and MSE, the lower the relative error the more accurate the forecast.

It should be noted that in some cases the ability of the forecast to change quickly to respond to changes in data patterns is considered to be more important than accuracy. Therefore, one's choice of forecasting method should reflect the relative balance of importance between accuracy and responsiveness, as determined by the forecaster.

MAKING A FORECAST

William J. Stevenson lists the following as the basic steps in the forecasting process:

- Determine the forecast's purpose. Factors such as how and when the forecast will be used, the degree of accuracy needed, and the level of detail desired determine the cost (time, money, employees) that can be dedicated to the forecast and the type of forecasting method to be utilized.

- Establish a time horizon. This occurs after one has determined the purpose of the forecast. Longer-term forecasts require longer time horizons and vice versa. Accuracy is again a consideration.

- Select a forecasting technique. The technique selected depends upon the purpose of the forecast, the time horizon desired, and the allowed cost.

- Gather and analyze data. The amount and type of data needed is governed by the forecast's purpose, the forecasting technique selected, and any cost considerations.

- Make the forecast.

- Monitor the forecast. Evaluate the performance of the forecast and modify, if necessary.

- Establish cause and effect relationships that add validation to a forecast.

FRANCHISING

When an individual has the desire and drive to be an entrepreneur but lacks a strong idea for a company, franchising a proven business can be extremely rewarding. Franchising is an agreement or alliance between two organizations—the franchisor and the franchisee. The franchisor has the business model, training materials, and other materials for the business. The franchisee is the entrepreneur who agrees to operate a branch of the business while paying the franchisor various fees and royalties for the use of the business idea or model.

TYPES OF FRANCHISING

Business-format franchising exists when a franchisor allows someone to market products or services, using the business name or trademark, in return for fess and royalties. When franchising is mentioned, most people think of business-format franchising, like McDonald's, AAMCO Transmission, or Molly Maid. There is also product or trademark franchising. This is a limited franchise where a manufacturer may grant another party a license to sell goods produced by the manufacturer. This might include sale of cars through dealerships (e.g., Ford dealerships), sale of gasoline through service stations (e.g., Shell stations), and sale of soft drinks through local franchising (e.g., Coca Cola bottlers). A final type of franchising is conversion franchising. This franchising model is designed to bring formerly-independently-operating businesses together under the collective power of a national name and advertising. An example of conversion franchising is Century 21 Realtors, an affiliation of previously-established real estate agents.

FRANCHISE START-UP

Franchise fees typically include a lump-sum entrance fee and other charges for regular services, including royalties on sales, advertising fees, and marketing. In exchange for these licensing fees, the franchisor retains control over the delivery of the products and services, as well as marketing and the operational and quality standards of the franchise. The franchising company's revenue is generated through the franchisee that pays these on-going sales royalties, typically averaging 5 percent of sales. The contract, or franchise agreement, is signed by both parties and establishes the relationship between the franchisee and the franchisor. The contract also details the responsibilities and privileges of both parties.

Franchises include such popular names as H&R Block, McDonald's, 7-Eleven, Body Shop, Pizza Hut, and Jiffy Lube. These franchise operations have well-established names, brands, and reputations. The best franchises provide a strong brand or trademark of the concept, a proven business system, extensive training and product development, along with a number of initial and on-going managerial support services. Some help the franchisee secure funding and offer benefits, including discounted supplies. Typically, the franchised business is less risky than other forms of new venture creation because the business idea has been tested and there are mutual advantages to both parties. The Service Corps of Retired Executives (SCORE), a volunteer group involved in counseling would-be entrepreneurs, reports that franchises are safer than other business formats. Franchises experience less than a 5 percent failure rate compared to an 80 percent five-year failure rate for independent businesses and a 90 percent failure rate for independent restaurants. Banks are also supportive of the franchising business model and many will offer up to 70 percent of the initial capital costs.

WHY FRANCHISE?

Franchising allows a business to rapidly expand beyond its original owners. Franchisees pursue a new business, experience the advantages of running their own business and being their own boss, and gain wealth through a proven business idea. They provide the management skills to run the business, and contribute the capital to fund the opening and on-going operations. The franchisor also benefits from the partnership and gains economy of scope advantages as more franchises are established. National or international advertising becomes possible and the franchisor can more easily expand business locations with help and capital from the franchisee. The franchisee helps to build brand awareness through market proliferation. The franchisee has a unique opportunity to run a business with a greater chance of success. There is experience from the franchisor for starting the business and many of the initial

mistakes have already been made, learned from, and corrected.

Franchisees create their own jobs and often create a number of new jobs in operation areas as they hire employees. As the franchise becomes successful, the franchisee may choose to open other stores to create even more wealth. Franchising is popular in the United States and abroad. Franchising is at a mature level in the United States, Europe, and Australia, while Asia, South America, Mexico, and Central America report rapid growth. China, too, is experiencing franchise business growth.

RESEARCHING FRANCHISES

It is important to carefully perform initial due diligence and to thoroughly examine any franchise offering. A Federal Trade Commission (FTC) rule was created and adopted in the mid-1970s that requires franchisors to disclose to franchisees very specific information, including information about themselves, the business, and the terms of the relationship. This document is the Uniform Franchise Offering Circular (UFOC) and provides important legal information about the franchisor and its franchising program.

When deciding on a franchise, it is important to first ascertain personal goals for business ownership and to examine the franchise offering to find a compatible opportunity. While there are no guarantees in franchising, a well-developed operating plan is often an advantage. An entrepreneur should consider a number of issues regarding a possible franchise. For example, is the franchise in only one local market, or does it have a regional, national, or international presence? Lower-risk franchises have a national or global presence and benefit from the size advantage. The franchisee will also want to consider if most of the existing outlets are profitable, and whether the franchise is the market leader with the largest market share among competitors. The entrepreneur should evaluate the presence of a national marketing and purchasing program. The lower-risk franchises also have documented training, manuals, field support, marketing and promotion, standardized operating procedures, and on-going feedback channels between the franchisor and the franchisees. The terms of the license agreement vary from less than ten years to more than twenty years and some have automatic renewal. Capital requirements for obtaining the franchise also vary. Other factors to consider include territory limitations, failure rates, and any relevant litigation history against the franchise. Investment requirements should also be clearly disclosed.

It is often a good idea to interview existing franchise owners to determine if start-up costs and processes are realistic. Legal counsel may be required to negotiate and interpret the franchise agreement contract. SCORE also recommends that potential franchising clients plan and analyze their options. This planning and analysis should include researching Chamber of Commerce and Better Business Bureau records for a given franchise. SCORE agrees that the most important step for choosing a franchise is also considering the entrepreneur's interests, skill set, and experience. It is easier to evaluate an established franchise than a new franchise. There may be few, if any, owners with whom to speak about the franchise. It is important that the new franchise have strong franchisee support and a proven business system. The business strategy should also be examined carefully.

FRANCHISING AND THE ECONOMY

In 2005 more than 11 million people were employed by franchised businesses. This group of approximately 3,000 franchised names—ranging from automobile dealers to food operations—generates nearly 5 percent of gross income in the United States. Giving nearly 8 percent of able-bodied workers a job, curbing unemployment during tough economic times, and creating wealth where there previously was none, these businesses are clearly important to the economy. The IFA reports that for franchising the start-up costs can range from less than $5,000 to more than $1,000,000. Growth in the franchise sector is on an upward trend even during otherwise questionable economic times. For this reason, PricewaterhouseCoopers suggests the outward growth of franchises may not necessarily have an end in sight. IFA offers information on franchising, including newsletters about events and discussion forums and educational materials. It also includes information on government regulations for franchising.

In a 2004 study conducted by PricewaterhouseCoopers (for the International Franchise Association Educational Foundation) on the economic impact of franchised businesses, more than 760,000 franchised businesses exist in the United States and generate some $1.53 trillion yearly. This represented 9.5 percent of the private sector economic output in the United States. These franchises generate one out of every seven jobs in America.

The IFA established a Franchise Index to track the market performance of the top fifty U.S. public franchisors. The index has increased steadily since January 2000, compared to a drop of 20.1 percent in the Standard and Poors (S&P) 500 Index over the same period. Interestingly, the franchise index has grown during tough economic times. Thus, franchising is a major economic force with a significant impact on the nation's economy.

The franchising business model attracts a number of qualified individuals, particularly in times of recession or slow business growth. Individuals are attracted to franchising and the opportunity to create their own jobs. While franchising is not a get-rich-quick proposition, many do have attractive returns on investment. Most analysts agree a three- to five-year period of hard work and dedication is

needed before the franchised business is profitable. Over the years, more individuals are touting the advantages and value of franchising. These franchises pick up on key business trends that affect—and are affected by—social and demographic changes and changing lifestyles. Healthy fast food, at-home care for the elderly, pet care, Internet education, personal services, automotive services, green living, and travel services are all industries that have grown because of changing attitudes. Many of these industries offer exclusive territories in a given market.

Additional advice on finding and comparing franchising opportunities is available on the franchise-broker Web sites (e.g., www.FranNet.com, www.FranChoice.com, and www. francorpconnect.com). FranNet.com is a franchise-broker Web site representing franchise consultants. Some potential franchisees prefer using a broker to find a franchise.

While there are many advantages to franchising, there are some disadvantages. Once a business grows beyond a certain size, it could make more money if it were wholly owned, since a percentage of the profit goes to the franchisor. Even if a franchise is capable of making large profits, the franchise manager must deal with the franchisor as well as business operations. The franchisee must be committed to the idea and business model. The franchisee must also be supportive of the franchisor's system, as the key to a successful franchise operation is consistency. Customers expect a similar product or service from all branches of a franchise. Entrepreneurs who do not want to follow the predetermined structure and operating procedures of a franchise may not be successful.

The franchising arrangement is a balance of entrepreneurial spirit, standard business procedures, and following instructions. The venture, like other start-ups, will require a serious time and energy commitment. It can be difficult for a franchisor to find a franchisee with drive, energy, and the experience necessary to run a business according to franchise guidelines. A franchise also needs an appropriate location. Aside from who runs the franchise, where it is located is of the highest importance. A franchise location must be researched thoroughly to determine its growth potential.

The combination of franchisor guidance, franchisee know-how and determination, reasonable capital investment, and well-researched location will almost always result in successful franchise operation regardless of economic climate, season, or trends. A strong business model coupled with a determined business owner are the keys to success in franchising.

FREE TRADE AGREEMENTS AND TRADING BLOCS

Sovereign nations join together, usually on a regional scale, to create free trade agreements. Free trade agreements are created to lower trade barriers and to stimulate trade between member countries. Member countries belonging to the free-trade area trade freely with each other while maintaining trade barriers and tariffs for non-member countries. Free trade agreements are generally seen as having a positive impact on economic growth, especially for smaller countries in the agreement. Trading blocs are groups of countries that have reached a common agreement to lower trade barriers throughout the group (e.g., NAFTA, ASEAN, and the European Union).

HISTORY

According to the Congressional Budget Office, since the end of World War II there has been significant support, especially from the United States, to eliminate artificial trade barriers and to support a greater liberalization of international trade. The General Agreement on Tariffs and Trade (GATT) was created shortly after World War II, between twenty-three countries, to facilitate and coordinate trade between the nations. In addition to creating a more liberal trade environment, it also had provisions and charters creating rules for employment, commodity agreements, restrictive business practices, international investments, and services. The process of creating a free trade agreement followed a pattern of discussion, negotiation, and eventual ratification. The complete process is called "rounds." There were eight rounds in the GATT treaty. Despite numerous difficulties and differences between the involved countries, much was accomplished by GATT; although portions were never fully ratified by all of the countries.

In 1995, during the Uruguay round of GATT negotiations, the World Trade Organization (WTO) was created. The WTO became the official successor to the GATT. The WTO is the only international organization dealing with the global rules of trade between nations. Its main function is to ensure that trade flows as smoothly, predictably, and freely as possible. At the center of the WTO is its multilateral trading system that functions by seeking consensus between all member nations (over 150). The notion of consensus facilitates cooperation and, potentially, an agreement that is most beneficial to all involved countries.

MOST FAVORED NATION

An important component of free trade agreements is the most favored nation status. The most favored nation status within a free trade agreement creates a situation where all countries are treated equally. Benefits, reduction of tariffs, and other trading privileges applied to one country will be applied to all countries with the most favored nation status.

TRADING BLOCS

Trading blocs are relationships between countries, generally in the same region, to facilitate free trade agreements. Trading blocs include: North American Free Trade Agreement (NAFTA), Central American Free Trade Agreement (CAFTA), Association of Southeast Asian Nations (ASEAN), European Union (EU), Mercado Comun del Sur (Mercosur), and Southern African Development Community (SADC). Southeast Asia has enjoyed unparalleled and astonishing economic growth in the past three decades since the establishment of ASEAN. In 1967, ASEAN's overall trade was worth $10 billion. In 2006, total trade reached a staggering $1.4 trillion.

NAFTA. NAFTA, along with its two supplements, the North American Agreement on Environmental Cooperation (NAAEC) and the North American Agreement on Labor Cooperation (NAALC), is the largest trade agreement on Earth today. The combined effects on trade, labor, and environmental bylaws has created a colossal force in trade that determines when and how all Canadian, American, and Mexican goods and services will be dispersed amongst its most powerful consumers—each other.

NAFTA does have its controversies and opponents, but overall it is widely considered to be the most impressive free trade agreement to date. Opponents suggest that energy taxes, especially those that caused billions in losses in 2006, are caused directly by NAFTA regulations that do not guard private citizen interest between nations well enough. Additionally, some say that government-issued subsidies given to those protected by NAFTA are an unfair

monetary advantage against those who are not listed under NAFTA, especially those in the agricultural industries. A 2008 poll of U.S. voters suggests that roughly 53 percent of Democrats do not approve of NAFTA, while in Canada, NAFTA has an approval rating of more than 62 percent.

DR-CAFTA. DR-CAFTA, previously known as CAFTA, is the free trade agreement between Costa Rica, Guatemala, Honduras, El Salvador, Nicaragua, the United States and, most recently, the Dominican Republic, which put the agreement into effect in March of 2007. Very similar in its common goals to NAFTA, DR-CAFTA is seen by many as just another step in creating a completely globalized free trade agreement. DR-CAFTA represents the future of free trade and the evolution from smaller free trade areas to larger areas, with the end goal being to include nearly every nation.

DR-CAFTA is probably most important to the creation of new highways that will traverse the terrain from Panama to Mexico and even Texas. In order for these roads to become a reality between these separate nations, a trade agreement such as DR-CAFTA will need to lower or totally eliminate tariffs to bring materials and labor in and out of construction areas. Opponents of DR-CAFTA suggest that this trade agreement, like NAFTA, is just another way to globalize and monetize the interests of massive corporations, not the interests of small business or citizens of a given nation. Supporters of DR-CAFTA see it as a natural progression for the area as well as a thoughtful way to compete against global mass-producers such as China.

Mercosur. Established in 1991 and updated in 1994, Mercosur—the free trade agreement between Uruguay, Paraguay, Brazil, and Argentina—has welcomed other nations, including Peru, Bolivia, Chile, Columbia, Ecuador, and in 2006, Venezuela. The latter nations have only partial membership in the trade agreement. Mercosur has lowered tariffs for all member nations, but most notably in 2005 for Columbia, which is now able to bring products and services to more than 200 million people who would not have had access previous to Mercosur.

Like all trade agreements, Mercosur has its issues. Some feel that it has been set up in such a way that it solidifies the status quo of both underdeveloped and wealthy nations, making it difficult for the poor to rise up and truly take advantage of any of the agreement's offerings. Others say that the extreme class separations in the geographic area effected by Mercosur can only stand to gain wealth, even if it is through a trickle-down system.

Free trade areas, the logical progression of free trade agreements, will most likely be implemented until all separate agreements make up one larger, almost completely universal agreement.

CRITICISM OF FREE TRADE

The expansion of free trade and the creation of trading blocs cause concern for some people. As reported by the Congressional Budget Office, the pursuit of free trade could "divert the world from multilateral negotiations and lead to the development of rival trading blocs." Other concerns include: the exploitation of developing countries by industrialized countries; environmental concerns as the production of goods overseas is not consistently regulated from country to country; and labor concerns over fair wages and the loss of jobs from industrialized countries to the developing countries, as well as political concerns that may influence the negotiations between trading partners.

BENEFITS OF FREE TRADE

Multilateral and free trade agreements create benefits by increasing imports and exports of goods. Countries are not the same in their production capabilities. Access to raw materials, necessary levels of technological development, and education of the workforce all have an impact on developing a product or service. Free trade agreements create the opportunity for countries to focus on what they do best, while being able to acquire goods and services at, potentially, the lowest price possible. Free trade makes it possible for countries rich in certain natural resources (such as oil) to trade them with the world for a fair price while also importing traded goods from other nations that are scarce in their own, such as produce. By opening doors for other countries to compete fairly, without burdensome tariffs or trade policies, there is a belief that increased free trade is a deterrent to monopolistic activities.

FUTURE OF FREE TRADE AGREEMENTS

The most recent round of negotiations for multilateral trade in the World Trade Organization continues to drag on due to the increasing number of participants with their own opinions on what each country, including their own, should be entitled to. The attractiveness of free trade agreements will remain high as the benefits evolve with a changing, globalizing marketplace—with the advent of the Internet and other technologies and English-speaking workforces abroad, it's not just tangible goods that are traded between countries anymore. Countries interested in increasing trade will circumvent the delays in the WTO by making their own agreements. The expansion of current trade agreements is also taking place—as with the expansion of NAFTA into the Free Trade Agreement for the Americas (FTAA). The U.S. market is extremely desirable and lucrative for smaller countries' exports, while also providing access to a wider variety of goods and services from the United States and other potential trading partners.

FULFILLMENT

Fulfillment in business generally refers to the steps a firm takes to fulfill orders that have been placed via the phone, Internet, or in person. Fulfillment can also refer to a specialized firm known as a specialty fulfillment center that does nothing but fulfill orders; these companies do so by handling all the steps of fulfillment for other firms or for other branches of the same firm.

Regardless of who is handling order fulfillment, the steps are fundamentally the same. How a given enterprise takes care of the orders its customers place at its point of sale is the basic definition of fulfillment. Some firms have to custom-build an item to each different customer's specifications to fulfill orders, while other firms simply pick products off of shelves, pack them, and ship them off to ordering clientele. What makes fulfillment important is how it shapes the future of a given business—the numbers of customers buying (or not buying) and the amount of product selling (or not selling) can be used to forecast the future of the business and how much inventory will be needed the same time next week, month, or year. What sales are forecast to be and what they actually turn out to be are always two different things, but sales forecasts will always determine how much product is warehoused by the fulfilling entity.

THE STAGES OF FULFILLMENT

The stages of fulfillment include the sale of a product or service; the confirmation of that order; the production, assembly, or custom-building of the ordered good; the billing and charging of the client for the good; the packing, shipping, and delivery of the product; and lastly, any returns or exchanges associated with the original order placed.

The Sale. A product can be sold in any number of locations: from a sales floor, over the Internet, through television and radio offers, or from a catalog order form that came in the mail. For many smaller retailers, the use of a specialty fulfillment center begins here. An entity like Amazon.com or eBay will allow anyone from a sole proprietor to a medium-sized retailer to place their items on sale through their Internet portals. From here, the customer can browse and pick the product they want to buy, and Amazon.com or similar online retail centers will handle the rest of the fulfillment process.

Order Confirmation. Orders can be confirmed in multiple ways, but a growing method for many companies is the e-mail confirmation. Easier and faster than a follow-up phone call and also less wasteful of resources like time and paper, the e-mail confirmation is a convenient way for both firm and client to keep confirmations for record-keeping purposes. E-mail confirmations usually come with an order tracking number, company contact information, and even links where the order's status can be checked. Also, if an order needs to have any information edited, a client can usually respond to the e-mail confirmation or find the information needed within the confirmation that leads them through the process of changing the order or any address or payment information.

Readying the Order. Once the order has been confirmed, the next step is to ready the order's contents for delivery to the client. In some instances, assembly or special creation may be required. For example, a custom-order T-shirt company may have to silk screen T-shirts with a specific image for an order. In other instances, an order will be "picked and packed" from existing inventory by warehouse workers and then simply double-checked for accuracy before shipping.

Billing and Charging the Customer. A customer can be billed and charged immediately when they order online. Usually this requires the customer to input credit card information or checking account and bank routing numbers into fields on a Web site's point-of-sale page. In other sales settings, the customer will be charged immediately by a sales staff member; in some cases, a customer can be charged upon delivery of the item.

Shipping the Product. Often times, an order will not be shipped until payment has cleared. Payment will also usually include the cost of shipment, which is determined by the customer's choice of regular or some method of expedited shipping. Each fulfillment house will use a different method for shipping goods, but popular choices include UPS, DHL, the United States Postal Service, and Federal Express.

Returns and Exchanges. If a customer is shipped the wrong item or if upon receipt the customer is unhappy, the firm in charge of fulfillment will be asked to remedy the situation by use of its return or exchange policy. In some cases, no refunds are granted but exchanges for other products are allowed. In other cases, a firm will allow exchange for credit or simply exchange the product with the same product of the correct size, shape, or color.

OUTSOURCING FULFILLMENT

There are pros and cons to outsourcing fulfillment. One of the major advantages is not having to worry about the cost or space needed to warehouse goods. Additionally, contracting a fulfillment house frees up employees from packing orders, dealing with returns and exchanges, and keeping tabs on warehouse inventory. In this way employees can be hired to focus on other aspects of maintaining and accelerating the growth of a firm. Choosing a fulfillment house is not always an easy choice; final decisions should be based on price, proximity, and range of services offered.

While outsourcing fulfillment has its advantages, by doing so a business eliminates a critical avenue of contact between itself and the consumer. If order processing goes smoothly, all is well, but businesses run the risk of losing customers if the customer has trouble dealing with the outsourced fulfillment agency. If there is a problem of some kind (such as a delay or a lost order), many customers will wonder why they are dealing with a third party (the outsourced firm), and not speaking directly to someone at the business itself. In other words, having satisfied customers by using a more expensive, in-house fulfillment center might leave a company better off than if it switched to a less-expensive outsourced fulfillment agency that somewhat alienates its customer base. With this and other potential problems in mind, businesses should take extreme caution to insure that the advantages to outsourcing fulfillment are not outweighed by a decrease in customer service.

FUTURING

Futuring is the field of using a systematic process for thinking about, picturing possible outcomes, and planning for the future. Futurists are people who actively view the present world as a window on possible future outcomes. They watch trends and try to envision what might happen. Futuring has its roots in the post during the World War II era. Scientists, politicians, and academics began to consider ways of anticipating the future. This initial consideration led to a more cohesive and developed field of futuring in the mid-1960s. An association, the World Future Society, exists to provide a forum for further discussion and analysis.

Explorers often found themselves in situations where they had no idea what the future held for them. What was around the next bend, over the next mountain range, or across the next river was a complete unknown. They were forced to make decisions that were literally life and death. Futurists can look to these explorers for guidance. Edward Cornish, former president of the World Future Society, highlights seven lessons that can be learned: (1) prepare for what you will face in the future; (2) anticipate future needs; (3) use poor information when necessary; (4) expect the unexpected; (5) think long term as well as short term; (6) dream productively; and (7) learn from your predecessors.

A major instigator of forecasting the future is the incredible rate of change that is taking place. Technologically, culturally, and environmentally change is all around and moving at a very fast rate. Mankind has lived through the Agricultural, Industrial, and Cybernetic Revolutions. There will undoubtedly be another, if not several more, revolutions that will affect the planet. Futuring delves into this process of revolutions to attempt to forecast what might be the next one. Cornish discusses six current "super trends" that are dramatically affecting the present and the future.

- **Technological Progress.** Improvements in computers, medicine, transportation, communications, and other industries are all affected by technology.

- **Economic Growth.** Impacted by technological progress the improvement of people's economic well-being continues to steadily improve over time.

- **Improving Health.** Impacted by the aforementioned super trends—technological progress and economic growth—the average lifespan and overall health of the average person continues to improve over time.

- **Increased Mobility.** Technological progress, economic growth, and improving health combine to improve mobility of people and products, creating both advantages and disadvantages as the world shrinks.

- **Environmental Decline.** The scope of this progress and mobility and increasing population is impacting the earth with severe environmental issues that do not have a short-term solution.

- **Increasing Deculturation.** Mankind has had a wide variety of cultures and races; due to some of the above trends, these cultures are being erased by poverty, migration, and tourism.

FORCES THAT AFFECT THE FUTURE

Futurists must account for several powerful forces that impact future events and trends. These forces are systems, chance, and chaos.

Systems. Systems exist in most every setting. Relationships between people, the human body, and cities sewage and transportation services are all examples of systems. Actions that impact one part of the system can inevitably affect other parts of the system.

Chance. Chance events occur continuously. These events can shape future outcomes. Small actions or details can have a profound effect that can cause major worldwide events.

Chaos. Chaos is the idea that minor differences in something can have a profound effect on other things and then inevitably on the future. This means that there is always a wide array of possible outcomes; only extremely minor differences separate these possible outcomes from actually happening.

These three forces: systems, chance, and chaos, must all be considered at some level if a person is to try and forecast the future.

FUTURING METHODS

Futuring is accomplished by rather normal means of forecasting. There are four methods used in futuring to determine possible outcomes. These methods are: polling, gaming, modeling and simulation, and visioning.

Polling. Polling is a method that involves consulting with others, preferably experts, who are knowledgeable on the topic in question. It consists of a series of questions to elicit responses that are then collated to determine what

the overall perception of the group is. This is best performed when the participants cannot interact with each other and bias their answers.

Gaming. Another method of forecasting that is used by researchers, and especially by the government, is gaming. Gaming is a method of possible events where participants are placed in mock situations and are expected to make actual decisions based on the information and actions that are happening around them. Gaming possible events and situations with computer simulations is becoming more popular. Gaming assists with understanding how people will react in their roles and what possible outcomes of a given situation might be.

Modeling and Simulation. Modeling is a method used in forecasting future outcomes. Modeling generally involves computer processing of data to provide possible outcomes. Data for the relevant variables is entered into the computer with the model then run repetitively with minor variations to observe potential outcomes.

Visioning. Many futurists use the visioning method to not only forecast, but to encourage potential futures. Visioning involves discussing and creating preferred futures. The result of visioning is a plan of action for following through with the ideas that are generated.

The different methods of forecasting the future can be used in a variety of settings depending on the people and information available. Other methods that are also used in futuring are:

- *Scanning*—systematic survey of information sources focusing on trends

- *Trend Analysis*—in-depth look at a specific trend and all of its related issues and elements

- *Trend Monitoring*—continuous monitoring of important trends

- *Trend Projection*—using numerical data to project where a trend should eventually end up

- *Brainstorming*—generating new ideas by small group interaction

- *Historical Analysis*—using historical events to anticipate current developments

- *Deja Viewing*—reviewing the past to determine if anything similar has happened

- *Bringing the Future to the Present*—looking ahead to the future and painting a picture of what you want to happen

- *Experience Hitchhiking*—gaining experience by "hitchhiking" with people who have gone through similar experiences already

SCENARIOS

Scenarios are recognized as an effective method for forecasting the future. Scenarios are beneficial in forecasting because they deal with the uncertainty of a situation. Scenario creation focuses on identifying what might happen. This allows for analyzing the problem and determining what the consequences might be in light of the information available and in light of our own reactions to possible events. Futurists often use five different variations of scenario building: (1) *Continuation*—things will continue much as they are now; (2) *Optimistic*—things will get considerably better; (3) *Pessimistic*—things will get considerably worse; (4) *Disaster*—things will go terribly wrong; and (5) *Miracle*—things will go stunningly well.

Each scenario is then given a percentage of probability on the likelihood that it will happen. Cost for each scenario in effort or outcome is important to consider. Scenarios assist in clarifying thinking about issues so that better decisions can be made.

WORLD FUTURE SOCIETY PREDICTIONS

The World Future Society brings together experts from around the world to report on future directions in their areas of expertise. The November 2007 issue of *The Futurist* contained the WFS's top predictions for the future. A sampling of the trends is provided here:

- **The world will have 1 billion millionaires by 2025.** Technology and globalization will drive this prosperity, but the world's newfound wealth will also cause problems like water shortages.

- **Commerce will become cashless.** As technology becomes more accessible, there will be more frequent counterfeiting attempts, pushing society toward cash-free commerce. All transactions will be processed instantaneously and "grace periods" will no longer exist.

- **The U.S. federal deficit will worsen.** America's fiscal imbalance will become even worse if federal spending continues along its current trend. In twenty years, the deficit will become unsustainable and reach more than 10 percent of the economy.

- **The world population will reach 9.2 billion people by 2050.** Previous estimates of population growth have been adjusted due to increased longevity in richer countries and slower than expected decreases in fertility in developing countries. At the same time,

infant mortality rates may rise due to HIV/AIDS and other issues.

- **Water shortages will be a continuing problem for much of the world.** Implications of this include: (1) the growth of famine and desertification in developing areas of the world; (2) water wars are possible in certain areas of the world; and (3) water impurities will become a growing problem.

- **A major species will become extinct.** As a result of overpopulation, increased resource consumption, and environmental destruction, the earth will experience a species extinction event 100 to 1,000 times greater than any experienced since the dawn of humanity.

- **The United States will experience an osteoporosis epidemic.** Currently 34 million Americans have a condition that is considered a precursor to osteoporosis, a number that is projected to grow to 47 million by 2020.

- **Generation X and Y will be far more likely to choose the wrong career path than their predecessors.** This effect will be caused by unrealistic expectations about a particular career.

- **Privacy as we know it will disappear.** As a result of the increase in cyber-exhibitionism as well as new surveillance technology, privacy will become a thing of the past.

Futurists are aware that random events can happen that can change the best forecasting; therefore, these techniques of trend-watching, reviewing past events, gaming, scenarios, and others all must allow for a certain amount of flexibility. Forces acting on any possible future include systems, chance, and chaos, as well as individual choice.

Developing the skills and techniques to see into the future is neither magic nor unattainable. Futurists are leading the way to envisioning possible futures. They believe that developing effective foresight can lead to better decision-making, greater discoveries, and an improved future. Futurists challenge the concept of fatalism—that the future is coming and there is nothing we can do about it. Using these forecasting methods, individuals can change and guide their future. They are in a position to positively influence their future, which can potentially make things better for others and possibly change the world.

FUZZY LOGIC

Most analytical and computational processes use strict (crisp) logic parameters to control their functions. They define objects simply in aspects of positive or negative, on or off. This is known as Boolean logic, and it is the same logic computer circuits use and system programmers use to code simple fragments of data with 0s and 1s that build up packets of information. Boolean logic is limited to certain basic pieces of definition, using AND, OR, and NOT statements to control variables. AND refers to two inclusive possibilities, OR refers to exclusive possibilities, while NOT refers to a negative result that excludes all values.

Fuzzy logic, on the other hand, deals with multiple possibilities, the area between the digits 1 and 0, the semantics of analysis, and the grayer areas between *true* and *false*. This is referred to with such concepts as "degrees of truth," fractional values that are not opposites. Since most business decisions involve more than one value, none of which are directly opposed, fuzzy logic has a wide variety of applications in analyzing data, comparing decisions, and evaluating automatic responses. Such statements as "the boy is tall" or "this room is very warm" cannot be expressed in true or false definitions, because peoples' perceptions of these events vary. Not everyone agrees on an exact height that signifies tall, just as no one defines a room as "very warm" at a precise temperature. It is these nonprecise qualities that fuzzy logic seeks to explain.

As seen in the example above, fuzzy logic can be shone graphically as the entire series of possibilities intersecting with one another. Cold, warm, and hot are all possibilities, but according to input data they intersect one another, based on general perception—there are certain temperatures that some would consider hot, others merely warm. A thermostat, then, can theoretically be set to respond according to nonprecise variables, shown in IF and THEN statements. These statements are conditioned by the input data—IF a situation manifests, THEN a specific response is chosen. The statements neither include nor exclude any

variables, but wait on actions of the system. IF-THEN concepts are flexible, and they form the basis of fuzzy logic.

IF-THEN statements of fuzzy logic can be elaborated upon by using "hedges." A hedge is an intuitive, linguistic descriptor that fuzzy logic allows to be expressed mathematically. "Very," for instance, is a hedge that usually implies the square of a value in fuzzy logic. "Somewhat," "sort of," and "more or less" are other examples of hedges used to define IF-THEN statements.

Fuzzy sets are theory sets that cannot be easily defined through crisp logic. These age sets—young, middle-aged, old—are examples of fuzzy sets, since their parameters are subjective, depending on the views of those within the sets and those perceiving the sets as a whole. In the early twentieth century, philosopher and mathematician Bertrand Russell famously suggested that set theory as a whole suffered from fuzzy dilemmas, since a set including all sets may not be of the same nature as the sets within it—the set, for instance, of all age groups must include itself, yet a set of sets is not an age group.

Fuzzy sets are usually defined as the entire system, the data inputted, and the data received. The data inputs and outputs may be crisp and rigidly defined, but the overall system is an IF-THEN, fuzzy process. Inputs and outputs may also either be crisp or fuzzy, so fuzzy systems can come in many types, as required by programmers or analysts. One of the most common types of fuzzy sets is referred to as a *type 2* fuzzy logic set, or a set consisting of many fuzzy situations that culminate in one output under a single classification. These type 2 fuzzy sets are necessary for business applications where numerous sets of data come together to form a practical decision.

Fuzzy logic sets, or FLs, is one of the four main types of fuzzy logic. There are several commonly used types of fuzzy sets in this type of fuzzy logic, including L-Fuzzy sets, bipolar fuzzy sets, and intuitionistic fuzzy sets. These sets are "granulated," or split apart through intuitive means. For instance, the category of Age as seen in the example is granulated into three different sets based on similarity, proximity, and human reasoning. The second type of fuzzy logic is FLl, or the narrowest sense of fuzzy logic, the "l" standing only for logic. FLl deals with generalizations, philosophic insights into fuzzy procedures. The third type of fuzzy logic, fuzzy logic estimator (Fle), works with knowledge and semantics. A great deal of fuzzy logic depends on language and the way words are understood within cultures. This linguistic function is very important in applying fuzzy logic to real-life situations, and programmers of fuzzy systems must be very aware of language implications. The last type of fuzzy logic is FLr, or relational fuzzy logic that deals with the IF-THEN statements that govern fuzzy responses. Some IF-THEN situations can depend on other IF-THEN choices, creating a relational chain representing realistic events.

HISTORY OF FUZZY LOGIC

Many trace the origins of fuzzy logic back to Plato and Aristotle, both of whom explored the idea of the "excluded middle." This theory assumes that logic deals with Boolean concepts, true or false statements that held no room for middle ground. This is the opposite of fuzzy theory, which deals with the excluded middle especially; Aristotle, in creating the excluded middle concept, also made way for its counterpart.

Bertrand Russell began to explore the limits of logic by questioning set theories in the early twentieth century, and others began developing ultra-logic systems to explain more complicated situations. It was not until 1961, when electronic circuits were used to demonstrate how programmed responses could be inclusive, that fuzzy logic concepts found their way into thesis papers. In 1965, Lotfi Zadeh, considered by many as the father of modern fuzzy logic, wrote the paper "Fuzzy Sets," which defined the field and gave the concept its name. Contrary to linguistic assumptions, fuzzy sets do not come up with fuzzy results—they take imprecise concepts and assign mathematical values to them to produce very clear and precise data. Zadeh created an algebra for fuzzy sets so that they could be applied to real life questions.

In the 1970s, active applications of fuzzy logic slowed. A scientist by the name of Ebrahim Mamdani designed a fuzzy logic program for a steam engine. Most practical work on fuzzy logic was used by NASA on space programs and various flexible life support technology. Other countries, however, most notably Japan, proved more eager to use fuzzy logic in public technology; Japan achieved success in several famous fuzzy systems, including a subway. By the 1990s, programmers were beginning to make use of some flexibilities in fuzzy logic through their coding, and before long, businesses were considering fuzzy logic in everything from appliance creation to corporate decision making. Today, a number of technologies use fuzzy logic to become more adaptive and powerful. Fuzzy data mining, one of the newest fields for companies, is still evolving into a useful tool.

BUSINESS USES FOR FUZZY SYSTEMS

Daily, corporations face events that either defy prediction or are difficult to respond to, given traditional analysis methods. The use of fuzzy logic in finding answers to these problems is often referred to as *uncertainty management*. The more adaptable systems and business reactions are (using IF-THEN statements), the more fuzzy logic they implement. Many businesses employ fuzzy logic abilities without even knowing it, bypassing the mathematical basis.

Fuzzy logic also helps businesses with entrepreneurial goals, offering more flexibility for the "fuzzy front end,"

or the point when radical innovation meets the market. It is here that more organic, fuzzy systems are being put into play, reducing costs and increasing efficiency and decision making. The tenets of a fuzzy approach to such innovation are known to many managers and are becoming widespread business concepts. Such practices include the following:

- Always have a plan, and consistently improve understanding of consumers and the market.

- Expect that the plan will change. Companies refuse to entertain illusions that their master plan can succeed unaltered. The act of entering the market will automatically create changes in any plan.

- Make decisions before it is too late, without overanalyzing or waiting too long for data that will never be fully complete.

- Be on guard for new developments in the industry and new technologies that can change existing business methods.

- Balance customer feedback with potential, not giving either side too much weight in business decisions.

- Focus on opportunities and capabilities rather than purely on financial returns.

DATA MINING AND OTHER ANALYSIS

As businesses move on in their endeavors, fuzzy logic can be implemented in data mining, forecasting, and Internet tools. Data mining is one of the newest fuzzy logic fields, where new methods can be used to sort information according to applicability. While data mining programs have greatly increased in complexity and efficiency, fuzzy logic can add a relational aspect, allowing data to be sorted according to its relationship with other data sets. A good example is financial analysis—a company may have several different levels of possible financial outcomes, showing a range of earnings in which the business will fall. Fuzzy logic can take all those earnings, assign values to them based on objectives (good, not bad, poor, more than expected), and create useful forms of analysis through these "belief possibilities." A company will then know, based on intuitive notions and past performance, the likely earnings for the next quarter and where that falls in their hedged rating system.

In 2001, Lotfi Zadeh stated that fuzzy logic was the "brainware of the Internet." By this he meant that the Internet as a whole is approximate, dealing not with true or false information but with the "degrees of truth" in between. This is mostly due to linguistic fuzziness, in which words have general, not specific meanings, creating an e-commerce environment where such headings as "very cheap" or "slightly used" have only approximate values. This is seen clearly in Internet search engines, where crisp logic often fails and fuzzy logic often succeeds. A user attempting to search by crisp logic might set parameters so severe (including such exact variables as cost, location, accommodation, and deadlines) that the search produces no results. A fuzzy searcher, on the other hand, will know what level of impreciseness is necessary to produce useful search results.

This fuzzy online searching becomes very important to businesses when they construct their own search engines, whether for common use or for their online stores. Many search engines use Boolean logic AND and OR statements to search for keywords and related information, which is the reason crisp logic users have difficulties finding needed information. Search engines, however, can be constructed using fuzzy logic, so that AND and OR statements are granulated to include a range of possibilities more applicable to the search (such as costs above and below a searched cost). Also, fuzzy search engines can be easily tailored to individual use, allowing companies to personalize online stores for their customers who will find the more they search, the more the search engine understands their needs and produces results tuned into their interests.

By using these and other fuzzy logic concepts, companies can improve their analysis and the ways they conduct business. Other advantages of fuzzy logic for business, as shown in Hossein Bidgoli's 1998 book *Intelligent Management Support Systems*, include:

- **Simplicity**. Fuzzy logic removes areas of technicality from mathematic modeling, allowing models to be based more on intuitive phrases and goals than only on formulas. Fuzzy logic's IF-THEN statements allow for more streamlined analysis without the lengthy rules needed by crisp logic.

- **Contradiction**. Since fuzzy logic does not need to decide between two opposing choices, contradictions that crisp logic would not be able to handle can be included. This is very helpful to programmers, who can use IF-THEN statements to deal with contradictory options, putting the contradictions into multiple sets based on their applicability.

- **Reduced development time**. Analysis made with fuzzy logic will not take as long, since much of the data analysts need is immediately available based on relationship parameters. Fuzzy analysis can also be conducted focusing on objectives and objective phrases instead of getting lost in formulas and numbers the more traditional analysis methods sometimes fall into.

- **System autonomy**. Fuzzy systems' rules function independently of each other. This means that one rule can be faulty without affecting the efficiency of the other rules included in the system. Fuzzy systems

can survive these errors in a crisis, whereas crisp logic programs might flounder. Such fuzzy systems can be tested by removing rules sequentially to test each possibility.

- **Expert systems**. Expert systems can be combined with fuzzy systems with excellent results. Superior information and application is bolstered by adaptability and evolving processes, creating a powerful tool of analysis that produces degrees of possibility instead of a more dangerous single decision.

FUZZY LOGIC AND NEURAL NETWORKS

One of the principle technological uses for fuzzy logic lies in neural networks (NN). Neural networks operate through relationships found in data, and they are based on the way human brains interact with information. A neural network is made from a complex system of nodes, interconnected elements that contain related pieces of data. Each node is a separate system, but it is also related to other nodes as necessary. Neural networks are applauded for their learning capabilities and adaptive qualities that allow them to respond effectively to a variety of situations and intuitively gather important sets of data for analysis.

Fuzzy logic is one of the principles used in the creation of neural networks. Fuzzy sets allow the networks to choose between different pieces of information as needed, including any knowledge that may be applicable.

EXAMPLES OF FUZZY LOGIC TECHNOLOGY

Subway systems. One of the most famous applications of fuzzy logic occurred in the early 1980s, when Japan created a subway system in the city of Sendai based upon fuzzy logic mathematics. This control, created by Hitachi Ltd., is regarded as the first practical use of fuzzy technology. According to programming created by Hitachi engineers, the subway system automatically responded to changes from many incoming variables. The subway would speed up, slow down, stop, or start based on this information. Small fluctuations in velocity, weight, direction, incline, and speed relative to maximum and minimum speeds all had their impact on the subway. This was considered an improvement over human drivers who made more errors and had worse reaction times than the fuzzy programming. The fuzzy logic also out-performed crisp logic systems, which could not equal the smooth, continuous subway motions of the Sendai controller. This subway spawned many other lines of fuzzy logic programming in Japan.

Air conditioning. One of the most popular uses for fuzzy logic is in climate control systems for commercial buildings such as offices. A fuzzy programming system can anticipate subtle changes in the atmosphere and alter climate control units to respond.

TV clarity. Normal TVs operate by illuminating approximately 525 scanning lines with electronic pulses at intervals. Half of the electron lines are lit to form the picture, followed by the other half, and the alternation produces picture quality and resolution. This process loses much of the information, a problem that high definition television sets bypass by utilizing over a thousand scanning lines. These normal TV functions were combined with fuzzy logic by Sony engineers in the early 1990s to produce an adapting TV set that compared different parts of the incoming signal to "perfect" images held with the TV database. The TV then altered the image immediately to create as perfect a picture as it could. Today's LCD and high definition screens use other methods to improve clarity, but fuzzy logic can still maintain clarity for video imaging.

Elderly care. In the late 2000s, The University of Missouri—in collaboration with the English De Montfort University (DMU)—is conducting a study on improving centers for care of the elderly by implementing fuzzy logic systems. These systems work through a series of sensors that can be placed throughout homes for elderly care. With fuzzy logic, sensors can tell the difference between normal background noise, heat, and rhythms, and the functions of the people at the home. Sleep patterns, respiratory patterns, and pulse feedback can all give valuable information to the system. Health problems can be discovered, and emergency care automatically sent for if required. To preserve privacy, no sensors are video enabled.

Household appliances. Many household appliances currently use fuzzy systems to regulate their performance. Washing machines can tell how large a load is and respond appropriately based on what wash cycle the user wants. Refrigerators can also use fuzzy logic to cool different sections of the refrigerator correctly.

Traffic management. Traffic management systems require a certain amount of intelligence from either crisp logic directions or fuzzy logic parameters. Because of the constantly shifting traffic situations, fuzzy logic has proved to be more useful in anticipating problems. It is difficult to create any models of traffic, but IF-THEN logic can deal with vague expectations and respond to situations. People looking for traffic advice have different perspectives and human needs that cannot be easily quantified—the better a fuzzy system is at predicting traffic, the more trust drivers have in the process, and the smoother the system runs.

ISSUES WITH FUZZY LOGIC

Although fuzzy systems can be very simple to use, they are not necessarily easy to create. A large amount of work goes into creating fuzzy logic programs, and the more variables there are, the more complicated the creation

can be. This is known as the *curse of dimensionality*—every new variable that fuzzy systems have to deal with increases its complexity exponentially. The larger the system grows, the more server space it takes and the less precise it will be.

When a fuzzy logic application is developed, it must also be utilized effectively. People must learn to mine fuzzy systems for proper information and utilize data received effectively. The knowledge fuzzification produces is only good if businesses can take the results and make high quality decisions.

G

GAP ANALYSIS

Gap analysis generally refers to the activity of studying the differences between standards and the delivery of those standards. For example, it would be useful for a firm to document differences between customer expectation and actual customer experiences in the delivery of medical care. The differences could be used to explain satisfaction and to document areas in need of improvement.

However, in the process of identifying the gap, a before-and-after analysis must occur. This can take several forms. For example, in lean management leaders perform a Value Stream Map of the current process. They then create a Value Stream Map of the desired state. The differences between the two define the "gap." Once the gap is defined, a game plan can be developed that will move the organization from its current state toward its desired future state.

Another tool for identifying the gap is a step chart. With the step chart, various "classes" of performance are identified—including world-class status. Then, current state and desired future state are noted on the chart. Once again, the difference between the two defines the "gap."

The issue of service quality can be used as an example to illustrate gaps. For this example, there are several gaps that are important to measure. From a service quality perspective, these include: (1) service quality gap, (2) management understanding gap, (3) service design gap, (4) service delivery gap, and (5) communication gap.

1. **Service Quality Gap.** Indicates the difference between the service expected by customers and the service they actually receive. For example, customers may expect to wait only 20 minutes to see their doctor but, in fact, have to wait more than thirty minutes.

2. **Management Understanding Gap.** Represents the difference between the quality level expected by customers and the perception of those expectations by management. For example, in a fast food environment, the customers may place a greater emphasis on order accuracy than promptness of service, but management may perceive promptness to be more important.

3. **Service Design Gap.** This is the gap between management's perception of customer expectations and the development of this perception into delivery standards. For example, management might perceive that customers expect someone to answer their telephone calls in a timely fashion. To customers, "timely fashion" may mean within thirty seconds. However, if management designs delivery such that telephone calls are answered within sixty seconds, a service design gap is created.

4. **Service Delivery Gap.** Represents the gap between the established delivery standards and actual service delivered. Given the above example, management may establish a standard such that telephone calls should be answered within thirty seconds. However, if it takes more than thirty seconds for calls to be answered, regardless of the cause, there is a delivery gap.

5. **Communication Gap.** This is the gap between what is communicated to consumers and what is actually delivered. Advertising, for instance, may indicate to consumers that they can have their cars' oil changed within twenty minutes when, in reality, it takes more than thirty minutes.

IMPLEMENTING GAP ANALYSIS

Gap analysis involves internal and external analysis. Externally, the firm must communicate with customers. Internally, it must determine service delivery and service design. Continuing with the service quality example, the steps involved in the implementation of gap analysis are:

- Identification of customer expectations
- Identification of customer experiences
- Identification of management perceptions
- Evaluation of service standards
- Evaluation of customer communications

The identification of customer expectations and experiences might begin with focus-group interviews. Groups of customers, typically numbering seven to twelve per group, are invited to discuss their satisfaction with services or products. During this process, expectations and experiences are recorded. This process is usually successful in identifying those service and product attributes that are most important to customer satisfaction.

After focus-group interviews are completed, expectations and experiences are measured with more formal, quantitative methods. Expectations could be measured with a one-to-ten scale where one represents "Not At All Important" and ten represents "Extremely Important." Experience or perceptions about each of these attributes would be measured in a similar manner.

Gaps can be simply calculated as the arithmetic difference between the two measurements for each of the attributes. Management perceptions are measured much in the same manner. Groups of managers are asked to discuss their perceptions of customer expectations and experiences. A team can then be assigned the duty of evaluating manager perceptions, service standards, and communications to pinpoint discrepancies. After gaps are identified, management must take appropriate steps to fill or narrow the gaps.

THE IMPORTANCE OF SERVICE QUALITY GAP ANALYSIS

The main reason gap analysis is important to firms is the fact that gaps between customer expectations and customer experiences lead to customer dissatisfaction. Consequently, measuring gaps is the first step in enhancing customer satisfaction. Additionally, competitive advantages can be achieved by exceeding customer expectations. Gap analysis is the technique utilized to determine where firms exceed or fall below customer expectations.

Customer satisfaction leads to repeat purchases and repeat purchases lead to loyal customers. In turn, customer loyalty leads to enhanced brand equity and higher profits. Consequently, understanding customer perceptions is important to a firm's performance. As such, gap analysis is used as a tool to narrow the gap between perceptions and reality, thus enhancing customer satisfaction.

In the early twenty-first century, work by innovation expert Anthony Ulwick discusses the limitations of popular qualitative research methods, including gap analysis. In his book *What Customers Want: Using Outcome-Driven Innovation to Create Breakthrough Products and Services*, Ulwick writes that gap analysis considers only the difference between importance and satisfaction. As an alternative, Ulwick has devised a tool focused on opportunity for customer satisfaction, which yields data about outcomes that would lead to highest customer satisfaction.

PRODUCT APPLICATIONS

It should be noted that gap analysis is applicable to any aspect of industry where performance improvements are desired, not just in customer service. For example, the product quality gap could be measured by (and is defined as) the difference between the quality level of products expected by customers and the actual quality level. The measurement of the product quality gap is attained in the same manner as above. However, while service delivery can be changed through employee training, changes in product design are not as easily implemented and are more time consuming. Many product innovation experts are discussing new methods of gathering requirements for product design.

Gap analysis can be used to address internal gaps. For example, it is also applicable to human resource management. There may be a gap between what employees expect of their employer and what they actually experience. The larger the gap is, the greater the job dissatisfaction. In turn, job dissatisfaction can decrease productivity and have a negative effect on a company's culture.

Ford Motor Co., for example, utilized gap analysis while developing an employee benefit program. While management may believe it has a handle on employee perceptions, this is not always true. With this in mind, Ford's management set out to understand employee desires regarding flexible benefits. Their cross-functional team approach utilized focus groups, paper and pencil tests, and story boards to understand employee wants and needs. Their team, consisting of finance, human resources, line managers, benefits staff, and consultants, identified gaps in benefit understanding, coverage, and communications. As a result of gap analysis, Ford implemented a communications program that gained employee acceptance.

GENERIC COMPETITIVE STRATEGIES

Three of the most widely read books on competitive analysis in the 1980s were Michael Porter's *Competitive Strategy*, *Competitive Advantage*, and *Competitive Advantage of Nations*. In his various books, Porter developed three generic strategies that, he argues, can be used singly or in combination to create a defendable position and to outperform competitors, whether they are within an industry or across nations. Porter states that the strategies are generic because they are applicable to a large variety of situations and contexts. The strategies are (1) overall cost leadership; (2) differentiation; and (3) focus on a particular market niche. The generic strategies provide direction for firms in designing incentive systems, control procedures, and organizational arrangements. Following is a description of this work.

OVERALL COST LEADERSHIP STRATEGY

Overall cost leadership requires firms to develop policies aimed at becoming and remaining the lowest-cost producer and/or distributor in the industry. Company strategies aimed at controlling costs include construction of efficient-scale facilities, tight control of costs and overhead, avoidance of marginal customer accounts, minimization of operating expenses, reduction of input costs, tight control of labor costs, and lower distribution costs. The low-cost leader gains competitive advantage by getting its costs of production or distribution lower than those of the other firms in its market. The strategy is especially important for firms selling unbranded commodities such as beef or steel.

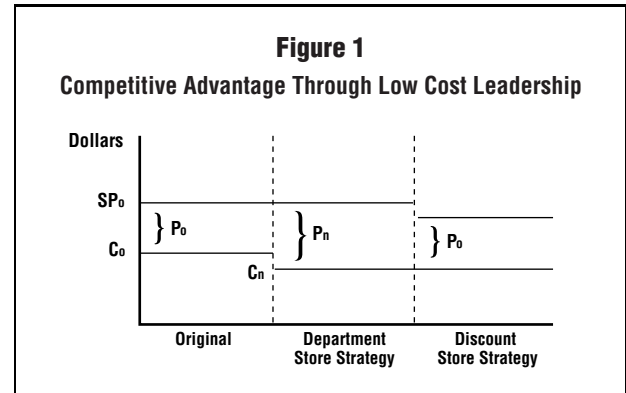
Figure 1
Competitive Advantage Through Low Cost Leadership


Figure 1 shows the competitive advantage firms may achieve through cost leadership. C is the original cost of production. C is the new cost of production. SP is the original selling price. SP is the new selling price. P is the original profit margin. P is the new profit margin.

If we assume our firm and the other competitors are producing the product for a cost of C and selling it at SP, we are all receiving a profit of P. As cost leader, we are able to lower our cost to C while the competitors remain at C. We now have two choices as to how to take advantage of our reduced costs.

1. Department stores and other high-margin firms often leave their selling price as SP, the original selling price. This allows the low-cost leader to obtain a higher profit margin than they received before the reduction in costs. Since the competition was unable to lower their costs, they are receiving the original, smaller profit margin. The cost leader gains competitive advantage over the competition by earning more profit for each unit sold.

2. Discount stores such as Wal-Mart are more likely to pass the savings from the lower costs on to customers in the form of lower prices. These discounters retain the original profit margin, which is the same margin as their competitors. However, they are able to lower their selling price due to their lower costs (C). They gain competitive advantage by being able to underprice the competition while maintaining the same profit margin.

Overall cost leadership is not without potential problems. Two or more firms competing for cost leadership may engage in price wars that drive profits to very low levels. Ideally, a firm using a cost leader strategy will develop an advantage that is not easily copied by others. Cost leaders also must maintain their investment in state-of-the-art equipment or face the possible entry of more cost-effective competitors. Major changes in technology may drastically change production processes so that previous investments in

production technology are no longer advantageous. Finally, firms may become so concerned with maintaining low costs that needed changes in production or marketing are overlooked. The strategy may be more difficult in a dynamic environment because some of the expenses that firms may seek to minimize are research and development costs or marketing research costs, yet these are expenses the firm may need to incur in order to remain competitive.

DIFFERENTIATION STRATEGY

The second generic strategy, differentiating the product or service, requires a firm to create something about its product or service that is perceived as unique throughout the industry. Whether the features are real or just in the mind of the customer, customers must perceive the product as having desirable features not commonly found in competing products. The customers also must be relatively price-insensitive. Adding product features means that the production or distribution costs of a differentiated product may be somewhat higher than the price of a generic, non-differentiated product. Customers must be willing to pay more than the marginal cost of adding the differentiating feature if a differentiation strategy is to succeed.

Differentiation may be attained through many features that make the product or service appear unique. Possible strategies for achieving differentiation may include:

- warranties (e.g., Sears tools)
- brand image (e.g., Coach handbags, BMW automobiles)
- technology (e.g., Apple iPhone)
- features (e.g., Jenn-Air ranges)
- service (e.g., Makita hand tools)
- quality/value (e.g., Pixar Animation Studios)
- dealer network (e.g., Caterpillar construction equipment)

Differentiation does not allow a firm to ignore costs; it makes a firm's products less susceptible to cost pressures from competitors because customers see the product as unique and are willing to pay extra to have the product with the desirable features. Differentiation can be achieved through real product features or through advertising that causes the customer to perceive that the product is unique.

Differentiation may lead to customer brand loyalty and result in reduced price elasticity. Differentiation may also lead to higher profit margins and reduce the need to be a low-cost producer. Since customers see the product as different from competing products and they like the product features, customers are willing to pay a premium for these features. As long as the firm can increase the selling price by more than the marginal cost of adding the features, the profit margin is increased. Firms must be able to charge more for their differentiated product than it costs them to make it distinct, or else they may be better-off making generic, undifferentiated products. Firms must remain sensitive to cost differences. They must carefully monitor the incremental costs of differentiating their product and make certain the difference is reflected in the price.

Firms pursuing a differentiation strategy are vulnerable to different competitive threats than firms pursuing a cost leader strategy. Customers may sacrifice features, service, or image for cost savings. Customers who are price sensitive may be willing to forgo desirable features in favor of a less costly alternative. This can be seen in the growth in popularity of store brands and private labels. Often, the same firms that produce name-brand products produce the private-label products. The two products may be physically identical, but stores are able to sell the private-label products for a lower price because very little money was put into advertising in an effort to differentiate the private-label product.

Imitation may also reduce the perceived differences between products when competitors copy product features. Thus, for firms to be able to recover the cost of marketing research or R&D, they may need to add a product feature that is not easily copied by a competitor.

A final risk for firms pursuing a differentiation strategy is changing consumer tastes. The feature that customers like and find attractive about a product this year may not make the product popular next year. Changes in customer tastes are especially obvious in the apparel industry. Polo Ralph Lauren has been a very successful brand in the fashion industry. However, some younger consumers have shifted to Abercrombie and Fitch, Aeropostale, and other youth-oriented brands.

Ralph Lauren, founder and CEO, has been the guiding light behind his company's success. Part of the firm's success has been the public's association of Lauren with the brand. Ralph Lauren leads a high-profile lifestyle of preppy elegance. His appearance in his own commercials, his Manhattan duplex, his Colorado ranch, his vintage car collection, and private jet have all contributed to the public's fascination with the man and his brand name. This image has allowed the firm to market everything from suits and ties to golf balls. Through licensing of the name, the Lauren name also appears on sofas, soccer balls, towels, tableware, and much more.

COMBINATION STRATEGIES

Can forms of competitive advantage be combined? Porter asserts that a successful strategy requires a firm to aggressively stake out a market position, and that different strategies involve distinctly different approaches to

competing and operating the business. An organization pursuing a differentiation strategy seeks competitive advantage by offering products or services that are unique from those offered by rivals, either through design, brand image, technology, features, or customer service. Alternatively, an organization pursuing a cost leadership strategy attempts to gain competitive advantage based on being the overall low-cost provider of a product or service. To be "all things to all people" can mean becoming "stuck in the middle" with no distinct competitive advantage. The difference between being "stuck in the middle" and successfully pursuing combination strategies merits discussion. Although Porter describes the dangers of not being successful in either cost control or differentiation, some firms have been able to succeed using combination strategies.

Research suggests that, in some cases, it is possible to be a cost leader while maintaining a differentiated product. One example is Netflix. Its online/mail order approach to video rental is a low-cost alternative to the overhead involved with a brick-and-mortar store (i.e. Blockbuster or Hollywood Video). At the same time, it is differentiated in the marketplace because it offers DVD rentals with no late fees.

Another firm that has pursued an effective combination strategy is Nike. When customer preferences moved to wide-legged jeans and cargo pants, Nike's market share slipped. Competitors such as Adidas offered less expensive shoes and undercut Nike's price. Nike's stock price dropped in 1998 to half its 1997 high. However, Nike reported a 70 percent increase in earnings for the first quarter of 1999 and saw a significant rebound in its stock price. Nike achieved the turnaround by cutting costs and developing new, distinctive products. Nike reduced costs by cutting some of its endorsements. Company research suggested the endorsement by the Italian soccer team, for example, was not achieving the desired results. Michael Jordan and a few other "big name" endorsers were retained while others, such as the Italian soccer team, were eliminated, resulting in savings estimated at over $100 million. Firing 7 percent of its 22,000 employees allowed the company to lower costs by another $200 million, and inventory was reduced to save additional money. While cutting costs, the firm also introduced new products designed to differentiate Nike's products from those of the competition. Fast forward to 2008, and one can see that Nike has retained its role as a leading brand in the apparel industry. It has been chosen by *Fortune* magazine as the most admired apparel brand, for attributes including social responsibility, innovation, and financial soundness. Nike contracts with 700 factories worldwide and employs close to 800,000. For the fiscal year ending in May 2007, the company reported record revenues of 16.3 billion dollars, a 1.3 billion increase over the previous year's earnings, proving the staying power of its strategy.

Some industry environments may actually call for combination strategies. Trends suggest that executives operating in highly complex environments such as health care do not have the luxury of choosing exclusively one strategy over the other. The hospital industry may represent such an environment, as hospitals must compete on a variety of fronts. Combination (i.e., more complicated) strategies are both feasible and necessary to compete successfully. For instance, DRG-based reimbursement (diagnosis-related groups) and the continual lowering of reimbursement ceilings have forced hospitals to compete on the basis of cost. At the same time, many of them jockey for position with differentiation based on such features as technology and birthing rooms. Thus, many hospitals may need to adopt some form of hybrid strategy in order to compete successfully, according to Walters and Bhuian.

FOCUS STRATEGY

The generic strategies of cost leadership and differentiation are oriented toward industry-wide recognition. The final generic strategy, focusing (also called niche or segmentation strategy), involves concentrating on a particular customer, product line, geographical area, channel of distribution, stage in the production process, or market niche. The underlying premise of the focus strategy is that a firm is better able to serve a limited segment more efficiently than competitors can serve a broader range of customers. Firms using a focus strategy simply apply a cost leader or differentiation strategy to a segment of the larger market. Firms may thus be able to differentiate themselves based on meeting customer needs, or they may be able to achieve lower costs within limited markets. Focus strategies are most effective when customers have distinctive preferences or specialized needs.

A focus strategy is often appropriate for small, aggressive businesses that do not have the ability or resources to engage in a nationwide marketing effort. Such a strategy may also be appropriate if the target market is too small to support a large-scale operation. Many firms start small and expand into a national organization. For instance, Wal-Mart started in small towns in the South and Midwest. As the firm gained in market knowledge and acceptance, it expanded throughout the South, then nationally, and now internationally. Wal-Mart started with a focused cost leader strategy in its limited market, and later was able to expand beyond its initial market segment.

A firm following the focus strategy concentrates on meeting the specialized needs of its customers. Products and services can be designed to meet the needs of buyers. One approach to focusing is to service either industrial

buyers or consumers, but not both. Martin-Brower, the third-largest food distributor in the United States, serves only the eight leading fast-food chains. With its limited customer list, Martin-Brower need only stock a limited product line, its ordering procedures are adjusted to match those of its customers, and its warehouses are located so as to be convenient to customers.

Firms utilizing a focus strategy may also be better able to tailor advertising and promotional efforts to a particular market niche. Many automobile dealers advertise that they are the largest volume dealer for a specific geographic area. Other car dealers advertise that they have the highest customer satisfaction scores within their defined market or the most awards for their service department.

Firms may be able to design products specifically for a customer. Customization may range from individually designing a product for a customer to allowing customer input into the finished product. Tailor-made clothing and custom-built houses include the customer in all aspects of production, from product design to final acceptance. Key decisions are made with customer input. However, providing such individualized attention to customers may not be feasible for firms with an industry-wide orientation.

Other forms of customization simply allow the customer to select from a menu of predetermined options. Burger King advertises that its burgers are made "your way," meaning that the customer gets to select from the predetermined options of pickles, lettuce, and so on. Similarly, customers are allowed to design their own automobiles within the constraints of predetermined colors, engine sizes, interior options, and so forth.

Potential difficulties associated with a focus strategy include a narrowing of differences between the limited market and the entire industry. National firms routinely monitor the strategies of competing firms in their various submarkets. They may then copy the strategies that appear particularly successful. The national firm, in effect, allows the focused firm to develop the concept, and then the national firm may emulate the strategy of the smaller firm or acquire it as a means of gaining access to its technology or processes. Emulation increases the ability of other firms to enter the market niche while reducing the cost advantages of serving the narrower market.

Market size is always a problem for firms pursing a focus strategy. The targeted market segment must be large enough to provide an acceptable return so that the business can survive. For instance, ethnic restaurants are often unsuccessful in small U.S. towns, since the population base that enjoys Japanese or Greek cuisine is too small to allow the restaurant operator to make a profit. Likewise, the demand for an expensive, upscale restaurant is usually not sufficient in a small town to make its operation economically feasible.

Another potential danger for firms pursuing a focus strategy is that competitors may find submarkets within the target market. In the past, United Parcel Service (UPS) solely dominated the package delivery segment of the delivery business. Newer competitors such as Federal Express and Roadway Package Service (RPS) have entered the package delivery business and have taken customers away from UPS. RPS contracts with independent drivers in a territory to pick up and deliver packages, while UPS pays unionized wages and benefits to its drivers. RPS started operations in 1985 with 36 package terminals. By 1999 it was a $1 billion company with 339 facilities. Federal Express was officially rebranded as FedEx Ground in late 2000, and is now part of a nationwide business-to-consumer package delivery network with capacity to serve every address in the United States.

GENERIC STRATEGIES AND THE INTERNET

Porter asserts that these generic competitive strategies were not only relevant for the old economy, but are just as vital today. Indeed, he goes on to say that terms such as "old economy" and "new economy" may be misguided, and the concept of a firm's Internet operation as a stand-alone entity preclude the firm from garnering important synergies. Furthermore, the Internet may enhance a firm's opportunities for achieving or strengthening a distinctive strategic positioning. Therefore, effective strategy formulation at the business level should pay off, not in spite of the Internet, but in concert with it.

Porter describes how companies can set themselves apart in at least two ways: operational effectiveness (doing the same activities as competitors but doing them better) and strategic positioning (doing things differently and delivering unique value for customers). "The Internet affects operational effectiveness and strategic positioning in very different ways. It makes it harder for companies to sustain operational advantages, but it opens new opportunities for achieving or strengthening a distinctive strategic positioning." Although the Internet is a powerful tool for enhancing operational effectiveness, these enhancements alone are not likely to be sustained because of copying by rivals. This state of affairs elevates the importance of defining for the firm a unique value proposition. Internet technology can be a complement to successful strategy, but it is not sufficient. "Frequently, in fact, Internet applications address activities that, while necessary, are not decisive in competition, such as informing customers, processing transactions, and procuring inputs. Critical corporate assets—skilled personnel, proprietary product technology, efficient logistical systems—remain intact, and they are often strong enough to preserve existing competitive advantages."

Consistent with the earlier discussion regarding combination strategies, Kim, Nam, and Stimpert found in their study of e-businesses that firms pursuing a hybrid strategy of cost leadership and differentiation exhibited the highest performance. These authors concluded that cost leadership and differentiation must often be combined to be successful in e-business.

Porter's generic business strategies provide a set of methods that can be used singly or in combination to create a defendable business strategy. They also allow firms that use them successfully to gain a competitive advantage over other firms in the industry. Firms either strive to obtain lower costs than their competitors or to create a perceived difference between their product and the products of competitors. Firms can pursue their strategy on a national level or on a more focused, regional basis.

Clearly, Michael Porter's work has had a remarkable impact on strategy research and practice. The annual Porter Prize, akin to the Deming Prize, was established in 2001 in Japan to recognize that nation's leading companies in terms of strategy.

Porter's ideas have stood the test of time and appear to be relevant both for profit-seeking enterprises and not-for-profit institutes in a variety of international settings. Torgovicky, Goldberg, Shvarts, and Bar Dayan have found a relationship between business strategy and performance measures in an ambulatory health care system in Israel, strengthening Porter's original theory about the impracticality of the stuck-in-the-middle strategy, and suggesting the applicability of Porter's generic strategies to not-for-profit institutes.

Research in 2006 (Akan, Allen, Helms, and Spralls) has focused on the experience of managers charged with implementing the generic strategies. According to some researchers, while the strategies seem self-explanatory, managers are still in need of further guidance. One study, which looked at more than two hundred organizations, found that managers need to follow several tactics in order to implement a single strategy. The researchers suggest that support is needed for managers to bridge the gap between theory and practice with regards to generic competitive strategy.

GLOBALIZATION

Globalization refers to the process of integration across societies and economies. The phenomenon encompasses the flow of products, services, labor, finance, information, and ideas moving across national borders. The frequency and intensity of the flows relate to the upward or downward direction of globalization as a trend.

There is a popular notion that there has been an increase of globalization since the early 1980s. However, a comparison of the period between 1870 and 1914 to the post-World War II era indicates a greater degree of globalization in the earlier part of the century than the latter half. This is true in regards to international trade growth and capital flows, as well as migration of people to America.

If a perspective starts after 1945, globalization is a growing trend with a predominance of global economic

Figure 1

International Export Trade, 1990-2003 (in billions of US dollars)
integration that leads to greater interdependence among nations. Between 1990 and 2001, total output of export and import of goods as a proportion of GDP rose from 32.3 percent to 37.9 percent in developed countries and 33.8 percent to 48.9 percent for low- to middle-income countries. From 1990 to 2003, international trade export rose by $3.4 to $7.3 trillion (see Figure 1). This amount continues to grow throughout the 2000s. Hence, the general direction of globalization is growth, but it is often unevenly distributed between wealthier and poorer countries.

RATIONALE

A primary economic rationale for globalization is reducing barriers to trade for the enrichment of all societies. The greater good would be served by leveraging comparative advantages for production and trade that are impeded by regulatory barriers between sovereignty entities. In other words, the betterment of societies through free trade for everyone is possible as long as each one has the freedom to produce with a comparative advantage and engage in exchanges with others.

This economic rationale for global integration depends on supporting factors to facilitate the process. The factors include advances in transportation, communication, and technology to provide the necessary conduits for global economic integration. While these factors are necessary, they are not sufficient. Collaboration with political will through international relations is required to leverage the potential of the supporting factors.

HISTORICAL BACKGROUND

Globalization from 1870 to 1914 came to an end with World War I, as various countries pursued isolationism and protectionism agendas through various treaties—the

Treaty of Brest-Litovsk (1918), the Treaty of Versailles (1918), the Treaty of St. Germain (1919), and the Treaty of Trianon (1920). U.S. trade policies—the Tariff acts of 1921, 1922, 1924, 1926, and the Smoot-Hawley Tariffs of 1930—raised barriers to trade. These events contributed to the implosion of globalization for more than forty years.

Toward the end of World War II, forty-four countries met in an effort to re-establish international trade. The milestone is referred to as Bretton Woods, named after the New Hampshire country inn where the meeting was held. Results of Bretton Woods included the creation of the International Monetary Fund (IMF), the World Bank, and subsequently, the General Agreements on Tariffs and Trade (GATT).

In 1948, the International Trade Organization (ITO) was established as an agency of the United Nations, with fifty member countries and the Havana Charter to facilitate international trade, but it failed. As a result, GATT rose to fill the void as a channel for multilateral trade negotiations and recognition of "Most Favored Nation" status that applied the same trading conditions between members that applied to other trading partners with "most favored" partner standing.

GATT involved a number of different multilateral rounds of trade negotiations to reduce trade barriers and facilitate international trade. In the first round, the twenty-three founding members of GATT agreed to 45,000 tariff concessions affecting 20 percent of international trade worth $10 billion. Many of GATT's trade rules were drawn from the ITO charter. Subsequent trade rounds involved more members and additional issues, but the basic foundation of GATT remained the same.

In the second round, the Kennedy Round of the mid-1960s, the focus continued with tariff reductions.

In the third round, the Tokyo Round (1973 to 1979), 102 countries participated to reform the trading system, resulting in tariffs on manufactured products which were reduced to 4.7 percent from a high of 40 percent at the inception of GATT. Important issues revolved around anti-dumping measures, and subsidies and countervailing measures. The reduction of trade barriers enabled about an average of 8 percent growth of world trade per year in the 1950s and 1960s.

In the fourth round, the Uruguay Round (1986 to 1993), 125 countries participated to develop a more comprehensive system. An increasing importance was placed on globalization and on new, uncharted territories such as intellectual property. Additionally, other areas were discussed for coverage under new regulations, including agricultural and other old world industries (including textiles).

On April 15, 1995, in Marrakesh, Morocco, a deal was signed to create the World Trade Organization (WTO), which replaced GATT with a permanent institution that required a full and enduring commitment. The WTO encompasses trade in goods, services, and intellectual property related to trade with a more efficient dispute settlement system.

The most recent round, formally titled the Doha Development Agenda, began in 2001 in Doha, Qatar. The mission of this round was to give a hand up to impoverished peoples and nations of the world by lowering more trade barriers and strengthening local workers, farmers, and other members of agricultural communities by creating new rules for assisting underdeveloped nations. The overall goal is to create a truly global economy by stimulating all economies everywhere, rather than favoring those that are already thriving in well-developed nations. However, the Doha round has been plagued by deadlock and contention; less-developed nations have accused wealthier nations of protectionist policies, especially regarding national agricultural subsidies and tariffs. Talks to reach an agreement collapsed in 2003, 2005, 2006, 2007, and 2008.

COMPLEXITIES AND CONTROVERSIES

The increase of globalization surfaced many complex and controversial issues as economies and societies became more interdependent with greater frequency of interactions between one another. A number of important trends make up globalization, including: (1) location of integration activities; (2) impact upon poorer societies; (3) flow of capital; (4) migration of laborers and labor; (5) diffusion of technology; (6) sustainability of the natural environment; (7) reconfiguration of cultural dynamics; and (8) development of organizational strategies for global competition.

Many authors specialize in exploring each issue with much greater depth. The purpose of reviewing the different trends in this essay is to provide some highlights concerning the interrelated complexities underlying globalization.

Location of integration activities. The extent of globalization unfolds in an uneven fashion to the degree that the question is raised whether international trade is more focused on regional rather than global integration. Trading blocs, such as the North American Free Trade Agreement (NAFTA), the European Union (EU), the Asia-Pacific Economic Co-operation (APEC), Mercosur (South American trading bloc), the Association of South East Asian Nations (ASEAN), The Dominican Republic-Central America Free Trade Agreement (DR-CAFTA), and the East Africa Community (EAC), support regional cooperation between geographical neighbors. According to global economists' forecasts, most of these agreements will eventually work in unison as parts of a larger, more global agreement.

Georgios Chortareas's and Theodore Pelagidis's 2004 research findings on openness and convergence in international trade indicate that intraregional trade increased more than global trade in most situations. They stated that "...despite the positive international climate resulting from important reductions in transportation costs, the development of new technologies and trade liberalization markets continue to be determined, to a large extent, regionally and nationally..."

Within NAFTA, intraregional exports rose from 34 percent in the 1980s to more than 56 percent in 2000; exports between Asian country members amounted to 48 percent in 2000; and exports within the EU were sustained at about 62 percent. By 2005, exports from the United States to Mexico had quadrupled, and exports from the United States to Canada doubled. The trend of rapid exports growth continued into 2008.

An example of limitations to fair market access for developing countries is that developed countries subsidize agricultural producers with about $330 billion per year, which creates a significant disadvantage for poorer economies without such subsidies. The impact is exacerbated because 70 percent of the world's poorest population lives in rural communities and depends heavily on agriculture as a staple of survival and economy. Hence, one of the concerns with uneven distribution of globalization is its impact on poorer economies by perpetuating systems of inequality. Opponents of free-trade agreements suggest that in many cases, especially the case of DR-CAFTA, trade agreements can further hinder the progress of the

poor and keep the wealthiest class well moneyed, perpetuating a centuries-old cycle of impoverishment for many.

Impact on poorer societies. A challenge to globalization is that inequality arises from imbalances in trade liberalization, where the rich gain disproportionately more than the poor. Ajit K. Ghose examined the impact of international trade on income inequality and found that intercountry inequality increased from 1981 to 1997, in a sample of 96 national economies, but international inequality measured by per capita GDP declined. The ratio of average income for the wealthiest 20 percent compared to the poorest 20 percent rose from 30 to 74 from the early 1960s to the late 1990s. According to a GDP listing of nations released by the *CIA World Factbook* from 2008, the per capita difference between the top 10 percent of countries and the remaining 90 percent shows an overall decline in international inequality, but a disparity remains nonetheless.

In 2004 one billion people owned 80 percent of the world's GDP, while another billion survived on one dollar. However, during the same period, when factoring average income that is weighted by population, income inequality dropped by 10 percent. Global income distribution became more equal with other measures such as purchasing power parity or the number of people living in poverty.

The World Development Indicators for 2004 showed a drop in the absolute number of people living on one dollar per day from 1.5 billion in 1981 to 1.1 billion in 2001 with most of the achievements taking place in the East Asia region. Thus, the impact of globalization on inequality is a complex issue depending on the particular measures. More specific examination needs to account for other contributing factors, such as how regionalism increases concentration of trade between countries that are wealthier and leaving poorer countries at or below the margin.

Flow of capital. The flow of capital relates to both regionalism and inequality issues. Two forms of capital flow are foreign direct investments (FDI) made by business firms and investment portfolios, diversified with foreign assets or borrowers seeking foreign funding. Data from the World Bank indicated that FDI grew from an average of $100 billion per year in the 1980s to $370 billion in 1997. Net private capital flow amounts to about $200 billion in 2004. According to OCO Global, the FDI increased by another 5.1 percent in 2007, bringing the global total to $947 billion.

Also, some economies have significant remittance flows from labor migration, which were approximately $100 billion in 2003 and $126 billion in 2004 for 90

developing countries. Some Caribbean countries receive more than 10 percent of their GDP from remittances. While developing countries are the primary recipients of remittances, transaction costs can amount to 10 to 15 percent per transaction. Reducing such obstacles would benefit poorer countries with heavy dependencies on remittances. The flow of money across national borders relates to the migration of both labor and work.

Migration of labor and work. An important dimension of globalization is the migration of people. While the proportion of migration was greater during the earlier mercantilism period, sovereign border controls to a large extent create a filtration process for migration. About 175 million people lived in a different country than their birth country in 2000. They can be separated into three categories: 158 million international migrants, 16 million refugees, and 900,000 asylum seekers.

An important global trend in the future is the movement of labor from developing to developed countries because of the latter's need for labor with an aging population. Family-sponsored migration makes up 45 to 75 percent of international migrants who mainly originate from developing countries to countries in Europe and North America.

Even before 9/11, legal migration of labor needed to overcome substantial bureaucracy in the border control process. The number applying for entry into developed countries often far exceeds the number permitted. Due to extensive legal processes, some migrants enter illegally, while others become illegal with expiration of legal status.

Anti-terrorism measures imposed shortly after the 9/11 attacks resulted in a minor shift in the flow of migrants away from the United States toward other developed countries. With the aging of baby boomers in many developed countries, future globalization of migrant labor flow is receiving more attention, especially in education, health care, retirement funding, and housing.

Although migrant labor often entails the movement of people in search of work, a related globalization trend is the migration of work to different geographical locations. While multinational corporations (MNCs) often seek low-cost labor, innovation advances in computer technology, satellite communication infrastructures, Internet developments, and efficient transportation networks enable companies to distribute work in ways not possible before.

Compression of time and space with Internet technology allows for the distribution of work to take place around the world with global virtual teams. The phenomena of outsourcing and offshoring expand on the earlier sourcing of low-cost manufacturing. During the 1960s

and 1970s MNCs switched to low-wage labor to manufacture products that entailed significant labor costs.

Expansion of MNCs in the 1990s encompassed highly skilled workers, service work, and global virtual teams. Firms started to outsource information technology (IT) functions as early as the 1970s, but a major wave of outsourcing started in 1989 with the shortage of skilled IT workers in developed countries. At the same time, the trend of shifting work around the globe to leverage the different time zones began with the financial industry's ability to shift trading between the various stock exchanges in New York, Tokyo, Hong Kong, and London.

Technological innovations in computers and the Internet enabled other industries, such as software engineering, data transcription, and customer service centers to also shift work around the globe. Higher education and high-skill health care jobs are also embarking on global outsourcing.

In 2001 outsourcing expenditures amounted to $3.7 trillion and approximately $5.1 trillion in 2003. Global outsourcing of just IT services cost nearly $830 billion in 2008 alone. The impact of global outsourcing is not just a relocation of jobs, but also a dampening of employee compensation levels in more developed economies. For example, in 2000, salaries for senior software engineers were as high as $130K, but dropped to about $100K at the end of 2002; and entry-level computer help-desk staff salaries dropped from about $55K to $35K. For IT vendor firms in India, IT engineering jobs offer a salary considered outstanding in India, that is a fraction of the going U.S. rate. The migration of labor and work create complex globalization dynamics in management of people and finances for most firms.

Diffusion of technology. Innovations in telecommunication, information technology, and computing advances all support progression of globalization. In 1995 the World Wide Web had 20 million users, exploded to 400 million by late 2000, and had over 1.4 billion users in 2008. However, the rapid growth and adoption of information technology is not evenly diffused around the world.

The gap between high versus low adoption rates is often referred to as the digital divide. In 2004, over 30 percent of Americans and Europeans had Internet access, while the number for Africa was 1.8 percent. The digital divide reflects other disparities of globalization. Globalization of computer technology also entails a growing trend of computer crimes on an international basis, which requires cross-border collaboration to address. Additional globalization trends related to computer technology include developments in artificial intelligence, high-speed connections such as wireless applications, the

use of handheld and mobile devices to access the Internet and e-mail, and integration with biotechnology.

Sustainability of the natural environment. The impacts of globalization on environment sustainability are hotly contested, with major environmental protests held at international economic meetings or prominent multilateral trade forums. In the United Nations 1987 publication *Brundtland Report* (named for Gro Brundtland, Prime Minister of Norway), galvanized international attention on sustainable development was a major concentration. The assumption was that the degradation of the environment in developing countries was due primarily to poverty.

Some advocates of globalization consider free trade to be a solution to alleviate poverty and subsequently, reduce pollution. However, the arguments depend upon corporate social responsibility, managerial knowledge of environmental sustainability, and the level of ignorance in the developing community.

Critics find that often large MNCs have greater financial resources than some developing countries, which can be used to compromise and derail regulatory regimes from protecting the environment. For example, while an MNC may not produce or sell certain environmentally damaging products in a country with tight regulatory controls, they may find their way to markets with fewer environmental regulatory constraints—"pollution havens." This line of logic leads to the notion of globalization becoming a "race to the bottom" as countries compete with lowering of environmental standards to attract foreign capital for economic development.

One of the landmarks on environmental globalization is the Kyoto Accord, an international treaty to reduce greenhouse gas emissions based on exchanging limited pollution credits between countries. After lengthy, multilateral, and complex negotiations, the Kyoto Accord was concluded in December 1997, for ratification by national governments. On February 16, 2005, the date for the Kyoto Protocol to take effect, 141 nations ratified the agreement. Even though the United States is the world's largest polluter in volume and per capita output of greenhouse gases, the Bush administration refused to ratify the Kyoto Accord.

Reconfiguration of cultural dynamics. Culture is another area of complex controversies with globalization. Competing perspectives about how globalization affects cultures revolve around the debates of cultural homogenization versus cultural diversification. The optimistic view of cultural globalization is that cultural diversity focuses on freer cultural exchanges with broader choices and enrichment of learning from different traditions. People have greater

choices of globally produced goods, in addition to local offerings, without being bound by their geographic location. Alternatively, critics of cultural globalization present evidence demonstrating the depletion of cultural diversity through processes referred to as "Disneyfication" or "McDonaldization."

Cultural diversity and quality are diminished with mass produced goods being directed toward a common denominator. The criticisms are related to a sense of "Americanization" of the world, rather than globalization. The process involves a sense of far-reaching, anonymous cultural imperialism. Debates from each perspective are intense with substantial evidence that also reveals complex ties to social and political dynamics within and between national borders.

Cultural globalization continues into the foreseeable future with many more controversial dynamics related to three important issues: 1) the impact of extractive industries on the socio-economic, cultural exclusion and dislocation of indigenous peoples and their traditional knowledge; 2) international trading of cultural goods and knowledge; and 3) inflow of immigration impacts on national culture, which creates a tension between a sense of threat to the national culture and migrant demands for respect to their traditions in a multicultural society.

Development of organizational strategies for global competition. The multiple dynamics of globalization—regionalism, inequality, financial flow, migration of labor and work, technological innovations, environmental sustainability, and cultural dynamics—form a turbulent and complex environment for managing business operations. While seven trends were highlighted to provide a brief sketch of interrelated complexities and controversies globalization, it also surfaced other significant issues.

Global concerns revolve around terrorism, rapid transmission of pandemic diseases and viruses, the rise of China's and India's economies, an aging population in wealthier northern countries versus younger growing populations in the southern hemisphere, and advances in biotechnology. These issues are intricately embedded in the globalization processes.

COMPETING IN THE GLOBAL ECONOMY

Globalization entails both opportunities and threats for creating and sustaining competitive strategies. Emerging economies offer resources in terms of labor, as well as expanding market opportunities. However, geopolitical relationships and backlashes from perceptions of cultural imperialism, such as the tensions between the United States and the European Union during the Iraq war create challenges for business operations.

Global managers have a wide range of options to deal with globalization. Organizational strategies for international operations involve two related demands—the need for local orientation and the need for integration (as shown in Figure 2). Firms with low need for local orientation, but high need for integration require a global strategy that centralizes core operations with minor modifications for local adaptation. However, firms with a need for high local orientation, but low need for integration, require a multinational strategy that decentralizes significant operations to respond to local market conditions. Firms integrating a high need for both local orientation and organizational integration should strive for a transnational strategy.

In addition to selecting a strategy for global competition, managers also need to make decisions regarding the internationalization process. Two processes are important.

First, the development of innovations in a home market as products move along the product life cycle stages. Firms can take products entering into the plateau of a mature stage to new international markets. Often the flow moves from developed to developing countries.

Second, stages of internationalization with foreign entry modes that involve increasing resource commitment and risks. The stage approach to internationalization takes time because it involves licensing and exportation, which can be mired with national and international bureaucracy.

Kenichi Ohmae argued that the speed and complexities of globalization require firms to rethink their internationalization processes because incremental stage models are often too slow. Given the rate and quantity of knowledge within the global business community, firms are likely to face competition in their home markets, with comparable innovations before they are able to establish a foothold in the international marketplace.

The incremental stage models are too slow for competing in an increasingly integrated global economy. Ohmae suggested that firms form global strategic alliances with partners established in three major markets—North America, Europe, and Asia, particularly Japan. Development of global competitive intelligence and innovation among partners provides for rapid market development and the establishment of strategic positions in multiple locations.

Basically, globalization into the twenty-first century creates a fundamentally different competitive environment that shifted from incremental internationalization processes to almost simultaneous deployment of innovations. This internationalization process also shifts the work of global managers from managing a field of expatriates to collaborating with strategic partners across national borders, managing global offshore outsourcing vendors in multiple geographical locations and working remotely with telecommuting staff in regions of import and export.

Figure 2
Skill Profile of the Effective Global Manager

- The ability to envision and implement the strategy of thinking globally while acting locally
- Being able to manage change and transition
- Being able to manage cultural diversity
- The ability to design and function in flexible organizational structures
- Being able to deal with stress and ambiguity
- Having the skills required to work with others-especially in team setting
- Being able to communicate well, and having a command of more than one language
- Having the ability to learn and transfer knowledge in a organization
- Entering into trusting alliances and operating with personal integrity and honesty
- Being able to turn ideas into action
- Having a stateless perception of the world
- Being willing to take risks and to experiment

Globalization is the culmination of complex and controversial trends that include a degree of geographical integration, inequalities, financial flows, labor and laborers, technological innovations, environmental sustainability, cultural dynamics, and organizational strategies for global competition. Given a historical perspective, globalization has fluctuated over time and many indicators support a trend of increasing globalization since the 1980s.

The United States is no longer the dominant superpower in the global economy; the rise of both China and India are the most important developments in globalization of the economy since the onset of the twenty-first century. Asia is proving to be a powerful competitor and excellent partner in commerce as economic trends move toward a universal system. The United States and China should not be considered foes—their mutual respect is a major consideration for international business in the future. Global managers have options for strategies and structures, as well as different internationalization processes. In summary, globalization creates a competitive arena as well as a platform for unlikely partnerships where MNCs evolve into global networks, the business model of the modern world.

GOALS AND GOAL SETTING

Goals and objectives provide organizations with a blueprint that determines a course of action and aids them in preparing for future changes. A goal can be defined as a future state that an organization or individual strives to achieve. For each goal that an organization sets, it also sets objectives. An objective is a short-term target with measurable results. Without clearly-defined goals and objectives, organizations will have trouble coordinating activities and forecasting future events.

According to Barney and Griffin, organizational goals serve four basic functions; they provide guidance and direction, facilitate planning, motivate and inspire employees, and help organizations evaluate and control performance. Organizational goals inform employees where the organization is going and how it plans to get there. When employees need to make difficult decisions, they can refer to the organization's goals for guidance. Goals promote planning to determine how goals will be achieved. Employees often set goals in order to satisfy a need; thus, goals can be motivational and increase performance. Evaluation and control allows an organization to compare its actual performance to its goals and then make any necessary adjustments.

According to Locke and Latham, goals affect individual performance through four mechanisms. First, goals direct action and effort toward goal-related activities and away from unrelated activities. Second, goals energize employees. Challenging goals lead to higher employee effort than easy goals. Third, goals affect persistence. Employees exert more effort to achieve high goals. Fourth, goals motivate employees to use their existing knowledge to attain a goal or to acquire the knowledge needed to do so.

The elements of goal-setting theory are shown in Figure 1. The goal-setting model indicates that individuals have needs and values that influence what they desire.

A need is defined as a lack of something desirable or useful. According to Maslow's hierarchy of needs, all individuals possess the same basic needs. Individuals do, however, differ in their values. Values are defined as a group of attitudes about a concept that contains a moral quality of like or dislike and acceptable or unacceptable. Values determine whether a particular outcome is rewarding. Employees compare current conditions to desired conditions in order to determine if they are satisfied and fulfilled. If an employee finds that he or she is not satisfied with the current situation, goal setting becomes a way of achieving what he or she wants.

Research suggests that individual differences play a role in determining goal effectiveness. Individuals may differ in their goal orientations, priorities, and self-regulation ability. Research suggests that an individual's goal orientation may influence goal effectiveness. Employees with a learning orientation desire to acquire knowledge and skills, whereas employees with a performance goal orientation focus on the outcome rather than the achievement process. While employees with a learning goal orientation view goals as a challenge, employees with a performance goal orientation may view goals as a threat. Studies provide some support that assigned goals are more effective for individuals with a learning goal orientation. Personal and organizational goals are not always congruent. For example, as the number of two-income families increases, work-family conflicts increase. Employees now have to balance professional and personal goals. An employee's desire to achieve personal goals may affect his or her motivation to achieve organizational goals.

When organizational and personal goals are not aligned, it may have a detrimental effect on performance. Self-regulation is also important in goal setting and goal achievement. Research has shown that employees improved self-regulation when they were trained in self-management. Self-regulation training can provide employees with an opportunity to set specific high goals, to monitor ways

Figure 1

Personal Values	Present Conditions	Goal Setting Process	Goal Setting Attributes	Behavior
Desired Conditions	Assessment of Current Conditions	1. Participative goals 2. Assigned goals 3. Do-your-best goals	1. Specificity 2. Difficulty 3. Acceptance 4. Committment	1. Perfomance 2. Satisfaction

the environment may hinder goal attainment, and to identify and administer rewards for making goal progress, as well as assign punishments for failing to make progress.

GOAL-SETTING ATTRIBUTES

Goal-setting attributes have been the subject of extensive research. The four attributes are; specificity, difficulty, acceptance, and commitment. Studies show that there is a direct relationship between goal specificity and employee performance. The more specific the goal, the less ambiguity involved and the higher the performance. When employees are given do-your-best goals, they do not have an external reference by which they can measure their own performance. For example, telling a salesperson to "do the best you can" is an extremely vague goal that may not increase performance. However, "increase sales by 10 percent" is much more specific and encourages high performance because the employee has past sales as a reference point.

Goal difficulty also has a direct relationship with performance. Research shows that more difficult goals lead to higher performance, as long as the goals do not become so difficult that employees perceive them as impossible. Unreasonable goals frustrate, rather than motivate, employees. On the other hand, difficult but realistic goals lead to increased performance and motivation. Research suggests that employees are highly motivated when the probability of achieving a specific goal is 50 percent.

Goal acceptance is the degree to which employees accept a goal. Employees need to feel that the goal is fair and consistent in order to make it their own. Even if a goal is specific and attainable, individual acceptance is still necessary for effectiveness. Employees may reject goals for a multitude of reasons: they feel the work is meaningless, they do not trust the organization, or they do not receive feedback regarding their performance.

Finally, employees must be committed to the goal for it to be achieved. Commitment refers to the degree to which employees are dedicated to reaching the goal, and is determined by both situational and personal variables. Commitment to a goal can be increased by developing goals that appeal to employees' values and needs. Employees must be convinced that the goal is important. It should be relevant and significant to some personal value. For example, goals that are tied to company success, and therefore job security, often appeal to employees' need for security. It is also important that a leader or manager who is respected and credible convey the goal to employees. Goals must be attainable for employees to be committed. While goals may be challenging, employees should be convinced that goals are within reach. Research shows

that commitment to goals increases when employees have the opportunity to participate in goal setting. Additionally, developing strategies is useful in helping employees achieve goals. Organizations that provide continuous training for employees build confidence and increase commitment to organizational goals.

TYPES OF GOALS AND OBJECTIVES

Goals should be closely tied to an organization's mission and vision statement. The strategic goals, tactical goals and objectives, and operational goals and objectives support the mission statement of the organization.

Strategic Goals. Strategic goals are set at the top of an organization and directly support the mission statement. Strategic goals are related to the entire organization instead of any one department. There are eight types of strategic goals found in organizations. The first type of strategic goal affects market standing, for example "to control 45 percent of the market share in the United States by the year 2014." Strategic goals regarding market standing help position a company as a market leader in any given industry. An example of the second strategic goal, innovation, is "to develop three new applications for use in businesses in the United States over the next three years." Productivity, the third type of strategic goal, involves reductions in manufacturing costs or increases in output. The fourth type of strategic goal is the efficient use of physical assets and financial resources, such as human resources. The fifth type of strategic goal involves the organization's profits and is usually defined in terms of return on assets or market value of stocks. Management development and performance is the sixth type of strategic goal, which concerns the conduct of managers as well as their continuing development. An example of this type of strategic goal is "to increase the number of hours offered in management training courses by 15 percent over the next year." The seventh type of strategic goal addresses the conduct of employees, as well as the concern for their attitudes and performance. An example of this type of strategic goal is "to reduce turnover by 12 percent over the next two years." Finally, the eighth type of strategic goal is concerned with the public and social responsibility of the organization. These types of goals might be concerned with reducing pollution or contributing to different charities.

Tactical Goals. Tactical goals and objectives are directly related to the strategic goals of the organization. They indicate the levels of achievement necessary in the departments and divisions of the organization. Tactical goals and objectives must support the strategic goals of the organization. For example, if a strategic goal states that the organization is going to reduce total costs by 15

percent next year, then the different departments of the company would set tactical objectives to decrease their costs by a certain percentage so that the average of all departments equals 15 percent.

Operational Goals. Operational goals and objectives are determined at the lowest level of the organization and apply to specific employees or subdivisions in the organization. They focus on the individual responsibilities of employees. For example, if the department's tactical goal is related to an increase in return on assets by 5 percent, then the sales manager may have an operational objective of increasing sales by 10 percent.

Super-ordinate Goals. Super-ordinate goals are those goals that are important to more than one party. They are often used to resolve conflict between groups. Through cooperating to achieve the goal, the tension and animosity between groups is often resolved. Feelings of camaraderie are created along with trust and friendship. Super-ordinate goals can be powerful motivators for groups to resolve their differences and cooperate with one another. In order for them to be successful, the parties must first perceive that there is mutual dependency on one another. The super-ordinate goal must be desired by everyone. Finally, all parties involved must expect to receive rewards from the accomplishment of the goal.

GOAL-SETTING APPROACHES

When choosing goals and objectives, there are several approaches an organization can take. Three common approaches are the top-down approach, the bottom-up approach, and the interactive approach. In the top-down approach, goal setting begins at the top of the organization. Management by objectives (MBO) is a commonly-used top-down approach. This approach focuses on coordinating goal setting, incentives, and feedback. Studies suggest that approximately 50 percent of large organizations currently use or have used MBO. First, upper level managers (such as the CEO and other executives) establish the organizational mission and then determine strategic goals. The strategic goals determine the tactical goals and objectives as they are passed down to the next level of management.

The tactical goals in each department dictate the operational goals and objectives to individual employees. On the lowest level, the supervisor and employee agree upon performance objectives, as well as how goal attainment will be measured. This gives the supervisor a chance to address employee concerns or potential obstacles to goal achievement. When the next evaluation occurs, the supervisor and subordinate meet to assess to what extent performance objectives have been met. The top-down

approach has several advantages. It helps guarantee that the goals and objectives of the organization are directly tied to and support the mission statement. It increases the likelihood that ambitious goals set by upper-level managers will trickle down to lower levels of the organization; thus, ambitious goals will be set for everyone in the organization. However, the top-down approach has several disadvantages. Oftentimes, members of upper-level management are so far removed from the day-to-day activities of the employees that the goals may be overly ambitious and unrealistic. Goals set at the top of the organization do not change as quickly with the organization, so they are not as flexible as goals set at the bottom of the organization. Finally, the top-down approach does not always involve employee participation in the goal-setting process. Thus, employees may not have a sense of ownership.

The bottom-up approach begins at the lower levels of the organization. Individuals at the bottom of the organization's chart set the goals and objectives for members directly above. Operational goals and objectives determine the tactical objectives, which in turn determine the strategic goals and objectives. Finally, the organizational mission is defined according to the guidelines set by the employees. Goals determined by bottom-up goal setting are likely to be more realistic than those set at the top of the organization. They are more flexible and reflect the current situation of the organization. Finally, goals created by all levels of the organization, and by all types of employees, are more likely to encourage employee commitment. There are disadvantages to bottom-up goal setting. Goals and objectives formulated by bottom-up goal setting are not always in line with the organization's mission. Often, organizations that use a bottom-up approach lack clear direction and focus. There is no hierarchical alignment with the goals of the organization. Another disadvantage of this type of goal setting is that the goals created by employees are not always challenging and ambitious. Studies have shown that challenging (yet realistic) goals are more motivational than those that are not.

The third approach to goal setting is interactive. It is a process by which employees at different levels of the organization participate in developing goals and objectives. Top levels of the organization begin by developing a mission statement. Managers at different levels and departments of the organization then come together and determine the strategic goals. Next, discussions regarding the tactical goals and objectives are decided upon by including lower-level managers and supervisors. Finally, individuals contribute to the process by defining their own operational goals and objectives.

This approach to goal setting involves the consensus of many different levels of management and frontline employees. Interactive goal setting involves discussion

and cooperation among management and employees. The interactive approach enjoys the same advantages as bottom-up goal setting without many of the disadvantages. Goals are more realistic and current than in the top-down approach. Because it involves cooperation at all levels, employees feel valued and important. Their commitment to the organization, as well as the goals, is increased. Input from upper management helps to ensure that the goals are challenging and ambitious, which increases motivation. There are, however, a few disadvantages to the interactive approach. It is very time-consuming because of the cooperation and consensus involved. It is also difficult to manage and maintain. If managers do not stay actively involved, it can quickly turn into a top-down or bottom-up approach with the disadvantages of each.

FEEDBACK AND EVALUATION

Employees should be provided with specific performance-related feedback to help them determine if they are achieving their goals. Frequent feedback is beneficial because it allows employees to adjust their level of effort to achieve their goals. Feedback from management should consistently be provided. However, feedback can also come from coworkers or customers. It may be in the form of tallies, charts, or graphs that depict performance over time. Feedback not only allows employees to assess their accomplishments, but it also provides them with the continued motivation to achieve their goals.

Not only should the employees be evaluated, but goals should be evaluated periodically. Because organizations face many changes, goals need to be flexible enough so that organizations can respond to dynamic environments. Goals that were set at the beginning of the year may not be realistic at the end of the year. When organizations set goals that are unattainable or unrealistic in the long or short run, employees become unmotivated. When evaluating the appropriateness of a goal, managers should determine whether or not the goal covers the most important aspects of performance. Are the goals realistic yet ambitious enough to motivate employees? Objectives should be measurable and specific. Objectives that are not measurable are often not directly tied to the organization's overall mission. They should be linked to rewards that are valued by employees and associated with specific time periods.

Goal setting is a commonly used motivational approach. Numerous studies have shown that goal setting is related to profit and performance. In one study, goal setting led to improved productivity in 95 percent of the organizations. It also led to a 16 percent increase in worker productivity. Additionally, 61 percent of organizations surveyed used goal-setting theory specifically to increase performance. Organizations that set goals experienced higher levels of annual profit than those that did not.

Dissent to this opinion comes from a study conducted internally within Deutsche Telekom, an organization of more than 50,000 employees. As noted in 2008, the study found that goal setting was expensive and placed a huge drain on resources, thus decreasing productivity. The research identified large groups of employees within the organization who were not part of the goal-setting process. Dr. Christian Stein, the researcher in the study, lists several other flaws with the goal-setting approach. These include lack of proof of its positive cost-benefit ratio and the difficulty in setting goals that are mutual for employee and company. Stein also points to the extreme difficulty in coming up with a system that works for everyone without including a prohibitively large number of goals and subgoals. Stein concludes that in a time of high cost-pressure, abandoning goal-setting systems would do little harm and would, in fact, free up resources for processes that can be better controlled and managed.

As this study highlights, while goal setting may be advantageous to organizations, as well as employees, it is not an easy process to undertake. Managers sometimes underestimate the difficulty involved in setting goals. They are attracted to the benefits without understanding the limitations. Often beneficial are training courses on how to set goals, as well as a continuous follow-up process that involves all areas of the organization. Follow-up and refresher courses are often necessary to keep employees and managers focused on the goal-setting process. By offering courses that involve both managers and frontline employees, organizations are able to increase the level of consensus when it comes time to define goals.

GROUP DECISION MAKING

Group decision making is a type of participatory process in which multiple individuals—acting collectively—analyze problems or situations, consider and evaluate alternative courses of action, and select from among the alternatives a solution or solutions. The number of people involved in group decision making varies greatly, but often ranges from two to seven. The individuals in a group may be demographically similar or quite diverse. Decision-making groups may be relatively informal in nature, or formally designated and charged with a specific goal. The process used to arrive at decisions may be unstructured or structured. The nature and composition of groups, their size, demographic makeup, structure, and purpose, all affect their functioning to some degree. The external contingencies faced by groups (time pressure and conflicting goals) impact the development and effectiveness of decision-making groups as well.

In organizations, many decisions of consequence are made after some form of group decision-making process is undertaken. However, groups are not the only form of collective work arrangement. Group decision making should be distinguished from the concepts of teams, teamwork, and self managed teams. Although the words "teams" and "groups" are often used interchangeably, scholars increasingly differentiate between the two. The basis for the distinction seems to be that teams act more collectively and achieve greater synergy of effort. Katzenback and Smith spell out specific differences between decision-making groups and teams:

- The group has a definite leader, but the team has shared leadership roles.

- Members of a group have individual accountability; the team has both individual and collective accountability.

- The group measures effectiveness indirectly, but the team measures performance directly through their collective work product.

- The group discusses, decides, and delegates, but the team discusses, decides, and does real work.

GROUP DECISION-MAKING METHODS

There are many methods or procedures that can be used by groups. Each is designed to improve the decision-making process in some way. Some of the more common group decision-making methods are brainstorming, dialetical inquiry, nominal group technique, and the delphi technique.

Brainstorming. Brainstorming involves group members verbally suggesting ideas or alternative courses of action. The "brainstorming session" is usually relatively unstructured. The situation at hand is described in as much detail as necessary so that group members have a complete understanding of the issue or problem. The group leader or facilitator then solicits ideas from all members of the group. Usually, the group leader or facilitator will record the ideas presented on a flip chart or marker board. The "generation of alternatives" stage is clearly differentiated from the "alternative evaluation" stage, as group members are not allowed to evaluate suggestions until all ideas have been presented. Once the ideas of the group members have been exhausted, the group members then begin the process of evaluating the utility of the different suggestions presented. Brainstorming is a useful means by which to generate alternatives, but does not offer much in the way of a process for the evaluation of alternatives or the selection of a proposed course of action.

One of the difficulties with brainstorming is that despite the prohibition against judging ideas until all group members have had their say, some individuals are hesitant to propose ideas because they fear the judgment or ridicule of other group members. Some online tools attempt to change this equation. For example, VERN, a tool developed by researchers at UC Berkeley, allows users to make decisions using a visual interface so that all members of the group can contribute equally. Other tools, such as ThinkTank, provide anonymity in polling; this allows for more creativity with less fear of judgment.

Dialetical Inquiry. Dialetical inquiry is a group decision-making technique that focuses on ensuring full consideration of alternatives. Essentially, it involves dividing the group into opposing sides, which debate the advantages and disadvantages of proposed solutions or decisions. A similar group decision-making method, devil's advocacy, requires that one member of the group highlight the potential problems with a proposed decision. Both of these techniques are designed to try and make sure that the group considers all possible ramifications of its decision.

Nominal Group Technique. The nominal group technique is a structured decision-making process in which

group members are required to compose a comprehensive list of their ideas or proposed alternatives in writing. The group members usually record their ideas privately. Once finished, each group member is asked, in turn, to provide one item from their list until all ideas or alternatives have been publicly recorded on a flip chart or marker board. Usually, at this stage of the process verbal exchanges are limited to requests for clarification—no evaluation or criticism of listed ideas is permitted. Once all proposals are listed publicly, the group engages in a discussion of the listed alternatives, which ends in some form of ranking or rating in order of preference. As with brainstorming, the prohibition against criticizing proposals as they are presented is designed to overcome individuals' reluctance to share their ideas. Empirical research conducted on group decision making offers some evidence that the nominal group technique succeeds in generating a greater number of decision alternatives that are of relatively high quality.

Delphi Technique. The Delphi technique is a group decision-making process that can be used by decision-making groups when the individual members are in different physical locations. The technique was developed at the RAND Corporation. The individuals in the Delphi "group" are usually selected because of the specific knowledge or expertise of the problem they possess. In the Delphi technique, each group member is asked to independently provide ideas, input, and/or alternative solutions to the decision problem in successive stages. These inputs may be provided in a variety of ways, such as e-mail, fax, or online in a discussion room or electronic bulletin board. After each stage in the process, other group members ask questions and alternatives are ranked or rated in some fashion. After an indefinite number of rounds, the group eventually arrives at a consensus decision on the best course of action.

ADVANTAGES AND DISADVANTAGES OF GROUP DECISION MAKING

The effectiveness of decision-making groups can be affected by a variety of factors. Thus, it is not possible to suggest that "group decision making is always better" or "group decision making is always worse" than individual decision making. For example, due to the increased demographic diversity in the workforce, a considerable amount of research has focused on diversity's effect on the effectiveness of group functioning. In general, this research suggests that demographic diversity can sometimes have positive or negative effects, depending on the specific situation. A demographically diverse group may have to overcome social barriers and difficulties in the early stages of group formation and this may slow down

the group. However, some research indicates that diverse groups, if effectively managed, tend to generate a wider variety and higher quality of decision alternatives than demographically homogeneous groups.

Despite the fact that there are many situational factors that affect the functioning of groups, research through the years does offer some general guidance about the relative strengths and weaknesses inherent in group decision making. The following section summarizes the major pros and cons of decision making in groups.

Advantages. Group decision making, ideally, takes advantage of the diverse strengths and expertise of its members. By tapping the unique qualities of group members, it is possible that the group can generate a greater number of alternatives that are of higher quality than the individual. If a greater number of higher quality alternatives are generated, then it is likely that the group will eventually reach a superior problem solution than the individual.

Group decision making may also lead to a greater collective understanding of the eventual course of action chosen, since it is possible that many affected by the decision implementation actually had input into the decision. This may promote a sense of "ownership" of the decision, which is likely to contribute to a greater acceptance of the course of action selected and greater commitment on the part of the affected individuals to make the course of action successful.

Disadvantages. There are many potential disadvantages to group decision making. Groups are generally slower to arrive at decisions than individuals, so sometimes it is difficult to utilize them in situations where decisions must be made very quickly. One of the most often cited problems is groupthink. Irving Janis, in his 1972 book *Victims of Groupthink*, defined the phenomenon as the "deterioration of mental efficiency, reality testing, and moral judgment resulting from in-group pressure." Groupthink occurs when individuals in a group feel pressure to conform to what seems to be the dominant view in the group. Dissenting views of the majority opinion are suppressed and alternative courses of action are not fully explored.

Research suggests that certain characteristics of groups contribute to groupthink. In the first place, if the group does not have an agreed upon process for developing and evaluating alternatives, it is possible that an incomplete set of alternatives will be considered and that different courses of action will not be fully explored. Many of the formal decision-making processes (e.g., nominal group technique and brainstorming) are designed, in part, to reduce the potential for groupthink by ensuring that group members offer and consider a large number of decision alternatives.

Secondly, if a powerful leader dominates the group, other group members may quickly conform to the dominant view. Additionally, if the group is under stress and/or time pressure, groupthink may occur. Finally, studies suggest that highly cohesive groups are more susceptible to groupthink.

Group polarization is another potential disadvantage of group decision making. This is the tendency of the group to converge on more extreme solutions to a problem. The "risky shift" phenomenon is an example of polarization; it occurs when the group decision is a riskier one than any of the group members would have made individually. This may result because individuals in a group sometimes do not feel as much responsibility and accountability for the actions of the group as they would if they were making the decision alone.

Decision making in groups is a fact of organizational life for many individuals. Because so many individuals spend at least some of their work time in decision-making groups, groups are the subjects of hundreds of research studies each year. Despite this, there is still much to learn about the development and functioning of groups. Research is likely to continue to focus on identifying processes and tools that will make group decision making more efficient and effective. It is also likely to examine how the internal characteristics of groups (demographic and cognitive diversity) and the external contingencies faced by groups affect their functioning.

GROUP DYNAMICS

A group can be defined as several individuals who come together to accomplish a particular task or goal. Group dynamics refers to the attitudinal and behavioral characteristics of a group. Group dynamics concern how groups form, their structure and process, and how they function. Group dynamics are relevant in both formal and informal groups of all types. In an organizational setting, groups are a very common organizational entity and the study of groups and group dynamics is an important area of study in organizational behavior.

The following sections provide information related to group dynamics. Specifically, the formation and development of groups is first considered. Then some major types or classifications of groups are discussed. Then the structure of groups is examined.

GROUP DEVELOPMENT

As applied to group development, group dynamics is concerned with why and how groups develop. There are several theories as to why groups develop. A classic theory, developed by George Homans, suggests that groups develop based on activities, interactions, and sentiments. Basically, the theory means that when individuals share common activities, they will have more interaction and will develop attitudes (positive or negative) toward each other. The major element in this theory is the interaction of the individuals involved.

Social exchange theory offers an alternative explanation for group development. According to this theory, individuals form relationships based on the implicit expectation of mutually beneficial exchanges based on trust and felt obligation. Thus, a perception that exchange relationships will be positive is essential if individuals are to be attracted to and affiliate with a group.

Social identity theory offers another explanation for group formation. Simply put, this theory suggests that individuals get a sense of identity and self-esteem based upon their membership in salient groups. The nature of the group may be demographically based, culturally based, or organizationally based. Individuals are motivated to belong to and contribute to identity groups because of

the sense of belongingness and self-worth membership in the group imparts.

Group dynamics as related to development concerns not only why groups form but also how. The most common framework for examining the "how" of group formation was developed by Bruce Tuckman in the 1960s. In essence, the steps of group formation imply that groups do not usually perform at maximum effectiveness when they are first established. They encounter several stages of development as they strive to become productive and effective. Most groups experience the same developmental stages with similar conflicts and resolutions.

According to Tuckman's theory, there are five stages of group development: forming, storming, norming, performing, and adjourning. During these stages group members must address several issues and the way in which these issues are resolved determines whether the group will succeed in accomplishing its tasks.

1. **Forming.** This stage is usually characterized by some confusion and uncertainty. The major goals of the group have not been established. The nature of the task or leadership of the group has not been determined (Luthans, 2005). Thus, forming is an orientation period when members get to know one another and share expectations about the group. Members learn the purpose of the group as well as the rules to be followed. The forming stage should not be rushed because trust and openness must be developed. These feelings strengthen in later stages of development. Individuals are often confused during this stage because roles are not clear and there may not be a strong leader.

2. **Storming.** In this stage, the group is likely to see the highest level of disagreement and conflict. Members often challenge group goals and struggle for power. Individuals often vie for the leadership position during this stage of development. This can be a positive experience for all groups if members can achieve cohesiveness through resolution. Members often voice concern and criticism in this phase. If members are not able to resolve the conflict, then the group will often disband or continue in existence but will remain ineffective and never advance to the other stages.

3. **Norming.** This stage is characterized by the recognition of individual differences and shared expectations. Hopefully, at this stage the group members will begin to develop a feeling of group cohesion and identity. Cooperative effort should begin to yield results. Responsibilities are divided among members and the group decides how it will evaluate progress.

4. **Performing.** Performing, occurs when the group has matured and attains a feeling of cohesiveness. During this stage of development, individuals accept one another and conflict is resolved through group discussion. Members of the group make decisions through a rational process that is focused on relevant goals rather than emotional issues.

5. **Adjourning.** Not all groups experience this stage of development because it is characterized by the disbandment of the group. According to Luthans, some groups are relatively permanent. Reasons that groups disband vary, with common reasons being the accomplishment of the task or individuals deciding to go their own ways. Members of the group often experience feelings of closure and sadness as they prepare to leave.

GROUP TYPES

One common way to classify groups is by whether they are formal or informal in nature. Formal work groups are established by an organization to achieve organizational goals. Formal groups may take the form of command groups, task groups, and functional groups.

Command Groups. Command groups are specified by the organizational chart and often consist of a supervisor and the subordinates that report to that supervisor. An example of a command group is an academic department chairman and the faculty members in that department.

Task Groups. Task groups consist of people who work together to achieve a common task. Members are brought together to accomplish a narrow range of goals within a specified time period. Task groups are also commonly referred to as task forces. The organization appoints members and assigns the goals and tasks to be accomplished. Examples of assigned tasks are the development of a new product, the improvement of a production process, or the proposal of a motivational contest. Other common task groups are ad hoc committees, project groups, and standing committees. Ad hoc committees are temporary groups created to resolve a specific complaint or develop a process. Project groups are similar to ad hoc committees and normally disband after the group completes the assigned task. Standing committees are more permanent than ad hoc committees and project groups. They maintain longer life spans by rotating members into the group.

Functional Groups. A functional group is created by the organization to accomplish specific goals within an unspecified time frame. Functional groups remain in existence after achievement of current goals and objectives. Examples

of functional groups would be a marketing department, a customer service department, or an accounting department.

In contrast to formal groups, informal groups are formed naturally and in response to the common interests and shared values of individuals. They are created for purposes other than the accomplishment of organizational goals and do not have a specified time frame. Informal groups are not appointed by the organization and members can invite others to join from time to time. Informal groups can have a strong influence in organizations that can either be positive or negative. For example, employees who form an informal group can either discuss how to improve a production process or how to create shortcuts that jeopardize quality. Informal groups can take the form of interest groups, friendship groups, or reference groups.

Interest Groups. Interest groups usually continue over time and may last longer than general informal groups. Members of interest groups may not be part of the same organizational department but they are bound together by some other common interest. The goals and objectives of group interests are specific to each group and may not be related to organizational goals and objectives. An example of an interest group would be students who come together to form a study group for a specific class.

Friendship Groups. Friendship groups are formed by members who enjoy similar social activities, political beliefs, religious values, or other common bonds. Members enjoy each other's company and often meet after work to participate in these activities. For example, a group of employees who form a friendship group may have an exercise group, a softball team, or a potluck lunch once a month.

Reference Groups. A reference group is a type of group that people use to evaluate themselves. According to Cherrington, the main purposes of reference groups are social validation and social comparison. Social validation allows individuals to justify their attitudes and values while social comparison helps individuals evaluate their own actions by comparing themselves to others. Reference groups have a strong influence on members' behavior. By comparing themselves with other members, individuals are able to assess whether their behavior is acceptable and whether their attitudes and values are right or wrong. Reference groups are different from the previously discussed groups because they may not actually meet or form voluntarily. For example, the reference group for a new employee of an organization may be a group of employees that work in a different department or even a different organization. Family, friends, and religious affiliations are strong reference groups for most individuals.

GROUP STRUCTURE

Group structure is a pattern of relationships among members that hold the group together and help it achieve assigned goals. Structure can be described in a variety of ways. Among the more common considerations are group size, group roles, group norms, and group cohesiveness.

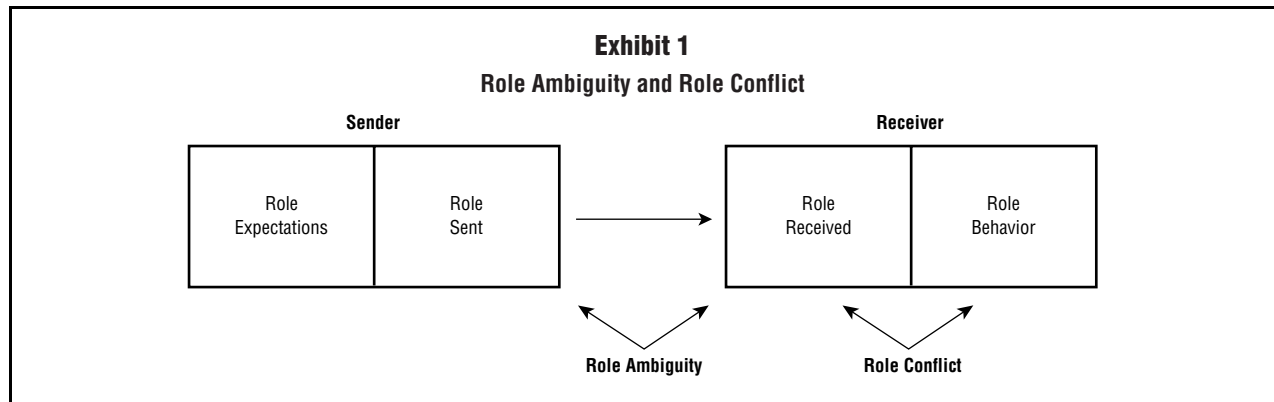
Group Size. Group size can vary from two people to a very large number of people. Small groups of two to ten are thought to be more effective because each member has ample opportunity to participate and become actively involved in the group. Large groups may waste time by deciding on processes and trying to decide who should participate next. Group size will affect not only participation but satisfaction as well. Evidence supports the notion that as the size of the group increases, satisfaction increases up to a certain point. In other words, a group of six members has twice as many opportunities for interaction and participation as a group of three people. If the size of the group increases beyond ten or twelve members, the result is decreased satisfaction. It is increasingly difficult for members of large groups to identify with one another and experience cohesion.

GROUP ROLES

In formal groups, roles are usually predetermined and assigned to members. Each role will have specific responsibilities and duties. There are, however, emergent roles that develop naturally to meet the needs of the groups. These emergent roles will often replace the assigned roles as individuals begin to express themselves and become more assertive. Group roles can then be classified into work roles, maintenance roles, and blocking roles.

Work roles are task-oriented activities that involve accomplishing the group's goals. They involve a variety of specific roles such as initiator, informer, clarifier, summarizer, and reality tester. The initiator defines problems, proposes action, and suggests procedures. The informer role involves finding facts and giving advice or opinions. Clarifiers will interpret ideas, define terms, and clarify issues for the group. Summarizers restate suggestions, offer decisions, and come to conclusions for the group. Finally, reality testers analyze ideas and test the ideas in real situations.

Maintenance roles are social-emotional activities that help members maintain their involvement in the group and raise their personal commitment to the group. The maintenance roles are harmonizer, gatekeeper, consensus tester, encourager, and compromiser. The harmonizer will reduce tension in the group, reconcile differences, and explore opportunities. Gatekeepers often keep communication channels open and make suggestions that encourage participation. The consensus tester will ask if the

Exhibit 1
Role Ambiguity and Role Conflict


group is nearing a decision and test possible conclusions. Encouragers are friendly, warm, and responsive to other group members. The last maintenance role is the compromiser. This role involves modifying decisions, offering compromises, and admitting errors.

Blocking roles are activities that disrupt the group. They may take the form of dominating discussions, verbally attacking other group members, and distracting the group with trivial information or unnecessary humor. Often times the blocking behavior may not be intended as negative. Sometimes a member may share a joke to break the tension, or may question a decision to force group members to rethink the issue. The blocking roles are aggressor, blocker, dominator, comedian, and avoidance behavior.

The aggressor criticizes members' values and makes jokes in a sarcastic or semi-concealed manner. Blockers will stubbornly resist the group's ideas, disagree with group members for personal reasons, and will have hidden agendas. The dominator role attempts to control conversations by patronizing others. They often interrupt others and assert authority in order to manipulate members. Comedians often abandon the group even though they may physically still be a part. They are attention-getters in ways that are not relevant to the accomplishment of the group's objectives. The last blocking role, avoidance behavior, involves pursuing goals not related to the group and changing the subject to avoid commitment to the group.

Role ambiguity concerns the discrepancy between the sent role and the received role, as shown in Exhibit 1. Supervisors, directors, or other group leaders often send (assign) roles to group members in formal groups. Group members receive roles by being ready and willing to undertake the tasks associated with that role. Ambiguity results when members are confused about the delegation of job responsibilities. This confusion may occur because the members do not have specific job descriptions or because the instructions regarding the task were not clear.

Group members who experience ambiguity often have feelings of frustration and dissatisfaction, which ultimately lead to turnover.

Role conflict occurs when there is inconsistency between the perceived role and role behavior. There are several different forms of role conflict. Interrole conflict occurs when there is conflict between the different roles that people have. For example, work roles and family roles often compete with one another and cause conflict. Intra-role conflict occurs when individuals must handle conflicting demands from different sources while performing the tasks associated with the same role.

Group Norms. Norms are acceptable standards of behavior within a group that are shared by the members of the group. Norms define the boundaries of acceptable and unacceptable behavior. They are typically created in order to facilitate group survival, make behavior more predictable, avoid embarrassing situations, and express the values of the group. Each group will establish its own set of norms that might determine anything from the appropriate dress to how many comments to make in a meeting. Groups exert pressure on members to force them to conform to the group's standards. The norms often reflect the level of commitment, motivation, and performance of the group.

Performance norms determine how quickly members should work and how much they should produce. They are created in an effort to determine levels of individual effort. They can be very frustrating to managers because they are not always in line with the organization's goals. Members of a group may have the skill and ability to perform at higher levels but they don't because of the group's performance norms. For example, workers may stop working a production machine at twenty minutes before quitting time to wash up, even though they produced fewer items that day than management intended.

Reward-allocation norms determine how rewards are bestowed upon group members. For example, the norm

of equality dictates equal treatment of all members. Every member shares equally so rewards are distributed equally to everyone. Equity norms suggest that rewards are distributed according to the member's contribution. In other words, members who contribute the most receive the largest share of the rewards. Members may contribute through effort, skill, or ability. Social responsibility norms reward on the basis of need. Members who have special needs therefore receive the largest share of the reward.

The majority of the group must agree that the norms are appropriate in order for the behavior to be accepted. There must also be a shared understanding that the group supports the norms. It should be noted, however, that members might violate group norms from time to time. If the majority of members do not adhere to the norms, then they will eventually change and will no longer serve as a standard for evaluating behavior. Group members who do not conform to the norms will be punished by being excluded, ignored, or asked to leave the group.

Group Cohesiveness. Cohesiveness refers to the bonding of group members and their desire to remain part of the group. Many factors influence the amount of group cohesiveness. Generally speaking, the more difficult it is to obtain group membership the more cohesive the group. Groups also tend to become cohesive when they are in intense competition with other groups or face a serious external threat to survival. Smaller groups and those who spend considerable time together also tend to be more cohesive.

Cohesiveness in work groups has many positive effects, including worker satisfaction, low turnover and absenteeism, and higher productivity. However, highly cohesive groups may be detrimental to organizational performance if their goals are misaligned with organizational goals. Highly cohesive groups may also be more vulnerable to groupthink. Groupthink occurs when members of a group exert pressure on each other to come to a consensus in decision-making. Groupthink results in careless judgments, unrealistic appraisals of alternative courses of action, and a lack of reality testing. It can lead to a number of decision-making issues such as the following:

1. Incomplete assessments of the problem

2. Incomplete information search

3. Bias in processing information

4. Inadequate development of alternatives

5. Failure to examine the risks of the preferred choice

Evidence suggests that groups typically outperform individuals when the tasks involved require a variety of skills, experience, and decision making. Groups are often more flexible and can quickly assemble, achieve goals, and disband or move on to another set of objectives. Some early twenty-first century research focuses on the traits that comprise a good team player in order to identify specific facets relevant to team performance. This in turn may help increase team effectiveness. Driskill, Goodwin, O'Shea, Salas, and Gavan have identified core teamwork dimensions underlying effective team performance. Further work in this area will provide guidance for managers in successful group formation.

Many organizations have found that groups have many motivational aspects as well. Group members are more likely to participate in decision-making and problem-solving activities leading to empowerment and increased productivity. Groups complete most of the work in an organization; thus, the effectiveness of the organization is limited by the effectiveness of its groups.

HANDHELD COMPUTERS

Handheld computers—also known as personal digital assistants (PDAs)—are small, portable devices that offer users many of the same features and capabilities as desktop computers at a fraction of the size. Although the terms "handheld computer" and "PDA" are often used interchangeably, handhelds tend to be larger and feature miniature keyboards, while PDAs tend to be smaller and rely on a touch screen and stylus for data entry.

Since their introduction in the late 1990s, handheld computers have become standard equipment for many professionals, providing them with tiny, versatile electronic alternatives to paper day planners. "Once the domain of early-adopting gadget lovers, handhelds now organize and update millions of mobile business professionals," reports Mike Brown at Handheldcomputerdepot.com. Users have found PDAs to be particularly helpful tools for organizing and maintaining personal data, such as address books, appointment calendars, project lists, and expense reports. Later incarnations of the technology have also offered users mobile access to electronic mail, news, and entertainment through connectivity to the Internet.

When shopping for a handheld computer, experts recommend that users start by identifying their needs. They should consider, for example, whether they require only personal information management (PIM) functions, or whether they also wish to take notes during meetings, download e-mail and other information from the Internet, and connect with other users through a company computer network. Considering such needs, as well as the available budget, will help users decide among the basic options in handheld computers, including size, display, memory, operating system, and power source.

The size of handheld computers ranges from credit card to small notebook computer, and the available features and power generally increase with greater size. The most popular size for the devices is palm size, which falls somewhere between a calculator and a paperback book. Most handheld computers utilize a liquid crystal display (LCD), which acts as both an input and an output device. Larger PDAs feature keyboards, and most others require users to enter information on a touch screen, either by tapping letters with a stylus or by writing letters on the screen, which the device interprets using handwriting-recognition software. In the future, many handheld units are expected to incorporate voice-recognition technology.

In a 1999 article for *Computerworld,* Matt Hamblen and Sharon Gaudin warned that many corporate information technology (IT) managers were unprepared to deal with the proliferation of handheld computers among employees. They found that some companies ignored the devices, while others simply banned them from connecting to corporate networks. Instead, Hamblen and Gaudin recommended that IT managers embrace the new technology, helping employees choose products and find ways to use them to increase productivity. They argued that businesses should take an active role in deciding which handheld platforms and software applications their networks will support. They cautioned that businesses should also be aware of the security threats posed by handheld devices and take steps to protect the corporate network by establishing software synchronization standards.

SECURITY

A chief concern for companies who have adopted the widespread use of handheld computer devices is the growing number of security threats affecting handheld technology. Many businesses cannot take the risk of sending, receiving, or searching for sensitive information when there is the danger of having that information stolen. PDA devices do not often include the same security technology that protects a company's intranet and desk computers. According to a 2008 survey by the Computing Technology Industry Association spanning four countries, about 71 percent of the companies used some sort of handheld device technology to conduct business, including accessing company data. However, only 39 percent of those companies provided security awareness training to their employees.

Symantec Business Solutions offers a helpful series of guidelines on what steps to take and what habits to form to avoid dangerous security breaches on business handheld devices:

- Create a security program that informs employees on how to use their handheld devices, including where they can use the devices, what areas are off-limits, what sort of company data is to be stored and accessed from the devices, how to create passwords, and what programs may or may not be downloaded.

- Use various security measures, especially file encryption and authentication. This can protect any company data that is lost or stolen, making it unreadable or locked for outside users. Current devices will usually offer some sort of encryption, but for sensitive material a company can hire an outside firm to give them an even more reliable encryption program.

- Take care when transmitting data to and from handheld devices, whether by beam or other methods. Viruses can be spread between handhelds in such transmissions, regardless of which is the sender and which is the receiver. Even when connecting the handheld devices to desktops, security precautions should be taken.

- Consistently update handheld devices through connections to a desktop computer. If data is synchronized with a desktop at regular intervals, then there is a better chance information will be saved. If the data has been copied, the handheld can be compromised without losing much information.

- Install and run antivirus software on all devices: handheld, laptop, and desktop.

- Always go through the proper channels when connecting to the business network.

- Consider using a bit-wiping package to help protect handhelds. Bit-wiping programs erase all data and application on computer devices, formatting the memory so that no information can be recalled. Such programs can be set to activate when a certain number of attempts to access the device have failed, such as failed passwords.

- Be very careful with downloads. Download only from Web sites and from other devices that can be trusted. Be wary when accepting free downloads, and always double-check download packages and instructions.

- Create strong passwords as the first line of defense for handheld devices. Many devices are hacked directly through the user interface, so having a good password is an effective deterrent.

SMARTPHONES

The past several years have seen the a steady decline in the number of PDAs bought and used by companies in the United States. The first quarter of 2006, for instance, dropped more than 22 percent from the previous year's first quarter. Although Palm still dominates the PDA market, more and more businesses are investing in other handheld devices, especially smartphones. Smartphones are high-tech cell phones with wireless capabilities, Internet connections, and often the same keypad capabilities that PDAs have.

Since smartphones can be used to manage e-mail, edit spreadsheets and notes, and search the Internet with the same interfaces that true handheld devices do, it is an easy step for companies to make between PDAs and the new technology that also allows them to receive calls. The devices are seen as more versatile because phone and text messages can be sent in areas that do not provide wireless technology, and e-mails can be used in areas that do not offer telephone service. The most common smartphone platforms used in business are the RIM Blackberry and Windows Mobile. The popular iPhone is not usually used for business purposes because of its unfamiliar interface and the security issues of the older models.

Companies looking to choose a smartphone for their business transactions should carefully consider which type of system is best for their purpose. CEOs may prefer a different sort of application than managers or the sales force. Depending on where the smartphones will be used, a more durable, long-lasting device or one with superior wireless capabilities should be considered. A particular platform should also be chosen: Windows Mobile works well with browsing and managing e-mail, while Blackberry platforms are useful for more general purposes.

PUSH TECHNOLOGY

Push technology refers to the ability of transferring data through a system automatically to a specific user, often to a handheld device. E-mail is usually "pushed" from a desktop to a smartphone or PDA in this fashion, and other programs can be set to respond in the same fashion, so that users receive updates instantaneously no matter what device they are using. Pushing is defined by its automatic nature.

HEALTH SAVINGS ACCOUNTS

A health savings account (HSA) is an investment vehicle from which individuals can withdraw funds to pay qualified medical expenses as defined by the Internal Revenue Code. Accumulated funds can be used to pay current medical expenses or can be saved for medical expenses incurred in the future. The account can be set up by an employee in conjunction with his or her employer, but may also be set up by individuals through participating insurance companies and banks. To participate, an individual must have a high-deductible health insurance plan as their only form of health insurance and must not be eligible for Medicare. According to the IRS, for 2009, a high-deductible health care plan is one with at least a $1,100 deductible for an individual or $2,200 for a family, and annual out-of pocket expenses (deductibles and co-payments but not premiums) of up to $5,800 for self-only coverage or $11,600 for family coverage. Participants contribute to the HSA and pay a premium for the high-deductible medical insurance, which is usually lower than the premium for conventional medical insurance. Also, an eligible individual cannot be a dependent of another taxpayer.

The Health Opportunity Patient Empowerment Act of 2006 specified that the maximum annual contribution is the indexed statutory amount for taxable years beginning after December 31, 2006, rather than the previous maximum contribution which was the lesser of the deductible of the accompanying high deductible health plan or the indexed statutory amount.

For 2009, the maximum annual HSA contribution for an eligible individual with self-only coverage is $3,000. For a family, the maximum annual HSA contribution is $5,950. Those who are 55 or older are permitted to make so-called "catch up contributions." In 2009 and all years going forward, the maximum catch-up amount is increased by statute to $1,000.

Eligible individuals on the first day of the last month of the taxable year are allowed the full annual contribution (plus catch-up contribution, if 55 or older by year's end), regardless of the number of months the individual participated.

The individual's contributions to the account are tax deductible and, if an employer contributes to the account on behalf of an employee, the contribution is not taxable to the employee and the employer's taxable income is reduced by the amount of the contribution. Money placed in the account may be invested in a variety of investment vehicles, including stocks, bonds, and mutual funds. Investment gains are non-taxable, as long as money withdrawn from the fund is used for qualified medical expenses. There are maximum annual contributions, which are adjusted for inflation annually.

PURPOSE

Most individuals in the United States who are not self-employed and who are not eligible for Medicare or

Medicaid obtain their health insurance through their employers. There are two major problems with the current system of employer-sponsored health care coverage. First, since the employer usually pays some or all of the insurance premiums and bears the brunt of health care cost increases, the true cost of coverage is hidden from individuals, who therefore have little incentive to manage their health care efficiently. Second, employer-sponsored insurance creates a link between employment and health care that may be broken when an employee loses his or her job. These facts, combined with the tremendous increase in health care costs in the United States since the 1980s, has led the government and employers to look for ways to deliver health care insurance more efficiently and effectively.

Health maintenance organizations (HMOs), adopted by many employers in the 1980s, addressed the cost problem by allowing employers to make arrangements with health care providers to deliver health care services to their employees on a fixed-fee basis. In return for price concessions, employers essentially restricted the choices of participating employees to participating providers. HMOs were successful in reducing health care cost inflation, but their lack of flexibility and perceived over-emphasis on cost containment led to widespread dissatisfaction. Less restrictive preferred provider organizations, which allowed employees more freedom of choice if they were willing to pay a higher portion of costs, became the dominant form of employer-sponsored plans in the 1990s. But PPOs appear to be less successful in restraining health care costs. Thus, the government and employers continue to search for alternatives.

Attention focused on attempting to decouple health insurance from employment and increasing consumer involvement in health care decisions. Such consumer-driven approaches place greater responsibility on individuals to choose and manage their health care. The goal of such approaches is to encourage individuals to be more careful consumers of health care. Flexible spending accounts and medical savings accounts are both consumer-driven approaches.

Health savings accounts overcome many of the difficulties with the earlier approaches to consumer-driven health care. For example, flexible spending accounts require the individual to use all contributed funds annually or lose the funds. Accumulated funds in HSAs carry over from year to year and can be held for life. Medical savings accounts are available only to the self-employed or those employed by small businesses. HSAs are available to anyone, regardless of employment status.

HUMAN RESOURCE INFORMATION SYSTEMS

Human Resource Information Systems (HRIS) have become one of the most important tools for many businesses. Even the small, twenty-person office needs to realize the benefits of using HRIS to be more efficient. Many firms do not realize how much time and money they are wasting on manual human resource management (HRM) tasks until they sit down and inventory their time. HRIS is advancing to become its own information technology (IT) field. It allows companies to cut costs and offer more information to employees in a faster and more efficient way. Especially in difficult economic times, it is critical for companies to become more efficient in every sector of their business; human resources (HR) is no exception.

In his 2008 book, *The New Human Capital Strategy*, Bradley Hall defines human resources management as watching over and growing human capital, one of the greatest aids businesses have in gaining competitive advantage. The modern human resource concept is based on four integrated parts: skills, structure, systems, and shared values. Skills are the abilities and knowledge that people bring to an organization. Structure refers to the communication channels within the human resource department, who manages and who is accountable. Systems are the tools used to make human resource decisions, the reviews and measures HR managers control. Shared values are the less tangible beliefs and cultural strengths an organization possesses. This four-part concept has been used since the 1960s and still functions as a basic understanding of human resources in the business world.

Although the basic components of the modern human resource system have stayed relatively unchanged since their inception, HR operations are still subject to flaws. According to a study cited by Hall, 75 percent of

studied companies attempt to bend prefabricated HR plans to their particular needs without considering a more integrated, top-down strategy. In many cases, lower-level managers were involved neither in creating the HR processes nor in implementing them. Others chose to focus more on assumed HR positions such as compensation director and staffing director, rather than overall business strategy. Few implemented third-party regular reports and accountability standards. There are, then, many opportunities available for companies to improve their existing HR systems.

ETHICS IN HUMAN RESOURCE MANAGEMENT

Ethical considerations are becoming increasingly important to HR departments in American industries. A tension often exists between a company's financial goals and strategies to improve profits, and ethical considerations with right-behavior concerns. Since human resources departments are often most focused on employees and employee behavior, it falls to them to define ethical behavior, communicate specialized ethical codes, and update or elaborate on existing right-behavior expectations. Human resource management systems are expected to communicate ethical values and so improve company performance.

In the absence of a fully separate ethics department, HR departments can struggle with this ethical burden. A 2008 study done by SHRM, the Society for Human Resource Management, showed that over 50 percent of employers did not make ethical considerations part of their employee evaluations. About half of employees did not think they had means to find ethical advice within their company, and even 19 percent of human resources professionals felt pressure to compromise their ethical standards, coming from multiple directions within their companies, though the HR department was the primary resource for ethical information in 80 percent of studied companies.

One of the ways the HR department can support ethics management for their company is through the maintenance of a code of ethics. Briefly, an ethical code for a business should help employees build trust with each other and their company, while clarifying any uncertain or gray areas that may exist in the company's ethical considerations. Instead of only supporting existing ethical standards, a proper code of ethics should seek to raise the standard and improve employee behavior. The code should show members of the company how to make judgment decisions and encourage such proper decision making, while at the same time providing enforcement protocols to prevent misconduct. When writing the code

of ethics, an HR department should be sure to do the following:

- Create clear objectives for the code and other ethical endeavors to accomplish within the organization.

- Bring all levels of the organization into the process of creating the code, gaining support throughout the company.

- Check on all the latest legislation, both national and state, that may affect the company's ethical processes, expectations, and requirements, so that the ethical code can be as current as possible.

- Use the clearest language possible, making the code accessible and simple to understand.

- Willingly answer realistic problems and address real-life scenarios so that employees will have clear answers to their questions.

- List several resources for employees to seek continuing ethical education, from other reports by the HR department to helpful Web sites that can provide guidance.

- Keep in mind that the code of ethics is meant to be used, making sure that it is communicated to all levels of the organization and readily available to any employee who may need aid making judgment calls.

A code of ethics is only one part of the entire ethical system in an organization. The HR department should also make use of several other ethical tools to ensure employees are practicing right-behaviors and fully understand their ethical requirements.

MERGING AND HR

Whenever there is merger activity, the HR department often has a large responsibility to make sure that employee transitions go smoothly. When companies merge, some of the most significant changes occur in number and treatment of employees. If human resources can successfully deal with these important issues, they can have enormous impact on the success of the transition.

First, the HR department should ascertain the precise number of companies and company subsidiaries involved in the merger. This will give a clear idea of how many employees will be involved in the transition. Some of these employees may work in different businesses or on different products than the HR department has previous experience in, requiring new protocols. Employees across all companies involved will have a variety of reactions to the merger, raising both ethical and temperamental issues for the HR department to solve. To prepare for these issues, HR should pinpoint the managers involved in the

company integration, and gain their assistance throughout the merging of the business lines.

In certain mergers there will be an excess of employees, requiring multiple layoffs. The HR department should ascertain how many excess positions there are and how they will communicate the layoff information to employees and managers alike. Legal issues should also be dealt with; a legal consult with someone who has experience in mergers can be an excellent asset. If employees will be terminated in the merger, it is also up to HR to find out how severance pay and extended benefits will be distributed. Will the company provide assistance for employees seeking new jobs? The HR department will be in charge of such out-placement assistance, and the protocols for who gets such assistance and what qualities (experience, position, etc.) extended benefits will be based on.

While layoff deadlines are being established and employee benefits managed, the HR department should also perform a careful internal audit. The companies merging will have differing employee handbooks offering two sets of employee instructions regarding training and expected behavior. Most will also have different instructions for managers and their treatment of personnel, including chains of communication and conflict resolution. The HR department should be sure to review these separate manuals and create one unifying handbook for the merged procedures. Other plans requiring combination by HR include compensation plans, employee benefits, and ethical standards.

EMPLOYEE SEPARATION AND TURNOVER

One of the most important functions of HRM is to oversee smooth and successful employee separations and turnover. There is always a certain amount of employee turnover at any company, with people voluntarily quitting their jobs for a host of different reasons. These employee separations differ from normal personnel losses resulting from acquisitions, in which employees are laid off and not replaced. For every separation, HR must use recruitment strategies to find a new employee and make sure that the company workforce does not suffer through less skilled workers or workers who are more likely to quit.

There are three types of external employee movement that concern HR departments. The first consists of pure growth, or acquisitions where the company only gains employees without having an excess to lay off, usually involving the annexation of a department or production line. The second type is pure reduction, or movement that only loses employees, such as a series of layoffs to cut costs. Third is all the possible combinations of the first two.

When HR needs to manage such employee separation (and the collective efforts to replace them with other talented workers), separation is divided into three different components, from which policies toward the change can be formed. The first component is quantity: how many employees are leaving the company? These leaving employees, once quantified, are sometimes separated further into categories based on company branches or position. The second component is the quality of employees leaving the organizations. This can refer to the positions they held, the particular talents they possessed (which may be hard to replace), and how they fit into the company's strategies. The third component consists of the costs to the company (costs involved in losing employees, recruiting new ones, and/or training those acquired during a merger).

Succession Planning. Succession planning is another vital part of the HR planning process. It refers to the way in which a company forms policies for replacing key members of its organization, shifting transfer of authority and responsibility carefully from a leaving member to a new member. Often, this means making sure that an arriving employee has the necessary training and experience to fulfill their functions.

RECORDKEEPING IN HR

Another major concern of the HR department are employee personnel records. These records are filed, maintained, and updated through HRM processes. A good HRM system will allow access to files both by the employee they belong to and the managers who require them. Among the informational data kept in employee files, HR should make sure the files include names, addresses, telephone numbers, marital status, dependents, and beneficiaries.

Most HRM strategies have policies established regarding treatment of personnel information. Companies usually collect information that is required only for legal reasons, or reasons necessary to that business. Employees are given chances to read and correct their files, and files are kept strictly by the company, with rules in place for viewing, maintenance, and outside transfer.

Certain pieces of legislation passed affect the storage and retrieval of personnel records. The Sarbanes-Oxley Act requires that every company has some confidential system in place for the communication of fraud-related activities and malfeasance. The Securities and Exchange Commission (SEC) has recently begun to penalize brokers who do not keep complete and detailed records of all their transactions, and the Health Insurance Portability and Accountability Act (HIPAA) requires that all

electronic records concerning patients be put into an easy-transfer format.

BACKGROUND CHECKS

HR departments also manage background checks for potential employees, an increasingly important job as the risk of hiring a misrepresenting employee rises. USA Fact, a provider of screening services for recruiting departments, recently conducted a survey of over 300,000 background checks, and found that among the potential employees, 5 percent had criminal histories, more than a third had motor vehicle violations, 18 percent had employment histories that could not be verified, and approximately 11 percent had been falsifying their education experience. By catching fraudulent records such as these, human resources departments can significantly reduce employee theft, turnover, and even workplace violence.

The sorts of background checks companies can perform include criminal background reviews, Social Security number verification, employment history and education verifications, professional license verification, credit history reviews, and motor vehicle record checks.

There are several guidelines that can be used when HR departments form policies on conducting background checks. First, all inquiries should be strictly related to the position HR is trying to fulfill. Second, all background checks should first be agreed upon by the employee—formal consent in writing is the best way. This gives employees a chance to rethink their applications, especially if they realize a background check would disqualify them for the position. Third, employers should be reasonable. If background checks become over-extensive, they could cost the company too much money and the organization could risk invasion of privacy charges.

HUMAN RESOURCE PLANNING

HR planning attempts to connect employees to the vision, needs, and strategic plans of the company, including management of all aspects of human resources. Essentially, good HR planning will ensure that the best possible employees (with the right talents, ambitions, and personalities) will find the best possible positions within the organization. HR planning can be done in both the short and long term, although long-term strategies are the most common for HR planning purposes.

When HR planning, the company should tie in all of its HR processes to the company's goal and objectives. If HR planning does not exist to further specific objectives of the country, it is not fulfilling its purpose. This can lead to very wide parameters in HR planning, which can include most activities involving connections between employees and the structure of the business itself. There

Exhibit 1

HR Trend Analysis for a Manufacturing Firm

	2006	2007	2008	2009	2010
Projected sales (thousands of dollars)	10,200	8,700	7,800	9,500	10,000
Number of employees	240	200	165	215	?

are many types of analysis HR planning can use, including the following:

- *Workforce analysis* judges the future trends of specific jobs in the company and how they will change, such as technological trends, expected surpluses or layoffs, and needed skill sets.

- *Internal scans* are used to identify key movements and patterns within the organization which may affect HR operations.

- *External scans* look at outside factors which affect employment, such as economic conditions and the need for certain skills.

- *Gap analysis* is used to plot where the HR policies currently are, where they will need to be to meet future goals, and how a company can move ahead in its human resources strategy.

- *Priority setting* allows HR managers to set HR priorities and form strategies for reaching them, based on information previously gathered through other scans.

Demand Forecasting. Demand forecasting is the process of judging future trends in the employment market so that good HR recruitment decisions can be made. It involves analysis of such factors as competition, international movements, legislation, and changes in both technology and society. With proper demand forecasting, employers will be able to tell what skill sets their new employees will need and what positions will become more necessary to business. They will also be able to accurately budget for recruitment endeavors.

There are many different techniques used in demand forecasting, including those listed here:

- Managerial judgment is a type of brainstorming that involves a meeting of managers who gather to diagnose and predict the future job market. These can generally be either top-down or bottom-up, with either the executives forming their plans and trend analysis for discussion, or the mid-level managers bringing their forecasts to the meeting. The best

Exhibit 2

Regression Line Depicting Relationship Between Sales Volume and Workforce Size

The value on the Y axis corresponding to that point (i.e., 230) reflects the needed workforce size.

- The Delphi technique involves recruiting experts on employees and employee trends, and gathering their various forecasts concerning job markets. The resulting statistics are then combined and recombined until the final result is a usable forecast.

- Structured analogies are similar to regression analyses, but they are more creative-oriented, comparing past scenarios involving employment trends and looking at examples from similar situations in the past.

- Judgmental decomposition tries to break a forecasting situation down into smaller parts, which are then separately analyzed and recombined to form a complete view.

These are just some of the techniques used in demand forecasting—what other techniques a company decides to use are based on its HRM strategy.

Judgmental Approaches. Judgmental approaches to demand forecasting involve the use of human judgment, rather than a manipulation of numbers. Two of the most commonly used judgmental techniques are group brainstorming and sales force estimates. The group brainstorming technique of demand forecasting uses a panel of experts (i.e., people within the organization who collectively understand the market, the industry, and the technological developments bearing on HRM needs). These experts are asked to generate a forecast through the process of brainstorming. A variety of brainstorming techniques exist. Most involve a face-to-face discussion among group members, who are asked to reach a consensus.

When using a *group brainstorming* technique to forecast human resources demand, participants must make certain assumptions regarding the future. That is, they must examine the firm's strategic plans for developing new products or services, expanding to new markets, and so forth, and then try to predict such things as:

- Future marketplace demands for the organization's products and services

- The percentage of the market that the organization will serve

- The availability and nature of new technologies that may affect the amounts and types of products or services that can be offered

The accuracy of the forecasts depends on the correctness of these assumptions. Of course, the future is very difficult to predict because it is subject to many uncertainties. Therefore, the organization must continually monitor its demand forecasts in light of any unexpected

types of managerial judgment will combine forecasts from many sources, including HRM.

- Ratio-trend analysis involves researching past trends in organizational employment, with an eye on current changes the organization is going through, to come up with reliable projections concerning future activity. This usually involves ratios, such as that between the number of workers and the revenue of the company. An example of a trend analysis is illustrated in Exhibit 1, which depicts the relationship between a business factor (namely, sales volume) and workforce size. As one can see from the exhibit, if the company expects its 2010 sales to be $10 million, it will need to increase its workforce to a size of nearly 240, which is the number of employees it had in 2006 when sales were $10.2 million.

- Regression analysis is a more advanced version of ratio-trend analysis, involving the plotting of past relationships so that regression lines can be drawn and trends planned out. An example of how regression analysis can be used to project HR demand is shown in Exhibit 2. In this example, the figures used in the trend analysis (Exhibit 1) are now depicted in the form of a scatter diagram. The line running through the center of the points plotted on the scatter diagram is the regression line. To determine the number of employees needed when the sales volume is $10 million, one would follow the path indicated by the dashed line. One would start at the point on the X axis reading "10,000" and then move up vertically until reaching the regression line.

changes. HRMS packages facilitate the calculation and monitoring of demand forecasts.

The use of *sales force* estimates represents another judgmental approach for forecasting HR demand. This approach is most appropriately used when the need for additional employees arises from the introduction of new products. When a new product is launched, sales personnel are asked to estimate the demand for the product (i.e., expected sales volume) based on their knowledge of customer needs and interests. The organization then uses this information to estimate how many employees will be needed to meet this demand. One drawback of this approach is the possibility of bias. Some sales personnel may purposely underestimate product demands so they will look good when their own sales exceed the forecasts. Others may overestimate demand because they are overly optimistic about their sales potential.

SUPPLY FORECASTING

Once a demand forecast has been made, an organization has a relatively good idea of the number and nature of positions it will need to carry out its work at a particular point in time. It then estimates which of these positions will be filled at that time by individuals who already are employed by the company. The process used to make this estimation is called supply forecasting.

Supply forecasting is a two-step process. HRMS packages provide the employer with the means to automate much of these two steps. In the first step, the organization groups its positions by title, function, and responsibility level. These groupings should reflect levels of positions across which employees may be expected to advance. For instance, the HRM group might include the job titles of HR assistant, HR manager, and HR director. The secretarial group might include secretarial clerk, principal secretary, senior secretary, and administrative assistant.

The second step of supply forecasting is to estimate, within each job group, how many current employees will remain in their positions during the planning period, how many will move to another position (e.g., through transfer, promotion, or demotion), and how many will leave the organization. These predictions are partially based on past mobility trends (e.g., turnover and promotion rates). The organization also should consider any plans for mergers, acquisitions, unit or division divestitures, layoffs, retrenchments and downsizing, and even hostile take-overs. When making its supply forecast, the organization also should look at specific individuals. Some may have already announced, for instance, that they are retiring at the end of the year, returning to school in the fall, or getting married and planning on moving to a different part of the country.

Computerized statistical packages are available to help estimate the flow of employees through an organization. The estimates generated by these packages can be fairly accurate in stable environments. When the environment is unstable, of course, these estimates are suspect. For instance, an organization may base its estimates on past turnover rates, which have been about 10 percent during each of the past five years. If the turnover rate were to change drastically because of factors such as job dissatisfaction or downsizing, the organization would severely underestimate its future staffing needs.

OUTCOMES OF THE HR PLANNING PROCESS

When the HR planning process is completed, a firm must establish and implement HRM practices in order to meet its human resource needs. Following is a brief overview of how HRM practices can help organizations deal with anticipated oversupplies and undersupplies of personnel.

The trend toward organizational restructuring usually results in a smaller workforce. Therefore, when an organization's strategic plan calls for restructuring, the HRM response usually is one of downsizing. Downsizing usually results in layoffs. Because of the negative outcomes that are often associated with layoffs, employers are encouraged to seek alternatives, such as hiring freezes, early retirements, restricted overtime, job sharing, and pay reductions.

When the results of demand and supply forecasting project an undersupply of personnel at some future point in time, the organization must decide how to resolve this problem. The solution may involve hiring additional staff, but there are other options. When HR plans indicate an undersupply of employees, firms can recruit personnel to staff jobs with anticipated vacancies. HRMS packages provide employers with capabilities to carry out recruitment in all of its steps. The first step is to conduct a job analysis to determine the qualifications needed for each vacant job.

The next step is to determine where and how to recruit the needed individuals. For instance, a company must decide whether to fill its vacancies externally (i.e., from the external labor market) or internally (i.e., from its own current workforce). When recruiting externally, an organization should first assess its attractiveness in the eyes of potential applicants; unattractive employers may have trouble generating a sufficiently large applicant pool. Such employers should attempt to increase the number of people who are attracted to the organization and thus interested in applying for a job there. This may be accomplished by increasing starting pay levels and/or improving benefit packages. Another option is to target certain protected groups whose members may be

underemployed in the local labor market, such as older, disabled, or foreign-born individuals.

Internal recruitment efforts can be improved through the use of career development programs. When designing such a program, the organization should collect work history and skill-level information on each of its employees. Such information would include age, education level, training, special skills (e.g., foreign language spoken), and promotion record, and should be stored on a computer. This employee information allows the organization to identify current employees who are qualified to assume jobs with greater responsibility levels. For instance, in departments where skilled managers are in short supply, a management replacement chart can be prepared that lists present managers, proposes likely replacements, and gives an estimate of when the replacement candidate will be trained and available to fill an open position.

Instead of hiring new workers to meet increasing demands, an organization may decide to improve the productivity of the existing workforce through additional training. Other options include the use of overtime, additional shifts, job reassignments, and temporary workers. Another option is to improve retention rates. When this aim is met, firms will have fewer job vacancies to fill.

Retention rates can be improved at the outset of the employer/employee relationship, when applicants are first recruited. Retention rates are likely to improve when applicants are given a realistic preview of what their jobs would actually be like (warts and all), rather than an overly glowing one.

Workers want to feel valued and needed by their organization. In a climate characterized by mergers, acquisitions, and layoffs, many workers feel very insecure about their jobs. Employees with such feelings often begin shopping around for other jobs. These fears can be eased by implementing HR plans for training and cross-training. Such plans allow workers to perform a variety of functions, thus ensuring that they have the necessary skills to continue making contributions to the firm. Management training also is crucial in this regard. Organizations must train managers to be good supervisors. Poor "people management" is a primary cause of voluntary turnover. Managers at all levels should know what is expected of them, in terms of managing people instead of just managing budgets.

HUMAN RESOURCE MANAGEMENT SYSTEMS

Several major software companies provide HRMS packages. SAP, PeopleSoft, Oracle, and ADP are the largest. Depending on the company's needs and size, package options may include some or all of the following services:

- Employee career cycle management
- 24/7 data access to authorized managers
- Customized levels of access to confidential data
- Pre-populated forms and templates
- Access to real-time data—with instantaneous updates
- Employee administration
- Benefits administration
- Compliance
- Recruitment
- Performance and development
- Safety and health
- Succession planning
- Time-off management
- Organization management
- Payroll
- Training
- 401(k) plan administration

The opportunities to add more services are endless and continue to improve.

For most companies, the hardware and software needed to run these programs are fairly standard. Hardware and software is dependent on the complexity of the HRMS package; more complex HRMS packages require more hardware (e.g., server space and speed).

Another benefit of HRMS includes allowing HR to transition from an administrative department to a strategic management department. The strategic value aspect of the HRMS investment focuses on managing human capital by supporting functions such as recruitment, performance/competency management, employee development, and employee customer service. By executing well in these areas, companies can reduce employee turnover, reduce hiring costs, and improve individual performance.

Another HRMS trend is the use of online surveys. This allows companies to get fast information on their employees, policies, procedures, competition, and anything else they decide to survey. This also gives employees a sense of belonging and contributing to their company. Online employee surveys usually have an 80 percent return ratio, which is much higher than paper surveys.

Employees are becoming more self sufficient in the workplace because of HRMS and the growth of technology. They are able to answer questions, download forms, enroll in benefits, change payroll options, and complete training on their own. This saves both time and money. An employee does not have to make several phone calls in order to speak with the one person who knows the answer

to their questions. Answers are readily available, usually on the company intranet. This also frees up HR to focus on more profitable activities for the company, such as recruiting and employee development.

Another growing trend includes improved methods for monitoring and managing employees' use of the Internet. This helps management to improve productivity, reduce legal liabilities, and control IT costs. Companies are blocking e-mail that may be offensive in order to reduce legal liabilities. They also are blocking Web sites that are inappropriate for workplace viewing. This has improved productivity by reducing nonproductive activities.

HRMS providers have products for companies of all sizes. These providers profit by maximizing the services they offer. Therefore, they are going to target large companies that need more support. However, providers are still interested in small companies, and those that will need more support as they grow.

SOFTWARE EXAMPLES

There are many software programs designed to help in HRIS process. The following are only a few of the companies currently providing HRIS software:

- *Ascentis* offers payroll and HRM programs for small- to mid-level organizations, software that tracks many traditional employee benefits and several nontraditional such as paid parking and club memberships.

- *Apex Business Software* offers HR programs to meet company objectives and manage many facets of the HR process, including employee leave and benefit tracking. They also offer instant access to employee attendance information that can be made available even to customers, thereby enforcing accountability.

- *People Trak* has a wide variety of HR software, including personnel, compensation, safety, applicant, and position management. They also have programs for COBRA and benefit administration, for both simple tasks and strategic planning of HRM.

- *ManagerAssistant* offers software with many different modules developed to assist HR employees in each stage of HR analysis.

- *Atlas Business Solutions* creates programs that allow easy filing and retrieval of employee information, including vacation accruals and performance evaluations, in their software package called Staff Files.

As the need for corporate cost-cutting, efficiency, and productivity becomes more important, the HRMS industry is going to continue to have strong growth potential. Not only can HRMS help with employee administration from recruiting to benefits, it can save companies thousands of dollars by lowering workforce and employee turnover levels. By 2005, the corporate world had only seen the beginning potential of HRMS.

HUMAN RESOURCE MANAGEMENT

Human resource management (HRM), also called personnel management, consists of all the activities undertaken by an enterprise to ensure the effective utilization of

employees toward the attainment of individual, group, and organizational goals. An organization's HRM function focuses on the people side of management. It consists of practices that help the organization to deal effectively with its people during the various phases of the employment cycle, including pre-hire, staffing, and post-hire. The pre-hire phase involves planning practices. The organization must decide what types of job openings will exist in the upcoming period and determine the necessary qualifications for performing these jobs. During the hire phase, the organization selects its employees. Selection practices include recruiting applicants, assessing their qualifications, and ultimately selecting those who are deemed to be the most qualified.

In the post-hire phase, the organization develops HRM practices for effectively managing people once they have "come through the door." These practices are designed to maximize the performance and satisfaction levels of employees by providing them with the necessary knowledge and skills to perform their jobs and by creating conditions that will energize, direct, and facilitate employees' efforts toward meeting the organization's objectives.

HRM DEVELOPMENT AND IMPLEMENTATION RESPONSIBILITIES

While most firms have a human resources or personnel department that develops and implements HRM practices, the ultimate responsibility lies with both HR professionals and line managers. The interplay between managers and HR professionals leads to effective HRM practices. For example, consider performance appraisals. The success of a firm's performance appraisal system depends on the ability of both parties to do their jobs correctly. HR professionals develop the system, while managers provide the actual performance evaluations.

The nature of these roles varies from company to company, depending primarily on the size of the organization. This discussion assumes a large company with a sizable HRM department. However, in smaller companies without large HRM departments, line managers must assume an even larger role in effective HRM practices.

HR professionals typically assume the following four areas of responsibility: establishing HRM policies and procedures, developing/choosing HRM methods, monitoring/evaluating HRM practices, and advising/assisting managers on HRM-related matters. HR professionals typically decide (subject to upper-management approval) what procedures to follow when implementing an HRM practice. For example, HR professionals may decide that the selection process should include having all candidates (1) complete an application, (2) take an employment test,

and then (3) be interviewed by an HR professional and line manager.

Usually the HR professionals develop or choose specific methods to implement a firm's HRM practices. For instance, in selection the HR professional may construct the application blank, develop a structured interview guide, or choose an employment test. HR professionals also must ensure that the firm's HRM practices are properly implemented. This responsibility involves both evaluating and monitoring. For example, HR professionals may evaluate the usefulness of employment tests, the success of training programs, and the cost effectiveness of HRM outcomes such as selection, turnover, and recruiting. They also may monitor records to ensure that performance appraisals have been properly completed.

HR professionals also consult with management on an array of HRM-related topics. They may assist by providing managers with formal training programs on topics like selection and the law, how to conduct an employment interview, how to appraise employee job performance, or how to effectively and appropriately discipline employees. HR professionals also provide assistance by giving line managers advice about specific HRM-related concerns, such as how to deal with problem employees.

Line managers direct employees' day-to-day tasks. From an HRM perspective, line managers are mainly responsible for implementing HRM practices and providing HR professionals with necessary input for developing effective practices. Managers carry out many procedures and methods devised by HR professionals. For instance, line managers are responsible for the following activities:

- Interview job applicants.

- Provide orientation, coaching, and on-the-job training.

- Provide and communicate job performance ratings.

- Recommend salary increases.

- Carry out disciplinary procedures.

- Investigate accidents.

- Settle grievance issues.

The development of HRM procedures and methods often requires input from line managers. For example, when conducting a job analysis, HR professionals often seek job information from managers and ask managers to review the final written product. Additionally, when HR professionals determine an organization's training needs, managers often suggest what types of training are needed and who, in particular, needs the training.

HISTORICAL MILESTONES IN HRM DEVELOPMENT

Table 1 identifies some of the major milestones in the historical development of HRM. Frederick Taylor, known as the father of scientific management, played a significant role in the development of the personnel function in the early 1900s. In his book, *Shop Management*, Taylor advocated the "scientific" selection and training of workers. He also pioneered incentive systems that rewarded workers for meeting and/or exceeding performance standards. Although Taylor's focus primarily was on optimizing efficiency in manufacturing environments, his principles laid the groundwork for future HRM development. As Taylor was developing his ideas about scientific management, other pioneers were working on applying the principles of psychology to the recruitment, selection, and training of workers. The development of the field of industrial psychology and its application to the workplace came to fruition during World War I, as early vocational and employment-related testing was used to assign military recruits to appropriate functions.

The Hawthorne Studies, which were conducted in the 1920s and 1930s at Western Electric, sparked an increased emphasis on the social and informal aspects of the workplace. Interpretations of the studies emphasized "human relations" and the link between worker satisfaction and productivity. The passage of the Wagner Act in 1935 contributed to a major increase in the number of unionized workers. In the 1940s and 1950s, collective bargaining led to a tremendous increase in benefits offered to workers. The personnel function evolved to cope with labor relations, collective bargaining, and a more complex compensation and benefits environment. The human relations philosophy and labor relations were the dominant concerns of HRM in the 1940s and 1950s.

HRM was revolutionized in the 1960s by passage of Title VII of the Civil Rights Act and other anti-discrimination legislation—as well as presidential executive orders that required many organizations to undertake affirmative action in order to remedy past discriminatory practices. Equal employment opportunity and affirmative action mandates greatly complicated the HRM function, but also enhanced its importance in modern organizations. As discussed more fully in a later section, these responsibilities continue to comprise a major part of the HRM job. Finally, changes in labor force demographics, technology, and globalization since the 1980s have had a major impact on the HRM function. These factors also are discussed in more detail in a later section.

PRE-HIRING, HIRING, AND POST-HIRING

Pre-hire phase. The major HRM activities in the pre-hire phase are human resource planning and job analysis.

Table 1

Milestones in the Development of Human Resource Management

1890-1910	Frederick Taylor develops his ideas on scientific management. Taylor advocates scientific selection of workers based on qualifications and also argues for incentive-based compensation systems to motivate employees.
1910-1930	Many companies establish departments devoted to maintaining the welfare of workers. The discipline of industrial psychology begins to develop. Industrial psychology, along with the advent of World War I, leads to advancements in employment testing and selection.
1930-1945	The interpretation of the Hawthorne Studies begins to have an impact on management thought and practice. Greater emphasis is placed on the social and informal aspects of the workplace affecting worker productivity. Increasing the job satisfaction of workers is cited as a means to increase their productivity.
1945-1965	In the U.S., a tremendous surge in union membership between 1935 and 1950 leads to a greater emphasis on collective bargaining and labor relations within personnel management. Compensation and benefits administration also increase in importance as unions negotiate paid vacations, paid holidays, and insurance coverage.
1965-1985	The Civil Rights movement in the U.S. reaches its apex with passage of the Civil Rights Act of 1964. The personnel function is dramatically affected by Title VII of the CRA, which prohibits discrimination on the basis of race, color, sex, religion, and national origin. In the years following the passage of the CRA, equal employment opportunity and affirmative action become key human resource management responsibilities.
1985-present	Three trends dramatically impact HRM. The first is the increasing diversity of the labor force, in terms of age, gender, race, and ethnicity. HRM concerns evolve from EEO and affirmative action to "managing diversity." A second trend is the globalization of business and the accompanying technological revolution. These factors have led to dramatic changes in transportation, communication, and labor markets. The third trend, which is related to the first two, is the focus on HRM as a "strategic" function. HRM concerns and concepts must be integrated into the overall strategic planning of the firm in order to cope with rapid change, intense competition, and pressure for increased efficiency.

These activities form the cornerstone upon which other HRM practices are built. Human resource planning helps managers to anticipate and meet changing needs related to the acquisition, deployment, and utilization of employees. The organization first maps out an overall plan called a strategic plan. Then, through demand and supply forecasting it estimates the number and types of employees needed to successfully carry out its overall plan. Such information enables a firm to plan its recruitment, selection, and training strategies. For example, assume that a firm's HR plan estimates that fifteen additional engineers will be needed during the next year. The firm typically hires recent engineering graduates to fill such positions. Because these majors are in high demand, the firm decides to begin its campus recruiting early in the academic

year, before other companies can "snatch away" the best candidates.

Job analysis is the systematic process used for gathering, analyzing, and documenting information about particular jobs. The analysis specifies what each worker does, the work conditions, and the worker qualifications necessary to perform the job successfully. The job analysis information is used to plan and coordinate nearly all HRM practices, including:

- Determining job qualifications for recruitment purposes
- Choosing the most appropriate selection techniques
- Developing training programs
- Developing performance appraisal rating forms
- Helping to determine pay rates
- Setting performance standards for productivity improvement programs

For example, an organization may decide to use a mechanical aptitude test to screen applicants because a job analysis indicated that mechanical aptitude is an important job skill for a specific position. Or, a firm may raise the pay of one of its employees because a job analysis indicated that the nature of the work recently changed and is now more demanding or requires further education.

Hiring Phase. The hiring phase of human resource management is also called staffing. Staffing involves policies and procedures used by organizations to recruit and select employees. Organizations use recruitment to locate and attract job applicants for particular positions. They may recruit candidates internally (i.e., recruit current employees seeking to advance or change jobs) or externally. The aim of recruitment practices is to identify a suitable pool of applicants quickly, cost-efficiently, and legally. Selection involves assessing and choosing among job candidates. To be effective, selection processes must be both legal and technically sound, accurately matching people's skills and experience with available positions.

Post-Hiring Phase. Training and development are planned learning experiences that teach workers how to effectively perform their current or future jobs. Training focuses on present jobs, while development prepares employees for possible future jobs. Training and development practices are designed to improve organizational performance by enhancing the knowledge and skill levels of employees. A firm must first determine its training needs and then select/develop training programs to meet these needs. It also must take steps to ensure that workers apply what they have learned on the job. Many companies will pay for refresher courses for long-term employees

or offer a tuition reimbursement program for courses an employee takes that enhance his or her on-the-job ability.

Through the performance appraisal process, organizations measure the adequacy of their employees' job performances and communicate these evaluations to them. One aim of appraisal systems is to motivate employees to continue appropriate behaviors and correct inappropriate ones. Management also may use performance appraisals as tools for making HRM-related decisions, such as promotions, demotions, discharges, and pay raises.

Compensation entails pay and benefits. Pay refers to the wage or salary employees earn, while benefits are a form of compensation provided to employees in addition to their pay, such as health insurance or employee discounts. The aim of compensation practices is to help the organization establish and maintain a competent and loyal workforce at an affordable cost.

Productivity improvement programs tie job behavior to rewards. Rewards may be financial (e.g., bonuses and pay raises) or nonfinancial (e.g., improved job satisfaction). Such programs are used to motivate employees to engage in appropriate job behaviors, namely those that help the organization meet its goals.

CONTEMPORARY ISSUES

HRM departments within organizations, just as the organizations themselves, do not exist in a vacuum. Events outside of work environments have far-reaching effects on HRM practices. The following paragraphs describe some of these events and indicate how they influence HRM practices.

As mentioned previously, the enactment of federal, state, and local laws regulating workplace behavior has changed nearly all HRM practices. Consider, for instance, the impact of anti-discrimination laws on hiring practices. Prior to the passage of these laws, many firms hired people based on reasons that were not job-related. Today, such practices could result in charges of discrimination. To protect themselves from such charges, employers must conduct their selection practices to satisfy objective standards established by legislation and fine-tuned by the courts. This means they should carefully determine needed job qualifications and choose selection methods that accurately measure those qualifications.

Social, economic, and technological events also strongly influence HRM practices. These events include:

- An expanding cultural diversity at the workplace
- The emergence of work and family issues
- The growing use of part-time, seasonal, contracted, and temporary employees
- An increased emphasis on quality and teamwork

- The occurrence of mergers and takeovers
- The occurrence of downsizing and layoffs
- The rapid advancement of technology
- An emphasis on continuous quality improvement
- A high rate of workforce illiteracy

These events influence HRM practices in numerous ways. For example:

- Some firms are attempting to accommodate the needs of families by offering benefit options like maternity leave, child care, flextime, telecommuting, and job sharing.
- Some firms are attempting to accommodate the needs of older workers through skill upgrading and training designed to facilitate the acceptance of new techniques.
- Some firms are educating their employees in basic reading, writing, and mathematical skills so that they can keep up with rapidly advancing technologies.

Unions often influence a firm's HRM practices. Unionized companies must adhere to written contracts negotiated between each company and its union. Union contracts regulate many HRM practices, such as discipline, promotion, grievance procedures, and overtime allocations. HRM practices in non-unionized companies may be influenced by the threat of unions. For example, some companies have made their HRM practices more equitable (i.e., they treat their employees more fairly) simply to minimize the likelihood that employees would seek union representation.

Legal, social, and political pressures on organizations to ensure the health and safety of their employees have had great impacts on HRM practices. Organizations respond to these pressures by instituting accident prevention programs and programs designed to ensure the health and mental well-being of their employees, such as wellness and employee assistance programs.

Today's global economy also influences some aspects of HRM. Many firms realize that they must enter foreign markets in order to compete as part of a globally interconnected set of business markets. From an HRM perspective, such organizations must foster the development of more globally-oriented managers: individuals who understand foreign languages and cultures, as well as the dynamics of foreign market places. These firms also must deal with issues related to expatriation, such as relocation costs, selection, compensation, and training.

EMPLOYMENT

Someone wishing to enter the HRM field may choose one of two routes: generalist or specialist. Entry-level HRM

Exhibit 1a

HRM Specialty Areas

Traditional Specialty Areas

Training/Development
Conducts training needs analysis; designs/conducts/evaluates training programs; develops/implements succession planning programs.

Compensation/Benefits
Develops job descriptions; facilitates job evaluation processes; conducts/interprets salary surveys; develops pay structure; designs pay-for-performance and/or performance improvement programs; administers benefits program.

Employee/Industrial Relations
Helps resolve employee relations problems; develops union avoidance strategies; assists in collective bargaining negotiations; oversees grievance procedures.

Employment/Recruiting
Assists in the HR planning process; develops/purchases HR information systems; develops/updates job descriptions; oversees recruiting function; develops and administers job posting system; conducts employment interviews, reference checks, and employment tests; validates selection procedures; approves employment decisions.

Safety/Health/Wellness
Develops accident prevention strategies; develops legal safety and health policies; implements/promotes EAP and wellness programs; develops AIDS and substance abuse policies.

EEO/Affirmative Action
Develops and administers affirmative action programs; helps resolve EEO disputes; monitors organizational practices with regard to EEO compliance; develops policies for ensuring EEO compliance, such as sexual harassment policies.

HRM Research
Conducts research studies, such as cost-benefit analysis, test validation, program evaluation, and feasibility studies.

(cont. Exhibit 1b)

---

generalist positions are most often found in small or mid-sized organizations that employ few HR professionals—one or two people who must perform all functions. Because of their many responsibilities, HRM generalists have neither time nor resources to conduct in-depth studies or projects. They usually hire outside consultants who specialize in these kinds of services. For example, consultants might help the organization to revamp its compensation system, validate its selection practices, or analyze its training needs.

In larger organizations, each HR professional's area tends to be more focused, zeroing in on particular HRM tasks. Individuals holding these positions are called HRM specialists. Exhibits 1a and 1b describe some traditional and newer HRM specialty areas.

In most professions a direct path leads to entering the field. For instance, someone aspiring to be a lawyer, physician, accountant, or psychologist enrolls in appropriate educational programs and enters the field upon receiving a degree or license. HRM is atypical in this

---

Exhibit 1b

HRM Specialty Areas (cont.)

New HRM Specialty Areas

Work and Family Programs
Develops and administers work and family programs including flextime, alternative work scheduling, dependent-care assistance, telecommuting, and other programs designed to accommodate employee needs; identifies and screens child- or elder-care providers; administers employer's private dependent-care facility; promotes work and family programs to employees.

Cross-Cultural Training
Translates the manners, mores, and business practices of other nations and cultures for American business people. Other cross-cultural trainers work with relocated employees' families, helping them adjust to their new environment.

Managed-Care
As a company's health-care costs continue to escalate, employers are embracing managed-care systems, which require employees to assume some of the costs. Employers hire managed-care managers to negotiate the best options for employees.

Managing Diversity
Develops policies and practices to recruit, promote, and appropriately treat workers of various ages, races, sexes, and physical abilities.

---

regard; people may enter the profession in a variety of ways. For instance, most of today's HR professionals enter the field through self-directed career changes. Approximately one-third of these individuals entered HRM by transferring from another part of the company; the remainder entered from other fields such as education, social services, accounting, sales, and administrative secretarial positions.

HR professionals entering the field directly out of college (about one-third of all HR professionals) traditionally come from a variety of academic backgrounds, including business, psychology, and liberal arts. More recently, however, HRM new hires have earned degrees in some area of business, such as HRM, management, or general business. For instance, when it hires recent graduates for entry-level HRM positions, Bell Atlantic considers business school graduates with concentrations in business administration, finance and commerce, management, or industrial relations. A survey of HR professionals revealed the following college majors: HRM (17 percent), business administration (23 percent), management (13 percent), psychology (12 percent), and labor/industrial relations (10 percent).

As one might expect, large organizations provide the greatest opportunities for HRM career growth. Most senior-level HR professionals take one of two paths up the corporate ladder. Some begin their careers as specialists and eventually become managers of their specialty units. To advance beyond this level, they must broaden their skills and become HRM generalists. The other path to securing a senior-level HRM position is to begin as an assistant HRM generalist at a small plant or unit within the organization and advance into an HRM managerial role at successively larger plants or units. An HRM career in manufacturing might progress as follows:

1. The individual is hired as an HRM assistant at a manufacturing plant.

2. Within five or six years, the individual advances to the HRM manager's post at the plant.

3. Between six and ten years, the HR professional becomes the HRM manager at a larger plant.

4. During the eleven- to fifteen-year range, the person reaches a senior-level HRM position at the divisional level and has several HRM generalists and/or specialists reporting to him or her.

5. Between fifteen and twenty years, the person reaches a senior-level executive position, such as vice president of human resources.

ORGANIZATIONAL ETHICS

HR professionals primarily are responsible for developing HRM practices that enhance a firm's competitive advantage. HR professionals also have the responsibility to ensure that employees are treated ethically. Almost all HRM decisions have ethical consequences. Despite the abundance of laws designed to ensure fair treatment at the workplace, employees often are treated in an unethical manner. In some instances, employers skirt the law; in others, the law is followed meticulously, but employees are nonetheless treated unfairly by management or by other employees. One survey revealed that the most serious ethical problems involve managerial decisions regarding employment, promotion, pay, and discipline that are based on favoritism, rather than ability or job performance.

HR professionals play three roles in the area of workplace ethics. One role is monitoring: they must observe the actions of organizational members to ensure that all individuals are treated fairly and legally. Second, HR professionals investigate complaints bearing on ethical issues, such as sexual harassment or violations of employees' privacy rights. Third, HR professionals serve as company spokespeople by defending the company's actions when confronted by a regulatory agency or the media.

HR professionals should act ethically themselves. When faced with ethical dilemmas, HR professionals must be willing to take a strong stand, even if it means putting their jobs at risk. If they choose not to recognize a situation that needs their attention, they become part of the problem and thus must assume some of the blame.

HR professionals should be guided by the Society for Human Resource Management Code of Ethics, which dictates that HR professionals should always:

- Maintain the highest standards of professional and personal conduct

- Encourage employers to make fair and equitable treatment of all employees a primary concern

- Maintain loyalty to employers and pursue company objectives in ways consistent with the public interest

- Uphold all laws and regulations relating to employer activities

- Maintain the confidentiality of privileged information

The future of HRM includes a strong concentration in managing the people side of a multinational, globally positioned firm. In other words, those in the HRM field will need to know how to manage employees from many cultures and countries as well as those who work from home and those who work in other countries and regions. With the U.S. economy depending heavily on China and India for workforces and for products and services, HRM will have to evolve into a comprehensive study of global sociology in order to understand the needs of the ever changing workforce.

IMPORTING

SEE *Exporting and Importing*

INCOME STATEMENTS

The income statement is one of the three major financial statements that all publicly held firms are required to prepare annually. It provides a record of a company's revenues and expenses for a given period of time, and thus serves as the basic measuring stick of profitability. In fact, the income statement is often referred to as the profit-and-loss statement, with the bottom line literally revealing which result a company achieved. Along with the balance sheet and cash flow statement, the income statement provides important financial information to business managers, investors, lenders, and analysts.

"The income statement is simply a scorecard that summarizes the revenues and expenses of an organization for a specific period of time," Jayson Orr wrote in *CMA Management*. "It reveals critical information about the operations and profitability of a business unit. It also reveals little secrets that may not be so obvious. In short, the income statement tells how successfully a business unit is fulfilling its prime directive—to generate profit."

Preparing an income statement is one of the basic responsibilities of the accounting function. Accounting is the process of recording and disclosing the financial information for a company so that operating results can be known and comparisons between different years and different companies can be made. Accounting has been described as the language of business. Because managers

of all organizations use accounting information, perhaps on a daily basis, it is critical that they understand the language. One of the obstacles to the best use of accounting information is that its terminology is confusing, especially when some of the terms used in accounting have alternate meanings in other business settings.

One of the purposes of this essay is to provide logical definitions for key business terms from an accounting perspective, thus avoiding misunderstandings from applying an inappropriate definition. A second purpose is to describe the contents of the typical income statement prepared for a profit-seeking corporation.

ACCRUAL ACCOUNTING VS. CASH BASIS ACCOUNTING

An area of confusion for many people is the concept known as accrual accounting. When individuals and small companies spend money, the expenditure is generally considered to be an *expense*. This is what accountants refer to as the *cash basis* of accounting. But larger companies, particularly publicly held corporations, are required to use the *accrual basis* of accounting. From the accrual accounting perspective, the purpose of the expenditure determines whether or not the expenditure is an expense at the time of payment. For example, if a business expends cash for office supplies, no expense occurs until the office supplies are used in business operations. The spending of cash is not the critical event. Thus, when a business buys postage stamps, it has purchased an *asset*, that is, an item that has a future potential to benefit the company. If the stamps are used to mail an invoice to a customer or supplier, then the *expense* occurs because the stamp (asset) has no further benefit for the company.

The same logic would apply to other expenditures wherein a company acquires an asset that offers future benefits on a long-term basis, such as a delivery truck. Identifying when the benefit occurs, and therefore when the expense occurs, is a more difficult task in this instance, and the point will be discussed later as the concept of *depreciation.* One unique aspect of an expense is that expenses are incurred in order to produce revenues.

The concept of revenues also proves confusing to some people. Revenues can be defined as the amount charged to customers for the services and products that are provided to them. When employees receive paychecks, they consider that they have earned their pay at that time. The paycheck represents the completion of labor for the previous work period. For a company that uses accrual accounting, however, the receipt of payment is not the critical event for determining when revenues have been earned. From an accrual accounting perspective, a company generally earns revenues at the time a product or service is provided to the customer. Thus, whether a customer pays for the purchase of a product or service with cash (or check) or charges the purchase on a credit card, the company earns revenue when the product or service is provided. This concept is complicated because revenue is earned, and yet no cash might be paid to the company at the time that accounting says that revenue is earned. Using the paycheck example, employees actually earn their pay on a daily basis as they perform services for their company, but they do not receive payment until payday.

To merge the two concepts of revenues and expenses together, consider a rule accountants refer to as the *matching principle.* This rule can be summarized as follows: revenues are recorded in the time period when earned and expenses are matched (offset) against the revenues in the same time period that they cause revenues to be earned. More formal definitions can be summarized as follows: revenues can be defined as the total amount earned from providing goods and services to customers. Revenues are equal to (measured by) the amount of cash or legal claim to receive cash or other items of value to be received at a later date in payment from the customer. The receipt of payment might occur immediately or it might occur, say, thirty days after the invoice's date. In either case, the revenues are earned when the service or product is provided, not necessarily when the cash is received.

Expenses can be viewed as representing the use of the benefits that an employee or asset provides; the payment for the asset or services might or might not occur at the same time that the benefits are used. The important thing to remember is that expenses are incurred, and therefore matched with revenues, in the period in which the company earns the revenues.

THE INCOME STATEMENT

The income statement is considered by many to be a company's most important financial statement. It discloses the dollar amount of the profitability for a company during a specific period of time. Since published annual financial statements usually cover a twelve-month period, this will be the assumption here.

The heading of the income statement should contain three crucial elements of information: the name of the company involved, the title of the statement identifying it as an income statement, and the specific twelve-month period during which the income was earned. The basic format of the income statement is represented by the following equation: revenues minus expenses equal net income.

Revenues. The income statement discloses total revenue and total expenses for the period in question. The amount of the revenues in excess of the expenses is the net income, or profit, earned by the company for the year covered by the statement. Notice that revenues are considered as a total or gross concept, whereas profit is considered a net concept, as in net income. Revenues represent the total amount that products and services are worth, expenses represent the amount that products or services cost the company, and the excess of the revenues over the expenses is the profit.

Consider a simple example: say that a company sells automobiles for profit. The company buys a car for a cost of $20,000 and sells it for $30,000 in revenue. Ignoring expenses other than the cost of the car, the profit can be determined by taking the $30,000 in revenue minus the $20,000 in expenses (the cost of the car), giving a figure of $10,000. If the total of all such sales for a year are shown and all related expenses incurred in that same year to produce the sales are deducted, the result is an income statement.

There are two basic formats of the income statement. The one summarized above is known as the *single-step income statement,* used by many service companies. All revenues are disclosed at the top of the statement, followed by all expenses of the company for the same time period. Some companies prefer to disclose their income tax expense after having deducted all other expenses from the revenues, since it doesn't relate directly to operations of the company, as do the other expenses. Net income is the bottom line, just as the expression says. However, for a company that is a corporation, an amount that is roughly the net income earned per share of corporate voting stock is disclosed last. This figure is entitled *earnings per share,* and when tracked over time it is used widely as an indicator of corporate performance from period to period.

The other format for the income statement is known as the *multiple-step income statement.* Its form is somewhat more complex; its purpose is to disclose in more detail

Table 1

Sales Revenues	$1,000,000
Less Cost of Goods Sold	-600,000
Gross Profit on Sales	400,000
Less Operating Expenses	-250,000
Income Before Income Taxes	150,000
Less Income Tax Expense	-50,000
Net Income	$100,000
Earnings Per Share	$1.00

certain relationships that many users of financial statements consider important. An abbreviated version of the multiple-step income statement is shown in Table 1.

The following paragraphs examine each line in this hypothetical income statement. To begin with, revenues would follow the general description presented earlier; in other words, they would be recorded on an accrual basis as customers take delivery of products. Thus, in this sample the *sales revenue* refers to the revenue earned from providing products to the customer. Note, however, that a bank would not have sales revenue but, instead, would have interest revenue, while a car rental company would have rental revenue. The nature of the revenue would determine the adjective used to describe the source of the revenue. There are other points in time that revenue may be recorded as being earned, but point of sale is the dominant usage.

Cost of Goods Sold. *Cost of goods sold* (often abbreviated COGS) is the expense representing the cost that a company expends to manufacture a product, if it is a manufacturing firm, or to acquire a product for resale, if a wholesaler or retailer. This represents only the direct cost of providing the product to the customer; other costs of operating the business, such as management and sales staff salaries, are deducted as expenses in other locations of the income statement. Of course, a company that provides a service instead of a product would not have a COGS expense to be deducted on its income statement.

Gross Profit on Sales. *Gross profit on sales* (or simply gross profit or gross margin) represents the total profit on the sales, if only the cost of the product itself is considered. This amount is used in calculating numerous financial ratios, such as the gross margin percent; thus it is provided for the financial statement user's benefit to analyze operating performance and make comparisons with other firms in the same line of business.

Operating Expenses. *Operating expenses* are deducted next. Sometimes this category is divided into two major components: selling (marketing) expenses and general and administrative (G&A) expenses (or both together, SG&A). Selling expenses include any expense incurred in an attempt to sell the products. Expenses such as advertising, salaries of sales personnel, and sales commissions would be included. G&A expenses include all other expenses; these relate to the general administration activities needed to run the business for the current year covered by the income statement. Examples of G&A expenses include rent expense, insurance expense, and other expenses related to the general administration of the company.

A few special expenses in this category require added discussion. Based on the accrual accounting definition of expenses presented above, expenses are deducted when incurred to earn revenue, and this may not correspond with the point in time that cash is spent to pay for the expense. For example, one of the operating expenses might be *warranty expense.* A product might be sold with a two-year warranty to cover labor and parts needed for repairs. In the year that the product is sold and the revenue from the sale is recorded, the future two years of warranty expense must also be recorded. This might seem illogical except for two important reasons. First, accrual accounting requires that expenses be matched with related revenues when the revenues are earned. Second, the warranty expense was incurred to create the sale in the first place. The sale might not have occurred without the warranty made available to the customer. This means that the accountant, with management's approval, must estimate and currently deduct what the future sacrifice will be during the subsequent two-year period, long before any cash expenditures are made.

Another example of an estimated expense is an *uncollectible accounts expense* or *bad debt expense.* Any company that offers credit terms to its customers will experience a few instances when customers are unable to pay the balance of an account when it comes due. Since accrual accounting requires the disclosure of revenue when it is earned, even when on a credit basis, the company must deduct at the time the revenue is recorded an estimate of the total of the accounts that may prove to be uncollectible in the future.

The next example of an expense that must be estimated, but one that is common to many income statements, is *depreciation expense.* If a company owns a long-lived asset, such as a building, delivery truck, machine, or computer equipment, the company should not (and often cannot for tax purposes) deduct the total cost of the item in the year it is acquired and placed into service. Since the asset has potential benefit to the company in future years, the asset's cost must be allocated over the years of its estimated life as the company receives its benefits. When a long-lived asset is first acquired for use, therefore,

management must make some good-faith estimates concerning the asset. The accountant can then calculate, by one of a number of mathematical formulas, the amount of the asset's cost that will be recorded as an expense each year of the asset's life. If, after a few years, it becomes clear that the original estimate was incorrect, an updated estimate is then used to calculate the new depreciation for the asset's remaining life. The total of all depreciation expensed over an asset's life should be equal to its cost less any amount for which it can be sold at the end of its useful life.

The final estimated expense that will be covered here is a *pension expense.* The nature of the pension expense is somewhat similar to the warranty expense. Pension expenses are also deducted before they are paid in cash. The main distinction is that a pension expense is much more difficult to estimate. Nonetheless, management must make a good-faith effort to determine the expense to be deducted each year. What makes the amount so difficult to estimate is that the actual payment to the employee might not occur for decades into the future. Meanwhile, management, with the assistance of actuaries, must make assumptions as to how long the employee will work for the company, how much the employee will earn in future years, how long the employee will live after retirement, and other such seemingly insurmountable hurdles. It will sound repetitive, but accrual accounting requires that expenses be deducted in the year that they are incurred to earn revenue. Since the employee is working currently to help the company earn revenues, the cost of all post-employment benefits must be deducted while the employee is currently employed. This is true for medical and dental benefits, just as it is for pension benefits.

Income before Income Taxes. *Income before income taxes* is the result of subtracting operating expenses from gross profit on sales. This amount is shown separately so that the profit from regular operations—before the impact of income taxes—can be seen easily.

Income Tax Expense. The final expense normally shown as a deduction on the income statement is the *income tax expense.* The amount of the expense is the result of accrual accounting rules, which differ from rules required for filing tax returns. In other words, the income tax expense is matched to the revenues that give rise to that expense, regardless of the amount computed on the tax return or paid to the IRS.

Net Income. This is the "bottom line" amount that shows the excess of the revenue over all the expenses. It does not reflect the amount of cash left over at year-end. Because revenues are recorded when they are earned (and not necessarily when they are collected), and expenses are

deducted from revenues when the expenses are incurred (and not necessarily when they are paid), net income is not correlated directly to cash left over at year-end. In the long run, however, all revenues should be collected in the form of cash and all expenses should be paid in the form of cash. In the short run, accrual accounting provides a more meaningful measurement of the profitability of the company than do mere cash receipts and expenditures.

Earnings Per Share. The final presentation on the income statement for a publicly held corporation is the amount of earnings per share of stock outstanding. In effect, this is the entire income statement condensed to show the amount of net income that each share of common voting stock earned for the income statement time period. If a stockholder owns 100 shares, the stockholder's investment earned 100 times this amount. This amount should not be confused with *dividends per share.* Dividends per share represents the amount of cash that the board of directors, as representatives of all stockholders, chooses to pay to the stockholders as a return on their investment in the company for the current period. Again, earnings and cash received do not mean the same thing.

OTHER SPECIAL ISSUES

A few other issues deserve some explanation. In the lower portion of many income statements (following operating expenses), there may be a different caption from income before income taxes. The caption income from operations is substituted when a company has experienced gains and losses. Gains and losses usually occur whenever a company sells an asset (other than inventory for which it is in business to sell) for more or less than the value of the asset in its records. The accounting concept here is to separate the disclosure of normal sales activities from the unusual disposal of other assets. (See also the discussion of *extraordinary items* below.)

There may also be up to three unique items that follow income tax expense at the end of the income statement. These items are *discontinued operations, extraordinary items,* and *cumulative effect of accounting changes.*

A company would include discontinued operations if it had disposed of a significant segment of its operations. This event would be of such a magnitude (usually defined in percentage terms) that the information on the income statement would be misleading if it were not separately disclosed from what the reader could consider to be regular recurring operations of the company.

Extraordinary items are major gains or losses that are defined to be both highly unusual in nature and infrequent in occurrence, such as expenses stemming from a natural disaster or the restructuring of long-term debt. These extremely rare gains and losses are disclosed apart

from regular operations, including normal gains and losses as discussed above, so that the user of the income statement can better judge the results of normal recurring operations.

The last item disclosed as part of the income statement before the earnings per share data may be the cumulative effect of accounting changes. This caption is used only when the management of a company has decided that changing from one *generally accepted accounting principle* (as defined by independent standards organizations for the accounting profession) to a different generally accepted accounting principle will better disclose the results of operations for the users of the statements. This change is based on management's judgment, and the accounting firm that audits the company's financial statements reviews this change. Generally, any previous years' accounting data will be restated to use the new accounting rule so that comparisons of current and previous data will be made on the same basis.

COMPREHENSIVE INCOME

A relatively new concept that may be included at the end of the income statement is *comprehensive income.* Comprehensive income results from changes in certain assets and liabilities on the balance sheet (a financial statement of corporate assets and liabilities). These unique gains and losses are not included in calculating net income, but they may be added after net income is shown. They are excluded from net income itself because they would distort the basic purpose of the income statement: to disclose the results of operations. These particular gains and losses result, instead, from two main sources not related to operations. First, comprehensive income results from market value changes of certain investment securities that are reported in the financial statements at their current trading values. Second, these gains and losses also result from foreign exchange rate changes used to report the values of assets and liabilities in foreign subsidiaries. These items may also be shown on other financial statements rather than as an addition to the income statement.

PROBLEMS WITH THE INCOME STATEMENT

Studying a company's income statement can help managers, investors, creditors, and analysts to form an understanding of the business's performance and profitability. Yet the income statement has come under criticism in recent years because the two main figures—income and expenses—are often obscured by accounting adjustments and subjective estimates. In the wake of accounting scandals at several major corporations, many analysts began pushing for expanded reporting standards that would limit companies' ability to overstate revenue or understate

expenses. In any case, rather than relying on the income statement alone, users should examine all three major financial statements to gain further information about a company's results.

INDUSTRIAL RELATIONS

Most definitions of industrial relations acknowledge that industrial relations involves the complex interplay among management, workers and their representatives, and the government. Each of these three players has different needs and goals that determine how they interact with the other two parties. In general, management's goals center upon labor costs, productivity, and profitability. In contrast, workers and their representatives (i.e., unions) are concerned with securing high wages and benefits, safe working conditions, fulfilling work, and a voice in the workplace. Finally, as the representative of the members of the society in which employers and unions reside, the government's objectives include balancing the rights of labor and management. Perhaps even more important, the government has the obligation to protect the rights of the members of society by maintaining relative harmony between workers and employers. In the U.S. private sector, industrial relations are governed by the National Labor Relations Act (1935, as amended).

There is a three-tier structure of industrial relations in the United States. Local unions deal with the daily interaction with employers at the workplace level. Typically, these local unions are affiliated with a national union such as the Service Employees International Union, which, as of 2008, is the largest national union in the United States. Labor federations, like the AFL-CIO, serve as umbrella

organizations for national unions and provide overall direction for the labor movement, as well as services like training and government lobbying. However, the lack of advancement of organized labor in recent years has caused some national unions to leave the AFL-CIO and attempt to form a competing labor federation.

Industrial relations have changed substantially in the United States since 1980; there has been a change in the shared ideology among the three players. Prior to 1980, all three parties acknowledged the legitimacy of the others' roles. Employers kept their relationship with unions at a distance, neither embracing unions nor aggressively seeking to destroy them. This produced some level of stability within the industrial relations system. However, since 1980 employers have moved away from an "arms length" relationship with unions and have either pursued greater collaboration with labor or sought to aggressively suppress unionization, even to the point of intentionally violating U.S. labor law.

The percentage of workers represented by unions (i.e., union density) in the United States decreased from a high of 35 percent in 1945 to 12.5 percent by 2005. By 2007, this number rose again and nearly 16 million workers were registered with a union. According to the U.S. Department of Labor, membership between 2006 and 2007 rose by 311,000. Interestingly, union density is substantially greater in the public sector than in the private sector—nearly five times higher as of 2007. In the public sector, unions represent approximately 37.2 percent of government workers, with the highest density being in local government (41 percent). This level of unionization in the public sector may decline in the future; however, given the trend toward privatizing government services. In the private sector, unions represent only 8 percent of workers, with the transportation industry and utilities maintaining the highest level of union density (25 percent). Union density in the private sector is approximately half of what it was in 1983.

Union membership rates vary considerably by state. New York, Hawaii, Michigan, and Alaska have the highest membership rates—with 25 percent, 24 percent, 22 percent, and 20 percent, respectively—while North Carolina and South Carolina have the lowest rates (approximately 3 percent). As of 2007 full-time wage and salary workers who are represented by a union make more than those workers not represented by a union ($781 versus $612). Workers between the ages of forty-five and fifty-four make up nearly 16 percent of union members, and those between the ages of fifty-five and sixty-four make up a similar 16.1 percent. Interestingly, much younger workers—between sixteen and twenty-four years of age—make up less than 5 percent of union members.

There are many reasons for the long-term decline in union density other than the change in management attitudes toward unions. Employment has moved from manufacturing jobs and other jobs that have traditionally been represented by unions (e.g., railroads and mining) to more service-oriented and high technology jobs. There are more white-collar and part-time jobs now than ever before, which have contributed to the decline in union density, because it is harder for unions to organize people in these jobs. Furthermore, employers have learned that using positive human resource management practices—like installing formal grievance systems, comprehensive benefit plans, and worker involvement programs—suppresses union organizing activity. Finally, in the past several decades the government has increasingly provided for the protection of workers's rights by passing a variety of legislative actions, including the Civil Rights Act (1964), the Occupational Safety and Health Act (1970), the Americans with Disabilities Act (1990), and the Family and Medical Leave Act (1993).

Workers of the twenty-first century may not be as enticed to join a union because they may not see the benefit. With an economy moving toward globalization and the workforce trend moving into home offices, more and more workers are stay-at-home moms, telecommuting professionals, and contracted employees who pay their own taxes. Most likely, these trends will diminish the numbers in union members overall—unless unions change to take these kinds of workers into account more often.

The number of strikes by unions has declined in the last two decades due to the fact that employees have a greater understanding of the impact of globalization on competition. Also, more employees are shareholders now than ever before. Some of these same factors appear to be reducing union density levels in other developed nations, although Canada is an exception; it has twice the union density of the United States.

In 1993 the Dunlop Commission was established by the Clinton Administration to propose ways to reform the labor policies set forth in the National Labor Relations Act. In general, the Commission concluded that labor law needed to be altered to make it easier for workers to seek union representation and to remove the constraints upon worker involvement. However, these recommendations have not been adopted, even though both labor and management acknowledge the need to change the antiquated labor laws that prevent closer, more trusting relations and hamper the flexibility needed by businesses to compete in the global economy. Consequently, there is a continuing need for labor law that reflects the changes that have occurred since the National Labor Relations Act was passed in 1935.

INDUSTRY LIFE CYCLE

SEE *Product Life Cycle and Industry Life Cycle*

INFORMATION ASSURANCE

Defending data and the platforms that house it is quickly becoming one of the most important technical jobs in any major corporation. Information assurance (IA) is the technical discipline of data protection. Keeping information and its warehousing safe are a part of overall information security, but it also includes the practice of forecasting future dangers and preparing offensively for any possible risk factors that are detected. Of all that is accomplished by information assurance, likely the most important factor for most firms is keeping privileged and proprietary information out of the hands of the public. A second high priority of information assurance is keeping information platforms safe from the kind of intrusion that could potentially dismantle warehousing, thus endangering or causing the loss of vital company information.

KEY FUNCTIONS

The purpose and function of information assurance can be broken down into three main categories: keeping information confidential; maintaining the integrity of stored data; and making data readily available to those who need access to it. Of these three major functions, maintaining confidentiality of important data is often deemed the highest priority of information assurance. At its most essential core, information assurance means that only those who have permission will have access to the specific information that they have the authorization to access. Additionally, information assurance is time sensitive, meaning that authorized figures will have access to data only when it is deemed necessary or allowed by the systems in place. This is achieved in a number of ways, but mainly with the use of passwords and login names and other similar "sign in" type methodologies.

Information assurance means protection against those who wish to do harm to information and information storage systems as well as the viruses and other coded programs created by hackers to destroy data and the storage facilities for data. The ways in which information is kept secure must comply with government standards but must also be "smart" and progressive enough to keep up with the ever-changing demands associated with handling the constantly evolving viruses and malware that destroys data that is not properly defended.

Information assurance also means the reconstituting of data and its housing after it has been compromised. This means refurbishing, rehousing, and resecuring data as well as reestablishing the list of those who are authorized to have access to it and assigning new login names and pass codes for all authorized parties.

THE FIVE PILLARS OF INFORMATION ASSURANCE

According to the Central Security Service, successful information assurance can be broken down into five pillars: availability, integrity, authentication, confidentiality, and nonrepudiation. These five pillars make up a specific information assurance strategy that ensures the highest level of success for the corporate entities that apply it to their day-to-day business and operations.

Used by the United States government for their information assurance, the five pillars will each receive different amounts of use depending on the type of threat in play. The same is true for any company that uses the five pillars for the protection of information. Additionally, each firm will have varying needs for security based on the industry they are in as well as their size, reputation, Internet presence, and other factors. Of the tools that fall under the headings of the five pillars, those most widely used involve the education of personnel, the use of encryption, the implementation of the most up-to-date information technologies, and the use of some form of alarm system with the ability to warn personnel of an intrusion.

TOOLS OF THE TRADE

The ways in which data is protected vary based on need and the amount of data as well as the types of risks the particular data is likely to face. For example, the enormous amounts of proprietary information at Wal-Mart headquarters in Bentonville, Arkansas, will need a much higher level of protection than the recipe book for a local

bakery. Not to lessen the importance of the recipes, but the data contained in the Wal-Mart files involves not just insider information about Wal-Mart, but information about its thousands of suppliers, merchandisers, and affiliates, as well as thousands of other entities that interact with the retailer. So, information that is leaked from the Wal-Mart information system could conceivably impact the entire global economy, whereas a leaked cookie recipe, while important, only causes problems for the local baker.

Some of the tools of information assurance are physical, such as combination locks or keyed entries, paid guards, and access controlled by keycards. Other tools of information assurance are logical, meaning they are able to control people's access to information by way of computers and networks. These security tools include login names and passwords as well as firewalls, encryption of information, alarms that sound when they detect intrusions or irregularities in the system, and access control that is monitored and managed by system administrators. Still other information assurance tools are purely procedural, meaning they are tools that are used only by upper management and those with administrative access. These kinds of tools include the rules and regulations of an individual firm, often found in an employee handbook or appendix of company policies. These kinds of regulations determine how both physical and logical security measures will be used, monitored, and controlled; typically, the regulations also outline what kinds of disciplinary actions will be taken in the event that the laws or regulations of the firm are broken or disregarded. Sometimes procedural information assurance tools are the rules and regulations of a particular industry, and not those of an individual company. In these cases, the bending or breaking of rules and what the consequences are will not be determined by a firm, but by the regulating body in charge of that industry or the state or federal governments.

INFORMATION ASSURANCE IN E-COMMERCE

The job of information assurance for Internet retailers and other e-commerce vendors is not only to secure vital company information, but to secure customer data that is used to make purchases or to retrieve data from a Web site. The most important person who will need to be convinced that information security is intact will be the customer. Above all other reasons for information security in the e-commerce setting, security and privacy of customer and company information are the most important factors.

Customer data such as credit card information, address, social security number, date of birth, or any other personal information obtained by an Internet merchant must be secured during transactions. Many Web assurance services will help to secure private information obtained by the customer, and often, putting the well-known logo or

seal of some of these Internet security companies on the home page or bill-of-sale confirmation page of a merchant Web site will help customers feel safer about releasing personal information. WebTrust, BBBOnline, BizRate.com, Secure Site, and the Online Privacy Alliance are all Web assurance service companies that offer extensive transaction security and other online protection for both consumers and online merchants.

Due to the steady rise of Internet sales throughout the 2000s, information assurance in the field of e-commerce will likely be under development for many years to come. The future of successful e-commerce depends heavily on how well it can safely be conducted. This includes security and integrity of online transactions that are controlled by software, the establishment of stronger password and username generation technologies, better software for the detection of intrusion, and ironclad proxy servers. The implementation and consistent use of these logical, physical, and procedural tools will ensure consumer safety, lessen identity theft, and help to eradicate the Internet fraud that plagues e-commerce today.

DEFENSE-IN-DEPTH

According to the National Security Agency, bringing employees trained in information assurance together with the technology and specific company procedural guidelines across all levels of the corporate model will allow for the highest degree of information security. The practice of intentionally bringing the people, procedures, and technology together for the best and safest practice is referred to as *defense-in-depth* and calls for personnel trained in the technologies needed to achieve information security on every single level of the corporate model. Defense-in-depth is also an information assurance philosophy that mandates that regardless of where an enemy may stage his attack, he will encounter some level of security that makes the data he wants inaccessible. Additionally, when and if he is able to break through a specific secured area, the enemy will immediately encounter another form of defense, ideally until the attack is ultimately stopped altogether. This type of defense-in-depth barrier is only successful when the people, tools, and information assurance regulations are present on every level of a corporation's framework.

In addition to the most up-to-date technologies, the best training and education, and the most experienced personnel, many large corporations are now heading up information assurance teams with a chief information officer (CIO) who is responsible for keeping all pertinent company data accessible to authorized users and maintaining the safety and integrity of that information. A CIO should always be asking the questions: If information about my company's brand is compromised, what

will the repercussion to our finances and reputation be? Does the cost of security assurance solutions outweigh the cost of a potential threat? How at risk is our firm to dangers such as hackers and viruses? What types of security assurance measures will work best for our brand and in our industry? CIOs are becoming the mainstay for many IT departments and information safety branches of corporations and likely represent the future of the information assurance industry.

INITIAL PUBLIC OFFERING

An initial public offering (IPO) is the process through which a privately owned business sells shares of stock to the public for the first time. Also known as *going public*, an IPO provides a growing business with access to public capital markets and increases its credibility and exposure. It has long been considered a rite of passage that marks an important phase in a business's development. At the same time, however, staging an IPO is both time consuming and expensive. It requires companies to navigate a complex Securities and Exchange Commission (SEC) registration process and disclose a great deal of confidential information to potential investors. Furthermore, the success of an IPO is not guaranteed, and depends in part upon industry, economic, and market conditions that are beyond a company's direct control. Overall, the decision to go public is a complicated one that requires careful management consideration and planning.

There is no doubt that becoming a public entity offers a number of advantages to a business. In addition to gaining immediate access to capital to fund expansion, it also makes it easier for the firm to obtain capital in the future. The IPO process provides a company with a great deal of publicity, which may help increase its credibility with suppliers and lenders, attract new customers, and create new business opportunities. Going public also offers an opportunity for the company's founders and venture capitalists to cash out on their early investments, and provides a public valuation of the company to facilitate future mergers and acquisitions.

Some of the major disadvantages associated with going public include the high cost of staging an IPO (which may claim 15 to 20 percent of the proceeds from the stock sale), the demands on the time of managers (the process may take between six months and two years to complete), and the dilution of ownership and associated loss of management flexibility and control. In addition, the process of going public requires a private company to disclose confidential information about its strategy, capital structure, customers, products, competitors, profit margins, and employee compensation. Finally, becoming accountable to shareholders sometimes leads to an increased emphasis on short-term financial performance.

The first step in the IPO process involves applying to the SEC for permission to sell stock and preparing an initial registration statement according to SEC regulations. This statement includes a prospectus of detailed information about the company, financial statements, and a candid management analysis of the risks and benefits of investing in the company. The next step involves selecting an underwriter—usually an investment bank—to act as an intermediary between the company and the capital markets. The underwriter helps determine the valuation of the company and the suggested share price. It also helps assemble an underwriting team, which includes attorneys, accountants, and financial printers.

While the SEC completes its review of the registration statement—a period of time known as the *cooling off* or *quiet* period—the company undergoes an audit by independent accountants, files forms with the states where the stock will be sold, and begins marketing the investment to potential investors through *road shows* featuring top executives. Once the SEC review is complete, the company finalizes the registration statement, files a final amendment with the SEC, and agrees to an asking price for the shares of stock. Then the sale of stock finally takes place, overseen by the underwriter. Afterward, the underwriter meets with all involved parties to distribute funds from the sale, settle expenses, arrange for the transfer of stock, and file final reports with the SEC.

The pace of IPOs peaked in 1999, fueled by investor interest in Internet-related businesses. It declined markedly in 2000, as a drop in the value of technology stocks led to an overall drop in the stock market. Over the next few years, investors largely adopted a more cautious, back-to-basics approach toward IPOs. They increasingly demanded that companies demonstrate a proven business model, solid management team, large customer base, and strong revenue potential if they hoped to stage a successful

IPO. Another factor limiting the number of IPOs was the Sarbanes-Oxley Act (SOA) of 2002. Passed in the wake of several high-profile corporate accounting scandals, the act required the boards of public companies to include independent directors with financial experience. It also required public companies to form auditing committees chaired by an outside director. As a consequence of Sarbanes-Oxley, companies who are "IPO ready" are now larger and more established than in the past.

INNOVATION

Innovation is the act of developing a new process or product and introducing it to the market. It is essentially an entrepreneurial act, whether it takes place in a start-up firm, a large organization, a not-for-profit, or a public-sector agency. Innovation means change: sometimes radical change, such as the development of the computer, and sometimes incremental change, such as the modification of existing computer software. In either case, managers must develop processes to encourage and guide the changes taking place.

Sources of, and opportunities for, innovation in organizations are described below. Finally, the management principles underlying an innovative organization are identified.

INNOVATION MODELS

Business innovation has certain parameters and can be divided into categories based on company objectives. Three of the most common classifications are industry, revenue, and enterprise. Industry innovation involves pro-

duction methods and products themselves. Some successful companies achieve industry innovation by moving into new markets or producing complementary goods, finding new ways to profit on their existing business and resources. Other companies choose to invent new delivery methods, eliminating intermediaries. Still others create entirely new types of industries to sell in and create new customer bases.

Revenue innovation refers to new methods in pricing and value models that companies can use to improve their profits. This can work many different ways, such as using new legislation, new customer demands, and new resources to raise revenues. Anything that can be used along the production chain to decrease costs and change pricing plans can be considered revenue innovation.

Enterprise innovation is a wide category involving companies venturing into new areas, often involving vertical integration up and down the supply chain, where businesses begin to create their own products or begin plans to supply themselves with necessary resources. Enterprise innovation can also work through methods of concentration, where companies outsource or drop various stages of production to focus on others.

SOURCES OF INNOVATION

Innovation generally stems from the purposeful search for opportunities. Management guru Peter Drucker identified that opportunities for innovation exist both within and outside a company or industry. Opportunities internal to a company include unexpected events, incongruities in processes or between expectations and results, process needs, and changes in the marketplace or industry structure. Opportunities external to a company include demographic changes, changes in perception, and new knowledge.

Incongruities. Incongruities result from a difference between perception and reality. Federal Express was able to capitalize on consumer dissatisfaction with the U.S. Postal Service and demonstrate that individuals and companies were willing to pay a premium for overnight delivery of packages and documents.

Likewise, Southwest Airlines provided a dramatically different approach to airline service. Its low-fare, no-frills, first-come-first-seated approach has garnered devoted customers. Southwest Airlines has remained profitable for thirty-five straight years (as of 2008), even during the economic downturn following the terrorist attacks of 2001, when many airlines struggled to remain in business.

Process Needs. Process needs innovations are those that are created to support some other process or product. The development of the ATM (automatic teller machine) and

now Web-based and Internet banking options allow individuals to do their banking when the bank is closed and without relying on tellers being available. This has freed tellers from performing many routine functions such as cashing checks and has improved both efficiency and profit margins for banks.

Market and Industry Structure Changes. Industry structures change in response to growth and changes in the marketplace. One of the most dramatic changes can be seen in the health care industry. The rise of HMOs (health maintenance organizations) and the decline of the traditional fee-for-service plans have impacted the health-care industry as a whole. The development of the personal computer also had a far-reaching impact on the computer industry as a whole. Until the personal computer, manufacturers of large mainframe computers, terminals, and software developed for specific uses within a firm dominated the computer industry. With the adoption of the personal computer and advent of the laptop computer, the composition of computer sales and marketing changed dramatically.

Demographic Changes. Demographic changes are shifts in the makeup of the population. Increases in the Hispanic and Asian populations in the United States create opportunities for new products and services, such as cable television stations targeting these audiences. Innovations in prepared meals and takeout food are meeting the needs of busy two-income families and single-parent families.

Changes in Perception. Americans have become more health conscious and we have seen the rise in popularity of stores such as GNC which cater to the demand for vitamins and other supplements. Similarly, stores such as Whole Foods provide organic produce, meats, dairy, and fish free from additives to satisfy a growing market demand for chemical-free products.

New Knowledge. New knowledge or technology is one of the strongest forces for innovation. Many companies, of all sizes and levels of sophistication, now have a Web presence on the Internet with the capability of connecting their products with customers nearby or on the other side of the globe. No longer are consumers limited to the daytime hours for their activities; online stock trading, shopping, and banking are examples of services that are accessible at any time of day or night via the Internet. Other opportunities are being explored in the fields of genomics and nanotechnology. These technologies and systems will develop even further as consumers continue to demand new and innovative products and immediate access to information, goods and services.

MANAGING INNOVATION

Innovation must be seen as a process occurring within an organization, not a single event. This process can be managed. In general, the process follows five stages: (1) idea generation, (2) initial screening, (3) review, (4) seeking sponsorship, and (5) sponsorship and commercialization. At each of these stages the organization's culture must be designed to support the innovation process.

Idea Generation. Idea generation requires a supportive organizational culture. Ideas, and the people who develop them, are fragile, and if the organization does not support them, they will not develop. A supportive culture requires that the organization allow for experimentation and failure. In other words, not every idea will be commercially viable, but mistakes are to be learned from and learning should be celebrated. W.L. Gore is a company that celebrates learning and innovation. Each plant is kept small and everyone in the company is allowed to experiment with the products. In addition to the familiar GoreTex polymer coating, the company also manufactures products for the medical industry, NASA, and industrial use. The company operates internationally and holds hundreds of patents.

Initial Screening. The screening process can be made easier by assigning a facilitator from outside the organization who can help guide the initial idea through the organization's systems, as well as act as an advocate for the idea. At this stage, the idea is evaluated and possibly revised before being sent on to a group to review for further development.

Review. At this stage, the idea should be sufficiently developed to present to a group within the organization who will make a decision about funding further development. 3M has a long-standing process such as this. The Post-It notepads are probably the best-known illustration of the effectiveness of the process. Although no uses for the adhesive were initially found, the researcher was allowed to continue to spend time developing the product. The review process did not initially continue direct funding, but by allowing the researcher time, the company indirectly funded the development of a very successful product.

Seeking Sponsorship. In most organizations, an idea needs a sponsor to continue to move forward. The sponsor must be convinced of the value of the idea to the organization. Effective champions frequently are managers who know how to navigate the corporate structure for support and resources. In addition, they are effective at putting together a cross-functional team to help develop all aspects of the new idea. Both 3M and W.L. Gore have instituted systems that facilitate this process.

Sponsorship and Commercialization. At this stage, the champion or sponsor takes the project forward through the final phases of corporate approval to commercialization. Many organizations, including Dow Corning, PepsiCo, 3M, and Black & Decker, spend a great deal of time interacting with customers at this stage. Customer input can help with final design issues, with searching out new uses for a product, and with simplifying processes. According to N. Radjou as quoted in *Industrial Management,* "Customers seek innovations that enhance their life cycle experience with a product—not the product-centric improvements in functionality and reliability that R & D engineers focus on." Utilizing consumer input can help companies focus their creativity on the products and improvements that will most satisfy consumer needs and wants.

DISRUPTIVE INNOVATION

Disruptive innovation is a type of innovation that reinvents a market or creates an entirely new system, product, or business concept. It is disruptive because it causes the entire industry to react, either by making innovations of their own or by copying the first innovation to stay profitable. Some types of disruptive innovation create entirely new industries that force all other industries to react, such as the adoption of a new technology or new product. Recent examples of disruptive technology include:

1. Peer-to-peer networking software
2. Audio and video compression technology
3. Personal computers
4. Steel mini-mills
5. E-commerce
6. Cell phones

Other potential disruptive technologies include renewable energy sources and advances in biochemistry. Disruptive innovation will always have certain identifiable effects on the companies that develop them and the surrounding business. Those looking to foster or create disruptive innovations can depend on several key pieces of advice:

- Expect growth from disruptive innovation. Whatever type of innovation a company attempts, whether it affects the way business is done or produces a new type of business completely, it will place that company ahead of its competitors. In order to fully capitalize on the innovation, the company should create processes to keep their ideas sustainable. Some disruptive innovations are simply vast improvements on older designs, which require excellent marketing and integration into existing processes. Other disruptive innovations are breakthroughs into new

fields that will rocket companies into prominent positions, which they must then learn to maintain by designing ways to steadily produce or use their discovery. A company can enter into an unexplored field and then use more innovations along the way to refine and market their ideas.

- As previously mentioned, disruptive innovations will either create markets that did not exist before or transform the lower ends of existing markets. In the first case, companies have a serious advantage—their competitors will, in the beginning, lack the means to enter the new market. The new company must concentrate on making their product or offering their service and marketing it to the correct people, because a new market means an entirely new set of customers. The second type of disruptive innovation will occur at the lower end of some existing market, transforming a process that has already been in place. This will allow the innovating company to grow within its own industry, pushing it ahead of its old competitors through new ways of doing business.

- Opportunities go through several phases before they become full innovations. Some companies have a system in place to help ideas move through the business until senior management accepts them and forms plans to implement the innovation. Unfortunately, these systems can hamper the development of true disruptive innovation. Disruptive opportunities, once fielded by a company's process, are usually stripped of their unique qualities and made to fit into a preexisting expectation that the company has for useful creativity. To truly create disruptive innovations, a company must learn to accept potential ideas even if they may appear outlandish.

- When forming a new product, businesses should attempt to market it to the proper consumers. This does not necessarily mean trying to appeal to their existing customers, but focusing on locating customers who would profit by their innovation. Innovative products can fail if not marketed to the correct audience. Customers should not be asked to accept completely new products without good reason.

- Innovation requires decisions concerning product integration. Companies can choose to be involved in every part of their new product's creation, or they can choose to specialize in one particular part of the supply chain. Choosing the correct activities to specialize in allows the company to maximize benefits from the innovation process.

- Disruptive innovations cannot be expected to grow into international businesses overnight. Managers

encouraging innovation should aim for profitability before growth. Profitability, though it may take trial and error, will ensure success in the long-term, while growth can easily collapse on itself if not accompanied by sustainability.

Companies can seek disruptive innovation in other areas beside products. Services and supply chain methods can also be subject to disruptive ideas. Companies can attempt transporting their old products in new fashions, as the band Radiohead famously did in 2007 by allowing their fans to download their album *In Rainbows* from their Web site, at whatever price the music-buyer thought was fair. They can also try to reinvent old processes in such ways that they appeal to new customers.

EMPLOYEE INNOVATION

Employees can be a reservoir of potential ideas, innovations, and new ways of thinking; companies just have to find a way to tap into them. Even in companies that encourage employee innovation, employees can feel restricted by the heavy company process involved in developing an idea. Expression should be encouraged by companies looking for internal innovation, but how? GovLeaders has some ideas, in the form of five 2008 suggestions designed to foster employee input:

- Managers should get to know every employee. If managers know their employees, they can know how to encourage each person to develop their own unique ideas. Motivation can often depend on knowledge of what is important to employees.

- Employees should be challenged to improve processes. If employees are asked specifically to look at the operations they are involved in, they will be much more likely to notice areas of possible improvement. Managers can implement plans to ask employees for improvement ideas at regular intervals.

- There is a mechanism that some companies use called "Employee for a Day." This involves employees taking regular turns in running through their business process from the outside, following a product or service naturally from start to completion. This way people can see problems they may not have normally noticed.

- Reward systems can be implemented specifically to award employees who improve the operation process in some way. "Idea" awards can build enthusiasm for new ideas and encourage an atmosphere of creative solutions and healthy competition.

- How will employee ideas make any difference? In order to profit from their employees' ideas, companies need a system to implement employee ideas. The employee who created the innovation process should, as much as

possible, oversee its implementation so that a healthy sense of ownership can be developed. Managers, after all, will usually have enough to deal with without managing someone else's ideas.
