SOCIAL DYNAMICS

The term "social dynamics" is used in a wide variety of contexts that vary in level from the societal to the individual and in approach from qualitative (verbal) to quantitative (mathematical). For example, on the societal level, one can point to Sorokin's ([1937-1941] 1957) qualitative approach in *Social and Cultural Dynamics*. At the other extreme, though also at the global level, there are works such as Forrester's (1971) mathematical, computer-oriented approach in *World Dynamics* and the statistical, empirical approaches found in Ramirez et al.'s (1997) study of the adoption of women's suffrage throughout the world and Frank et al.'s (1997) research on the spread and development of a world environmental regime. On the individual level, examples of qualitative approaches include Hareven's (1982) *Family Time and Industrial Time* and the relevant chapters in Bertaux and Thompson's *Pathways to Social Class* (1997). Also on the individual level, there are mathematical approaches such as White's *Chains of Opportunity* (1970) and statistical, empirical approaches such as Zhou et al.'s (1996, 1997) studies of stratification dynamics in China. Studies that combine qualitative and quantitative approaches are rare. A classic example is Elder's *Children of the Great*

Depression (1974). Because of the great diversity in substance and approach, one cannot identify a single line of cumulative research on social dynamics. Instead, there are distinct, loosely related developments that arise in several contexts.

This article has five main sections. The first describes the three main sociological contexts for studies of social dynamics and summarizes their contributions to cumulative sociological research. Since the term “social dynamics” invariably implies a focus on change over time in a social entity, it is closely related to the term “social change.” Some of the key differences between the two terms are discussed in the second section. The third section summarizes reasons for studies of social dynamics in general and the formulation of dynamic models in particular. The fourth section explains the fundamental differences between dynamic models and other types of models. The fifth section reviews the main variations in the types of dynamic models that sociologists have used.

MAIN CONTEXTS

In one context, social scientists refer to the *dynamics of a phenomenon*, meaning that they focus on how it changes over time. In this traditional usage, the emphasis is primarily on a substantive social phenomenon, and research progress depends on acquiring a deeper theoretical understanding and expanding empirical knowledge about that phenomenon. Topics vary, for example, from “group dynamics” (social interactions among the members of a small group over time) to the “dynamics of development” (change from a traditional rural society to a modern urban industrial society and then to a postindustrial society that belongs to a global system). It is hard to identify substantive commonalities across disparate topic areas except ones of the most abstract sort, for example, that social change is universal but varies in speed. Despite the limited number of substantive generalizations about social dynamics, the study of social dynamics is theoretically and methodologically helpful for reasons that are summarized in the third section.

In a second context that is more typical in recent work, researchers refer to a *dynamic model of a phenomenon*, meaning that their goal is to formulate, test, or explore the consequences of a set of mathematical assumptions or a computer algo-

rithm that is intended to mimic the behavior of the phenomenon of interest. For example, researchers may use a model of population growth and decline in a society; a model of foundings, reorganizations, divestments, mergers, and failures in businesses or other organizations; or a model of the diffusion of an innovation through a population (e.g., the adoption of a new social policy by governments or a new contraceptive by women). Despite the substantive diversity, the formal properties of dynamic models of different phenomena are often similar. This similarity has fostered cumulative progress in studies of social dynamics because a model developed for one topic may be transferable to another topic after only minor modifications of its formal properties. For example, the notion that growth rates are “density-dependent” (depend on population size) arose first in dynamic models of population growth, with the main rationale being that a growing population increases competition among members of the system and depletes environmental resources, eventually leading to a lower rate of population growth. Later this notion was applied to explorations of dynamic models of the formation and survival of unions, businesses, and other kinds of organizations and how those processes depend on the structure of competition (Hannan and Carroll 1992; Carroll and Hannan 2000).

In a third context, authors use a *dynamic analysis of empirical data on a phenomenon*, meaning some form of temporal (longitudinal) analysis of data pertaining to different points in time. Since dynamic analyses are based on dynamic models, work done in the second and third contexts has close parallels. Typically, however, a focus on dynamic models implies a greater emphasis on the model itself, whereas a focus on dynamic analyses indicates a greater stress on the problems of estimating and testing the model as well as the resulting substantive empirical findings. Advance made in methods for the dynamic analysis of one social phenomenon often can be used in dynamic analyses of other phenomena. This also has facilitated cumulative progress in research on social dynamics. For example, Tuma et al.’s (1979) proposal for *dynamic analysis of event histories*, which originally was applied to data on marriage formation and dissolution, subsequently has been applied to dynamic analysis of data on occupational and geographic mobility, organizational mergers and fail-

ures, changes in political regimes, the adoption of governmental policies, and many other social phenomena.

SOCIAL DYNAMICS VERSUS SOCIAL CHANGE

Although the terms “social dynamics” and “social change” both indicate a focus on change over time, they are used in different circumstances. Social dynamics has a more precise meaning.

First, social dynamics usually presumes change within a social *system*. That system may consist of similar entities (e.g., members of a family, families in a neighborhood, nations in the world) or disparate entities (e.g., different types of actors in a political or economic system) or various attributes of a single social entity (e.g., an individual’s education, occupational prestige, and income or a business firm’s age, size, and structure). The system usually is regarded as bounded, allowing the rest of the world to be ignored for purposes of explanation.

Whether the system consists of actors or variables, the term “system” presumes interdependence and typically involves feedback. Thus, action by one entity in the system leads to counteraction by another entity. For example, managers of a firm may counter a strike by workers by acquiescing to the workers’ demands, outwitting them, or hiring nonunion laborers. Alternatively, change in one variable in the system leads to an opposing or reinforcing change in one or more other variables. For example, an increase in educational level is followed by an increase in prestige and then an increase in income. Changes resulting from interdependent forces and feedback effects within the system are called *endogenous* changes.

There also may be *exogenous* changes, that is, unexplained (perhaps random) changes that influence change within the system under study but whose causes originate outside that system. For example, in analyses of interaction between a husband and wife, changes in the economy and society in which the couple lives usually are treated as exogenous changes that affect the couple’s behavior, but the societal-level changes themselves are not explained.

Because of interdependent forces and feedback effects as well as possible exogenous changes,

social dynamics typically implies a concern with *complex changes*. Simple linear changes or straightforward extrapolations of previous trends are rarely of primary interest.

Second, social dynamics connotes social changes that have a *regular pattern*. That pattern may be one of growth (e.g., economic expansion, growth of a population), decline (e.g., rural depopulation, the extinction of a cultural trait), cyclical change (e.g., boom and bust in the business cycle), a distinctive but nonetheless recurring transition (e.g., ethnic succession in neighborhoods, societal modernization, the demographic transition from high mortality and fertility to low mortality and fertility), or simply a drift in a particular direction (e.g., the slow but accelerating spread of a social belief or practice through a population).

Third, social dynamics usually implies a degree of *predictability*: Social change not only can be comprehended in terms of post hoc reasons but also can be explicitly modeled. The model, whether it consists of verbal statements or mathematical equations or computer instructions, involves a set of assumptions or propositions that permit fundamental patterns of change to be deduced. In contrast, although a unique historical event may foster social change, its uniqueness makes successful prediction impossible. One challenge in studies of social dynamics is therefore to convert phenomena that are unique on one level to ones that are representative and therefore predictable on another level. Thus, what some regard as a unique historical event, others see as an example of a regular pattern of change. For example, to a historian, the Russian Revolution of 1917 is a unique event, whereas a sociologist may regard it as exemplifying a response to changes in underlying social conditions. Thus, while recognizing many distinctive factors, Skocpol (1979) argues that similar patterns of causes underlie the dramatic political and social transformations that historians call the French, Russian, and Chinese revolutions.

Fourth, the term “social dynamics” is used more commonly than is the term “social change” when regularity in patterns of change is associated with some kind of *equilibrium* (steady state or homeostasis), that is, when feedback effects are such that small deviations from equilibrium lead to compensating effects that cause equilibrium to be restored. For example, in the United States, the

distribution of family income (the share of total income received by different families) was remarkably stable throughout the twentieth century despite tremendous growth in population and economic output and social upheavals such as the civil rights and women's liberation movements. This stability suggests that the process governing the allocation of family income was nearly in equilibrium. The term "social change," especially change seen as part of a unique historical process, usually is associated with change from one distinctive situation to another, very different situation. It implies the antithesis of social equilibrium. The way in which the social status of women and minorities has changed during the twentieth century exemplifies social disequilibrium.

Studies of social dynamics do not necessarily assume the existence of an equilibrium. This point is made clear by studies of the dynamics of economic growth, which often envision a process of never-ending expansion and improvement. Similarly, some dynamic processes imply not a steady-state condition but continual oscillation between conditions. A classic sociological example is Pareto's (1935) analysis of the circulation of elites.

Fifth, the term "social dynamics" is almost always used in situations in which there is an interest in the *process* of change: the step-by-step sequence of causes and effects and the way in which intermediary changes unfold. It is rarely used when only a simple before-after comparison of the condition of the system is the object of interest. Instead, when authors use the term "social dynamics," there is usually a sense that the details and sequencing of changes are important because changes are contingent: If the sequence had been interrupted or altered at an intermediary point, the final outcome might have been different. For example, models of social protest often recognize that the state's response to protests may range from peaceful conciliation to violent suppression. The nature of the state's response is an important contingency because it affects the likelihood, timing, and character of future protests.

Sometimes the sequence of changes occurs on the level of the system as a whole rather than on the level of individual members. For example, in a simple model of population growth, individual-level changes are very elementary: birth followed by death, with the timing of the two being the only

question. On the population level, the addition and loss of individuals over time represent a sequence of changes even though on the individual level there may be few, if any intermediary changes and thus little sense of a sequence of causes and effects.

REASONS FOR STUDYING SOCIAL DYNAMICS

What motivates sociological interest in social dynamics in general and dynamic models in particular? The most potent reason is the long-standing interest of sociologists in social change, coupled with an increasing recognition that a tremendous amount of scientific leverage can be gained from identifying regularities in patterns of change and then formulating sociological theories that explain them, that is, from studying social dynamics and not just unique historical events. Leverage comes not only from the increased richness of theories of social dynamics but also from greater methodological power in discriminating among competing explanations, as is indicated in more detail below.

As observers of the great social transformations of the nineteenth century, the founders of modern sociology (e.g., Marx, Spencer, and Weber) were keenly interested in social change. However, in the middle of the twentieth century, when structural functionalism and Parsonian thought were dominant, social change was regarded as a minor subfield of sociology. Interest in social change was renewed after a reawakened recognition of social conflict and the concomitant criticism of the assumption of social equilibrium in structural functional theories.

An accelerating pace of global change has added to this interest (Sassen 1988; Boli and Thomas 1997). Rapid growth of the world's population; high levels of mobility of people, goods, and capital between and within nations; the transformation of agricultural societies to industrial and postindustrial societies; social upheavals ranging from strikes, to social protests, to revolutions, to wars; the creation of new organizational forms (e.g., holding companies, multinational corporations, international organizations); fundamental transformations of political regimes, including the failure of communist governments; steady increases in the number and volume of new technological innovations; depletion of natural resources; ex-

tion of plant and animal species; and changes in climate induced by human activities are only a few of the world-level changes that make it virtually impossible for sociologists who study large-scale social systems not to be interested in social change.

Although some scholars view many of these changes as historically unique, the concrete social and economic problems that result from them motivate attempts to find regular patterns and predict future changes, in short, to develop dynamic models of societal and global changes. Consider the massive changes in eastern European nations that began in the late 1980s. From the late 1940s to the late 1980s, those nations were governed by totalitarian polities and had command-type socialist economies. Now most of them appear to be headed in the direction of market-type capitalist economies and democratic polities. The intellectual challenge, as well as a major problem for policymakers, is to develop a theory of the transition from one to the other, that is, a theory of the dynamics of the social change that is expected to occur. The fact that no satisfactory theory existed when the transition began was apparent to the general public as well as to social scientists. It points to the practical as well as scholarly value of studying social dynamics.

Sociologists who study micro-level phenomena (individuals and families) also cannot ignore social change. The life course of individuals in modern societies has a typical sequence of activities associated with aging (e.g., birth, day care, school, work, marriage, child rearing, retirement, death) that commands considerable attention by sociologists. Historical changes in family patterns (e.g., increases in premarital cohabitation, delays in marriage, changes in husband–wife roles, increases in divorce, baby booms and baby busts, increasing institutionalization of the elderly) also put social change at the forefront of the attention of sociologists who study the family. These subjects are perhaps more easily viewed in terms of social dynamics than are ones pertaining to global and societal changes because similar patterns across individuals and families are more readily apparent.

Sociologists who study behavior in small groups were among the earliest to express an interest in social dynamics. This interest received a major boost from Bales's *Interaction Process Analysis* (1950).

Game theorists, who attempt to explain the moves and countermoves of actors in highly structured situations, also exemplify a concern with social dynamics in small groups, though they, much more than Bales and his intellectual descendants, concentrate on formal models and deemphasize hypothesis testing and empirical results (see Shubik 1982).

There are also metatheoretical and methodological reasons for studying social dynamics even when the primary intellectual concern is with statics, that is, with relationships among actors or variables at a single point in time.

First, studies of relationships at a single point in time implicitly assume a steady state or equilibrium. Otherwise relationships at a given time point must be transitory and in the process of changing, a situation that would degrade their potential contribution to enduring sociological knowledge. A steady state may or may not exist. If it does not exist, one needs to study social dynamics to understand relationships at a point in time. If a steady state does exist, much can be learned by studying social dynamics that cannot be learned easily by studying relationships at a single point in time. For one thing, two theories may imply the same relationship among variables at a given point in time but imply different time paths of change. In that case, a study of social dynamics can differentiate between them, whereas a study of the steady state cannot. For another thing, a theory of relationships at a point in time is invariably the special case of one or more theories of change over time, and the latter theories almost always have a richer set of implications than do the former. This means that in general there are more ways to test theories of social dynamics than to test theories of social statics.

THE NATURE OF DYNAMIC MODELS

As was noted earlier, developments in dynamic models (and derivative developments in methods of dynamic analysis) are the major commonality in sociological studies of social dynamics. To understand the main features of dynamic models, it is important to differentiate them from other types of models.

The most basic distinction is between *static* and *dynamic* models. Static models describe rela-

tionships among social actors in a system or among the attributes of a social entity at a given point in time. As was noted earlier, they implicitly assume a steady state or equilibrium, a phenomenon that is about as common in nature as a vacuum. In contrast, dynamic models describe the process or sequence of changes among actors in a social system or among the attributes of a social system.

Dynamic models also can be contrasted with *comparative static models*, which are especially common in economic analyses and analyses of social experiments. Although both deal with change over time, they differ in an important way. The process of change leading from conditions at the earlier time point to conditions at the later time point is fundamental to a dynamic model. In contrast, the change process is ignored in a comparative static model, which resembles a black box that relates conditions at one point in time to conditions at a later time.

To illustrate this distinction, consider alternative ways of explaining a son's occupational prestige. In a comparative static model, the son's prestige may be related to his father's socioeconomic status and his own education without any attention being paid to the mechanisms and processes that lead from those background conditions to the son's condition as an adult. In a dynamic model, the father's socioeconomic status and the son's education may be seen as giving access to certain entry-level jobs, which in turn provide opportunities for further career mobility, leading to jobs with varying levels of prestige. In a dynamic model, the timing and sequence of job shifts are of concern, not just the son's initial condition (i.e., his father's social status and his own education). In summary, dynamic models are used to explain not only why the later condition of a phenomenon differs from its earlier condition but also how a sequence of changes leads from one condition to the other.

TYPES OF DYNAMIC MODELS

Different types of dynamic models are distinguished on the basis of a variety of formal properties. One basic distinction seems to be whether the components of the system are social actors or the attributes of a social entity. In the former case, dynamic models of the behavior of social actors are developed: Actor A does X, in response actor B

does Y, then actor A does Z, and so on. Although much of game theory is not concerned with dynamic models, some of it formulates precisely these kinds of models. In the latter kind of dynamic model, values of variables describing the social entity are related to one another. Ecological theories of organizational survival utilize these models, for example, relating the degree of environmental variability and the degree of specialization of various types of social organizations in the environment to the survival of these types (Hannan and Freeman 1987). The distinction between systems of actors and systems of variables is not as important as it may seem at first because the behaviors of actors usually can be translated into variables.

A more basic and important distinction is whether time is discrete or continuous. Most empirical phenomena can change at any moment, and this leads one to expect that time should be treated as continuous in most dynamic models. In fact, time more often is treated as discrete for two main reasons. First, the empirical data used to test a dynamic model usually measure time at only a few discrete points. Some researchers then find it convenient to build a dynamic model of the data rather than model the underlying social process. Second, some researchers consider discrete-time models to be simpler and believe that little information is lost from approximating truly continuous-time processes with discrete-time models. If the discrete time points in the data are sufficiently numerous and close together, the approximation is almost always satisfactory. If they are not, important intermediary steps in the process are likely to be ignored, possibly resulting in misleading conclusions. Whether discrete-time models are simpler than continuous-time models is less clear. To some extent, it is a matter of a researcher's taste and training.

Another key distinction concerns whether the variables that describe the social system are discrete, metric, or a mixture of the two. Discrete variables have a finite set of values; for example, political regimes may be categorized into a small number of basic types. Metric variables have a continuum of values; for example, a person's income and occupational prestige usually are treated as continuous variables. In fact, in both instances, the number of values is finite but is so large that treating the values as continuous may be conve-

nient and is often fairly realistic. Age is a continuous variable, but measurements of it are always discrete (e.g., to the nearest year, month, or day).

A distinction also may be made in the way in which variables in a system change over time. By their nature, discrete variables can change only in jumps. For example, there may be a sudden change from a military political regime to a multiparty government. Metric variables often are regarded as changing gradually. For example, a firm's profits may be treated as shifting upward or downward by small increments. In fact, metric variables also may change in jumps. For example, income may fall from a high value to nearly zero when a family's main breadwinners lose their jobs.

Another important distinction is whether the change process is treated as deterministic or stochastic (having a random component). There is a broad consensus that stochastic models are almost always more realistic. Few social changes occur in a strictly determined fashion, and those which do change deterministically are rarely sociologically interesting. Nevertheless, deterministic models can be useful when the solution of realistic stochastic models presents severe technical problems. Those formidable problems tend to occur when there is a high degree of interdependence in the social system (e.g., in models of the diffusion of an innovation) and when both time and outcomes are treated as continuous.

Whether time is treated as discrete or continuous, models of changes in discrete variables are invariably stochastic because changes by jumps almost dictate reference to probabilities. By contrast, continuous-time models of changes in metric variables are typically deterministic.

Some progress has been made in developing empirically estimable stochastic models of heterogeneity in the spread of a social practice in the presence of interdependent influences in a social system (Strang and Tuma 1993). Davis and Greve (1997) provide an intriguing application of this modeling approach to the use of "poison pills" and "golden parachutes" among firms.

Formal dynamic models are of two main types. In one type, the model consists of a set of mathematical equations that relate some elements of the system to other elements. In the other type, the model consists of a set of computer instructions

that relate inputs of various variables and/or actors at one time to outputs at a later time. The computer instructions in fact represent mathematical equations that are so complex that they cannot be solved in practice without the aid of a computer. Still, it is convenient to think of computer models as very complicated mathematical models.

A clear introduction to both discrete-time and continuous-time deterministic models of metric variables can be found in Baumol's *Economic Dynamics* (1951), which also introduces several economic theories of potential interest to sociologists, including theories of wages and profits in firms and economic growth. For a discussion of deterministic models of change in metric variables, see Doreian and Hummon (1976).

Two of the early classic discussions of stochastic models of change in discrete variables are Coleman's *Introduction to Mathematical Sociology* (1964) and Bartholomew's *Stochastic Models for Social Processes* (1973). Tuma and Hannan's *Social Dynamics: Models and Methods* (1984) discusses both deterministic and stochastic models of change in metric variables in continuous time as well as continuous-time stochastic models of change in discrete variables. This work also discusses metatheoretical and methodological reasons for studying social dynamics, applies dynamic models to a variety of different sociological problems, and provides an extensive bibliography pertaining to models and methods used in studying social dynamics. It also contains a comprehensive introduction to event history analysis.

CONCLUSION

Sociologists, whether studying whole societies or small groups, have had a long-standing and far-reaching interest in social change. Traditional approaches focused on specific substantive phenomena and, especially in macro-level studies, often stressed unique historical occurrences rather than common dimensions underlying patterns of change. Recent studies of social dynamics usually focus on what is regular and predictable about social change and the social mechanisms that generate a sequence of contingent changes. Often they embed ideas about change in dynamic models and test them in dynamic analyses of over-time data. This

approach has been especially valuable in fostering cumulative research.

NANCY BRANDON TUMA

SOCIAL EXCHANGE THEORY

Social exchange theory is a major theoretical perspective in sociology. Within this framework, social behavior is viewed primarily in terms of the pursuit of rewards and the avoidance of punish-

ment and other forms of cost. Individuals engage in interaction to meet their needs. The basic unit of analysis is the relationship between actors. Thus, exchange theorists view social relations and the social structures generated by the ties that bind people in different forms of association as the central object of sociological inquiry. Major topics of study within this tradition of research include the nature and effects of the interconnections among actors and the distribution of power within exchange structures. Power and status relations among actors in different types of social structures are considered key forces in determining the nature of structural change over time. The major exchange theorists all have treated power, structural sources of power, and the dynamics of power use as primary in their theoretical formulations.

Social exchange theory derives from several distinct lines of theoretical work in the social sciences, including social behaviorism, utilitarianism, and functionalism (Turner 1986). Major proponents of the social exchange perspective within sociology include Homans (1961, 1974), Blau (1964, 1987), and Emerson (1962, 1972a, 1972b). Within psychology, the work of Thibaut and Kelley (1959; Kelley and Thibaut 1978) bears a strong resemblance to social exchange theory in its emphasis on the interdependence of actors and the social implications of different forms of interdependence. Anthropologists such as Malinowski (1922), Mauss (1925), Schneider (1974), and Levi-Strauss (1949, 1969) have contributed in different ways to the emergence of this theoretical perspective (see Ekeh 1974). In addition, the foundation of microeconomics has much in common with some variants of social exchange theory (Heath 1976). This affinity is clearest in Blau's *Exchange and Power in Social Life* (1964) and in subsequent theoretical developments (e.g., Cook and Emerson 1978; Coleman 1972, 1990). The breadth of the intellectual heritage of social exchange theory accounts in part for its continued significance in the social sciences.

Homans's well-known essay "Social Behavior as Exchange" (1958) clarified the nature of this theoretical orientation and introduced it into mainstream sociology. An elaboration of Homans's perspective was published in *Social Behavior: Its Elementary Forms* (revised in 1974). An important distinguishing feature of Homans's work was its reliance on the language and propositions of behavioral psychology. The use of operant psychol-

ogy as the behavioral basis of exchange theory created much of the early controversy surrounding the utility of this perspective for sociologists. In particular, the corresponding claim made by Homans that laws of social behavior could be "reduced to" the basic underlying principles of psychological behaviorism generated much debate (e.g., Deutsch 1964). According to Homans, "The general propositions we shall use in explanation are psychological in two senses: they refer to the actions of individuals and they have . . . been formulated and tested by psychologists" (1974, p. 12). However, Homans explicitly took as the major theoretical task the explanation of social phenomena. This emphasis on social behavior and the social structures generated and altered by human social interaction has sustained the influence of social exchange theory in sociology. In this regard, Homans viewed the line drawn between psychology and sociology as fundamentally arbitrary.

The initial theoretical formulation developed by Homans (1961) and revised in 1974 included five main propositions, all of which have to do with the fact that behavior is a function of its payoffs: the consequent rewards and punishments. The first proposition is the "success proposition," which states that the more frequently an activity is rewarded, the greater is the likelihood of its performance. Behavior that generates positive consequences for the individual is likely to be repeated. The second proposition, the "stimulus proposition," stipulates that similar environmental or situational circumstances will stimulate behavior that has been rewarded on similar occasions in the past. This allows for the generalization of behavioral responses to "new" situations. The "value proposition" specifies that the more valuable the result of an action is to the actor, the more likely that action is to be performed. This proposition is qualified by the "deprivation-satiation" proposition, which introduces the general ideal of diminishing marginal utility. According to this proposition, the more often a person has recently received a particular reward for an action, the less valuable is an additional unit of that reward. Thus, some rewards become less effective over time in eliciting specific actions, though this is less true for generalized rewards such as money and affection and for anything for which satiation is less likely to occur except at extreme levels. The fifth theoretical proposition in Homans's basic framework specifies the

conditions under which persons react emotionally to different reward situations. This proposition has two parts. People who do not receive what they anticipate are expected to become angry and behave aggressively, based on the original Miller and Dollard (1941) "frustration-aggression" hypothesis (see Homans 1974, p. 37). People who receive more than they expect or do not receive anticipated punishments will be happy and will behave approvingly. This system of propositions forms the original core set of ideas of what has come to be called social exchange theory.

Homans's (1961, 1974) uses this set of theoretical ideas to explain phenomena such as the exercise of power and authority, cooperation, conformity and competition, structures of sentiment and interaction, status and influence, satisfaction and productivity, leadership, distributive justice, and the emergence of stratification. He addressed these social phenomena primarily in terms of the nature of the interpersonal relations involved. Furthermore, he emphasized "elementary" forms of behavior, or what he referred to as the "subinstitutional" level of analysis. "We gain our fullest understanding of the elementary features of social behavior by observing the interactions between members of small, informal groups," Homans (1974, p. 356) argued. By studying such forms of behavior, he hoped to illuminate the elementary, informal subinstitutional bases of more complex forms of social behavior that often are more formal and institutionalized. What he bequeathed to modern-day sociology, besides his particular form of theorizing, was an emphasis on the microfoundations of social structures and social change.

Whereas Homans focused on elementary forms of behavior and the subinstitutional level of analysis, Blau (1964, 1987) moved beyond the micro level to the institutional level, dealing with authority and power, conflict, and change in the context of institutionalized systems of exchange. In disagreement with Homans's reductionistic strategy, Blau (1987, p. ix) claims that his "theory is rooted in the peculiarly social nature of exchange, which implies that it cannot be reduced to or derived from psychological principles that govern the motives of individuals, as Homans aims to do." In distinct contrast to Homans's reductionism, Blau assumed that social structures has "emergent" properties that cannot be explained by character-

istics or processes that involve only the subunits. Thus, Blau parted company from Homans in two major ways. First, Blau's framework was not based on principles of behavioral psychology; instead, he introduced microeconomic reasoning into the analysis of distinctly social exchange. Second, he explicitly introduced the notion of emergent processes into his theoretical treatise, not only rejecting reductionism but also expanding the theory to extend far beyond its original subinstitutional base.

Blau (1964) developed a general framework for analyzing macro structures and processes based on an extension of his micro-level theory of social exchange processes. Drawing on Simmel's understanding of social life, he explains the general structure of social associations rooted in psychological processes, such as attraction, approval, reciprocation, and rational conduct. Group formation, cohesion, and social integration as well as processes of opposition, conflict, and dissolution are explained in terms of social exchange processes. These forms of social association generated by exchange processes come to constitute very complex social structures (and substructures) over time. These more complex social structures are then examined by Blau as they are created and changed by power processes and the dynamics of legitimation and political opposition. Common values mediate and make possible indirect exchanges and thus the coordination of action in large collectivities. According to Blau, they also "legitimate the social order." Throughout this major work, Blau contrasts and compares social exchange processes in simple structures with those in more complex social structures and institutions. The major social forces he analyzes include differentiation, integration, organization, and opposition that sets up the dialectic necessary for the explanation of structural change.

The strategy of building a theory of macro structure and processes on an explicitly micro-level theory was a distinguishing feature of Blau's (1964) original work, which also became the focus of a major stream of theoretical work in sociology on the "micro-macro link" in the 1980s and 1990s. Ironically, Blau (1986) himself challenged the utility of his approach in his subsequent writings (Blau 1987), fueling the debate further. In his introduction to the second printing of his book on exchange and power (1986), he argues that microsociological and macrosociological theories

“require different approaches and conceptual schemes though their distinct perspectives enrich each other” (1986, p. xv). This theoretical debate will not be over soon since it lies at the heart of the nature of sociological analysis and relates to broad issues of the primacy of particular units and levels of analysis as well as to complex metatheoretical and methodological issues.

Blau (1964) and subsequently Emerson (1962, 1972, 1972b) made power the central focus of analysis. Blau treated power, authority, opposition, and legitimation as key topics in his discussion of macro structures and the dynamics of structural change. Emerson’s (1962) theory of power-dependence relations was partially incorporated into Blau’s (1964) treatment of power imbalance and the conditions of social independence. For Emerson (1962), these strategies were power-balancing mechanisms. The central proposition in Emerson’s (1962) article classic was that power, defined in relational terms, is a function of the dependence of one actor on another. In a two-party exchange relation, the power of one party (A) over another party (B) is a function of the dependence of B on A. Dependence is a function of the value one actor places on the resources (or valued behavior) mediated by the other actor and the availability of those resources from alternative sources. The greater the availability of these resources from other actors (or alternative sources), the lower one actor’s dependence on another. Two features of this approach to power are important: (1) It treats power as relational (a feature of a social relation, not simply a property of an actor), and (2) it treats power as potential power; that is, it may or may not be exercised. This relational conception of power became the basis for most subsequent work on exchange and power.

Emerson (1972a, 1972b) expanded his treatment of power and dependence to form a more extensive exchange theory of social relations. In many ways, his work combined the approaches of Homans (1961) and Blau (1964). In the original formulation, Emerson (1972a) adopted the language and principles of behavioral psychology to form a theory of social relations. However, he quickly moved beyond behavioral principles to the formation of more complex propositions regarding the emergence of various kinds of social structures. Here the theory picks up the Simmelian focus of Blau’s work as well as the concern with

emergent properties and complex social structures. Emerson (1972b), like Blau (1964, 1986), viewed the major task of exchange theory as the creation of a framework in which the primary dependent variable is social structure and structural change. The major task was eminently sociological, not psychological, even though all three theorists explicitly incorporated into their thinking notions about the psychology of actors. Emerson and Cook’s subsequent work (e.g., Cook and Emerson 1978) adopted a more cognitive perspective on the actors involved in social exchange. Molm’s (1981, 1987) earlier work extended the original behavioral underpinnings of the theory.

Exchange theory, though originally dyadic in focus, has been extended to apply to the analysis of exchange networks. Both Homans and Blau recognized the ubiquity of social networks and different forms of social association, but Emerson (1972b) made networks and corporate groups a central focus of his theoretical formulation. The definition of exchange relations as being “connected” in various ways to form network structures was the key to this development in the theory. Emerson defined two major types of connections between exchange relations: negative connections and positive connections. Two relations are negatively connected if the magnitude or frequency of exchange in one is negatively correlated with the magnitude or frequency of exchange in the other. In essence, the two relations are strictly alternatives. If a supplier gets parts in an exchange with one vendor, he or she does not need to get the same parts from another vendor. Negatively connected relations are thus competitive in nature. In contrast, when two relations are positively connected, exchange in one relation enhances exchange in the other. For example, the resources one party gets in exchange with one supplier can be used to obtain needed goods from another supplier. In this case, a positive connection exists and the two exchange relations are positively correlated. Such exchange relations are more cooperative than competitive in nature and form the basis for some types of division of labor and specialization within exchange networks. Subsequent theorists such as Willer (1987), Markovsky et al. (1988), Bonacich (1986), and Yamaguchi (1996) have developed other ways of classifying types of exchange connections. Some of this work is discussed below in the discussion of alternative perspectives.

A key concept in Emerson's exchange theory of power is the idea that exchange relations can be balanced or imbalanced. A power inequality results from an imbalance in power relations between two or more actors. An exchange relation is balanced if both parties are equally dependent on each other for exchange (or resources of value). If they are equally dependent, they have equal power. The central idea that power is based on dependence allows for the specification of ways in which dependencies are altered so that they affect the balance of power in the exchange relation and in networks of exchange relations.

Emerson postulated four power-balancing mechanisms to explain some of the ways in which exchange relations and the networks they form change either to maintain and preserve existing structural arrangements and distributions of power or to alter them. Coalition formation is one of the mechanisms by which power-disadvantaged actors in less powerful network positions can gain power through the collective advantage gained through cooperative action. Not all coalitions are power-balancing, however. In subsequent work, Emerson addressed the kinds of coalitions that form between powerful actors (sometimes referred to as collusion) or between powerful actors and a subset of the less powerful actors (a divide-and-conquer strategy).

Division of labor, or specialization within a network, may operate as a power-balancing mechanism, since it can result in changes in the distribution of power in a network through modifications in the distribution of resources and the nature of the structural arrangements. For example, two suppliers of the same resource who have been competitors may decide to specialize and offer different services in a way that makes them no longer competitive with each other in a particular network. Network extension also can alter the balance of power in a network as new exchange partners become available. In addition, when other strategies are not available, actors can devalue what they obtain from a more powerful actor as a way to reduce their dependence on the relationship. This strategy may be a precursor to an exit from the relation in many instances. Various theorists have continued this line of work, specifying the principles that predict the distribution of power in different exchange structures and the

processes that modify it (e.g., Cook et al. 1983, 1986; Bonacich 1986; Yamaguchi 1996).

Other extensions of the exchange theory originally developed by Emerson have focused on the links between structure and process and on other bases of power. In a major research program that extended over a ten-year period, Molm (1997) investigated the role of coercive power in social exchange. Emerson's work and that of most of the exchange theorists had focused almost exclusively on reward power, or the control over positively valued goods and services. Coercive power is the ability to control negative events (e.g., to withhold rewards) or to inflict punishment on another in an exchange relation. Unlike reward power, coercive power is used less often in exchange relations, especially by those in power-advantaged positions, who seem to understand that it may be viewed as unjustified in many circumstances. The fear of retaliation is also a deterrent to the use of coercive power. The use of coercive power is more costly since it imposes losses on the exchange partner in addition to the opportunity costs involved. Molm's (1989, 1997) major accomplishment was to expand the treatment of power in the classic power-dependence formulation to include forms of coercion. Since exchange relations often involve control over both things people value and things people wish to avoid, this is a significant extension of the theory.

Alternative theoretical formulations have been developed for investigating power processes in exchange networks. They include the "elementary theory" developed by Willer and his collaborators (e.g., Willer and Anderson 1981; Markovsky et al. 1988), Friedkin's (1992) "expected value model" of social exchange, and game theory, which has been applied to the analysis of exchange networks by Bienenstock and Bonacich (1992). While some of these formulations have an affinity with the original power-dependence framework developed by Emerson (1972a, 1972b), most have explored other bases of power. For example, Willer and his collaborators have developed a different terminology for specifying the nature of the relations in an exchange network. They define three types of relations: null (no connection), inclusion (when someone has to be involved in an exchange for it to take place) and exclusion (when someone may be involved in an exchange but is in competition with others and thus may be excluded from the

exchange at any time). These theorists go on to develop different principles for the distribution of power in networks characterized by different types of relations. Exclusion is viewed as the main determinant of power. The ability to exclude others from exchange is thus the key source of power in this theory.

Bienenstock and Bonacich (1992, 1997) analyze exchange networks by using a game theory perspective. They attempt to understand the efforts of actors to maximize certain well-defined interests by adopting strategies that can be analyzed usefully with the tools of game theory. Based on different solution concepts (e.g., the core, the kernel), they make predictions concerning the outcomes of the exchanges in various types of network structures. In addition, this application of game theory provides predictions about the role of information in exchange processes. Building on the early contributions of Blau, Coleman, Emerson, and Cook, Yamaguchi (1996) works out a rational choice model for predicting the distribution of power and the effects of network centrality in what he terms substitutable and complementary exchange relations.

Further developments in the theory of exchange include the formulation of explicit propositions concerning the use of power in different types of exchange network structures and the specification of some of the determinants of power use. These factors include concern over the fairness of the distribution of outcomes, the commitments that emerge between actors (e.g., Lawler and Yoon 1996), the formation of coalitions, particular strategies of action, and whether the power is reward power or punishment power. More recent developments focus more on methodologies for specifying the distribution of power in complex network structures (see, for example, Markovsky's work). Interest in this topic is in part driven by the potential for synthesizing exchange theoretic conceptions of power with network models of social structure (see Cook 1987; Cook and Whitmeyer 1992). Another arena of current theoretical and empirical work is the specification of dynamic models of power use and structural change that include a more sophisticated model of the actors involved and the strategies they adopt in their attempts to obtain resources and services that are of value to them. These general theoretic

and empirical efforts will be important if exchange theory is to fulfill its promise of providing an approach to linking micro-level theories of action and interaction with macro-level explanations of structure and processes of social change, an agenda that was originally set by Homans, Blau, and Emerson.

The application of exchange theory to understanding a variety of social phenomena has grown over the last two decades. Early applications focused on the explanation of the initiation and termination of social relations in work settings and families and then in the domain of romantic relationships and dating. Topics of interest to researchers included the conception of fairness in social exchange relations and its link to relational satisfaction and dissolution, the use of power in social relations based on control of both rewards and costs, and the abuse of power as well as the role of coalitions in altering the balance of power among actors in a network of individuals or organizations. Beyond the application to family and work settings, exchange theory has been applied in many different contexts to the study of organizations and interorganizational relations. Since organizations typically require resources from other entities much of their time is devoted to the strategic management of those dependencies. The resource dependence perspective (Pfeffer and Salancik 1978) in the field of organizations represents a straightforward application of exchange reasoning to the strategic actions of organizations and their subunits (e.g., at the divisional level). The developing field of economic sociology is now drawing to some extent on ideas derived from exchange theory to explain the emergence of network forms of organization and the nature of the power processes that emerge in those networks. Network effects on labor practices, informal influence among organizations, the organization of business groups, and the formation of international linkages that cross traditional national boundaries of economic and productive activity are central topics of inquiry in economic sociology. Some of these efforts involve understanding the effects of network location on outcomes and the various strategies actors use to enhance their bargaining power and influence. These efforts derive in part from the power-dependence reasoning first introduced by Emerson and Blau into exchange theorizing.

Other applications of exchange theory include broader efforts to investigate the balance of power in the health care industry, the strategic role of insurance companies in an era of managed care, and the response of physicians to the loss of power and autonomy. Several researchers have attempted to analyze the nature of physician referrals in network exchange terms and to characterize the nature of physician-patient interaction as an exchange relation in which power is asymmetrical (or imbalanced) and trust plays a key role in "balancing" that power differential. The patient must place his or her fate in the hands of a more competent, more informed actor and trust that the physician will do no harm. Future applications of the exchange model of interaction and of network exchange in other domains will help clarify and extend the underlying theoretical framework.

KAREN S. COOK

SOCIAL FORECASTING

Forecasting has been important in sociological thought. Early European sociologists argued that societies progress through inevitable historical stages; those theories helped sociologists predict all societies' futures. Early American sociologists adopted the pragmatists' rule that a science proves it "works" by predicting future events (Schuessler 1971). Sociologists, however, have only recently adopted methods appropriate for those early goals. The review in this article of the delayed development of social forecasting includes (1) three sociologists' conceptual uses of forecasting and some reasons their suggestions were not followed, (2) qualitative and quantitative methods of forecast-

ing, and (3) recent indications of increased interest in forecasting.

FORECASTING TRADITIONS

Sociologists have contributed several social forecasting concepts that were historically significant enough to become traditional orientations in the analysis of the future. William F. Ogburn "held that in the modern world technological inventions commonly come first and social effects later. By reason of this lag, it is possible, he argued, to anticipate the future and plan for its eventualities" (Schuessler 1971, p. 309). For example, new possibilities came into conflict with family values when the invention of effective birth control gave women new choices. Ogburn's contribution was to suggest that cultural lags are inevitable but that the period of disruption they cause can be shortened (Reiss 1986).

Merton (1949) challenged Ogburn's idea that the effects of inventions can be easily anticipated. Each invention has an apparent goal, or manifest function, that it is hoped it will perform in society. Each change, however, also contains the possibility of performing a number of *latent functions*. These are unanticipated side effects that often are not desired and sometimes are dangerous. The institutions of society are closely intertwined, and an invention in one area can cause shocks throughout the system. The automobile is an example. Its manifest function of changing transportation has been fulfilled, but at the cost of serious ecological and sociological changes.

Merton's (1949) second warning was that social forecasting is unique because it tries to predict the behavior of humans, who change their minds. The *self-fulfilling prophecy* is a forecast that makes people aware of real or imagined new opportunities or dangers to be avoided. Merton demonstrated that false forecasts can have powerful effects if they gain public acceptance. For example, a sound bank can be destroyed by a run on its funds caused by a prediction of failure. Henshel's more inclusive concept—the self-altering prediction—shows that forecasts can be self-defeating as well as self-fulfilling. W. I. Thomas's theorem, "If men define situations as real, they are real in their consequences," applies particularly to the definitions societies make of the future (Henshel 1978, p. 100).

Moore challenged sociologists to go beyond safe prophecy based on orderly trends and attack the difficult problem of “how to handle sharp changes in the magnitude of change, and sharp (or at least clear) changes in direction” (Moore 1964, p. 332). There are four types of *discontinuous societal change*: (1) Some societies are changed drastically by an *exogenous variable*, an idea or value from another society. Modern Japan is an example. (2) A society’s rate of development can increase spontaneously, creating an abundance of new ideas. This is an exponential acceleration, a *change in the rate of change*. (3) Moore attributes *changes in the direction of change* to the existence of a dialectic of values in each society’s apparent trend. For example, a society may appear to be profit-oriented and ecologically exploitative, but there also exists a counterset of values that stress harmony with each other and with nature. If a shift in such basic value emphases could be predicted, many other associated forecasts could be made. (4) Finally, Moore recognizes that there are pure *emergents*, inventions such as money and writing, that cannot be thought of as parts of trends.

Moore drew a methodological moral from these complexities: “One must somehow move from discrete necessary conditions to cumulative and sufficient ones” (Moore 1964, p. 334). That is, the search for the one trend or causal variable that drives societal change should be abandoned. The summation and particularly the interaction of many component developments create events.

In 1966 Moore asked sociologists to put aside value-free scientific rules and attempt to construct *preferable futures* that might help “mankind survive for the next twenty years” (Moore 1966, p. 270). Moore was confronting what he felt to be the main reason why forecasting was done so infrequently. It is professionally permissible for sociologists to examine social change both currently and retrospectively, but making a forecast leaves one liable to being labeled a utopian (Winthrop 1968, p. 136). Utopian thinking is in disrepute because past advocates allowed their values to cloud their constructions. However, images of the future provide goals and determine how people plan and therefore how they behave in the present. Moore sought utopias that would perform a necessary social planning function by constructing alternative directions for human purpose.

WHY SOCIAL FORECASTING HAS DEVELOPED SLOWLY

Sociologists’ basic methodological orientations preclude an interest in forecasting. Sociologists analyze society’s static interconnections and concentrate on the social structures that persist. They have not developed skill in isolating the sequences of dynamic social behavior (Moore 1966). They are better at categorizing and typing people than at predicting how individuals might change from one type to another.

Many sociologists feel that not enough is known to predict future events. They point to economists and demographers and ask, If they are failing with their more quantifiable data, how can complex social changes be anticipated? One school of thought sees sociology as a qualitative art form that will never be a statistically modeled science. Critical sociologists object on moral grounds. They feel that society requires essential restructuring before positive change can be effected. Since most forecasting is based on models of the current structure, they feel that it sanctions unjust social arrangements (Henshel 1982).

JUDGMENTAL AND QUALITATIVE FORECASTING METHODS

The futurists (Bell 1997; Kurian and Molitor 1996) see “the challenge being not just to forecast what the future will be, but to make it what it ought to be” (Enzer 1984, p. 202). The actual future is too complex to be predefined, but possible futures can be constructed that can be instructive. In addition, secondary forecasts can be made that estimate the effects of policy actions on the original course of development (Colquhoun 1996). The pace of change is considered too rapid to be captured by traditional methods reliance on a careful quantitative reconstruction of the past. This justifies the use of experts’ opinions, and futurists’ methods are ways of systematizing those judgments (Allen 1978, p. 79).

A discontinuous social change usually is preceded by a “substantial restructuring of basic tenets and beliefs” (Holroyd 1978, p. 37). Such paradigm shifts are revolutionary, such as the rejection of the earth as the center of the universe. They appear in fields of knowledge in which one system

of thought seems to be in control but is unable to solve important problems. Holroyd, for example, predicts a paradigm shift in economics because its current theories are unable to deal with essential problems such as scarcity of natural resources. Futurists anticipate shifts by compiling lists of crucial issues in the institutions of society. When the gap between current and desired conditions is large, that area is monitored closely for discontinuous change (Holroyd 1978, p. 38).

Cross-impact matrices are constructed by listing all possible future events in the problem area under study (Allen 1978, pp. 132–145). Each event is recorded as a row and a column in a square matrix. This allows the explicit examination of every intersection of events when one asks: What is the probability that the first will occur if it has been preceded by the other? The probabilities of occurrence can be derived from available data but are often judgments. Cross-impact analysis is a systematic way of heeding Merton's warning about not overlooking possibly damaging latent consequences. It is a tool for spotting crucial turning points or originating novel viewpoints by examining the intersections of change at which experts' judgments conflict.

Delphi surveys constitute an ingenious method for allowing the interaction of expert judgments while avoiding the contamination of social status or damage to reputations because of radical or mistaken pronouncements (Henshel 1982). In a series of survey rounds, everyone sees the distribution of others' responses without knowing the proponents' identities. A composite forecast emerges as anonymous modifications are made at each round.

After a review of forecasting methods, Ascher (1978) chose *scenarios* as one of only two methods he could recommend. A scenario is "a hypothetical sequence of events constructed for the purpose of focusing attention on causal processes and decision points" (Herman Kahn, quoted in Wilson 1978, p. 225). It is a story, but a complex one based on all available data and usually constructed after a cross-impact analysis has isolated possible turning points. Usually, two or three related scenarios are constructed to illustrate alternative futures that could be determined by particular decisions.

It is not surprising that an expert's decision process can be made explicit. What is surprising is

that in many studies the systematic model of an expert often forecasts better than the person does (Armstrong 1978). In *bootstrapping*, the forecaster's individualized decision procedures become the "bootstraps" by which a systematized procedure is "lifted" into an orderly routine. Such a model can be made deductively through interviews that isolate and formalize the decision rules or inductively by starting with a series of past forecasts and attempting to infer the rules that accounted for the differences between them.

Metaforecasting (Makridakis 1988) represents an essential summary of these considerations and a bridge to more quantitative methods. It combines judgmental and statistical estimates. It attempts to include historical and social information to overcome the tendency to ignore or overreact to changes in established patterns or relationships.

SOCIAL DEMOGRAPHY

Demography is the most established form of social forecasting, and its methods and record can be found elsewhere (Henshel 1982). This article will discuss only two elements from its continuing development: a method that has had wide influence and what can be learned from its frequent failures to predict future population sizes.

A cohort is an aggregate of individuals of similar age who therefore experience events during the same time period (Reiss 1986, p. 47). *Cohort analysis* was first used by Norman Ryder to study the changing fertility behaviors of women born during the same five-year periods. Since that time, cohorts have been used in the study of many areas of social change to differentiate the changes that are result from individuals maturing through the stages of life from those caused by powerful societal events or value shifts.

Demographers failed to anticipate the post-war baby boom and the onset of its decline. These errors were due to *assumption drag*, "the continued use of assumptions long after their validity has been contradicted by the data" (Ascher 1978, p. 53). Henshel (1982) says that demographers probably ignored these turning points because they simply talked to each other too much. They reassured each other that their assumptions and their extrapolations from past trends would soon reas-

sert themselves in the data. Recognition of this error of developing an isolated club of forecasters has helped economists and will help sociologists avoid a similar regimentation of estimates.

The mix of assumptions and actual data varies widely in *simulation models*. The most useful models test a set of explicit assumptions so that no interactions between variables are overlooked. Models have contributed the idea of the feedback loop as an important caution against unidirectional thinking. This common system characteristic occurs when an effect reaches a sensitive level and begins a reaction that modifies its own cause (Simmons 1973, p. 195). Often, however, the mix of assumptions and facts in simulations leans too heavily toward judgments. So-called black-box modeling (McLean 1978), in which equations are hidden, can produce output that is plausible and provocative but also unrealistic. The creator of the *Limits to Growth* study admitted that “in *World Dynamics* . . . there is no attempt to incorporate formal data. . . . All relationships are intuitive” (Simmons 1973, p. 208). That study extrapolated what have come to be seen as extreme assumptions of geometric growth unchecked by social adaptation. Its dramatic predictions of imminent shortages had a wide but unwarranted impact (Cole et al. 1973). A comment on those failed predictions and their popularity at the time of their publication sets the context in which all “modeled” forecasts should be received: “The apparent detached neutrality of a computer model is as illusory as it is persuasive. Any model of a social system necessarily involves assumptions about the workings of that system, and these assumptions are necessarily colored by the attitudes and values of the individuals or groups concerned. . . . [C]omputer models should be regarded as an integral part of political debate. . . . The model is the message” (Freeman 1973, p. 7).

PRAGMATIC STATISTICAL ANALYSIS OF TIME SERIES

Attention has shifted to techniques that are less concerned with demonstrating the effects of assumed patterns. Time series are records of observations through time. Traditional *time series analysis* projects “future values of a variable based entirely on the past and present observations of that vari-

able” (Levine et al. 1999). It involves isolating the trend inside the many “noisy” or seasonal factors that may obscure it. The techniques have been well developed, are taught in undergraduate management statistics courses, and have been adapted for spreadsheet software available on most computers. The problem, however, is how much faith one can put in the idea that “people do what they usually do.” Time series projections are essential first steps in discovering patterns of behavior of aggregates of people over time. Such patterns often persist, but some shock (invention, immigration, social redefinition such as “the sixties,” or adjustment of tradition such as decreasing sexism) may cause disruption. In recognition of these sociological disruptions, time series are being explored from the viewpoint that any variable may be uniquely complex and subject to sudden change.

Time series regressions uncover structural relationships involved in the history of two or more variables. Before the relationship can be assessed, sources of error must be isolated and controlled. The most important of these errors are (1) the overall trend of change that would obscure any specific interrelationship and (2) the autocorrelation effect of internal dependence of an observation on previous observations. If a relationship seems to explain the data series’ movements, it is tested with ex-post forecasts that can be verified within the range of available data. If these succeed, “ex-ante-forecasts can be used to provide educated guesses about the path of the variables into the blind future” (Ostrom 1990, p. 77).

Autoregressive moving average (ARIMA) models predict a variable’s current status by using a combination of its previous observations and mathematically approximated random shocks. The goal is to find a pattern that fits the immediate data, not to understand relationships. ARIMA models are useful in interrupted *time series analysis*, in which the impact of a policy or another intervention can be examined by seeing how different the variable’s patterns are before and after the intervention (McDowall et al. 1980). Autoregressive models have a limitation important for social forecasting, in which historical data are relatively scarce. “Because ARIMA models must be identified from the data to be modeled, relatively long time series are required” (McCleary and Hay 1980, p. 20). Fifty observations are recommended.

Exponential smoothing is widely used and is as reliable as more complicated methods (Gardner 1985). In its simplest form, the next period's forecast is based on the current forecast plus a portion of the error it made. That is, the difference between the current time period's forecast and the actual value is weighted and used to adjust the next period's expected value. The higher the value of the weight used is, the more the error adjustment contributes and the more quickly the model will respond to changes. Exponential smoothing is used in early detection of curvilinear changes, when the rate of change speeds or slows (Gardner 1987).

FUTURE TRENDS

Forecasting is being done. It is central in business and government planning. Even though many of these forecasts' essential variables are social or are found in social contexts (such as family decisions to move, build, and purchase or the development of social problems), economists have become society's designated forecasters (Henshel 1982; Stimson and Stimson 1976). Sociologists will not change this imbalance easily, but there are some indications that forecasting may finally become part of everyday sociological work.

Assumptions that a particular cycle or curve is the natural or underlying process of all change have been abandoned, and pragmatic methods are now widespread. It is also accepted that a forecast is developed only to be monitored for possible discontinuities. Trend extrapolations rarely are done without accompanying methods for describing the expected deviations.

Two forecasting methods are particularly promising because they allow sociologists to build on traditional skills. Componential or segmentation forecasting (Armstrong 1978) recognizes that an aggregate forecast can be improved by combining forecasts made on the population's component social groups. Sociologists are best able to distinguish the groups that should be treated separately. Pooled time series analysis (Sayrs 1989) combines cross-sectional descriptions such as one-time surveys. Sociologists are expert at describing interconnections in the structures of organizations or societies, and now they have the opportunity to study these social arrangements over time.

Society has recognized the wisdom of the early concern about anticipating the latent effects of social and technological inventions. Progress no longer seems inevitable. The popular question now is, Can someone assure us that a new element will not be as destructive as past changes?

Sociologists seem to be uniquely suited to help forecasting become more plausible because their working assumptions counter the weaknesses of current methods. The idea that technological innovation or economic cycles drive social change has produced today's mechanistic, ultrarational, anti-individualistic models that assume that the population is homogeneous (Dublin 1992). All these weaknesses are naturally contradicted when sociologists expand their vision of a population to include the cultural diversity of the social contexts that produce, accept or reject, and always modify the effects of technological and economic circumstances.

The future acceptance of forecasting also depends on sociologists' ability to improve the preparation and presentation of forecasts by using their traditional strengths. Forecasts will be accepted by policymakers and the public only when the quasi-theories they hold about the future are specifically addressed and proved false. Sociologists know this better than other social scientists do; they often are called on to dispel labels and popular theories that are so entrenched that they make any new attempt at explanation seem a "fool's experiment" to the forecaster's audience. They also are used to the idea of various and multiple causes acting in a situation and therefore are skilled at isolating "unanticipated consequences."

Forecasts will improve and become more plausible when they place less importance on traditional scientific formulations. A forecast is not a hypothesis. Hypotheses must be made in advance of the behavior they are meant to predict to assure a full and objective test of the theories that produced them. Forecasts demand monitoring of predictions and adaptation of forecasts to circumstances. A forecast is as good as its ability to anticipate and allow the inclusion of changing social forces. That is, its main function is not to make an accurate prediction of future events but to isolate and interrelate the many factors in the current situation that may be causally powerful. Understanding

the current social situation's complexity is the most important factor.

SOCIAL INDICATORS

Social indicators are statistical time series that are “used to monitor the social system, helping to identify changes and to guide intervention to alter the course of social change” (Ferriss 1988, p. 601). Examples are unemployment rates, crime rates, estimates of life expectancy, health status indices such as the average number of “healthy” days (or days without activity limitations) in the past month for a specific population, school enrollment rates, average achievement scores on a standardized test, rates of voting in elections, and measures of subjective well-being such as satisfaction with life as a whole.

HISTORICAL DEVELOPMENTS

Social Indicators in the 1960s. The term “social indicators” was given its initial meaning in an attempt by the American Academy of Arts and Sciences for the National Aeronautics and Space Administration in the early 1960s to detect and anticipate the nature and magnitude of the second-order consequences of the space program for American society (Land 1983, p. 2; Noll and Zapf 1994, p. 1). Frustrated by the lack of sufficient data to detect such effects and the absence of a systematic conceptual framework and methodology for analysis, some in the project attempted to develop a system of social indicators—statistics, statistical series, and other forms of evidence—with which to detect and anticipate social change and to evaluate specific programs and determine their impact. The results of this part of the project were published in a volume (Bauer 1966) called *Social Indicators*.

The appearance of this volume was not an isolated event. Several other influential publications commented on the lack of a system for charting social change and advocated that the U.S. government establish a “system of social accounts” that would facilitate a cost-benefit analysis of more than the market-related aspects of society already

indexed by the National Income and Product Accounts (National Commission on Technology, Automation and Economic Progress 1966; Sheldon and Moore 1968). The need for social indicators also was emphasized by the publication of *Toward a Social Report* on the last day of the Johnson administration in 1969. The report was conceived of as a prototypical counterpart to the annual economic reports of the president, and each of its chapters addressed major issues in an area of social concern (health and illness; social mobility; the physical environment; income and poverty; public order and safety; learning, science, and art; and participation and alienation) and provided an assessment of the current conditions. In addition, the document firmly linked social indicators to the idea of systematic reporting on social issues for the purpose of public enlightenment.

Generally speaking, the sharp interest in social indicators in the 1960s grew out of the movement toward the collection and organization of national social, economic, and demographic data that began in Western societies in the seventeenth and eighteenth centuries and accelerated in the twentieth century (Carley 1981, pp. 14–15). The work of the sociologist William F. Ogburn and his collaborators at the University of Chicago in the 1930s and 1940s on the theory and measurement of social change is more proximate and sociologically germane (Land 1975). As chairman of President Herbert Hoover’s Research Committee on Social Trends, Ogburn supervised the production of the two-volume *Recent Social Trends* (1933), a pathbreaking contribution to social reporting. Ogburn’s ideas about the measurement of social change influenced several of his students—notably Albert D. Biderman, Otis Dudley Duncan, Albert J. Reiss, Jr., and Eleanor Bernert Sheldon—who played major roles in the emergence and development of the field of social indicators in the 1960s and 1970s.

Social Indicators in the 1970s and 1980s. At the end of the 1960s, the enthusiasm for social indicators was sufficiently strong and broad-based for Duncan (1969, p. 1) to write of the existence of a social indicators movement. In the early 1970s, this led to, among other things, the establishment in 1972, with National Science Foundation support, of the Social Science Research Council Center for Coordination of Research on Social Indica-

tors in Washington, D.C.; the publication of several major efforts to define and develop a methodology for the measurement of indicators of subjective well-being (Campbell and Converse 1972; Andrews and Withey 1976; Campbell et al. 1976); the commencement of a federal government series of comprehensive social indicators books of charts, tables, and limited analyses (U.S. Department of Commerce 1974, 1978, 1980); the initiation of several continuing data series based on periodic sample surveys of the national population (such as the annual National Opinion Research Center's [NORC] General Social Survey and the annual National Crime Survey of the Bureau of Justice Statistics); the publication in 1974 of the first volume of the international journal *Social Indicators Research*; and the spread of social indicators and/or social reporting to numerous other nations and international agencies, such as the United Nations and the Organization for Economic Cooperation and Development.

Social indicators activities slowed in the 1980s as funding cuts and nonrenewals led to the closing of the Center for Coordination of Research on Social Indicators; the discontinuation of related work at several international agencies; the termination of government-sponsored social indicators reports in some countries, including the United States; and the reduction of statistical efforts to monitor various aspects of society. Several explanations have been cited for this slowdown (Andrews 1989; Bulmer 1989; Innes 1989; Johnston 1989; Rockwell 1987). Certainly, politics and the state of national economies in the early 1980s are among the most salient proximate causes. Administrations that came to power in the United States and elsewhere based decisions more on a "conservative ideology" and less on current social data than had been the case earlier. Also, faltering economies that produced large government budget deficits provided an incentive to make funding cuts. In addition to these immediate factors, there was a perceived lack of demonstrated usefulness of social indicators in public policymaking that was due in part to an overly simplistic view of how and under what conditions knowledge influences policy; this topic is treated more fully below in the discussion of current uses of social indicators. Before that, a more detailed discussion of types of indicators and their measurement and organization into accounting systems is necessary.

THREE TYPES OF SOCIAL INDICATORS

Criterion Indicators. On the basis of the premise that social indicators should relate directly to social policymaking considerations, an early definition by the economist Mancur Olson, the principal author of *Toward a Social Report*, characterized a social indicator as a "statistic of direct normative interest which facilitates concise, comprehensive and balanced judgments about the condition of major aspects of a society" (U.S. Department of Health, Education, and Welfare 1969, p. 97). Olson stated that such an indicator is in all cases a direct measure of welfare and is subject to the interpretation that if it changes in the "right" direction while other things remain equal, things have gotten better or people are better off. Accordingly, by this definition, statistics on the number of doctors or police officers could not be social indicators, whereas figures on health or crime rates could be.

In the language of policy analysis (Fox 1974, pp. 120–123), social indicators are "target" or "output" or "outcome" or "end-value" variables toward changes in which a public policy (program or project) is directed. This use of social indicators requires (Land 1983, p. 4) that (1) society agree about what needs improving, (2) it be possible to decide unambiguously what "getting better" means, and (3) it be meaningful to aggregate the indicators to the level of aggregation at which the policy is defined.

In recognition of the fact that other meanings have been attached to the term "social indicators," the tendency among recent authors is to use a somewhat different terminology for the class of indicators identified by Olson. For instance, Land (1983, p. 4) termed this the class of "normative welfare indicators." Building on the Olson approach, MacRae (1985, p. 5) defined "policy indicators" as "measures of those variables that are to be included in a broadly policy-relevant system of public statistics." With a meaning similar to that of MacRae, Ferriss (1989, p. 416) used the felicitous term "criterion indicators."

Life Satisfaction and/or Happiness Indicators. Another class of social indicators has its roots in the work of Campbell and Converse in the early 1970s. In *The Human Meaning of Social Change* (1972), they argued that the direct monitoring of key social-psychological states (attitudes, expectations, feelings, aspirations, and values) in the popula-

tion is necessary for an understanding of social change and the quality of life. In this approach, social indicators are used to measure psychological satisfaction, happiness, and life fulfillment by employing survey research instruments that ascertain the subjective reality in which people live. The result may be termed “life satisfaction,” “subjective well-being,” or “happiness indicators.”

The Campbell-Converse approach led to two major methodological studies in the 1970s (Andrews and Withey 1976; Campbell et al. 1976) and a subsequent edited volume (Andrews 1986) exploring the utility of various survey and analytic techniques for mapping individuals’ feelings of satisfaction with numerous aspects (“domains”) of their experiences. These studies examine domains ranging from the highly specific (house, family, etc.) to the global (life as a whole). A large number of other studies and applications of these concepts and techniques have appeared over the past three decades (for reviews, see Diener 1994; Diener et al. Smith 1999; and Veenhoven 1996) and continue to appear; one or more studies of subjective well-being indicators can be found in almost every issue of *Social Indicators Research*. Research on the related concept of happiness as an index of well-being was surveyed by Veenhoven (1984).

The principle that the link between objective conditions and subjective well-being (defined in terms of responses to sample survey or interview questions about happiness or satisfaction with life as a whole) is sometimes paradoxical; therefore, the idea that subjective as well objective states should be monitored is well established in the social indicators literature. However, numerous studies of the measurement and psychodynamics of subjective well-being over the last three decades have led to a better understanding of this construct (Cummins 1995, 1998). While research continues and the debates have not been settled, it appears that this construct may have both *traitlike* (i.e., a durable psychological condition that differs among individuals and contributes to stability over time and consistency across situations) and *statelike* (i.e., a condition that is reactive to situational differences) properties (Stones et al. 1995; Veenhoven 1994, 1998).

With respect to the statelike properties of subjective well-being, Davis (1984) used an accumulated sample from several years of NORC Gen-

eral Social Surveys to document the responsiveness of happiness with life as a whole to (1) “new money” (recent changes in the respondents’ financial status compared with the current income level), (2) “an old man/lady” (being married or having an intimate living partner), and (3) “two’s company” (a household size of two compared to living alone or in a family of three or more). Many other studies have found additional factors that are more or less strongly associated with variations in subjective well-being, but the relevance of intimate living conditions and/or family status almost always is replicated. The connection of subjective well-being to income levels has been an intriguing problem for social indicators researchers since Easterlin’s (1973) finding that income differences between nations predict national differences in happiness but that the association of happiness with income within countries is much weaker (for a review of this research literature, see Ahuvia and Friedman 1998). However, Davis’s finding of a positive relationship between “new money” or recent income changes and happiness has been replicated by Saris (1998), using data from a panel study conducted in Russia in the period 1993–1995.

Descriptive Social Indicators. Building on Ogburn’s legacy of research on social trends, a third approach to social indicators focuses on social measurements and analyses designed to improve the understanding of what the main features of society are, how they interrelate, and how these features and their relationships change (Sheldon and Parke 1975, p. 696). This produces *descriptive social indicators*—indices of the state of society and the changes taking place within it. Although descriptive social indicators may be more or less directly (causally) related to the well-being goals of public policies or programs and thus include policy or criterion indicators, they are not limited to such uses. For instance, in the area of health, descriptive indicators may include preventive indicators such as the percentage of the population that does not smoke cigarettes as well as criterion indicators such as the number of days of activity limitations in the past month and an index of self-reported satisfaction with health. Ferriss (1990) published a compilation of descriptive indicators for the United States at the end of the 1980s; regularly published national social indicator compilations for other nations also contain numerous examples.

The various statistical forms descriptive social indicators can take are described by Land (1983, p. 6). These forms can be ordered by degree of abstraction from those which require only one or two data series and little processing (e.g., an age-specific death rate) to those which involve more complicated processing into a single summary index (e.g., years of life expectancy at a given age and years of active or disability-free life expectancy at a given age). Descriptive social indicators can be formulated at any of these levels of abstraction. Moreover, as described in Juster and Land (1981), these indicators can, at least in principle, be organized into demographic- or time-budget-based systems of social accounts.

THE ENLIGHTENMENT FUNCTION: MONITORING, SOCIAL REPORTING, AND FORECASTING

The social indicators movement was motivated by the principle that it is important to *monitor changes over time* in a broad range of social phenomena that extend beyond the traditional economic indicators and include *indicators of quality of life* (Andrews 1989, p. 401; Noll and Zapf 1994, p. 5). Many organized actors in contemporary society—including government agencies, organizations and activists interested in social change programs, scholars, and marketing researchers interested in market development and product innovations—monitor indicators in which they have a vested interest and want to see increase or decline (Ferriss 1988, p. 603).

A second principle that has been part of the social indicators movement from the outset (Biderman 1970; Land 1996) is that a critically important role of social indicators in contemporary democratic societies is *public enlightenment through social reporting*. In brief, modern democracies require social reporting to describe social trends, explain why an indicator series behaves as it does and how this knowledge affects interpretation, and highlight important relationships among series (Parke and Seidman 1978, p. 15).

It also is important to document the consequences that are reasonably attributable to changes in a series. This includes the systematic use of social indicators to *forecast trends in and/or turning points in social conditions* (Land 1983, p. 21). The

area of projection or forecasting is filled with uncertainties. Techniques range from the naive extrapolation of recent trends to future scenario construction to complicated model building with regression, time series, or stochastic process techniques. Moreover, there appear to be intrinsic limits to the accuracy of forecasts in large-scale natural and social systems (Land and Schneider 1987). However, demands for the anticipation of the future (at a minimum, a description of “what will happen if present trends continue”), foresight and forward thinking in the public and private sectors, and the assessment of critical trends (Gore 1990) appear to be an intrinsic part of contemporary postindustrial societies. Thus, it is prudent to expect that “anticipation” will become an increasingly important part of the enlightenment function of social indicators.

Social Reporting at the Turn of the Century.

As the decade of the 1990s unfolded, the model of a comprehensive national social report in the tradition pioneered by Ogburn and Olson clearly faltered in the United States, at least in the sense of federal government sponsorship and/or production. However, the key ideas of monitoring, reporting, and forecasting were evident to a greater or lesser extent in the production of continuing periodic subject-matter-specific publications by various federal agencies, including *Science Indicators* (published by the National Science Foundation), *The Condition of Education* (published by the Department of Education), the *Report to the Nation on Crime and Justice* (published by the Department of Justice), and numerous Census Bureau publications. Special topics involving groups of federal agencies also receive attention from time to time. For instance, in 1997 the Federal Interagency Forum on Child and Family Statistics began the annual publication *America's Children: Key National Indicators of Well-Being*. In addition, numerous private research organizations, policy institutes, and scholars continue to produce reports, monographs, and books interpreting social trends and developments in several areas of social concern.

In contrast to the situation in the United States, comprehensive social reports and social indicators compendiums continue to be published periodically in several other countries. Examples are the *Social Trends* series published annually since 1970 by the United Kingdom's Central Statistical Office, the *Datenreport* series published bien-

nially since 1983 by the Federal Republic of Germany, the *Social and Cultural Report* published biennially by the Social and Cultural Planning Office of the Netherlands, and *Australian Social Trends* published annually by the Australian Bureau of Statistics. Citations and summary reviews of these and other social indicators and social reports publications can be found in the quarterly newsletter and review of social reports *SINET: Social Indicators Network News* (see the World Wide Web home page: <http://www.soc.duke.edu/dept/sinet/index.html>).

The difference between the organization of social indicators and reporting work in the United States and that in other countries is in part attributable to the lack of a central statistical office responsible for the coordination of all government statistical activities in the United States. More generally, it is indicative of the fact that despite the invention of the ideas of social indicators and comprehensive social reporting in the United States, this nation has lagged in their institutionalization (Johnston 1989). Whether a new round of legislative efforts (e.g., then-Senator Albert Gore, Jr.'s, proposed Critical Trends Assessment Act [Gore 1990]) will create the necessary institutional base remains to be seen. Perhaps marking a turning point and indicative of things to come is Public Law 100-297, enacted April 28, 1988, which requires an annual education indicators report to the president and Congress.

Quality of Life as a Unifying Concept. Another development became vividly apparent in the 1990s (Land 1996): the widespread political, popular, and theoretical appeal of the "quality-of-life" (QOL) concept. As was noted above, this concept emerged and became part of the social indicators movement in the late 1960s and early 1970s as doubts were raised in highly developed Western industrial societies about economic growth as the major goal of societal progress (Noll and Zapf 1994, pp. 1-2). The "social costs" of economic growth were cited, and there was increasing doubt about whether "more" should be equated with "better." The QOL concept that resulted from this discussion was posed as an alternative to the increasingly questionable concept of the affluent society and entered discussions of social policy and politics as a new but more complex multidimensional goal. As a goal of social and economic

policy, QOL encompasses all (or at least many) domains of life and subsumes, in addition to individual material and immaterial well-being, collective values such as freedom, justice, and the guarantee of natural conditions of life for present and future generations. The political use of the idea of QOL is paralleled in the private sector by the widespread use and popularity of numerous rankings—based on weighted scales of multiple domains of well-being—of the "best" places to live, work, do business, play, and so on, whether they are cities, states, regions, or nations.

The theoretical appeal of the QOL concept as an integrating notion in the social sciences and related disciplines is due in part to the perceived importance of measuring individuals' subjective assessments of their satisfaction with various life domains and with life as a whole, as was reviewed above. For instance, QOL has become a concept that bridges the discipline of marketing research and strategic business policy with social indicators. Marketing is an importance social force—with far-reaching direct and indirect impacts on the prevailing QOL in a society—through consumer satisfaction (Samli 1987; Sirgy and Samli 1995) and its impact on satisfaction with life as a whole. The intersection of marketing research with social indicators through the QOL concept led to the organization in the mid-1990s of the International Society for Quality-of-Life Studies (for information about the society and its activities, see its Web homepage: <http://www.cob.vt.edu/market/isqols/>). Sociologists who want to become more involved in the field of social indicators should participate in this international and interdisciplinary society.

Summary Indices of the Quality of Life. As the twenty-first century approaches, it is evident that the field of social indicators is entering a new era of the construction of summary social indicators. Often these indices attempt to summarize indicators (objective and/or subjective) of a number of domains of life into a single index of the quality of life. They thus attempt to answer one of the original questions that motivated the social indicators movement: How are we doing overall in terms of the quality of life? With respect to our past? With respect to other comparable units (e.g., cities, states, regions, nations)? Many pioneers of the social indicators movement in the 1960s and 1970s backed away from the development of sum-

many indices to concentrate on conducting basic research on social indicators and the measurement of the quality of life and the development of a richer social database. With the tremendous increase in the quality of social data available for many societies today compared to two or three decades in the past, a new generation of social indicators researchers has returned to the task of summary index construction. Some examples are (1) at the level of the broadest possible comparisons of nations with respect to the overall quality of life, the Human Development Index (United Nations Development Programme 1993), Diener's (1995) Value-Based Index of National Quality of Life, and Estes's (1988, 1998) Index of Social Progress and (2) at the level of comparisons at the national level over time in the United States, the *American Demographics Index of Well-Being* (Kacapyr 1996), *The Fordham Index of Social Health* (Miringoff 1996), and the *Genuine Progress Indicator* (Redefining Progress 1995). The field of social indicators probably will see several decades of such index construction and competition among various indices, with a corresponding need for careful assessments to determine which indices have substantive validity for which populations in the assessment of the quality of life and its changes over time and across social space.

**THE POLICY ANALYSIS FUNCTION:
POLICY GUIDANCE AND DIRECTED
SOCIAL CHANGE**

Policy analysts distinguish various ways of guiding or affecting public policy, including *problem definition*, *policy choice and evaluation of alternatives*, and *program monitoring* (MacRae 1985, pp. 20–29). The social reporting–public enlightenment approach to social indicators centers on the use of social indicators in problem definition and the framing of the terms of policy discourse. Indeed, studies of the actual use of social indicators suggest that this is precisely the manner in which they have affected public action (Innes 1989).

However, policy analysts from Olson to MacRae always have hoped for more from social indicators: the shaping of public policy and planing through the policy choice process. At a minimum, this requires the identification of key variables that determine criterion indicators and changes in them

(i.e., causal knowledge). More generally, it requires the construction of elaborate causal models and forecasting equations (often in the form of a “computer model”) that can be used to simulate “what would happen if” under a variety of scenarios involving policies and actions. An example of this is the development of the National Cancer Institute model for the control and reduction of the incidence of cancer in the United States to the year 2000 (Greenwald and Sondik 1986). Various policy and action scenarios involving prevention, education, screening, and treatment and their implications for cancer mortality were simulated and estimated with this computer model. These simulations led to a decision to allocate funds to prevention, education, screening, and treatment, and their implications for cancer mortality were simulated and estimated with this computer model. These simulations led to a decision to allocate funds to a prevention program rather than to additional clinical treatment.

At a more discursive level, the following *model for directed social change* has emerged in policy uses of social indicators in areas such as health, education, and the welfare of children and youth in the United States (Ferriss 1998):

1. *Identify trends in criterion indicators*, the direction or rate of change of which should be changed.
2. *Gather intelligence* from experiments, field research, or theory that suggests what should be done to bring about the desired change.
3. *Launch a decentralized program to effect change in specific criterion indicators* by specific amounts, to be attained by a target date.
4. *Monitor progress* by periodically assessing trends on the specific indicators, modifying strategies as needed.
5. As initial goals are reached, *set new goals* for continued progress.

Many more applications of social indicators to policy choice and evaluation are likely to appear in the future. In particular, such applications probably will occur in three areas. The first is the additional development of well-grounded, theoretically informed, and policy-relevant indicators

and models for national and/or regional-level analyses in fields such as health, education, crime, and science (Bulmer 1989). In such applications, the phenomena to be included are definable and delimited and the limitations of the data on which the indicators are based are known. The second is the use of social indicators in the field of social impact assessment (Finsterbusch 1980; Land 1982), which has arisen as part of environmental impact assessment legislation and attempts to anticipate the social effects of large-scale public projects (e.g., dams, highways, nuclear waste disposal facilities) as well as to assess damage from both natural and human-made disasters (e.g., earthquakes, oil spills, nuclear plant accidents). This application of social indicators in impact assessments brings the field back full circle to its point of origination in the American Academy's effort of the 1960s. Finally, the many times series of indicators now available will increasingly be used by sociologists to assess theories, hypotheses, and models of social change, thus bringing social indicators data to bear on core issues in sociology.

KENNETH C. LAND

SOCIAL INEQUALITY

Social inequality refers to the graduated dimensions (Blau 1977), vertical classifications (Ossowski 1963; Schwartz 1981) and bounded categories (Tilly 1998), or hierarchical relations (Burt 1982) by which human populations at varying levels of aggregation are differentiated. This concept is among the oldest and most diversely defined in sociology, extending back at least as far as Plato's conception of the republic and developed subsequently in the social theories of Marx [1859] 1976–1978, Mosca (1939), Weber [1947] 1978, Simmel (1896), Sorokin (1941), Eisenstadt (1971), Merton (1968), and others. The construct often is used interchangeably with related (though relatively more specific) concepts such as social class, social stratification, socioeconomic status, power, privilege, cumulative advantage, dependence, and dominance. It is relevant for the study of social systems that range in size from the dyad (Simmel 1896) to the modern world system (Wallerstein 1974).

SOCIAL INEQUALITY AS A GRADUATED DIMENSION

When social inequality is conceptualized as a graduated dimension, it is treated as a distributional phenomenon. Here the approach is to define inequality in terms of the distribution of socially valued attributes such as education, income, information, health, and influence in a population. However, distributional phenomena can be examined from one of two very different assumptions. The first assumption views inequality as being an outcome of or generated by the underlying distribution of valued traits among individuals. In this sense, it refers to “regular differences in power, goods, services, and privileges among defined sets” of actors (Granovetter and Tilly 1988). The second assumption views inequality strictly as a system-level property with individual-level differences that are defined as derivative rather than generative (Blau 1977). Distributions such as the size of the system and its total volume of resources are exam-

ined as higher levels of aggregation, with the goal of determining the overall level of inequality (oligarchy) across systems and without reference to individual differences (e.g., Lenski 1966; Mayhew 1973; Mayhew and Schollaert 1980).

Both approaches operationalize inequality along criteria that usually are measurable at the level of individual actors (persons, races, gender categories, organizations, nation-states) in a system. Early applications of the first assumption can be found in Pareto's ([1897] 1980) examinations of income distributions and the circulation of elites. Pareto proposed that economic and political inequality emerged from the distribution and redistribution of “congenital abilities” that were valued within social systems. Sorokin (1941) proposed similar arguments to explain social and cultural processes of mobility and inequality.

Among the most influential and controversial conceptualizations of inequality as a graduated dimension emerging from individual differences was Davis and Moore's (1945) functionalist statement of the principles of stratification. Those authors argued that social inequality results from the differential distribution of societal rewards to individuals on the basis of their relative achievement of ranked social positions. This achievement process, with its implications for social mobility, was formally specified by Blau and Duncan (1967), who established that educational attainment mediated the process of intergenerational social mobility among men. Those researchers defined social inequality as socioeconomic status based on the economic and prestige rewards accorded to achieved occupational positions in American society. The strong parallel between this model of inequality and the neoclassical model of human capital (see Becker 1964) is well established (Wright 1978).

The most prominent distributional theories of inequality, however, are founded on macrosocial views of the division of labor, the rationalization of authority, and the distribution of social and economic rewards in industrial societies. Weber's ([1947] 1978) theory of economic organization proposed that capitalist systems of property, power, and prestige developed out of the conjunction of changing systems of economic exchange (money economies) and accounting (double-entry bookkeeping) with rationalized systems of social con-

trol (rational-legal authority). Thus, social inequality in industrial society developed along economic and political dimensions to produce the multidimensional bases of inequality: class, status, and party. Lenski's (1966) comparative study of the evolution of inequality attempted to test Weber's rationalization thesis that inequality evolves necessarily (functionally) with increasing differentiation in the direction of systems of privilege based on rational authority and away from socially illegitimate systems of force or economic dominance.

Accordingly, distributional inequality can be concerned with more than the single dimension of individual socioeconomic outcomes. It also addresses macrosocial patterns of inequality (Eisenstadt 1971). According to Blau (1977), the parameters of social structure include inequality and heterogeneity—or graduated and nominal dimensions, respectively—which intersect to constrain and differentiate individuals' opportunities as well as their motivations and outcomes. The intersection of graduated and nominal parameters creates diverse systems or populations with differing distributional properties that cannot be reduced to an original individual source. Blau's distributional theory is "macrosocial in the sense that the 'cases' are populations or communities and the 'variables' measure some aspect (a rate or a distributional property) of these populations" (Skvoretz and Fararo 1986, p. 30). Following this approach, indicators of inequality can be defined in terms such as Lorenz curves (e.g., Gini indices, Theil coefficients), social welfare functions, or similar distributional properties (see Allison 1978; Wolfson 1997).

The emergence of the new global economy over the last two decades of the twentieth century has been associated with what has been characterized as a "surge" in wage and household income inequality (Gottschalk and Smeeding 1997) and a "winner-take-all income market" (Levy 1998) in advanced industrial countries. By and large, the growth of very high incomes in some sectors and the stagnation of wages in selected labor markets have produced a widening distribution of income. Distributional measures of economic inequality such as Gini and Theil coefficients reveal growing inequality among employed workers across advanced industrial societies with some of the highest inequality observed in the United States.

Economic inequality also may intersect with the nominal category of race, for example, and produce more diverse outcomes than traditional functional or neoclassical economic theories would predict. Examinations of patterns of interracial/interethnic marriage, for example, indicate that the association between occupational achievement and race is mediated by the extent of interracial/interethnic marriage in a community (see Blum 1984; Blau et al. 1982). This treatment of inequality, which is based on notions of dispersion and association, departs from the simple reduction of unequal outcomes to individual attributes and embeds the process in extended distributional contexts.

Other distributional approaches introduce constructs to explain inequality at levels above individual attributes, although individuals usually remain the units of analysis. Spatial and temporal contexts, for example, define and constrain distributions of individual outcomes. The examination of occupational mobility within organizational or labor-market contexts attempts to nest the process of inequality in the workplace within organizational and occupational boundaries. The availability of occupational positions within a system is seen as being independent of the motivations and other attributes of workers. White's (1970) influential notion of "vacancy chains" exemplifies this approach with its argument that job vacancies produce opportunity structures for individual mobility and define the mobility chances, and thus distributional outcomes, of individuals. Vacancy-chain models have been particularly useful for examining closed opportunity systems, such as internal labor markets (Sorensen 1977).

Distributions of individuals in systems of inequality also are influenced by temporal factors. Merton's (1968) provocative discussion of the "Matthew effect" in scientific career systems argues that over time, initial inequalities in a system bias distributional outcomes in favor of initial advantage. Formal extensions and applications of Merton's notion of accumulative advantage have been applied across contexts (Cole and Cole 1973; Allison and Stewart 1974) to establish patterns of temporal regulation of distributional outcomes over and above the attributes of individuals over time. The cumulative advantage hypothesis has received considerable attention in research on the relationship between age and inequality within cohorts (Dannefer

1987; O'Rand and Henretta 1999). Succeeding cohorts of U.S. populations display growing inequality across the age span, with higher coefficients of inequality at older ages within cohorts and (in recent decades) increased inequality among the aged in successive cohorts (Crystal 1995).

SOCIAL INEQUALITY AS A VERTICAL CLASSIFICATION OR BOUNDED CATEGORY

When social inequality is conceptualized as a vertical classification system, it is treated as an oppositional phenomenon. Here the approach is to define inequality in terms of "the relative position in a matrix of oppositions" (Schwartz 1981, p. 94) of social categories that determine relations of dominance, such as class, race, and gender. Vertical classifications grow out of antagonistic and contradictory interests in the relations of "objective" positions in the social division of labor, not out of the dispersed motivations and interests of individuals. Dominance and subordination emerge from the objective opposition of social categories. Dichotomous, binary, and polar conceptions of inequality (e.g., ruler-ruled, rich-poor, white-black, masculine-feminine) generally are informed by an oppositional framework. Some researchers have argued that this approach to inequality may be the most ancient in human social consciousness (Ossowski 1963; Schwartz 1981).

Class theories that follow Marxian frameworks dominate this approach (Braverman 1974; Wright 1985). Marx's theory of class proposes that class relations in capitalist systems are inevitably in conflict. Since all value is ultimately produced by labor, all (capitalist) profit must be at the expense of labor. The objective positions of the owning class (bourgeoisie) and the laboring class (proletariat) therefore are necessarily antagonistic. Advanced capitalist systems sustain the exploitation of labor through rationalized job-definition systems and the degradation of work (Braverman 1974). Wright (1978) has argued, furthermore, that in advanced capitalist societies, the elaborate differentiation of functions originally embodied in entrepreneurial capitalism into many different categories has not overcome the fundamental oppositional inequality of its origins; contradictory class positions continue to exist as a result of the underlying structure of capitalist relations.

Oppositional frameworks lend themselves to the examination of classlike relations such as those observable in race- and gender-centered systems of inequality. Oppositional approaches to the examination of race inequality can be traced to Myrdal's (1944) pioneering analysis of racial exploitation in the U.S. context. These approaches argue that race is an invariant principle of vertical classification that is masked by ideologies of economic progress and attainment (Pinkney 1984). Debates regarding the inevitability of racial opposition as the basis of inequality center on the substitutability of race and class as categories in the recent history of U.S. inequality. Wilson (1980) has proposed the controversial argument that class inequality has superseded race inequality as the basis of cross-race differences in economic and social outcomes.

Theories of gender inequality extend back to Mill's libertarian essay on the subjection of women (Mill 1859) and Engels's Marxian analysis two decades later (Engels [1884] 1942) of the relationship between private property and the stratification of family (gender) roles. However, contemporary feminist theories provide the strongest argument for gender inequality as an oppositional, vertical classification system. The sex/gender system, it is argued, subordinates women in patriarchal relations that exist over and above class relations (Jaggar 1984), since male dominance over women's productive and reproductive roles predates the emergence of capitalism (Harding 1983). This system of inequality leads inevitably to a conflict of interests and to the emergence of competing ideologies.

Since the notion of dominance is central to vertical-classification approaches to inequality, these approaches are readily applied to the analysis of large-scale systems of inequality, such as the state (Skocpol 1979) and the modern world system (Wallerstein 1974). Mechanisms of domination extend beyond class (or classlike) interests and are observable in the historical relations of nation-states (Reddy 1987) and multistate sectors of the modern world system (Wallerstein 1974). Asymmetrical relations of exchange and dependence between states and geopolitical state sectors create relations of dominance, which define global inequalities. Those inequalities can be formulated as distributional phenomena by following a functional framework; however, the historical analysis

of dominance systems lends itself more readily to oppositional analysis. The classification of the world system into core and periphery sectors that resulted from historically contingent factors introduces notions of centrality and dominance that suggest more than an underlying distribution of resources (Wallerstein 1974).

Tilly's (1998) statement on "durable inequalities" argues that persistent inequalities based on exploitation, opportunity hoarding, adaptation, and emulation largely take the form of bounded (usually dichotomous) categories (male-female, slave-owner, citizen-foreigner, white-black, etc.) that are resilient and readily generalizable across time and social systems. Relationships of inequality persist because participants in paired categories adapt to and participate in the perpetuation of those arrangements.

SOCIAL INEQUALITY AS HIERARCHICAL RELATIONS

When social inequality is conceptualized as hierarchical relations, it is treated as a system of interactions or interdependencies characterized by relative symmetry (equality) and asymmetry (inequality) among relations. Here the approach usually is to define the form of social relations rather than the attributes of individuals in those relations and to account for patterns of unequal relations without referring to oppositions. Inequality or dominance stems from positions in hierarchical relations, not from the a priori possession or control of resources or power by individuals, groups, or categories (Marsden 1983). This relational approach to inequality can be traced to Simmel (1896), whose studies of the structures of superordination-subordination by persons, groups, and principles continue to inform research on hierarchical relations and social networks in modern life (Coleman 1982).

Because social relationships have formal properties such as connectedness, transitivity, reciprocity, and multiplexity, they are measurable units of analysis in the study of social inequality within populations at all levels, from siblings to communities to transnational trading systems (Lin and Marsden 1982). These social units make up complex configurations of social relations within which distinctive positions of relative equivalence or cen-

trality can be revealed (Burt 1982). Thus, in their study of coalitions and elite structures in the German community of Altneustadt, Laumann and Pappi (1976) determined the relational bases of influence between natives and newcomers by using network techniques that emphasized associational patterns rather than personal attributes. Patterns of social distance and connectedness among corporate actors, not the preexisting distribution of resources, defined the influence process in that community.

A study by Granovetter (1974) of the job-search process clearly demonstrates the relative utility of relational over distributional approaches to inequality. Granovetter demonstrates that weak ties, rather than strong ties, in a community prevail in a successful job search. The "strength of weak ties" hypothesis (related to Simmel's *tertius gaudens*, or the third who enjoys) provides the counterintuitive argument that weaker (secondary) social contacts increase individuals' access to jobs more than stronger (primary) ties do. These ties operate independently of the attributes of individual job seekers.

The "strength of weak ties" phenomenon can be extended beyond the job-search process to examine structures of relational inequality in different contexts. Studies of interlocking directorates and informational brokerage systems, for example, demonstrate that loosely coupled relational systems of different forms produce different systems of social inequality (Burt 1982). The network of ties constitutes a social-constraint context within which actors are "captured." Burt's (1983) study of corporate philanthropy as a cooptive relation is a specific example of the relational bases of inequality in a market context. Using Internal Revenue Service data on firm expenditures for advertising and philanthropy, Burt demonstrates that firm philanthropy co-opts the household sector by legitimizing the firm to the public as a protector and by improving the ability of specific classes to purchase the firm's products (Burt 1983, p. 424). The strength of this approach is that advertising, which is more blatantly co-optive, does not escape public suspicion, whereas philanthropy does so more easily. Firms in an economic sector perform unequally as a result of their relative co-optive relations with the public, and the public has a co-optive relationship as consumers in that context.

Finally, it should be mentioned that despite the rationale provided above for the bulk of sociological research on relational inequality, the relational approach has been used to examine the importance of individual resources for social inequality. Indeed, early experimental efforts to study small group processes of inequality demonstrated that both individual resources and social relations can create systems of inequality, whether measured as leadership processes or as communication networks (Thibaut and Kelley 1959). More recently, studies of what Burt (1982) has termed "ego-centered" networks examine network position itself as an individual resource with implications for social inequality.

APPROACHES TO SOCIAL INEQUALITY

The three major approaches to the study of social inequality outlined above have different implications for theory as well as for method. The distributional approach that examines social inequality as a graduated dimension depends primarily on sample data and can be directed toward individual as well as structural explanations of inequality. The oppositional approach to vertical classifications and bounded categories may use sample data but has tended to adopt historical and qualitative approaches to study the institutionalization of dominance in various forms, such as class, race, and gender, as well as other forms of domination/subordination. The relational approach, which provides a direct method for examining the social context of inequality, may use sample or case data to map the configurations of the relations of inequality with implications for explanation at both the individual and structural levels.

SOCIAL JUSTICE

Justice is a basic element of social life. It is a central moral standard in human affairs that involves the necessity of "assuring that each person receives what she or he is due" (Cohen 1986, p. 1). Distributive justice is in the eye of the beholder, and debate usually surrounds the questions of what each person is due and what principles and procedures should be used to decide this. These differences not only occur among persons and social categories within a society but also vary across time and across cultures. A range of competing principles—rights or entitlements, equality of outcomes, equality of opportunity, equity or proportionality of rewards, and the satisfaction of basic needs—are prevalent standards of justice in most realms of

social existence. These principles compete for recognition and application in human affairs, and there is considerable interest in this subject among philosophers, social and behavioral scientists, and others; substantial effort has been invested in the understanding of justice in human life.

Questions of justice, or fairness, arise in virtually all aspects of social life, and the topic of social justice covers a vast array of subjects. The social goods that are of concern in questions of distributive justice include a wide array of things that people want, usually referred to as *primary goods*, including basic freedoms, political enfranchisement, power, authority, status, income and wealth, education and employment opportunities, housing, and health care. In most discussions, it is assumed that those things are scarce, although in some cases that is clearly not always the case; for example, there should be an unlimited supply of basic freedoms in a well-ordered democracy. However, even if social goods are abundant, they have inherent satisfaction value—they are things that bring both extrinsic and intrinsic satisfaction to the individual—and their distribution is governed in part by principles of justice.

A major form of justice that concerns sociologists as well as legal scholars is *criminal or legal justice*, but justice issues pervade many other types of social relationships as well. Justice issues arise very often when inequalities of outcomes exist, but equalities of outcomes also raise questions in regard to justice. In *Nicomachean Ethics*, Aristotle (1953) stated: “For if the persons are not equal, they will not have equal shares; it is when equals possess or are allotted unequal shares, or persons not equal, equal shares that quarrels and complaints arise.” Thus, in certain circumstances, equality of outcomes may be perceived as unjust while inequality of results may be seen as perfectly just.

The experimental literature in social psychology indicates that when persons perceive “inequitable” inequalities, they frequently experience cognitive tensions and a drive to reduce those tensions by changing their judgments about relative investments and contributions or changing their values in regard to the importance of reward-relevant criteria. Research also shows that when experimental subjects in task-oriented settings have well-defined expectations linked to objective indica-

tors and contributions and investments, they find reward inequalities more acceptable (Brickman 1977; Cook 1975). Inequalities in the distribution of rewards also result from power differentials, and those in disadvantaged positions are more likely to view such inequalities as unfair (Cook and Hegtvedt 1986; Molm 1991).

There are several overlapping spheres of equality/inequality in which justice issues are especially important. These spheres concern the *legal, political, economic, and social* realms of existence and cover a broad range of human social behavior. They can be summarized as follows: (1) *legal justice*: the application of laws and procedures to individuals and organizations through a system of rules laid down or established, whether by custom or through the will of the state, for which penalties exist for disobedience, (2) *political justice*: other aspects of social life in which issues of dependence/independence arise from interdependence and from the extent of power and influence held by actors and other parties to the relationship, (3) *economic justice*: the distribution of the material outcomes of existence, where the economic well-being of parties to the relationship is at issue, including access to basic needs and shelter, and (4) *social justice*: the realm of status, respect, and the sense of worth given and received in social interaction or in relation to society.

Because questions of justice in society are so pervasive, most social sciences claim to understand the ways in which human societies deal with them. Thus, the literature on justice is massive and is perceived differently from a variety of perspectives. Extensive scholarship exists in philosophy (Buchanan and Mathieu 1986), anthropology (Nader and Sursock 1986), economics (Boulding 1981; Solo and Anderson 1981; Worland 1986), psychology (Deutsch 1975, 1986; Folger 1984; Furby 1986; Greenberg and Cohen 1982; Mukula 1980; Messick and Cook 1983), and political science (Barry 1981; DiQuattro 1986; Elster 1989; Hochschild 1981; Rae 1981). Justice is also a prominent theme in many traditions within sociology (Alwin 1987; Hamilton and Rauma 1995; Hegtvedt and Markovsky 1995; Kluegel et al. 1995; Markovsky 1985; Rytina 1986; Jasso 1980; Jasso and Wegener 1997), but the issues of justice have been studied primarily by those working in the tradition of social psychology; this article reflects that emphasis.

PERCEIVING JUSTICE

As was noted above, justice sentiments occur with respect to what each person receives relative to what he or she is expected to receive in regard to an important social good in which expectations may be governed by the application of a principle of justice. People's expectations and perceptions of justice focus on a wide range of phenomena, such as sentiments about the fairness of social exchange and contracts, fairness in interpersonal relationships, and the treatment of themselves and others by a social group or by society as a whole. Justice concerns thus represent a ubiquitous aspect of social life at many different levels and in many different spheres.

Expectations are formed not only by reward recipients but by others as well, including both people who are involved in the relationship and observers. Justice sentiments thus derive from comparisons of what is received with what one believes should be received, that is, a comparison of the real with the ideal in a particular context. Those evaluations of differences between these two entities or quantities engage human faculties of perception, cognition, and emotion. Even if one knows little else about justice evaluations, one knows that they are subjective, and justice almost always refers to "justice in the eyes of the observer" (Walster et al. 1973). Of course, these facts complicate the application of justice principles because, even setting aside the issue of which principle of justice to invoke in a particular situation, actors may not agree on what is real, that is, what the true outcomes are. However, to paraphrase a theme in interactionist sociology (from W. I. Thomas), *what is real in the perceptions of humans is real in its consequences*. Thus, if individuals perceive the social mechanisms for allocating scarce social resources and/or rewards as just, presumably the resulting distribution of outcomes also will be perceived as just.

From a social psychological viewpoint, then, a focus on justice is a focus on *beliefs* about inequality and *perceptions* of justice. Justice perceptions are pervasive in interpersonal interaction and exchange as well as in the nature of the relationship of the individual to the larger social collective in the macro-social realm. One way to simplify the vastness of this sociological terrain is to separate ques-

tions of justice and its evaluation posed at the micro-social level from those which occur at the macro level of society or the state (Brickman et al. 1981; Markovsky 1985; Hegtvedt and Markovsky 1995). Micro justice concerns justice evaluations at the individual level with regard to a person's immediate circumstances. Macro justice involves the evaluation of justice above the individual level, for groups or for society as a whole. Clearly, justice evaluations take place across several domains at different levels and focus on the abstract or the concrete. Within each level, one also may distinguish between beliefs about inequality and perceptions of justice at an abstract level, such as how things should be distributed in a fair world, and the evaluation of justice in the "real world," that is, assessments of how fair things are in reality (Kluegel and Smith 1981). In most cases, these various levels and degrees of abstraction cannot be easily separated, for example, in the evaluation of the fairness of child support payments (Schaeffer 1990), the fairness of child custody resolutions (Elster 1989), and the fairness of economic rewards (Sennett and Cobb 1972), but it is useful to draw many of these conceptual distinctions for research purposes.

PHILOSOPHICAL ROOTS

The historical roots of Western conceptions of justice lie in classical philosophy, the Judeo-Christian religious traditions, and the theoretical and ideological underpinnings of legal, economic, and political arrangements. Aristotle's *Nicomachean Ethics* (Book V) provides the classical formulation of the problem of justice. Aristotle's work sought to clarify principles of distributive and retributive justice and formulate the rules for the regulation of social exchange. The Aristotelian logic of justice in market relationships stressed the *proportionality* principle with regard to expected reward given considerations of merit and indicated that most contracts and purchases comply with the going rate of exchange (Cohen and Greenberg 1982, p. 4). Of course, it is not always easy for parties to agree on the "going rate." Worland suggests a crucial dilemma is revealed in Aristotle's work involving competition between justice principles:

It becomes clear that the reference to two different kinds of justice and two different

rules of proportions poses a crucial dilemma. If commodities sell at their fair price—or at a price that reflects the “fair” rate of exchange—then how can society guarantee that exchange at such prices will also provide society’s participants with an income proportionate to their relative “merit” or their standing in the community? How is the rule requiring distribution of common goods in proportion to “merit” to be reconciled with the rule requiring “reciprocal proportionate equality” in the contractual, private exchange of commodities? (1986, p. 48)

Eighteenth- and nineteenth-century philosophers and social theorists resolved this dilemma in a number of competing ways. Marx’s labor theory of value (see Buchanan and Mathieu 1986, p. 12) suggested that the need for principles of justice provided evidence that social institutions would be restructured, abolishing the market system and private goods. Although the notion of communal ownership of the means of production can be traced back to early Greek philosophy and before, this has not been viewed as the most adequate solution to Aristotle’s dilemma. Indeed, communism poses its own dilemmas, and the recent unpopularity of socialism as a political and economic system may provide some evidence of this (see Alwin et al. 1996, p. 124). Markets exist even under state socialism, and from the point of view of studying justice, the existence of a market for social exchange, as well as its comprehension and acceptance, seems to represent an important component in understanding the fairness of social interaction (Thiabaut and Kelley 1959; Lane 1986, p. 384).

Adam Smith, who is considered the philosophical father of modern capitalism, posed the Aristotelian dilemma differently. He observed that the modern economic system had become specialized in the sense that the production, distribution, and exchange of social goods had evolved to a stage in which economic activity was highly differentiated as an institution (Worland 1986, p. 50). Smith believed the “natural” rules by which markets developed and the moral issues of justice were resolved could be determined empirically. What is just, then, was clearly a question of what individual actors considered just not only at the subjective level but also at the macro-social level. The opera-

tion of principles of supply and demand to set a going rate was seen as providing the answer to the moral question of justice. Thus, Smith propounded an early example of a principle that later was articulated in the social psychology literature: the principle that “what is” determines “what ought to be” (see Homans [1961] 1974, p. 250; Heider 1958, p. 235). This, however, falls short of resolving the Aristotelian dilemma because it gives too great a role to existential factors in defining justice.

As Worland (1986, p. 57) suggests, Marx’s theory of surplus value, in which Marx identified the real sources of profit and nonwage income as exploitation of working people by the capitalist class, did much to clarify what can now be seen as a condemnation of capitalist economies in Aristotelian terms. The twentieth-century response to Marx’s critique of capitalism in economics is known as marginal utility theory, which explains the issue of injustice in terms of market imperfections and the existence of monopolistic forms of capitalism instead of real free enterprise. According to Worland (1986, p. 81), the neoclassical response is able only to isolate and clarify “the rules that a market society needs in order to comply with the Aristotelian moral imperative.” It does not answer the deeper question of moral psychology concerning “whether such a society would be able to achieve the social consensus necessary for the practical implementation of the rules.”

The perspective offered by neoclassical economics on moral issues of justice often is seen more as a justification for social inequalities than as a “natural law” of justice. It is reminiscent of Cohen and Greenberg’s (1982) suggestion that each social and economic system evolves its own unique concept of justice. For neoclassical economics, the idea that there may be merit in nonproductive activities or considerations is foreign. By contrast, contemporary political philosophers have attempted to address the broader question of merit. Rawls (1971) evaluates the Aristotelian imperative from a nonmaterial, rational perspective. Rawls’s principles of justice are as follows (quoted from Buchanan and Mathieu 1986, p. 27):

1. *The principle of greatest equal liberty: Each person is to have an equal right to the most extensive system of equal basic liberties compatible with a similar system of liberty for all.*

2. *The principle of equality of fair opportunity: Offices and positions are to be open to all under conditions of equality of fair opportunity—persons with similar abilities and skills are to have equal access to offices and positions.*
3. *The difference principle: Social and economic institutions are to be arranged so as to benefit maximally the worst off.*

According to Rawls (1971), these principles are ordered in terms of their primacy; that is, if principles conflict, the one listed first takes precedence. These principles obviously refer not only to social contracts and exchanges but also to the basic structure of society, including legal, political, economic, and social institutions. In most societies, that includes charters and constitutions, the means of production, competitive markets, the family, the legal system of laws and procedures, and so forth. The basic structure of society is said to specify how and by what principles society should distribute primary goods: basic liberties, powers, authority, opportunity, income, and wealth. The principle of greatest equal liberty specifies Rawls's theory of how basic liberties are distributed, the principle of equality of fair opportunities regulates the distribution of life chances or prospects in the domains of power and authority, and the difference principle governs the distribution of income and wealth (see Buchanan and Mathieu 1986, p. 28).

It is beyond the scope of this article to review Rawls's theory in full or summarize the critical comment that followed, except to note that his theory is utopian in the sense that it describes an ideal society run on the basis of just principles. Rawls does not spell out how one moves from states of injustice such as those found in contemporary society to the ideal situation. Still, no single book has generated more discussion and critique than his *A Theory of Justice*. A prominent contemporary critique is Nozick's (1974) entitlement theory, which departs radically from Rawls by stressing a libertarian view that a person is entitled to the ownership of a social good if it was acquired through just principles. Walzer (1983) argues that it is not possible to write a general theory of justice in the abstract without attempting to assay the "substantive ways of life" of different cultures. To Walzer, "justice" is a relative term, and no abstract

theory of the ideal society can really work because justice does not exist in an abstract theoretical sense but only in terms of social meanings ordained by a particular way of life.

DISTRIBUTIVE VERSUS PROCEDURAL JUSTICE

Distributive justice issues arise when one considers two sets of questions: Who gets what, and how? and Who should get what, and how? Some writers have suggested that the distinction between the concepts of *procedural justice* and *distributive justice* is critical to a complete understanding of the ways in which people evaluate justice (see Cohen 1986; Hegtvedt and Markovsky 1995; Thibaut et al. 1975; Tyler 1984, 1986). Procedural justice refers to the mechanisms or decision rules by which reward allocations of social goods are made, while distributive justice is concerned with the resulting allocation. These are two aspects of the same process and are clearly related, but conceptually they purport to refer to two distinct features of justice. Typically, distributive justice issues are thought of in terms of the comparison of the rewards received by a person or a group with a standard of fairness or deservedness, whereas procedural justice issues refer to the "mechanics" of the system that regulates the process of distribution.

It is useful to distinguish three components of the distributive justice process: (1) the principles for the allocation of goods, (2) the system that governs the application of those allocative principles, and (3) the resulting distribution. While separable in this sense, these are all components of what is best thought of in terms of distributive justice, which is the overriding concept. This view is in agreement with the work of Deutsch (1986, p. 35), who states that "procedural justice is a key aspect of distributive justice," not something that is necessarily separate or separable. Procedural justice matters come to the forefront, suggests Deutsch, and arouse complaints of injustice more often than do the principles of justice, primarily because justice principles are often taken for granted, whereas procedural matters are not.

From this formulation, one can see that these three components—principles, procedures, and distributive outcomes—are likely to be confounded and confused in social life. If there is consensus on evaluative principles and if a clear and just set of

procedures can be said to exist to implement those values, distributive justice presumably will follow. Procedural justice thus is an important component in the evaluation of distributive justice, and in the pure case the evaluation of distributive justice is not problematic. If, however, there is no consensus on the principles for allocating rewards in a social group or society or if there is a consensus but procedures are seen as ineffective or corrupted, distributive justice will be called into question. In such situations, the evaluation of distributive justice focuses on the evaluative principles that should be used, the application of the principles, or both. Therefore, the principles of allocation and the procedural aspects of allocation may be intrinsically inseparable, and it may not be clear whether unjust outcomes result from the "wrong" principle being used or from misapplication of the "right" principle.

In summary, while it seems useful to distinguish procedural justice from other components of the distributive process, it is not at all clear that procedural and distributive justice are really different forms of justice. Instead, they are different aspects of a common process. Clearly, distributive justice issues arise when persons perceive the allocative mechanisms to be unjust or perceive imperfections in the application of just mechanisms to real life. It can be seen, then, that overall evaluations of justice at the micro-social level or the macro-social level may be influenced by perceptions of the fairness of procedural or distributive justice issues. However, this distinction ultimately becomes the empirical issue of whether and under what sets of conditions distributive versus procedural injustice is perceived by the actors involved.

EQUITY THEORY

Much current research on distributive justice traces its theoretical roots to Homans's (1976, p. 249) discussion of the rule of distributive justice, which hypothesizes that unless persons' perceived inputs (contributions, investments, resources, etc.) are equal, some inequality of outcomes or rewards can be expected, and that rewards generally are expected to be allocated in proportion to inputs (see also Heider 1958, p. 288). Responding to what they saw as the need for a general theory of social behavior, Walster and her colleagues (see Walster

et al. 1973, 1978; Berkowitz and Walster 1976) formulated equity theory to integrate the insights from a variety of social psychological theories, including reinforcement theory, cognitive consistency theory, psychoanalytic theory, and exchange theory (Walster et al. 1978, p. 2). Building on the work of Homans, Lerner, and others, equity theory as formulated by Walster et al. (1978, p. 6) contains four basic propositions:

Proposition I: Individuals will try to maximize their outcomes.

Proposition IIA: Groups can maximize their collective reward by evolving accepted systems for equitably apportioning resources among their members. Thus, groups will evolve such systems of equity and attempt to induce their members to accept and adhere to those systems.

Proposition IIB: Groups generally will reward members who treat others equitably and punish members who treat others inequitably.

Proposition III: When individuals find themselves participating in inequitable relationships, they will become distressed. The more inequitable the relationship, the more distress individuals will feel.

Proposition IV: Individuals who discover they are in an inequitable relationship will attempt to eliminate their distress by restoring equity. The greater the inequity that exists, the more distress they will feel and the harder they will try to restore equity.

To define justice, equity theory distinguishes *inputs* and *outcomes*, both of which are expressed in the same units, say, dollars, points, or another unit. Assuming that inputs are positive (for simplicity), the equity principle states that under conditions of justice, there is an equality of relative gains. For two actors (persons, groups, nations, etc.) engaged in social exchange, equity is said to exist when the ratio of profits (outcomes minus inputs) to inputs is the same for both actors involved in the exchange.

While it is clear that rational self-interest is a strong motive for behavior in many types of situations and may be a safe assumption in competitive situations, there are other motivations for behavior (Becker 1996; Elster 1984, 1989). This can be

seen as one of the unnecessarily restrictive assumptions of equity theory; the prevalence of altruism, cooperation, and other forms of prosocial behavior strongly questions this basic assumption. There is plenty of evidence that competitive behavior in mixed-motive games such as the Prisoner's Dilemma can evolve into stable cooperation under certain conditions, such as the anticipation of future interaction (Axelrod 1984). In relationships where intimacy and identification are present, the importance of self-interest as a motive for behavior is considerably lessened (Austin 1977). As was noted earlier, Rawls's (1971) theory of justice, for example, suggests that one principle that underlies the moral judgments made in human society is the principle that social and economic arrangements are established to maximally benefit those who are less advantaged with respect to desirable social goods. Thus, one can see that equity theory as stated by Walster et al. (1978) probably overstates the need to specify a type of utilitarian-based logic for defining justice.

Implicit in this theoretical statement and the experimental literature on which it is based are the assumptions of cognitive dissonance theory (Festinger 1959). Thus, an important way to resolve dissonance is to adjust one's beliefs to conform to reality. However, while the theory's allowance for changes in beliefs is an important feature, there are limits to what people will believe. Elster comments as follows on the concept of "belief adjustment":

Dissonance reduction can also take the form of belief adjustment. Workers who take jobs in unsafe industries alter their estimated probabilities of accidents. As a result, when safety equipment becomes available, they may choose not to purchase it. Here, as in other cases, misformation of private beliefs (or preferences) creates a case for government intervention. . . . Belief-oriented dissonance reduction is a form of wishful thinking [but] . . . acting on beliefs formed in this way can be disastrous and is likely to force a change in beliefs. When action is not called for, the wishful beliefs can be more stable. The "just-world" theory, for instance, suggests that people adjust their beliefs about guilt and responsibility so as to preserve their belief that the world is fundamentally just. The best-known example is the "blame the victim" syndrome. . . . (Elster 1989, pp. 22–23)

Presumably, many beliefs, including beliefs about inequality and justice, achieve a high degree of stability relatively early in adulthood and may not be subject to alteration (Alwin 1994). Expectations may not be altered easily if they are rooted in firmly held beliefs about the legitimacy of inequality.

FROM EQUITY TO DISTRIBUTIVE JUSTICE

In the early 1970s, Deutsch (1975) began to question the proportionality, or equity, principle implicit in much theorizing about justice. He, among others, argued that equity is only one of several principles used to evaluate the justice of outcomes in social life. Principles of justice are used as a basis of "judging individual persons and in judging the basic structure of societies" (Cohen 1986, p. 1). At least five competing principles—equality, equality of opportunity, equity, rights or entitlement, and need—are applied routinely in most realms of social existence. Other principles, such as chance, are really devices for ensuring that a principle of justice—namely, equality of opportunity—is procedurally adhered to (see the discussion of lotteries in Elster 1989, pp. 62–122). While these principles may more or less exhaust the possible criteria for evaluating justice, perhaps the equity principle has been seen as most relevant in many cases. For example, in the work of Homans ([1961] 1974), the proportionality principle is given a prominent place in the discussion of distributive justice, and it is clearly present in many discussions of equity theory (see Adams 1965; Berkowitz and Walster 1976; Cook and Hegtvædt 1983).

However, with time, theoretical work and empirical research have cast the problem of equity into the broader framework of distributive justice, in which justice may be evaluated by one principle or a combination of many different principles. Contemporary interest in the study of distributive justice can be traced to the early articulation of relative deprivation theory, particularly in the work of Stouffer, Merton, and Homans (see Williams 1975). In the last several decades, issues of distributive justice have moved from a primary focus on the psychological and behavioral consequences of patterns of social reward distributions in small group settings (see reviews by Adams 1965; Berkowitz and Walster 1976; Crosby 1976; Cohen and Greenberg 1982; Hegtvædt and Markovsky 1995) to a more recent focus among sociologists on

studying principles of justice evaluation (Alves and Rossi 1978; Jasso and Rossi 1977; Jasso 1978, 1980; Jasso and Wegener 1997).

Justice Evaluation and Social Comparison

Current theories of distributive justice implicitly or explicitly specify *social comparison* as the basis for justice evaluation and the reference standard persons use in evaluating the fairness of social rewards. The following discussion summarizes the author's theory of justice evaluation and social comparison (Alwin 1987). As in most contemporary theories, it is assumed that in evaluating the fairness of a particular reward allocation, persons compare themselves with others (see Berger et al. 1972; Pettigrew 1967; Williams 1975; Gartrell 1982). For example, Homans's rule of distributive justice often is stated as follows (see Walster et al. 1978):

$$\text{Justice} = [\text{P's Reward} / \text{P's Inputs}] - [\text{O's Reward} / \text{O's Inputs}] = 0 \quad (1)$$

Here P and O are two persons in a *local exchange* in which P is assumed to evaluate his or her comparison ratio or rewards to inputs against that of another individual, O. If P perceives that O's comparison ratio is equal to his or her own, then he or she will perceive a state of justice. If this is not the case, some degree of injustice is presumed to exist, and P will perceive that he or she is underrewarded or overrewarded relative to O.

The term "inputs" is used in equation (1) to represent the general reward-relevant characteristics of individuals that are involved in making assessments of the fairness or justice of rewards. These may be contributions, investments, resources, or global status characteristics (see Cook 1975; Cook and Yamagishi 1983). This formulation ignores the concept of costs and their effects on rewards and inputs. In other words, inputs and rewards are thought of as positive quantities. For a somewhat different formulation involving negative inputs and rewards, see Walster et al. (1978).

Several investigators (e.g., Blau 1971; Berger et al. 1972; Jasso 1978) have pointed out that in viewing this identity (equation [1]) objectively, it is impossible to determine which parties are over- or underrewarded when perfect justice does not prevail. Moreover, formulations of justice evaluation as local comparisons cannot cope with the possibility that from the perspective of a more general

referential standard, both P and O may be unjustly rewarded even though their comparison ratios may be equal. This view in no way denies that people make local comparisons of such ratios. The point is that when people make local comparisons, referential standards existing outside the local situation typically are invoked to evaluate fairness.

Berger et al. (1972, p. 122) criticize this formulation, arguing that distributive justice issues arise only in the presence of a stable frame of reference and that justice evaluations are inherently made on the basis of reference to generalized individuals rather than specific others. Using this observation as a basis for reconceptualizing the classical exchange-based conception of justice, Berger et al. (1972) formulate a "theory of status value" that formalizes the process by which persons evaluate the fairness of rewards. They formulate the process in terms of *referential standards*: frames of reference that contain existing information regarding the characteristics and rewards of generalized others. The referential structure formalized by Berger et al. (1972) consists of information about the relationship between levels of characteristics possessed by general classes of persons and the associated levels of social reward. According to this theory, through social exchange persons develop normative expectations about the reward levels typically associated with general classes of individuals, and when persons perceive their reward-relevant characteristics to be similar to those of a particular general class of individuals, they come to expect that their reward levels also are similar. As a consequence of these beliefs about "what is," normative expectations are formed about reward levels that persons can legitimately claim (Berger et al. 1972, p. 139). This conclusion is consistent with Homans's ([1961] 1974) and Heider's (1958) observations that the "ought" is determined in the long run by the "is" and with recent sociological theorizing that argues that social inequalities are often the major basis of their own legitimation (Sennett and Cobb 1972; Della Fave 1980; Stolte 1983).

The Berger et al. (1972) *status-value formulation*, however, is limited in its consideration of the process by which a person selects a referential comparison standard among the many possibilities. Referential comparisons may be based on relatively small groups of persons such as one's coworkers or large classes of persons such as occu-

pational categories. This may appear to be a flaw in the status-value theory; however, it also may be viewed as an asset in that it allows flexibility in specifying the role of various types of referential standards in justice evaluation processes.

Referential Comparisons. While near consensus exists in the social psychological literature that persons use referential comparisons to evaluate how satisfactory their outcomes are, Gartrell (1982) observes that little is known about the origin and visibility of comparative frames of reference. In his own research, for example, Gartrell finds that information on wage rates is often invisible, and such information for persons in other jobs frequently originates from concrete, personal references rather than from knowledge of rates for broad social categories. Moreover, the awareness of wage comparisons frequently appears to relate to somewhat idiosyncratic factors, such as informal social contacts (see Walster et al. 1978). This is consistent with other studies of relative deprivation and status comparison, in which persons are found to rely heavily on information from their own social circles (see Runciman 1966; Rainwater 1974; Coleman and Rainwater 1978). Thus, it may be difficult to specify the origin or basis of a person's referential comparison with objective accuracy. Some experimental research (Major and Forcey 1985) suggests that subjects are most interested in same-sex and same-job wage comparisons.

Moreover, the individual's subjective judgment regarding the "fairness" of a given reward outcome may be a more relevant concept. Jasso's (1978, 1980) theory of distributive justice introduces the term "just reward" to refer to the reward level individuals expect on the basis of referential comparisons conceived in general terms. Jasso formulates the status-value model of Berger et al. (1972) for justice evaluation as follows (1978, p. 1402):

$$\text{Justice} = \text{P's Actual Reward} - \text{P's Just Reward} = 0 \quad (2)$$

That is, for a person to determine the justice or fairness of his or her reward, the actual level of reward is simply compared with the reward expected on the basis of existential (or other) criteria.

This formulation is more general than the one given by Berger et al. (1972) because it permits a

wide range of reference group comparisons and because both existential and nonexistential criteria may be used in the calculus of the "just reward" (see Jasso 1978, 1980). As Blau (1971, pp. 58-59) points out in his criticism of Homans ([1961] 1974), "not all existing practices reflect justice; some are unjust by prevailing moral standards, and the fact that they are expected to continue to exist does not make them just." Thus, there are both existential and nonexistential standards of justice, and either or both may be combined to determine the "just reward."

This "comparison difference" formulation of distributive justice makes the nature of over- or underreward clear, unlike the formulation used by most equity theorists (e.g., Walster et al. 1978). Moreover, in contrast with the classical formulation given in equation (1), both quantities in the equation are expressed in the same units: units of reward. Further, this formulation (equation [2]) satisfies the notion that the individual's subjective judgment regarding the "expected" or "deserved" reward may be the most relevant concept. Finally, the distinction between kinds and degrees of injustice can be measured on a scale that starts at zero, where "perfect justice" occurs. Southwood (1978, p. 1157) has proposed a model very similar to Jasso's model involving what he calls "subtractive interaction" that is intended to estimate the effects of departures of actual reward from expected (or just) reward. This model simply involves estimating the effects of the quantity $x_1 - x_2$, where x_1 represents the actual reward and x_2 represents the expected reward.

Reformulating the Justice Evaluation Model.

Using Jasso's concept of the just reward, it is possible to reformulate the classical exchange-based conception in a way that permits the measurement of the direction and magnitude of departures from justice. First, it is necessary to recast Homan's ([1961] 1974) "rule of distributive justice" given in equation (1) as an equivalence of the ratio of P's and O's rewards to the ratio of their inputs as follows (see Patchen 1961; Adams 1965; Homans [1961] 1974, 1976):

$$\text{Justice} = \text{P's Actual Reward} - \text{P's Just Reward} = 0 \quad (3)$$

Here the comparison ratios are different from those in the classical statement (Walster et al.

1978). They now involve terms in common units: reward units on the one hand and units of input on the other hand. The present formulation of the classical model has two desirable properties: It is intuitively simpler to have the numerator and denominator of such ratios in the same units, and this formulation fits with the psychological mechanism often assumed in justice evaluation: Persons expect their inputs (contributions, investments, resources, or general status characteristics) to be in constant proportion to the rewards they associate with a standard of comparison.

If the Berger et al. (1972) theory of status value is correct is stating that a person, P, uses referential structures that specify levels of reward-relevant characteristics that are similar, indeed equivalent, to his or her own (see also Pettigrew 1967; Williams 1975), it is possible to equate P's and O's inputs on the right-hand side of equation (3), setting the second term on the right at unity, as follows:

$$\text{Justice} = [\text{P's Reward} / \text{O's Reward}] - 1 = 0 \quad (4)$$

If one generalizes the concept of "O's reward" to be the same as Jasso's "just reward," the justice evaluation process devolves to a comparison of P's actual and expected/just rewards:

$$\text{Justice} = [\text{P's Actual Reward} / \text{P's Expected Reward}] - 1 = 0 \quad (5)$$

An examination of this expression indicates that the classical formulation restated in this way permits the distinction between kinds and degrees of injustice measured on a scale that starts at zero, where perfect justice occurs. These units may conveniently be thought of as justice units because when the comparison exceeds zero, overreward occurs, and when it is less than zero, P is said to be underrewarded.

Note the convergence of the reformulation of the classical model given here with that proposed by Jasso (1978), which was derived empirically from the analysis of vignette data. The natural logarithm of equation (5), which is derived from classical exchange and status value theories, equals the formulation for justice evaluation proposed by Jasso. I have derived theoretically a principle of justice evaluation that is equivalent to Jasso's (1978, 1980) empirically derived "Universal Law of Jus-

tice Evaluation." This formulation can be used as a basis for defining departures from justice.

Jasso argues, however, that the simple ratio of actual to just rewards does not capture the justice evaluation phenomenon precisely: It does not account for the fact that positive departures from justice (overreward) are not equivalent to negative departures (underreward), and "this appears to violate the human experience that deficiency is felt to be more unjust than a comparable excess" (Jasso 1978, p. 1403). In other words, the injustice created by an actual reward above the just reward k is not equivalent to the injustice created by an underreward of the same magnitude. Jasso (1978, p. 1415) resolves the problem by proposing the natural logarithm of the comparison ratio (i.e., actual reward/just reward). Such a formulation assumes that an overreward of k times is equal in the magnitude of injustice to an underreward of $1/k$ times. Using satisfaction with material well-being, Alwin (1987) empirically examined Jasso's hypothesis that the effects of underreward are more potent than the effects of overreward. While support was found for the importance of the sense of injustice in the prediction of material satisfaction, the hypothesis that the extent of satisfaction depends on measured departures from justice was not supported.

BELIEFS ABOUT INEQUALITY

As was mentioned above, distributive justice issues arise in response to two sets of questions: (1) the realm of the ideal, that is, who should get what, and how, and (2) the real, or who gets what, and how. As was noted, these issues may be phrased with regard to the individual, the micro-justice level, or groups of individuals or the whole society (i.e., macro-justice). Regardless of the justice principles one espouses, behavior and sentiment are conditioned by how the system works or is perceived to work. One of the important aspirations of social science is the understanding of who gets what and how, and it was the major focus of several important works on social stratification and mobility in the 1960s and 1970s (e.g. Blau, and Duncan 1967; Hauser and Featherman 1977; Featherman and Hauser 1978; Jencks et al. 1972, 1979; Levy 1988; Moynihan 1968; Sewell and Hauser 1975; Wright and Perrone 1977). As a result of that

work, a great deal more is known about the ways in which race, gender, and class affect inequalities and the manner in which families and educational institutions operate to promote or deny access to opportunities for socioeconomic advancement. However, the study of social stratification and mobility is an arcane field of inquiry, and there is not always agreement among social scientists about the main factors that create socioeconomic inequalities (see Herrnstein and Murray 1994 and the debate it provoked, e.g., Fischer et al. 1996).

Sociologists often assume that there is a causal linkage between the structural conditions of society (e.g., the standard of living and economic inequality) and public beliefs and sentiments regarding the acceptability of those conditions, but little is known about the nature of that linkage. There is a growing body of empirical data regarding trends in income distribution and income inequality, much of which indicates growing economic inequality and hardship for segments of the population (e.g., Duncan and Rodgers 1991; Levy 1988; Levy and Murnane 1992; Thurow 1987), but much less is known about subjective interpretations of economic conditions. Thus, while social scientists attempt to understand the inner workings of the stratification system, there is much that remains to be understood, and it is important to realize that a person's beliefs about sources of inequality affect evaluations of justice as much as if not more than objective conditions do (see Kluegel and Smith 1981, 1986; Robinson and Bell 1978; Kluegel et al. 1995).

SOCIAL JUSTICE RESEARCH

This article has argued that one can distinguish three components of the distributive justice process with regard to any primary good: (1) the principles for the allocation of goods, (2) the system that governs the application of those allocative principles, and (3) the resulting distribution. Justice sentiments derive from comparisons of what is received with what one believes should be received, that is, a comparison of the real with the ideal in a particular context.

According to Jasso and Wegener, empirical justice analysis has four major objectives:

(i) to obtain numerical approximations of the quantities and relations identified by jus-

tice theory; (ii) to gauge the extent of interindividual and intergroup variation in the quantities and relations; (iii) to explain their etiology, including the effects of social structure and of the observer's position in the stratification structure; and (iv) to assess their behavioral and social consequences (1997, p. 393).

Three fundamental quantities pertain to justice: the actual condition, the just condition, and the justice evaluation. While justice evaluations involve the comparison of the other two quantities, it is not clear that individuals actually quantify justice in the way theoretical formulations suggest, and it remains to be seen whether most people "calculate" more than a general "sense of justice" from this comparison.

To summarize current research on social justice, one would have to focus on a wide range of distributional issues with respect to the primary social goods of distributed in society, including basic freedoms, political rights, power, authority, status, income and wealth, education and employment opportunities, housing, health care, and the pursuit of happiness. Below, this article briefly mentions five areas in which a consideration of justice theory is relevant to sociological understanding: (1) income inequality and the welfare state, (2) discrimination and affirmative action, (3) gender, work, and comparable worth, (4) divorce, child custody, and child support, and (5) intergenerational relations.

Income Inequality and the Welfare State.

One of the central preoccupations of sociologists who study distributive justice has been the economic realm, with an explicit focus on wages or earnings (e.g. Alves and Rossi 1978; Gartrell 1982; Gartrell and Paille 1997; Jasso 1978, 1999; Jasso and Rossi 1977; Patchen 1961; Randall and Mueller 1995; Robinson and Bell 1978). Research in the United States shows convincingly that individualistic attributions for poverty and wealth predominate (Kluegel and Smith 1986). Such attributions are found across the spectrum of socioeconomic positions, and among lower socioeconomic status (SES) groups these beliefs are held concurrently with structural explanations. At the same time, Americans show considerable antagonism toward any form of systemwide redistribution of income

beyond current welfare assistance to children, the disabled, and the indigent and current forms of social security for senior members of the population.

Whereas Americans hold equality as the standard of justice in the political realm, inequality is the standard in the economic realm. A recent multinational comparison of a U.S. sample with comparable data from other Western nations showed that in assessing the deservingness of their own earnings, “what ought to be” is strongly linked to “what is” (Alwin et al. 1996). Thus, existential considerations play a strong role in the development of judgments about levels of deserved income, although there was considerable variation in the magnitude of those linkages. The weakest effects, as predicted on the basis of perceived system legitimacy, were in the postcommunist economies of eastern and central Europe and the former republics of the Soviet Union. The strongest effects were in the Western capitalist democracies. Indeed, the linkage between job desserts and job income was so strong in those countries (Germany, Great Britain, the Netherlands, the United States, and Japan) that it seemed hardly possible that any factors other than current income levels could contribute to variation in perceptions of justice. By contrast, the level of perceived family need played a much stronger role in evaluations of the justice of earnings in the eastern European countries than it did in the West (see Alwin et al. 1996, pp. 123–128).

Discrimination and Affirmative Action. Discrimination by dominant groups against ethnic minorities and women has been a significant concern of those interested in equality and justice. This set of issues can be addressed easily within the framework of social justice as an instance of the lack of congruence between justice principles such as equality of opportunity and the actual workings of society. Although considerable progress has been made in establishing constitutional prohibitions against discrimination on the grounds of race, ethnic origin, and sex in employment practices, education, and public accommodations, reality has lagged behind those ideals. Substantial inequalities among racial groups persist despite substantial opinion that racial discrimination is no longer a problem in American society (Blauner 1989). Considerable research has focused on the consequences of discrimination.

The concept of *affirmative action* has been used in the United States and other countries to refer to social policies that go beyond prohibitions against discriminatory practices that deprive minorities of their rights and aim social policy toward remedying the effects of past discrimination. Affirmative action represents an effort to restore equity to social groups, rather than to individuals, by targeting women and minorities for educational opportunities, jobs, promotion, government contracts, and other arenas where past discrimination has been documented. Affirmative action policies have been controversial because they appear to represent a form of *reverse discrimination* inasmuch as they violate the principle of equal opportunity by giving preferential treatment on the basis of race and national origin. These policies have faced a number of legal challenges that are likely to continue as long as they are perceived to be unjust by some members of society. Regardless of how one views these policies, they have placed increased numbers of women and minorities in good jobs and selective educational institutions, but they may have increased tensions over these matters.

Gender, Work, and Comparable Worth. An important application of the social justice framework has been the examination of equity in the job rewards of men and women. In the United States, as in other countries, there are legislative guarantees to the right of equal pay for equal work, such as Title VII of the Civil Rights Act of 1964. The concept of *comparable worth* was designed to go beyond this mandate to describe a situation of equal pay for work of equal value, that is, work that requires comparable levels of effort, skills, and responsibility. Rather than being a remedy for past discrimination, as in the case of affirmative action, this approach is aimed at developing policies that will guarantee equal treatment for men and women. While this idea seems to be catching on, there are still substantial gaps in the workplace authority and earnings of men and women throughout the world (see Wright et al., 1995; Jasso and Wegener, 1999), and researchers face a “paradox of the contented female worker” (Crosby 1982). Generally speaking, women have jobs with lower pay, less autonomy, and less authority than jobs held by men, but their level of earnings satisfaction is no different from that of men. Mueller and Wallace (1996) suggest that when levels of perceived justice are taken into account, substantial amounts of the

difference between men and women in their satisfaction with earnings can be explained. What remains to be understood are the factors that contribute to differences between men and women in perceptions of what is just.

Divorce, Child Custody, and Child Support.

Marital disruption is a conspicuous feature of the contemporary family that raises issues of justice not only for the people involved but for the public as well. Apart from justice matters arising from the division of property and assets in a divorce, when children are involved, the settlement becomes more complicated. Child custody disputes and child support issues present unique problems for justice analysis because in the first case the primary goods are indivisible and in the second case costs (or negative rewards) are being allocated. Procedures for resolving both sets of issues are governed by state and federal statutes or guidelines as well as by local customs and have varied considerably across time and culture. Historically, courts have employed justice principles involving parental entitlements to various degrees, but in recent times, the principle has evolved that the best interests of the child ought to be the sole or major consideration in custody decisions. As Elster (1989, p. 126) puts it, "although the child may to some extent and for some purposes be considered a consumption good for the parents, he is also and predominantly a person in his own right" who has an interest in the allocation. Elster argues, however, against the principle of the best interests of the child and suggests that in contemporary society, when joint custody is not feasible, three options present themselves: a presumption in favor of the mother, a presumption in favor of the primary caretaker (usually the mother), and tossing a coin.

Child support payments are vastly more determinate, and those judgments are considerably less Solomonic. Indeed, courts generally have allowed the participants, on the advice of counsel, to negotiate the nature of the awards. In child support situations, decision making occurs in two steps. There is a preliminary determination of an amount to be divided based on the needs of the child and then a decision on how that amount should be divided based on the relative resources of the parents. As Schaeffer (1980, p. 158) puts it, "beliefs about child support awards differ in important ways from other beliefs about justice . . . [because] allocating child support obligations involves allo-

cating not rewards, but responsibilities expressed as contributions." Schaeffer (1980) analyzed beliefs about the fairness of child support judgments by using a factorial survey involving vignettes. She found that child support awards are allocated according to a "proportional contribution-variable need" system in which parents' contributions are proportional to their resources. She concluded that preferences for child support awards embody a "modified version of 'from each according to their abilities, to each according to their needs'" (1980, p. 172).

Intergenerational Relations. Relationships among generations are one of the most important structural features in all societies. Some authors have argued that the prevailing social contract between generations in Western society regarding expectations, obligations, and well-being is changing (Bengtson and Achenbaum 1993). This is due to the changing demography of age but also to shifting cultural understandings of age differences and issues of equity. Bengtson (1993, p. 4) argues that "we have reached a cultural watershed concerning the implicit understanding of rights and obligations between age groups and generations in human societies. Never before have so many elders lived so long; never before have so relatively fewer members of younger age groups lined up behind them in the succession of generations." He argues further that as a consequence, "we are faced with new and historically unique dilemmas of family life and social policy agendas regarding the expectable life course and the succession of generations."

These observations raise a number of questions regarding the nature of intergenerational conflict and the linkage between age and economic expectations, economic performance, and evaluations of material well-being. The concept of justice has been applied to the study of intergenerational relations (see Norris 1987), but little work has explicitly linked social psychological theory regarding equity or justice evaluation to this range of issues. Moreover, researchers often have settled for conclusions based on conjecture or weak and inappropriate kinds of evidence. There is a wide range of intergenerational issues to which the justice framework can be applied, including not only the material well-being of older age groups but also the sense of obligation that adult children have about the support of their elderly parents as

well as public concern about the future health care and social security systems that will support the elderly in the future.

DUANE F. ALWIN

SOCIAL MOBILITY

The term "social mobility" describes the nature and amount of change in social position over time. In principle, this change can be defined for any social entity. Thus, one can study the "collective mobility" of classes, ethnic groups, or entire nations in terms of, for example, average health status, literacy, education, or gross domestic product per capita. More commonly, the term is used in connection with the movement of individuals or families. However, even though social mobility typically is defined with respect to micro units of society, the pattern of mobility across those units generally is considered a core characteristic of a society's social structure, and the study of this mobility generally is recognized as a fundamental area of macro-level sociology.

Social mobility typically is conceptualized in terms of the quantity of movement and the distribution of its direction and distance. The different rates that together constitute the mobility structure of a society is highly complex, however, for several reasons. First, societies have more than one dimension along which mobility can occur. Thus, one can speak of occupational mobility, social class mobility, educational mobility, job mobility, income mobility, wealth mobility, and so on. In principle, one also can use the term "social mobility" to describe movement among nonhierarchical social statuses, such as religious affiliation mobility and geographic mobility or mobility across categories that describe attitudes, belief systems, life

styles, and the like. The dominant use of the term in the literature, however, concerns mobility along a social hierarchy that defines a dimension of social inequality in a society. Second, even with respect to a single hierarchy, the mobility structure is not easy to summarize. A different rate of mobility can be calculated with respect to each combination of origin and destination position along the social hierarchy in question. Empirically, it may be possible to summarize this collection of rates accurately in terms of a function of the social distance between origin and destination or in terms of specific relationships between the origin and destination categories. In general, however, an accurate summary cannot be expressed in terms of a single number. Thus, for each social hierarchy, there is not a single rate of social mobility but a core set of rates that, taken together, can be termed the structure of mobility with respect to the particular hierarchical dimension.

Social mobility is an important issue in sociology for several reasons. For one thing, it is relevant to social equity. Philosophical and moral evaluations of social inequality often depend not only on the level of inequality in a society but also on the extent to which individuals or families can leave disadvantaged states during their lifetimes or across generations. Social mobility is also an important explanatory factor in social theory. The basic stratification variables affect a wide variety of social outcomes and behaviors, but these effects accumulate over time; social mobility therefore affects outcomes by changing the states and durations of these key explanatory variables. The societal rate of mobility also may have macro-level consequences. An early conjecture in this area appears in the work of Werner Sombart, who argued that the failure of early twentieth century socialist parties in the United States stemmed in part from the high rate of American social mobility, which prevented the formation of strong class identification.

The longest-standing tradition in sociological mobility research concerns mobility in occupational groupings or social classes. Much of this work has used "mobility tables" (cross-classifications of origin by destination position) to study "intergenerational mobility," that is, the extent to which the social position of adults differs from that of their parents. Another large body of work has focused on "intragenerational mobility," or the mobility experienced by individuals or families

over the course of their adult lives. Because male labor force participation generally has been higher and more persistent than female participation and because of the somewhat controversial presumption that the status of a family derives from the status of the male breadwinner, for many years these studies focused on intergenerational mobility between fathers and sons, although more recent literature has examined the structure of mobility for women as well.

An important question in intergenerational mobility research is whether overall rates of intergenerational social mobility differ by country. Earlier in the century, scholars hypothesized that the United States had especially high rates of mobility, and some argued that those rates were a consequence of the American meritocratic value system. More recently, it became clear that the primary factors in cross-national differences in mobility rates are structural, not cultural. Differences in so-called structural mobility across countries arise from the extent to which the distribution of positions for sons or daughters differs from the distribution of positions for their fathers. Changes in this distribution across generations (as well as more subtle factors such as class differences in fertility, death rates, and migration rates) necessarily produce intergenerational social mobility. Countries whose occupational distribution is changing rapidly (high rates of structural change) therefore have greater levels of mobility than do countries whose occupational distribution is changing slowly.

Not all social mobility occurs as a result of structural change. The component of social mobility that occurs beyond the amount produced by structural change is typically called circulation mobility, exchange mobility, or relative mobility. The Featherman, Jones, Hauser (FJH) hypothesis of the mid-1970s asserts that cross-national and historical differences in social mobility are accounted for almost completely by differences in levels of structural mobility. According to the strong form of this hypothesis, once structural mobility is taken into account, the pattern of relative mobility chances is invariant over time and across countries. This pattern has three principal features: (1) relatively high immobility at the top and bottom of the hierarchy, (2) higher levels of short-range mobility than long-range mobility (moves from the top to the bottom or from the bottom to the top of the hierarchy are especially rare), and (3) a rela-

tively small impact of origins on destinations in the middle of the hierarchy.

More recent research has determined that even though the weak form of the FJH hypothesis (overall mobility differences are due largely to differences in structural mobility) is supported by the data, the strong form (invariance of relative mobility chances) appears to be false. However, further progress on this issue has been elusive. In particular, the question of whether cross-national differences in relative mobility chances are the subject of such complex national historical differences that they are idiosyncratic or whether they are the product of a more parsimonious set of structural forces (e.g., the extent to which the political system is democratic, the level of modernization, and the level of social inequality) remains to be answered.

Another continuing challenge in mobility research concerns conceptualization and measurement of the component of mobility that is due to structural change. The specification of this causal force in terms of differences in the distribution of positions of fathers and their adult children is problematic for subtle but important reasons. Such an identification assumes that the observed destination distribution is caused by forces (such as technological change) that are not affected by (and therefore are a legitimate cause of) the observed mobility process. This amounts to assuming that the observed destination distribution constitutes a rigid supply constraint, a set of preexisting empty vacancies that are filled by the movement of sample members with respect to their origin positions. This assumption is never perfectly true. If the "supply constraint" is not rigid (and it is unlikely to be so), the observed distribution of destination positions (which by definition represents a summing up of the mobility outcomes for a particular statistical sample) is a consequence of the mobility process as well as of the "structural forces" that constrain the character of this destination distribution. It therefore cannot be taken to be a pure cause of social mobility. The logic of structural mobility becomes especially problematic when subgroups of the population are studied in this fashion. For example, if the distribution of women's occupations shifts toward high-status occupations relative to the total occupational distribution, it is problematic to argue that the relative improvement of women's destinations is a "cause" of

women's higher levels of social mobility as opposed to being a consequence of that mobility. This problem, which is sometimes referred to as the "reflection" problem, has not had a satisfactory solution.

Although structural change is a major part of the explanation for overall levels of intergenerational social mobility in a society, it cannot explain differences in the likelihood that particular individuals will be upwardly or downwardly mobile. The prevailing pattern of circulation mobility that was noted above (relatively high levels of immobility at the top and bottom, the predominance of short-range over long-range mobility, etc.) implies that class of origin is a significant predictor of the types of mobility that do occur. However, an explanation for destination positions that relied solely on the status of origin would be unsatisfactory in two respects: First, the predictive power of social origins by itself is relatively weak; second, the explanation does not indicate how and why social origins matter.

Efforts to redress these deficiencies stem largely from the publication of Blau and Duncan's *The American Occupational Structure* (1967). A major goal of that work was to understand whether the educational system operated primarily as a device that transmitted the status of parents to their children or as an engine of social mobility that freed children from the effects of the status of their parents. To accomplish that goal, Blau and Duncan developed what has come to be known as the status attainment model. Their approach to the study of mobility assumed a dominant metric to social hierarchy: the socioeconomic status of occupations. Their research showed that, at least for men (Blau and Duncan did not study the mobility of women), education was a more important determinant of a son's adult socioeconomic status than were his socioeconomic origins. Furthermore, while educational attainment was strongly influenced by socioeconomic origin, most of the individual-level variation in educational attainment was not explained by socioeconomic origin. Those authors also showed that most of the effect of socioeconomic origins on outcomes was indirect, derived from the effect of those origins on education. Finally, the effect of education on occupational attainment regardless of social background was much larger in the United States than was the direct effect of father's socioeconomic background

(regardless of the son's education). These findings led many to interpret Blau and Duncan's research to mean that the United States more closely approximated an "achievement" than an "ascription" society, although others pointed to the still large (even if not decisive) disadvantage arising from low socioeconomic origin along with the disadvantages associated with being a first-generation immigrant, an African-American, or a woman as constituting important qualifications to such a generalization.

The Blau and Duncan approach essentially divided the intergenerational mobility process into three segments. The first segment concerned the process of educational attainment, the second concerned the transition from school to work, and the third concerned the "intragenerational" mobility that occurs over the working life. Leaving aside the powerful but difficult to specify force of structural change, this division may offer the best possibility for understanding the mechanisms that lie behind intergenerational social mobility as well as identifying possible policy interventions and shedding light on three processes that have great importance in their own right. Each of these processes calls attention to specific institutions (in particular, the educational system and the labor market) that facilitate, limit, or channel social mobility. The focus on how institutional forces constrain the impact of individual resources on individual outcomes sometimes is referred to as the "fourth generation" of social mobility research (with early mobility studies being the first generation, the status attainment tradition being the second, and statistically sophisticated analyses of mobility tables being the third).

A large body of literature has grown around each of these components of the intergenerational mobility process. With respect to education, scholars have conceptualized the educational career as a set of transitions to successively higher grades and have asked whether family background has the same influence at each grade level of this transition process. Results for the United States and several other countries suggest that the effects of family background decline at higher-grade transitions, though these findings are controversial. Assuming that the decline is real, some scholars have argued that the historical raising of the minimum school-leaving age should have reduced the impact of family of origin on outcomes over time.

Again, however, while there is some evidence that the effects of family background have declined during the twentieth century and that these declines are caused by the expansion of education, empirical studies have failed to confirm this conjecture decisively.

A second major focus in the literature concerns the reasons why socioeconomic background is associated with educational performance. It has been appreciated since Sewell and associates developed the "Wisconsin model" in the early 1970s that there is a social psychological component to mobility in which family status is related to parental expectations for the child. In combination with grades in school, peer group influences, and teachers' expectations, this shapes a student's educational and occupational aspirations. More recent work has reconceptualized these family advantages or disadvantages in terms of cultural resources ("cultural capital"), which sometimes are specified as a family's participation in "high-cultural" activities (exposure to art museums, opera, theater, dance, etc.); in other studies, they are defined more broadly (and vaguely) as encompassing all the cultural advantages a family may possess that affect a child's ability to do well in school. Other recent literature focuses on "social capital," which sometimes is interpreted to mean the level and quality of interaction parents have with their children and at other times is interpreted to refer to the resources embedded in the parents' social networks that could in principle influence a child's outcomes. A third, rather controversial focus of attention in recent years concerns possible links between socioeconomic status and genes and the extent to which intergenerational correlations among status variables (particularly educational outcomes) indicate the presence of a genetic force. A fourth focus concerns the specific consequences of low income on children's development and later socioeconomic outcomes. A fifth focus concerns the extent to which the characteristics of schools, neighborhoods, and communities can mute or exaggerate the impact of family characteristics on educational outcomes.

The second mobility component is the transition from school to work. A large body of literature focuses specifically on aspects of this transition, including variation in the extent to which the diplomas, degrees, and advanced degrees provided by schools are linked by law or custom to

specific occupational careers; the extent to which credentials are standardized in a country; the extent to which the supply of those credentials is controlled by schools in light of estimated demand; and the extent to which students who graduate with these diplomas or degrees are provided with knowledge of the relevant job market. Many policy concerns in the United States focus on those who leave school before the tertiary level and the extent to which they are provided with a mix of academic and vocational skills and credentials that is valuable on the job market. Vocational education in particular is organized quite differently across industrialized societies, and in recent years comparative research on this transition has accelerated.

The third component concerns intragenerational mobility over the life course. This research has taken different forms. The Blau and Duncan approach largely emphasized the mean or typical pattern of life-course development as a function of education, first job, and father's occupation. In this form, the question of mobility is reduced to a question about the average status "return" to the resources an individual possesses on first entering the labor market. Although this approach is informative about the typical level of status advancement during the work career as a function of origin conditions, it suffers from two deficiencies: First, it does not explain how education and the first job lead to the current job; second, it does not provide an explanation of the frequency or consequences of deviations from the typical amount of status advancement during the work career.

An understanding of the full distribution of outcomes (i.e., both upward and downward career mobility) is made possible through the use of the "mobility table" approach that has been applied to the study of intergenerational mobility between the status of the father and the status of the son or daughter. The prevalent approach in recent sociology, however, has been more institutional. One line of work has focused on structural linkages between jobs in particular occupational or organizational labor markets. This work has addressed the implications of entering these "internal labor markets" for subsequent career advancement, with an important subset of it directed at questions about whether these institutional mechanisms reproduce, enhance, or mute racial or gender differences. Because these job linkages generally are not

expressed in terms of abstract hierarchical measures such as class and socioeconomic status, studies of these organized labor markets frequently have turned away from the earlier focus on class or status and toward more concrete reward variables such as earnings and job level within an organizational hierarchy. Jobs outside of organized hierarchies that lacked other forms of institutional protection (such as professional licensing requirements) were characterized as “open” or (if low-quality) “secondary” labor market jobs. For several years, sociologists hoped that a parsimonious set of labor market “boundaries” could be operationalized and used to explain labor market outcomes in terms of labor market segment early in one’s career. The promise of this “segmented labor market” approach to career mobility has faded, however. It is now recognized that the boundary between unstable, low-paying jobs in what once was commonly referred to as the “secondary labor market” and “internal labor market” jobs is by no means impermeable, especially in the early years of the adult life course. The segmented labor market approach has been undermined further by the appreciation of the numerically high levels of mobility (including involuntary mobility) out of corporate jobs, often as a result of plant closings and corporate restructuring. Literature on “displaced workers” that has developed largely in labor economics rather than sociology has attempted to quantify the short-term and medium-term career consequences of job displacement (the literature shows only transitory effects on employment but more durable effects on earnings). It can be assumed that job displacement is a principal mechanism by which structural change produces short-term and longer-term intragenerational (and ultimately intergenerational) occupational mobility. However, sociologists have only begun to explore the connection between job displacement and the structural mobility observed in mobility tables.

A separate body of literature has addressed the intragenerational mobility of people who at one time or another in their lives are poor. Aside from questions about the intergenerational transmission of poverty, much of this literature has focused on whether poverty is a permanent or transitory status. It has been recognized that most poverty in the United States is transient, although an important fraction of the poor remain poor for

long periods, while many who escape poverty have a relatively high probability of returning to poverty in the future. Much of this literature addresses the factors that influence rates of entry into and exit from poverty.

Poverty studies use a measure of income, especially income in relation to needs, rather than class or status as the basic measure of position. They typically make the family the relevant unit of measurement because it is family income, not individual earnings or status, that most directly determines poverty status. They also direct attention to the facts that income mobility is a household, not an individual-level, concept; that income mobility can be generated by labor market events involving one’s partner as well as oneself; that public transfers can be an important source of income and can play a significant role in determining levels of income mobility; and that changes in household composition (including marriage, cohabitation, and union dissolution) can strongly influence income mobility.

More recent mobility literature has focused as much attention on instability as on stability (or stable “career advancement”) over time. This emphasis raises important questions about an important presupposition underlying the sociological framework for mobility studies: that it was meaningful to conceptualize the socioeconomic status of the family of origin as a stable point and the “current” status of the adult son or daughter as a “realized” socioeconomic status that could be compared with the point of origin. Early studies were forced by the limitations of data to use parental status at a single point in time (e.g., the point at which the respondent was 16 years old) as the measurement of family status over the duration of childhood. The growing availability of multigenerational panel data that provide information about the possibly changing status of the family of origin during childhood has made it possible for scholars to study how temporal variations in the status of parents affect the process of intergenerational transmission. These more extensive data on the lives of parents and their grown-up children are allowing scholars to study intergenerational and intragenerational mobility with respect to statuses such as income, wealth, and poverty, which are perhaps more volatile than are occupational status and class position.

Questions about racial and/or ethnic or gender differences in mobility have largely been subordinated to gender and racial and/or ethnic inequality and changes in levels in inequality over time. In other words, the focus has been more on the *collective* mobility of these groups with respect to white males than on whether the structure of individual-level mobility within groups defined by race or gender is different from the structure of mobility for white males. This literature has perhaps paid more attention to economic outcomes than to class or status outcomes. Research on gender inequality in particular has avoided the use of status metrics or broad occupational groups, which understate the gender inequality that is visible in earnings. The issue of mobility still plays an important role in this literature because of the possible role of mobility processes in explaining how gender or racial and/or ethnic inequality comes about. In the case of women, the literature has focused on why women take a different mix of academic subjects than men do and on how gender differences in the transition from school to work and in career mobility produce differences in the average earnings of women and men over the life course. In this literature, the pattern and quantity of work experience and the different distribution of men and women across jobs and occupations ("sex segregation") have been the issues of greatest interest. In contrast, the role of specifically intergenerational processes and their possible impact on gender inequality or on the well-documented declining level of gender inequality in earnings has received less attention.

The issue of race is in some respects parallel to that of gender but has its own unique features. Women and men grow up in the same families, while whites and nonwhites grow up in different families, and these differences involve socioeconomic factors as well as race or ethnicity per se. Furthermore, racial and/or ethnic segregation by educational major, job, or occupation has not been as extreme as gender segregation in recent years. However, just as research has shown that the effects of race on income declined over the post-war years (though the trend has stalled and perhaps reversed since about 1980), it also has shown that the direct effects of race on socioeconomic attainment have declined, at least through the late 1980s. African-Americans experience no disadvantage at all in educational attainment because of

race per se (though they experience a disadvantage stemming from their lower average socioeconomic origins). Specifically race-based intergenerational factors still may affect the levels of black-white inequality in the next generation, but they probably operate through the quality (as opposed to quantity) of schooling, and these effects are not well understood.

Comparative analyses of mobility that go beyond the mobility table approach described above are complicated by substantive differences in institutional structures across nations and differences in the measurement of key variables. Nonetheless, progress is being made. In perhaps the most notable application of the original Blau and Duncan model to comparative analysis, Treiman and Yip used the ratio of the net effect of education on occupational attainment to the direct effect of the father's socioeconomic background (this might be conceptualized as a ratio of "achievement" to "ascription") to compare the process of attainment in different countries. This ratio varies from a relatively high level in industrialized societies (particularly in Scandinavia) to a low level in less industrialized societies (with India having the lowest value in their study). Scholars also are focusing on comparative studies of topics such as the transition from school to work, job mobility, earnings mobility, sex segregation, and family dynamics. Many of these studies are being carried out with newly available panel data on demographic and socioeconomic outcomes that are being collected in many industrialized societies. These new sources of data are complex, and it will take several years before a broad-based comparative literature that uses them becomes available. The direction and pace of research, however, are encouraging. Social mobility is likely to retain its vitality as well as its centrality in sociology for the foreseeable future.

THOMAS A. DiPRETE

SOCIAL MOVEMENTS

Social movements can be described most simply as collective attempts to promote or resist change in a society or group. The degree of change advocated and the level at which changes are pursued vary across all types of social movements, whether religious, political, or student. Some movements clamor for sweeping, revolutionary transformations, whereas others pursue specific moderate reforms. The level at which changes are sought

varies from global and national alterations of social structures to attitudinal, spiritual, and lifestyle changes.

TYPES OF MOVEMENTS

Revolutionary movements such as the Bolshevik, Palestinian, Islamic jihad, and Irish Republican movements seek fundamental structural changes. These movements pursue radical changes in a society's basic institutions or, in some cases, major changes in the world order. Because these groups challenge the legitimacy of extant authorities, powerful elites typically use every means, including violence, to repress revolutionary movements.

Reform movements, in contrast, attempt to modify structural relations without threatening existing institutions. Consequently, while some elites oppose any reforms, they are usually more tolerant of reform movements than they are of revolutionary ones. Some reform movements, such as the peace, women's, and environmental movements, are general in scope (Blumer 1946) and often blend a plethora of political and lifestyle objectives. Peace movements, for example, not only pursue a variety of political objectives (e.g., preventing and stopping wars, opposing specific weapons, promoting disarmament, changing foreign policy, establishing conflict resolution institutions) but also strive to persuade individuals to change their attitudes and live more peaceful everyday lives.

Other reform movements, such as the anti-abortion, women's temperance, and anti-drunken-driving movements, focus on specific issues. Although specific reform movements are considerably narrower in scope than general reform movements are, they also may organize around both political and lifestyle objectives (Staggenborg 1987).

Still other reform movements, such as various self-help, human potential, and New Age movements, focus almost exclusively on lifestyle and identity issues. In contrast to other movements, these movements tend to disregard social structural issues. Instead, they concentrate on changing individuals.

Finally, social movements frequently generate organized opposition in the form of countermovements. Countermovements attempt to prevent revolutionary or reform movements from securing the

changes they promote. As a result of their counterreformist tendencies, most countermovements (e.g., the antibusing, McCarthyist, stop-ERA, and Moral Majority movements) are conservative (Lo 1982); that is, they attempt to preserve extant institutions, cultural practices, and lifestyles.

Regardless of the particular type of social movement and the scope and level of change it advocates or opposes, all movements share certain common characteristics that are of interest to social scientists. First, all movements emerge under a specific, complex set of historical, cultural, and structural conditions. Second, as a movement emerges, a variety of participation issues arise, including recruiting new members, building commitment, and sustaining participation. Third, every movement is organized to some degree. The most visible manifestations of movements are their organizations and their strategies and tactics. Third, by virtue of its existence, every social movement has some consequences, however minimal. Although researchers frequently are concerned with the extent to which movements affect social change, definitive answers to this question have proved illusory.

MOVEMENT EMERGENCE

Social scientists have devoted considerable attention to the factors associated with the emergence of social movements. Early theory and research asserted that movements arise when societies undergo structural strain, such as during times of rapid social change (Smelser 1962). These “breakdown theories” posit that “large structural rearrangements in societies—such as urbanization and industrialization” lead to the dissolution of social controls and heighten “the impulse toward antisocial behavior” (Tilly et al. 1975, p. 4). Hence, these systemic “breakdowns” were said to cause an increase in strikes, violent collective action, and social movements.

Later social movement scholars criticized breakdown theories on empirical and theoretical grounds. Rather than viewing movement emergence and participation as aberrations, scholars now view them as “simply ‘politics by other means,’ often the *only* means open to relatively powerless challenging groups” (McAdam 1988, pp. 127–128).

However, if these groups are powerless, it is important to understand the conditions that affect the likelihood that they will mobilize. To do so researchers first turned to the structural factors that are conducive to the emergence of social movements.

One macro structural factor concerns the “structure of political opportunities” (Eisinger 1973). Movements emerge when there is a “receptivity or vulnerability of the political system to organized protest” (McAdam et al. 1988, p. 699). Researchers exploring the U.S. civil rights movement, for instance, conclude that that movement’s emergence was facilitated by a series of interrelated changes in the structure of political opportunities. Those changes included the decline of cotton markets, African-American migration to the North, the expansion of the black vote, and the electoral shift to the Democratic party (McAdam 1982).

Additionally, researchers have identified the absence of repression as a related macro structural factor. Social movements sometimes are spared a violent or otherwise repressive response from the authorities not only during times of breakdown or regime crisis but also during periods of expanding political opportunities such as times of state building. For example, as the former Soviet Union took strides between 1985 and 1989 to open discourse and other political opportunities (“perestroika”), there was a dramatic increase in protest activities (Zdravomyslova 1996). The result is what researchers have termed a cycle of contention: “the phase of heightened conflict across the social system” (Tarrow 1998, p. 142).

During times of increased movement activity, the authorities can, and sometimes do, take an active stance toward challenging groups. However, while their initial attempts to repress movements often fan the flames of discontent and fuel further protest activities, research suggests that the relationship between collective action and repression is bell-shaped (Tilly 1978). If the authorities later respond by increasing the severity of the repression, as occurred when the Chinese authorities ordered tanks and troops into Tiananmen Square to fire on student demonstrators, the cost of collective action usually becomes too high for movements to continue their challenges.

A nation-state can vary in structural factors such as institutional strength, access of challengers

to polity membership and/or decision making, and configurations of power (Kriesi 1996; Rucht 1996; Ferree and Gamson 1999). The political environment, or context structure, of a nation-state then can influence movements and movement emergence. For instance, France after 1981 had a strong, exclusive government and a political party system with large inter- and intraparty divisions. In this case, movement emergence and growth depended in part on the left's support of solidarity movements to gain political advantage. In contrast, Switzerland had a weak but inclusive government in the 1980s, allowing for the growth of diverse groups with multiple areas of focus (Kriesi 1996).

Many contemporary social movements are affected increasingly by globalization, or the creation and intensification of "worldwide social relations which link distinct localities in such a way that local happenings are shaped by events occurring miles away and vice versa" (Giddens 1990, p. 64). Technological revolutions in communications and transportation as well as economic, cultural, and political developments have increased global interdependence and consciousness of the global whole. Globalization thus spawns similarities in movement mobilizations and context structures across different nations (della Porta and Kriesi 1999). These similarities often lead to the cross-national diffusion of values and beliefs, facilitated in part by direct and indirect links between similar movements in various countries. German students studying in the United States in the early 1960s, for example, drew on the American student movement and later on access to networks they found during their stay in the United States in mobilizing their own student movement in Germany (McAdam and Rucht 1993).

Operating in much the same way as cross-national linkages, preexisting organizations in a nation-state serve as communication networks for the discontented members of a population (Freeman 1973). In fact, they can aid or inhibit the spread of information from cross-national linkages. More important, they provide a base for mobilizing the resources needed to sustain a movement. Churches, for example, were important indigenous organizations that contributed to the emergence of the contemporary peace, civil rights, and Moral Majority movements.

Several European scholars contend that state intervention into private domains of life has generated new social movements. According to this perspective, various structural changes in Western industrialized societies, especially changes in the system of production, led the state to seek control over previously private domains. Consequently, private domains such as sexual relations, biological identity, birth and death, illness and aging, and one's relationship to nature "have entered the realm of 'public' conflict" (Melucci 1980, p. 219). New social movements (e.g., the women's, gay rights, euthanasia, and environmental movements) emerged to reclaim those areas from the state.

The foregoing analysis indicates that numerous structural factors are crucial to providing an opportunity for the emergence of social movements, yet those factors alone cannot account for the rise of a particular movement. Why is it that when the structural conditions appear to be ripe for the emergence of a particular movement, frequently no movement appears? To address this question, some researchers have begun to investigate both the cultural and the micro interactional factors associated with the emergence of social movements. What is most important here are the reasons people take action in the first place: their grievances.

As a commonly shared stock of knowledge and activity, culture plays a role in movement emergence by giving individuals a sense of commonality with others. Specifically, culture can aid in the creation of a common identity that sets itself apart from that of other groups. Furthermore, when groups feel subservient in a society, they may create forms of activities and beliefs that express opposition to the dominant culture. This opposition can result in interests and needs that conflict with the dominant culture and in the development of grievances. In the 1980s, for example, the naming of the *Québécois* nationalist movement in Canada set that group apart from the rest of Canadian society by emphasizing the common culture shared by the group's members and symbolized a collective desire for political empowerment (Jenson 1995).

Culture is important in the emergence and cross-national diffusion of social movements, then, because it provides a common way in which to view the world and ways to express that worldview. Indeed, movements, such as the Japanese-based

Nichiren Shoshu/Sokagakkai Buddhist group may actively attempt to spread their worldviews and the cultural actions and artifacts to which they are attached to facilitate movement emergence in other countries (Snow and Benford 1999).

Worldviews are also important because they provide a yardstick by which to evaluate events. When an event fails to measure up against that yardstick, people experience a moral shock that can lead to movement emergence (Jasper 1997). However, although a single event may generate several movements with similar goals, culture can play a role in amplifying the moral shock that leads to collective action. Protests against the Gulf War emerged throughout the world more quickly than they had during previous wars, and there initially appeared to be similarity in the information received by those movements, along with the timing and stances taken by them. For example, the slogan “No Blood for Oil” was used by movements globally (Koopmans 1999). However, while they all were against the Gulf War, the peace movements in various countries mobilized differently on the basis of culturally filtered considerations. French peace movements, for instance, were against any coalition with the Americans. By contrast, the German peace movement was against any potential use of the German military on foreign soil.

The bulk of micro interactional research focuses on individuals’ processes of interpreting grievances. These processes refer to the means by which people collectively arrive at similar definitions of a situation or “interpretive frames” regarding social changes they support or oppose (Snow et al. 1986). Aggrieved but previously unmobilized people must revise the manner in which they look at a problematic condition or aspect of life; social arrangements must come to be seen as “unjust and mutable” (Piven and Cloward 1977, p. 12). This process of cognitive liberation typically involves an attributional shift from blaming oneself to blaming the system for particular problems (McAdam 1982). The expression of these understandings—the definitions of problems, protagonists, antagonists, ideas for change, and reasons for action—constitutes a movement’s collective action frame.

As a cycle of contention continues, movement emergence is influenced indirectly by the move-

ments that emerged early in the cycle. In addition to the structural influences, cultural influences, and need for cognitive liberation mentioned above, latecomers in a cycle must align their collective action frame with a master frame (Snow and Benford 1992). Early collective action frames may gain in both attention and popularity; they may resonate with the audience for which they are intended. In the minds of individuals, these frames are translated into generic codes that indicate how both audiences and movements should understand and react to events. Later attempts to extend the frames by adding further diagnoses, prognoses, and rationales for action may be met with resistance, constraining the emergence of a new movement.

In sum, social movements are most likely to emerge when the structural conditions for mobilization are ripe, cultural contexts provide a common worldview and set of activities to be applied to the situation, the collective interpretation of grievances produces cognitive liberation, and, if necessary, collective action frames are aligned to at least a minimal degree with a master frame.

MOVEMENT PARTICIPATION

Closely related to the issue of movement emergence are questions regarding movement participation: Who joins and why? What conditions affect the likelihood of participating? How do movements build membership and sustain participation? Initial attempts to address questions about movement participation were influenced by breakdown theories. Movement participation was viewed as an irrational response to social structural strains. The factors regarded as key determinants of movement participation ranged from alienation and social isolation to status strains and relative deprivation. Each of these approaches suggested that some sort of psychological malaise or personality defect predispose some individuals to react to structural strains by participating in social movements.

The outburst of collective action and the proliferation of social movements in the 1960s led many social scientists to reconsider the assumptions of breakdown theory. Some theorists redefined movement participation as a rational choice. According to this perspective, people take part in

social movement activities only when they perceive that the anticipated benefits outweigh the expected costs of participation (Klandermans 1984). Research on the conditions affecting cost-benefit participation decisions indicates that this is a complex process that involves numerous structural and social psychological factors (Snow and Oliver 1995).

Social networks also have a crucial effect on differential recruitment to social movements. Movements tend to recruit the majority of their new members from the networks of existing members (Snow et al. 1980). A person typically decides to attend her or his first movement function because a friend, coworker, or relative invited her or him. Those outside such networks are less likely to be aware of the existence of specific movement groups. They also are less likely to attend a movement function if they are not sure there will be others present whom they know.

Overlapping networks in a community increase the probability that an individual will participate in a social movement. For instance, during the 1871 Paris uprisings, persons who were in Parisian National Guard units drawn from their own neighborhoods were more likely to defect and join the communal revolution. Participation increased further when adjacent neighborhoods had similar overlapping networks. In short, the interaction and intricacy of multiple networks increased the likelihood of social movement participation (Gould 1991).

While having social ties to people who are movement participants increases the likelihood of movement participation, other social ties can diminish that probability. Social ties in the form of family and career attachments can constrain movement participation in a number of ways. For one thing, these competing commitments may result in role conflict. The demands of being a movement participant and the demands of being a parent or employee may be incompatible. Married persons who have parental responsibilities as well as full-time jobs may not have sufficient discretionary time to participate in social movements (McCarthy and Zald 1973). Furthermore, spouses and employers can be displeased by a person's participation in a social movement.

To justify their movement participation to themselves and others, participants develop vo-

cabularies of motives. These are rationales that offer compelling reasons for their participation, particularly when their actions are called into question by employers, family members, or friends. Movement participants socially construct these vocabularies of motive as they interact with one another. Activists in turn employ these rationales to encourage sympathizers and adherents to take action on behalf of movement goals.

Vocabularies of motives not only facilitate recruitment to movements but also serve as commitment-building mechanisms. They help participants justify to themselves making sacrifices for a cause. The more sacrifices the participants make, the more costly leaving the movement seems to be. As they relinquish old attachments in favor of new ones, their commitment grows deeper (Kanter 1968). Research indicates that contrary to popular myths regarding participation in new religious movements and cults, these conversion and commitment-building processes are typically voluntary (Snow and Machalek 1984).

Closely related to social ties and vocabularies of motives is the concept of collective identity. Usually based on shared values, beliefs, and personal identities, a collective identity refers to the qualities and characteristics attributed to a group by the members of that group (Hunt 1991). Movement actors develop this sense of "weness" or "groupness" in the course of participating in social movement activities. Participants who have made an emotional commitment to a movement "communicate, influence each other, negotiate and make decisions" (Melucci 1995, p. 45). During these interactions with others, participants continually create and re-create consensus on a movement's goals, strategies, and sites of activity.

Movements generate their collective identity in part by articulating the ways in which movement goals and interests appear to be aligned with the beliefs and values of potential supporters. In the case of the 1989 Chinese Democracy Movement, students framed their goals in ways that were consistent with traditional Chinese cultural narrations. Drawing on Confucian principles, communist ideology, and the rhetoric of nationalism, the students fashioned collective action frames and protest tactics that were concerned with patriotism and the way in which it was defined and drama-

tized. Through their words and deeds, the student demonstrators conveyed their deep sense of responsibility to their country and willingness to offer themselves in sacrifice for the greater good. Those framings tended to resonate well among the general population. Consequently, the Chinese Democracy Movement spread rapidly from students to ordinary citizens (Zuo and Benford 1995).

The emotional component is also important, since it can be changed through persuasion and thus can become a powerful motivation for initial involvement in a movement. Animal rights groups, for example, use pictures of stabbed bulls, starved dogs, clubbed baby seals, and cats with electrodes implanted in their skulls to create anger and draw recruits. Emotions also can help sustain participation. For instance, the songs and dances of Diablo Canyon nuclear power plant protestors in California generated a degree of bonding that helped sustain activity at the protest site (Jasper 1997).

By presenting images of movement participation, the mass media play an important role in the recruitment of individuals. Mass media allow the public to form a response to a potential social problem quickly because events are covered instantaneously. The media provide movements with a larger audience and at times are the only resource people have in constructing the meaning of an event. Although media representations of reality are filtered through people's experiences, the media serve as gatekeepers of information and thus exercise considerable influence on the framing of social problems and thus social movement recruitment.

Social movements do not necessarily rely exclusively on traditional media, however; sometimes movement activists devise their own means of communicating with their target audiences. In the Chinese Democracy Movement, the "illegitimate" status of the student protests precluded student activists from accessing major state-controlled media outlets such as newspapers, television, and radio. During the "crisis," the state even cut off student telephone and telegram services in most Beijing universities. To cope with communication problems, student leaders devised a number of creative means of communication, including protest notices and posters reporting the latest movement decisions and suggestions on campus

building walls and bulletin boards, bicycles to relay strategic and tactical information between campuses, pirate radio broadcasts, E-mail, fax machines, and on-campus speeches and press conferences, to mobilize additional support (Zuo and Benford 1995).

Taken together, research on social movements reveals that participation factors, motives, and experiences are diverse. No single explanation can account for movement participation. Instead, a confluence of factors affect the decision to participate. Similarly, there are a variety of ways in which individuals may participate, ranging from those which require little commitment of time, such as signing a petition and writing a letter to a political official, to those requiring extensive commitment, such as coordinating national campaigns and committing acts of civil disobedience.

MOVEMENT ORGANIZATIONS

The activities of movements and their participants are coordinated by social movement organizations (SMOs). These organizations vary in a number of ways. An important way in which they differ relates to their origins. Some SMOs are organized at the grassroots level by people directly affected by a particular social problem. For example, a woman whose child had been killed by a drunken driver founded Mothers Against Drunk Driving (MADD). Other SMOs are established and sustained by powerful elites from the top downward. Before the disintegration of the Soviet bloc, the state orchestrated official "peace movements" in several communist countries.

Social movement organizations also vary in terms of the level or levels at which a group operates. Some SMOs operate at only a local level, focusing their attention solely on community issues. Others operate primarily at a state, provincial, or regional level, mobilizing around issues that affect that jurisdiction. Still others mobilize at a national level, often attempting to affect national decision making, policies, and legislation. Finally, some SMOs operate in several countries simultaneously. Many of those transnational SMOs focus on issues of human rights (Smith 1995).

Finally, SMOs vary in terms of how they are structurally linked to one another. At one end of

the continuum, SMOs are formally linked to a central authority, usually a national or international SMO. Local Amnesty International chapters, for example, must follow specific guidelines and rules dictated by headquarters. At the other end of the continuum, SMOs are relatively autonomous, not answering to any central authority beyond their own group. Between those two poles, the social movement sector yields a variety organizational arrangements, including loosely federated clusters of SMOs, ad hoc coalitions, and more permanent coalitions.

Most general reform movements spawn numerous SMOs. For instance, by 1984, the U.S. nuclear disarmament movement included some 3,000 independent SMOs as well as another 1,000 local chapters of national organizations. Specific reform movements, by contrast, tend to generate fewer SMOs. Regardless, SMOs are formal groups that can be thought of as the command posts of movements. They acquire and deploy resources, mobilize adherents, and plan movement strategy.

Resource mobilization theorists were among the first to emphasize the importance of SMOs in performing these functions. In particular, they point out that in the absence of an organization, it is difficult for movements to acquire the resources needed to sustain their challenges (Tilly 1978). Contemporary movements require money for advertising, printing, postage, lobbying, staff, and the like.

Other resource mobilization theorists have suggested that studying SMOs reveals how the macro and micro levels are reciprocally linked (McAdam et al. 1988). For example, the resource level of a society affects the resources available to SMOs, which in turn affect recruitment efforts (McCarthy and Zald 1977). In times of economic prosperity, such as the 1960s, the entire social movement sector expands because there are more discretionary resources available for movements in those periods. In this illustration, the macro level (a society's surplus resources), mediated by SMOs, affects the micro level (individual participation).

However, many movements also try to affect the macro level from below, with SMOs again playing a mediating role. Individuals with similar grievances get together in an informal, small group

setting, what McAdam (1988) refers to as a "micro-mobilization context." Sometimes the participants in those ad hoc meetings decide to establish a more formal, enduring organization (i.e., an SMO) to act on their collective grievances. The SMO in turn devises a strategy aimed at changing the system in some way. Occasionally, SMOs succeed in bringing about macro-level changes.

The strategies and tactics a movement employs in pursuit of its objectives typically are selected or devised by SMOs. A movement strategy refers to the broad organizing plans for the acquisition and use of resources toward achieving movement goals. For instance, as was suggested above, movements may pursue social change by devising strategies aimed at changing structural arrangements, strategies aimed at changing people, or both. Similarly, movements may choose between legal and illegal strategies and between violent and nonviolent strategies.

Tactics refer to the specific techniques movements employ to carry out their strategies. Teach-ins, sit-ins, marches, rallies, strikes, and mass mailings are only a few of the tactics contemporary reform movements typically utilize. There appears to be considerable tactical borrowing across the political spectrum. Conservative movements of the 1980s and 1990s in the United States, such as the Moral Majority and the antiabortion movements, for example, employed many of the tactics originally developed by the civil rights and New Left movements of the 1960s.

Tilly made a similar observation regarding eighteenth-century American revolutionary movement tactics. He accounted for tactical similarities across movements and SMOs by noting that every place and time has limited "repertoires of collective action" that are well defined but limited compared with the various theoretically available tactical options. These "standard forms are learned, limited in scope, slowly changing, and peculiarly adapted to their settings" (Tilly 1979, p. 131).

While tactical diffusion across movements and SMOs occurs, a division of tactical labor also commonly arises within movements. Each SMO tends to develop its own specific tactical preferences and expertise. These specializations arise as a consequence of cooperation and competition among the various SMOs that constitute a movement. By

refining and employing specialized tactics, an SMO is able to carve out a niche the movement that distinguishes it from other movement organizations.

Once an SMO establishes an organizational identity, it can build a stable resource base. Some SMOs have been so successful in that regard that they have survived the decline of a movement. Research on the women's movement indicates that such "abeyance organizations" provide continuity from one cycle of movement activity to the next (Taylor 1989) by sustaining activist interaction and commitment during periods when the opportunity structures are unfavorable to mass mobilization. In sum mary, SMOs contribute stability to what is otherwise a fluid, emergent phenomenon.

MOVEMENT OUTCOMES

What effects, if any, do social movements have on social change? This crucial question is not as easy to answer as might be assumed. Because of the difficulties associated with studying a large sample of movements, most researchers study movements one at a time. Although these case studies provide researchers with rich, detailed data on specific movements, they are not helpful in making generalizations. However, even in case studies, the question of the effects of a particular movement is difficult to answer. First, the logic employed is counterfactual (Moore 1978). That is, in evaluating the effects of a particular movement, researchers have to speculate about what the outcome would have been if that movement had *not* existed. Second, the effects of movements are not always immediate and apparent. Some movements, such as the civil rights and women's movements, produce rippling effects that gradually engulf societal institutions, sometimes generating effects several decades after a movement's most intense period of agitation has ended.

To evaluate the outcomes of a movement, researchers examine its explicit and implicit goals, the direction of those goals, and the intended and unintended outcomes of attempting to reach those goals. For example, while the women's movement has ostensibly been geared toward enacting and changing policy, there is also an underlying goal of raising the consciousness of society concerning

women's issues (e.g., women's health, reproductive rights, violence against women, employment). Movement success may be evaluated with respect to a variety of dimensions, including a movement's ability to mobilize people to act, the diffusion of ideas across many cultures or countries, changes in a specific culture and individual sensibilities, and social policy changes. However, while a movement may succeed in some areas, it may fail in others. On the one hand, the women's movement could be considered successful in that it mobilized women both in the United States and elsewhere to take part in the struggle for rights and brought issues such as sexual harassment and unequal occupational status into the open. On the other hand, it has failed to persuade Congress to enact the Equal Rights Amendment, and despite popular myths to the contrary, women still suffer gross inequities in the workplace and at home.

In general, research suggests that movements seem to be more effective in producing cultural than structural change. The enduring legacy of the movements of the 1960s, for example, appears to be cultural. These cultural changes are reflected in attitudinal shifts regarding women and minorities, fashion trends (e.g., blue jeans), popular music, hedonistic lifestyles (e.g., the proliferation of illicit drugs), and the like. By contrast, these movements have had negligible success in terms of structural changes. While civil rights legislation helped dismantle caste restrictions and nearly equalized voting rights in the South, African-Americans continue to suffer "grinding poverty" and "persistent institutional discrimination in jobs, housing, and education" (McAdam 1982, p. 234). Women have realized even fewer structural gains. Finally, the sweeping changes in the economic, political, and educational institutions advocated by student activists never came to pass.

Social movements have been able to affect the sensibilities of both localized and broad publics. Researchers have argued that part of the function of social movements is to make use of and spread the knowledge created in various institutions (Eyerman and Jamison 1991). In the 1950s, a local grassroots environmental movement in Minamata, Japan, for instance, made use of rallies, disruptive protests, legal action, and increasingly favorable media attention during a cycle of contention to bring attention to what medical authorities called

“Minamata disease,” a methyl mercury poisoning caused by local industrial waste that contaminated the fish the local residents ate. Knowledge of how industries affect the inhabitants of the areas in which they operate became a matter of national attention by the late 1960s. However, the goal of obtaining local control over pollution eventually failed in the face of the nation’s need to sustain economic growth through increased national influence on industry after the mid-1970s (Almeida and Stearns 1998). Nevertheless, success may be judged on the basis of the movement’s ability to open lines of communication with the public and its use of those lines to spread new knowledge as it attempts to affect social change.

It should not be inferred, however, that movements always fail to achieve their structural objectives. The mid-nineteenth-century abolitionist movement succeeded in abolishing slavery. Over a century later, the global movement against apartheid in South Africa yielded dramatic successes. In the late 1980s and early 1990s, grassroots movements radically transformed the totalitarian political structures of a number of eastern European countries into more democratic states. Similarly, the transnational social movement organization Greenpeace has aided in the creation, enforcement, and increasing support for international policies controlling the trade in toxic waste. In short, although movements occasionally achieve dramatic outcomes, social structures initially tend to be more resistant than cultures to the revolutionary or reform efforts of social movements.

Gamson (1990) is one of the few researchers who have attempted to identify systematically the conditions under which social movements are likely to achieve their objectives. He traced the activities of a representative sample of fifty-three “challenging groups,” SMOs that emerged in the United States between 1800 and 1945. Gamson measured the relative success or failure of those SMOs in terms of whether they (1) gained new advantages and/or (2) gained acceptance from their antagonists. He found that thirty-one (58 percent) of them gained new advantages or acceptance while twenty (38 percent) gained both.

One of Gamson’s strongest findings pertained to the degree of change advocated. Movement groups that sought to displace extant elites rarely succeeded. Gamson reported that the SMOs most

likely to succeed exhibited the following characteristics: selective incentives for participants (some form of inducement, including rewards and punishments, to participate); unruly tactics (e.g., strikes, violence), especially when the target was relatively weak; bureaucratic, centralized organizational structures; and the absence of factional splits in a group. Although Gamson’s research has been criticized as being too simplistic, it identifies several factors that affect the outcomes of social movements.

In examining the effectiveness of a social movement, it is important to see that success in changing worldviews can be linked to success in changing social structures. Movement activists devote considerable time to the task of transforming the ways in which people view or frame a social issue or domain of life: their interpretive frames (Snow et al. 1986). If a movement’s framing efforts are successful either locally or on a global scale, a general shift in public opinion can occur, as has been the case for the movement against drunk driving (Gusfield 1981). Drivers who once were thought of as foolish or careless have been redefined as “killer drunks.” Subsequently, the movement has found it relatively easy to secure legislation raising minimum drinking ages and increasing the penalties for driving under the influence of alcohol. Although favorable public opinion is not a sufficient condition for social change to occur, it can lead to advantageous changes in the opportunity structure as well as the availability of resources.

Social movements may not always succeed in achieving their goals. Movements have, however, played a significant role in changing the way their members understand their world, the way others understand their world, and most societal reforms, revolutions, and changes in the world order.

SOCIAL NETWORKS

Social networks—structures of relationships linking social actors—are omnipresent in contemporary society. People often obtain information about such things as job opportunities, housing, and medical care through interpersonal contacts rather than from formal sources such as the mass media. Networks provide emotional support in times of crisis as well as instrumental aid such as help with household tasks. Identities are constituted by locations in networks; opinions are formed and decisions are made in light of information and conformity pressures that flow through network linkages. Also, social networks are important channels through which both infectious diseases and innovations are diffused.

Ties among individuals in social networks give rise to important larger-scale social patterns. Levels of socioeconomic or ethnoreligious segregation in a society, for example, reflect the degree to which social ties such as marriage and friendship are confined to sets of persons with a common social status or heritage. Such characteristics become salient as markers of differentiation to the degree that they serve as bases for the formation of intimate social relationships. Networks that link individuals to supraindividual units such as work organizations and voluntary associations may serve as modes of integration or separation. Thus, the study of networks contributes to the linking of micro and macro levels of analysis in sociology.

Many macro-level social phenomena can be understood as networks. Increasingly, systems of production for goods (such as automobiles) and services (such as care for the severely mentally ill) are located in multiorganizational fields consisting of separate but interdependent units linked by contingent cooperation rather than in self-contained units administered through elaborate formalized sets of rules. Innovations in corporate strategy and governance diffuse through overlap-

ping boards of directors and other interorganizational structures. Patterns of consensus and cleavage in community and national politics are shaped by alliances and conflicts in networks of governmental agencies, interest groups, and party organizations. In international relations, network ties among nation-states and international organizations define geopolitical alignments.

Emphasis on social networks grew as a result of substantive observations about contemporary society. Many early twentieth-century observers posited that large-scale transformations associated with industrialization—especially urbanization, bureaucratization, and the development of mass media—led to a “mass society” of atomized individuals in which formal, special-purpose ties supplanted diffuse interpersonal relations.

Several lines of research, however, pointed to the continuing vitality of social ties. Industrial sociologists found that informal structures were crucial to the day-to-day functioning of work organization. Indeed, workplace social networks came to be seen as a solution to the inflexibility and excess formalization of bureaucracies and as important incentives for (or impediments to) the performance of individual employees. Urban sociologists found that friendship, neighboring, and informal assistance remained prominent in large cities, although technological innovations in transportation and communication reduced the extent to which the formation and maintenance of those social ties were constrained by spatial considerations. Rural-to-urban and international migrants were not rootless citizens in a normless society but tended to settle in districts populated by persons from their places of origin. In contrast to the expectations of theories predicting protest and activism among those marginal and peripheral to society, researchers found that those active in social movements tended to be drawn from among the persons best integrated into communities, and social ties proved to be important channels through which new members were recruited to social movements.

A social network perspective highlights the interdependence among social actors. This extends beyond the competitive interdependence of actors competing for shares of a stock of scarce resources to encompass obligations and commitments that accumulate as a result of past social

interaction. Individual action is embedded in, and therefore continually affected by, preexisting ties between specific actors (Granovetter 1985). In some theories, individuals are viewed as largely passive recipients of environmental pressure; in this structural emphasis, social networks constitute constraints that limit an actor’s discretion. An alternative view makes more room for individual agency, viewing networks as structures of opportunity or social resources. Assuming a context of constrained voluntarism, it treats individuals as proactive, self-interested agents who use networks to manipulate outcomes to their advantage (Haines 1988; Emirbayer and Goodwin 1994).

Social scientists have used the term “social network” metaphorically for some time. Beginning in the 1970s, however, scholarly attention to the analytic development of the social network approach increased. It is now seen as a distinct specialty within several social science disciplines, especially sociology and anthropology, and has many adherents in professional schools, particularly those of business administration and public health. Mathematicians and statisticians have participated in this work, especially the development of novel techniques for studying relations between interdependent social units. These methods are distinct from the conventional ones used to study relations between variables within presumably autonomous units. The theoretical assumptions of formal network models are often implicit (Granovetter 1979), and a distinct “network theory” has not developed. Contemporary studies of social networks instead draw on diverse sociological and social psychological theories.

PRECURSORS

Some foundations of a methodology for studying networks of social relations were laid in Moreno’s *Who Shall Survive?* (1934). Moreno coined the term “sociometry” to refer to methods for describing group structures and individual positions within them. His work focused on the affinities and disaffinities of individuals for one another, and his “sociometric test” accordingly stressed affective choices and rejections. These network data were mapped in “sociograms” in which persons were located at different points, with lines indicating the connections between them. Such graphic representations are also common in contemporary

network analysis (Figure 1). On the basis of their locations in sociometric networks of affect, individuals were classified as attractive, isolated, rejected, and so forth.

Jennings collaborated with Moreno in developing sociometric methods; her (1943) work reported studies of attractiveness and emotional expansiveness. Sociometry as practiced by Moreno and Jennings had an applied component: They attempted to use sociometric measurements as a basis for rearranging groups to enhance both group functioning and individual creativity.

Displays such as sociograms are extremely useful as visualization devices but do not facilitate formal analysis. Forsyth and Katz (1946) and Luce and Perry (1949) were among the first to attempt to surmount the limitations of sociograms by representing networks in the form of matrices. They argued that this would reduce the subjectivity of statements about sociometric structure and allow objective identification of chains, groups, and cliques in network data. In later studies, the application of graph theory (Harary et al. 1965) to the analysis of networks has extended those early efforts.

A second set of influences on the development of social network analyses has emanated from the fieldwork of social anthropologists in complex societies. Those analysts observed that the categorical concepts of a structural-functional approach were insufficient for the study of societies in which not all behavior was regulated by “corporate groups”—institutions of kinship, community, or work. Barnes (1954) is credited with the first use of the term “social network” to refer to a set of existing social relationships as distinct from cultural prescriptions about the construction of such ties. In its initial formulations, the concept was used to refer to informal or extrainstitutional links, but it was soon noted that formalized relations and groups also could be analyzed as networks of interactions.

Classic studies in the anthropological tradition display the same variability in theoretical orientations seen in present-day work: Bott (1957) treated social networks as sources of norms prescribing an appropriate allocation of tasks between spouses, while Boissevain (1974) stressed the potential use of networks by maneuvering, self-interested entrepreneurs.

Figure 1. A Social Network Diagram

STRUCTURAL PROPERTIES OF NETWORKS

Social networks are studied from many standpoints, including the sociocentric and egocentric perspectives. Researchers with a sociocentric orientation examine complete networks of actors and relations, studying the global properties of a network and characterizing the position of any given actor by reference to all the others. Egocentric network analysis takes the perspective of individual actors and the “personal networks” surrounding them, focusing on the local structure of each actor’s interpersonal environment.

Figure 1 depicts a complete network with fourteen actors, with each one represented as a circle or square. Lines connecting those points indicate relationships between pairs of actors, such as communication ties and expressions of affect. An actor’s “first-order” egocentric network consists of the other actors to which it is linked and the relationships among them; actor G’s egocentric network includes C, D, and F, while that of H consists of B, L, and N. The “second-order” zone of a focal actor’s egocentric network includes those to which the actor is linked via one intermediary; the second-order zone of G’s network consists of actor A, while that of H includes both A and I.

Arrows indicate directionality; for example, actors A and E are involved in a *reciprocal* relationship, while A and C are linked by an *asymmetric* tie in which the relationship flows in only one direction. *Indirect* relationships join actors to one an-

other through intermediaries: for instance, H and I are indirectly linked through B.

The *density* of a network reflects the overall intensity of connectedness among actors. In Figure 1, sixteen of the ninety-one distinct pairs of actors have direct relationships, and so the network has a density of 18 percent. There are, however, wide variations in the density of the egocentric networks surrounding actors: G is in a very dense or closely knit locality, while H is in a sparse or loosely knit region.

Diagrams of more complicated networks might use lines of different thicknesses to represent relationships of varying intensity or different types of lines to show distinct relationships, such as providing emotional support versus giving instrumental aid. Different types of actors can be represented by different symbols; the actors in circles in Figure 1 might be men, while those in squares might be women. When a relationship typically joins actors that have the same attributes or statuses, as in Figure 1, it is said to display *homophily*.

Social ties, especially those involving positive sentiment, often create *transitive* configurations. In Figure 1, for example, transitivity implies that by virtue of the links between C and D and between C and F, there will also be a tie between D and F. Strong tendencies toward transitivity create closure and tend to fragment a group into distinct *cliques*: The mutually interconnected set of four actors (C, D, F, and G) provides an illustration. Relationships that do not conform to the transitivity principle are important sources of integration between otherwise separate parts of a social structure (Granovetter 1973): in Figure 1, the I-B and A-B ties exemplify *bridges* of this kind.

Actors may be *central* in a network because they are involved in many relationships, are in a controlling position between other pairs of actors, or are comparatively close to others (Freeman 1979). Sociometry referred to central actors as “sociometric stars.” In Figure 1, actors A and B occupy relatively central locations. Those such as E, J, and L are *peripheral* within the network. Actor M is not involved in any relationships and is said to be an *isolate*.

Two actors are said to occupy the same *position* in a social network when they have profiles of

relationships to other actors that are identical in a particular way (Borgatti and Everett 1992); these actors are therefore substitutable for each other from an observer’s standpoint. Two actors having the same relationships to the same others are *structurally equivalent*. In Figure 1, actors J and K both have a reciprocal relationship with actor I but no direct relationship with each other or any of the other actors. J and K are thus structurally equivalent, as are three other pairs: C and D, F and G, and L and N. Actors are said to be *role-equivalent* when they have the same types of relationships to the same types of other actors. Actors L and K are role-equivalent, but not structurally equivalent; although they occupy similarly peripheral locations in the system of relations, L’s direct link is to H, while K’s is to I.

Additional patterns often appear in networks that involve more than one type of social relationship. *Exchange* patterns arise when a flow of one type in one direction is directly or indirectly reciprocated by a flow of a second type. A *multiplex* pattern occurs when the relationship between two actors consists of two or more distinct strands, such as kinship and emotional support; a *uniplex* relationship has only one strand.

Concepts and methods for identifying subgroups within networks have drawn much attention. The two dominant approaches focus on cohesion and equivalence as grouping principles. Techniques that emphasize cohesion locate subsets of densely interconnected actors; fully connected cliques are a limiting case. Blockmodel analysis (White et al. 1976) and related positional methods group equivalent actors together. This yields considerable flexibility. Social positions can be defined by the common ties of actors to outsiders rather than by actors’ links to one another; for example, those in “broker” roles occupy mediating locations between other positions but are not necessarily linked to other brokers. Moreover, positional approaches are not confined to a single type of tie; they can identify subgroups on the basis of patterns in multistranded relations rather than focusing on a single type of tie extracted from its context, as approaches resting on cohesion generally must. Thus, positional analyses of international trade relations may examine flows of raw materials and flows of processed goods simultaneously.

THE STRUCTURING OF NETWORKS

Rational choice explanations of the formation of network ties are based on exchange theory: Social relations form when actors depend on one another for resources. Related behaviorist accounts stress a reinforcement history. An exemplar is Blau's (1955) description of the exchange of advice for expressions of deference among coworkers in a bureaucracy. The terms of exchange and thus the relative power of the actors involved depend on the number of alternative actors who control different resources, the extent of unity among those with a given resource, and the parties' relative interests in outcomes controlled by others (Cook 1982; Burt 1980).

Exchange-theoretic reasoning provides a basis for some commonly observed micro-level network patterns. To maintain autonomy and avoid power disadvantages, actors should avoid asymmetric relations in favor of reciprocal ones. Multiplex ties in which relations of solidarity overlie instrumental exchange links can protect people against exploitation by actors in positions of power. These ideas have played an important role in resource dependence theories of interorganizational relations. Such theories suggest, for example, that interdependent organizations tend to form network ties such as long-term contracts, joint ventures, interlocking directors, and mergers (Pfeffer 1987).

Some attempts to explain tendencies toward homophily are preference-driven accounts in which people actively seek out similar associates. From this viewpoint, communication is easier if people share implicit premises regarding interaction and trustworthiness in the face of uncertainty is enhanced if partners can assume that they have shared interests and predispositions.

Other lines of theorizing about the sources of homophily stress the structure of opportunities for association. Feld (1981) observes that most relationships arise within "foci" of association such as families, neighborhoods, workplaces, and voluntary associations. When segregating processes create foci composed of persons with similar attributes, they create systematic biases toward homophily. Blau's macrosociological theory (Blau and Schwartz 1984) postulates that networks vary with opportunities for association. Blau shows, without any assumptions about preferences, that intergroup relations—the converse of homophilous ones—

are more likely for small than for large groups, when there is great inequality or heterogeneity in a population instead of little, and when different characteristics (e.g., socioeconomic status, race, ethnicity) that structure the formation of social ties are intersecting (or uncorrelated) rather than consolidated. The implications of these factors for intergroup relations depend on the degree to which they penetrate into substructures such as Feld's foci: Distributional effects on intergroup association are strongest when heterogeneity, inequality, and intersection lie within rather than between substructures.

Transitivity has been most intensively studied for relations of positive sentiment; there the theoretical case for it rests on balance theories that posit pressures toward cognitive consistency (Davis and Leinhardt 1972). Tendencies toward closure also may result from increased opportunities for contact resulting from the copresence of actors in a triad, or an actor in contact with two others may facilitate or serve as a guarantor for a venture involving the other two. Principles of expectation states theory predict transitivity in dominance relations (Fararo and Skvoretz 1986).

CONSEQUENCES OF NETWORKS

A network perspective lends itself to the construction of theories at multiple levels. Contextual theories that examine the effects of an actor's position in a network on achievement, well-being, and other individual-level outcomes are common, and extensive research literatures have developed around some of them. Network entrepreneurship, diffusion and influence, social support, and power are among the most prominent themes in such works. Group-level theorizing about the properties of complete networks is less typical, although there have been important efforts in this direction. As Coleman (1990) stresses, group-level theorizing is a demanding enterprise.

Granovetter's (1973) discussion of "weak ties" has been a fruitful source of ideas for network analysts. Although Granovetter defines tie strength in terms of dyadic content (intimacy, intensity, exchange of services and time commitments), the "strength of weak ties" arises from their location within a network structure. Weak ties are less subject than strong ones to the transitivity pressures that induce closure and thus are more likely

to be bridges that join distinct subgroups, thereby serving as channels for integration and diffusion. Different contextual theories positing network effects may stress the virtues of either strong or weak ties.

The purposive use of networks as individual-level “social capital” is a prominent theme in writing about network effects. Much research has been done on how networks facilitate or impede instrumental actions, particularly job seeking. Granovetter (1995) stressed the informational advantages of wide-ranging networks composed of many weak ties. He reasoned that such networks are likely to connect actors to diverse information sources that provide novel information and access to powerful others; by contrast, persons in a densely connected clique are apt to have similar social standing and know similar things. Other writing in this vein emphasizes the content rather than the form of networks. Lin (1990) contends that networks composed of highly ranked contacts are the most advantageous to an actor. Weak ties may facilitate access to social resources, but the aid such contacts can provide reflects their power and influence rather than the type of channel that links them to the actor.

Burt (1992), developed influential ideas about network entrepreneurship. Like Granovetter, Burt stressed the benefits of loosely knit networks for obtaining information quickly. Structural holes refer to the absence of connections between an actor’s contacts in a sparse network; thus, in Figure 1 there are holes separating actor B’s contacts (A, I, and H). Beyond providing actors with the ability to acquire information sooner than competitors can, Burt argues that networks rich in structural holes confer control benefits. Actors at the middle of networks that bridge many holes gain autonomy and leverage over others by virtue of their unique interstitial positions. They are able to place their contacts in competition with one another, avoid excessive dependence, and negotiate favorable bargains. Empirical applications in diverse settings lend support to these ideas: Structural holes have proved advantageous in studies of competition for promotions and bonuses in firms and studies of comparative profit margins in manufacturing industries.

Studies of the role of networks in diffusion and influence processes echo debates over cohe-

sion and equivalence as bases for defining network subgroups (Marsden and Friedkin 1993). This work posits that networks provide actors with a basis for constructing reference groups and social comparisons (Erickson 1988). Approaches that stress the socializing potential of cohesive ties contend that people look to close associates for guidance toward appropriate attitudes or conduct in conditions of uncertainty. Network closure thus is viewed as a source of locally defined norms, as persons in dense networks respond to consistent conformity pressures from their strong ties.

Burt (1987) suggests an important alternative process of diffusion or influence, arguing that in seeking normative direction, actors look not to their close contacts but to their competitors. They engage in a process of role taking, examining the views held or the actions taken by structural peers who occupy similar positions within a system of relations. Conformity to norms here is less a matter of social pressure from the environment than the result of an actor’s mimicry of others (DiMaggio and Powell 1983).

An extensive research literature on the sociology of health and illness draws a connection between social networks, exposure to stressors, the availability of social support, and well-being (House et al. 1988; Thoits 1995). Social networks are “structural” elements that may facilitate access to supportive contacts but also may expose someone to additional stressors, conflicts, and demands; hence, the quality as well as the structure of ties within networks must be considered. A “direct effect” view states that receiving social support enhances health and well-being in all conditions. The “buffering hypothesis” suggests a conditional effect in which those with supportive networks have less severe responses to stressful life events.

Several mechanisms have been suggested to account for the way in which aspects of social networks translate into social support and measures of physical and mental well-being. Some of these suggestions have a Durkheimian emphasis, reasoning that people integrated into dense networks—that is, strongly tied to a number of partners who are strongly tied to each other—have better-defined social identities, stronger senses of internal control, and more positive self-evaluations, which in turn may lead to the use of more effective coping strategies under stress. Collins

(1988) suggests that network density indicates that an individual is integrated into the “interaction rituals” of a solidary group, a situation that produces moral sentiments and energies that enhance well-being.

It is relatively well established that the availability of a strong tie or confidant has health-promoting effects (Thoits 1995). Theories stressing the availability of support resources imply that the size of a personal network is linked to physical and psychological health. Large, diverse networks are thought to facilitate adjustment to change. Contacts in one’s network may offer companionship as well as both instrumental and emotional assistance; they can both provide health information and focus attention on it. Social contacts also may be sources of regulation and control, providing social feedback on one’s behavior and performance, discouraging harmful behaviors such as substance abuse, and encouraging beneficial ones such as adherence to treatment protocols. It is increasingly recognized that providing social support can be burdensome and that stress as well as aid may emanate from relationships within social networks.

Network theorists have given substantial attention to the connection between an actor’s location in a social network and social standing or prestige. Freeman’s (1979) discussion of the conceptual foundations of centrality measures focused on processes in communication networks. He observed that distinct measures are sensitive to communication activity, the capacity to control the communications of others, and the capacity to avoid the controlling actions of others. Many empirical studies have documented an association between centrality and manifestations of power or influence.

Exchange-theoretic approaches observe that actors with predominantly favorable exchange ratios with others are central within networks of dependency relations and hence acquire power (Cook 1982). No universal principle leads to that connection, however; instead, it depends on a particular form of exchange. For Cook this is “positively connected” or “productive” exchange in which actors must combine diverse resources to be successful; hence, the use of one exchange relation tends to encourage the use of others, and advantages emerge for those in intermediary “bro-

ker” positions. Willer (1992) terms these “flow” networks. For Coleman (1990), the requisite conditions include resource transferability or fungibility: For systems of social exchange to develop fully, actors must be able to transfer not only control over resources but also the right to further transfer such control.

Under other conditions of exchange, network positions have different consequences for power. Among these are what Cook (1982) calls “negatively connected” exchange networks and Willer (1992) terms “restricted” exchange networks. In these networks, resources do not flow through positions and the use of one relation rules out or makes less likely the use of others. Matching systems such as marriage and dating markets exemplify negatively connected or restricted networks. In these conditions no special advantages accrue to an actor in a central position; instead, power is concentrated in actors who can exclude others from exchanges (Markovsky et al. 1988). The capacity to exclude others can depend both on the nuances of a network’s structure and on the incentives or rules governing exchange in any given situation. Depending on such subtleties, there may be a nonlinear association between centrality and power; a network also may decompose into small substructures as some potential exchange relations fall into disuse.

Theorizing about network effects at the level of aggregates is less extensive than is that about networks as contexts for individual action. One line of work examines the implications of structural biases toward homophily or transitivity for the spread of diseases and innovations (Morris 1993). Another considers how the centralization or dispersion of networks shapes differences in system performance or effectiveness (Laumann and Knoke 1987). Still another deals with networks and collective action: Social density has been viewed as an infrastructure that allows latent “interest groups” to overcome social dilemmas (Marwell et al. 1988). Granovetter (1973) warns against excessive closure, however: Once formed, a coalition or “collective actor” may lack the social connections required for ultimate political success.

Some theorists have developed the notion of social capital as a collective rather than an individual property. Coleman (1990) suggests that closed social networks can create trust and enforce strong

norms that facilitate collective action. Actors in densely interconnected systems can expect to encounter one another frequently in the future, and a reputation for trustworthiness therefore becomes valuable. Moreover, frequent communication among densely linked actors means that information about a failure to honor obligations diffuses quickly and that sanctions can be applied rapidly. Coleman asserts that strong norms of trust are essential to the creation of "social credit": aid or assistance contributed in exchange for future compensation. Preexisting social networks thus are valuable as sources of social capital to the extent that they are appropriable for new purposes.

Different varieties of network theory make contrasting observations about network density. Density can integrate an actor into a subculture, provide a well-defined social identity, create and enforce norms, and promote the production of collective goods it simultaneously may subject one to conformity pressures and limit the diversity of one's affiliations. Reconciling these seemingly conflicting effects of density represents a challenge in the contemporary study of networks. Understanding the manner in which networks channel and block transactions among the elements of society will remain a crucial and intriguing task for twenty-first-century sociology.

FURTHER LITERATURE

A number of review articles and collections treat aspects of network analysis in greater depth. Mitchell (1974) provides a useful review of the anthropological approach. Wellman (1983) reviews basic principles from a sociological perspective. Review articles on substantive applications appear in Wasserman and Galaskiewicz (1994). The journal *Social Networks* (1978–present), edited by Linton Freeman, presents methodological advances and substantive studies. Marsden (1990) surveys the literature on measurement, and Wasserman and Faust (1994) provide a comprehensive review of analytic methods.

SOCIAL ORGANIZATION

NOTE: Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.

It is necessary to highlight this central area selectively, considering the breadth and variety in its specification, and to emphasize current concerns, relying on past overviews to detail their origins (e.g., by Znaniecki 1945; Gerth and Mills 1953; Faris 1964; Eisenstadt 1968; Parsons 1968; Udy 1968; Smelser 1988).

Social organization is nonrandom *pattern* within human populations that comprise society by shar-

ing the main aspects of a common existence over time as well as nonrandom *patterning*, the human and interhuman activities through which patterns are formed, retained, altered, or replaced. These twin aspects of social organization had been considered *structure*, relatively stable patterns of interrelations among persons or other social units, and *process*, the manner in which the patterns are produced, reproduced, or transformed (see, e.g., Faris 1964). The distinction is blurred to the extent that interrelations vary in *degrees* of regularity, uniformity, and permanence in the rhythms of coexistence, contact, or avoidance of which they consist (Williams 1976). In short, structure can also be viewed as patterned process among human agents (e.g., Blumer 1969, pp. 78–89; Giddens 1979, pp. 49–95; Coleman 1990, esp. pp. 1–44).

At issue is not what is patterned or how, but simply the extent to which there is any pattern or patterning at all. The antithesis of social organization is not opposition or discord. Conflict and other aspects of tension or unrest can, for example, exhibit regularity and uniformity as readily as can union, harmony, and tranquillity. Rather it is randomness, consisting of chaos, formlessness, and idiosyncratic human behavior (Blau 1975) and is called social disorganization. Yet patterned *occurrence* of disorganization is no contradiction.

Social organization is characterized by *interdependence*—that is, what occurs among certain components has, to varying degree, consequences for some or all of the other components and their relations with one another. These consequences can range from loss, even annihilation, to survival and other types of gain. Subsumed are regulation and stability as well as replacement and transformation.

The socially organized units or sets of units are generally activities or actors, individual or plural, that affect one another more immediately—even if simply by coexisting or by their sheer numbers—than do other activities or actors. The former are therefore distinguished (to varying extents) from an environment that might include those other units.

The units considered vary in their distinguishability, modifiability, and permanence. For some purposes they have been defined as concrete entities, such as persons or countries, or as activities by these entities, such as acts of persuasion or conquest. For other purposes the units have been

defined abstractly as only certain aspects of concrete entities or of their activities, called roles or functions (e.g., Hawley 1986, pp. 31–32), that signify position or participation in a particular aspect of collective living, or as complexes of these entities or activities. Examples are worker, labor, industry in production; official or bureau, directive, central administration in governance; judge or court, adjudication, court system in jurisprudence; supplicant or temple, prayer, denomination in religion; friend or friendship group, attachment, solidary web in emotional bonding; and lecturer or college, teaching, school system in social learning. It will be noted from these examples that units can be sets or combinations of other units. They are called substructures when they constitute broad components of social organization not detailed as to their composition. Examples of *societal* substructures are political state, economy, or moral community.

Structure subsumes both form and content: form generally in the senses of numbers, sizes, shapes, assemblage, connections among units, and directions of flow (say, of resources or persuasion); content in the sense of type of unit, substructure, relationship, or process. Clearly this distinction, though convenient for exposition, is not absolute. Units have been assigned to types on the basis of their forms. And there is form when the same everyday dramas can be “performed” in virtually any setting, whether work or nonwork (Goffman 1959).

FORM

In conventional usage, form implies arrangement in space (not necessarily physical space) and in time. It also implies relationships among elements, in this case the units, against a background—the environment—which is conceived as external to structure (Hawley 1986, pp. 10–44; Smelser 1988). The environment may contain units with which concrete portions of the structure have relationships. Thus environment’s separation from structure is often abstract, especially where environment’s nonphysical attributes are concerned.

Form can be classified by the processes that occur among the units. Among pure types that are widely investigated are markets, characterized by competition and exchange; arenas, characterized by interunit struggle and alliance; collectivities,

characterized by cooperation in joint activity—that is, acting in concert (Parsons and Smelser [1956] 1965, p. 15), even if coerced; and aggregates, characterized by the absence of relations between the units.

These forms occur with a variety of contents. For example, markets not only process goods, services, and labor; they can also process social resources, such as information, intimacy, commitment, information, influence, and prestige. Arenas need not only be political; they can also exist within, say, the family. Collectivities may be found in any or all aspects of human living. And labor forces, electorates, viewerships, school enrollments, and populations of organizations (Aldrich and Marsden 1988) may all be conceived to constitute aggregates. Crosscutting the degrees to which these pure types are approximated are the variables of segmentation, stratification, specialization, scale, and endurance.

Segmentation. Segmentation is division into or banding together of like units (Parsons and Smelser [1956] 1965, p. 256; Parsons [1966] 1977, p. 25; Luhmann [1977] 1982, pp. 231–235, 242–245; Wallace 1988). Tribal societies, for example, can, in their inception, be considered markets constituted by exchange of spouses among relatively small family groups—the segments—that avoid internal marriages (Habermas [1981] 1987, pp. 161–162). In the case of collectivities, segmentation—called categoric organization (Hawley 1986, pp. 70–73)—enables each to accomplish more than could be accomplished separately, as, say, in the union of family groups in hunting and gathering societies (Duncan 1964; Lenski 1975; Hawley 1986, pp. 34–35), in a union of persons pursuing the same occupation, or in the replacement of one national corporation with several regional units. Categoric organization can also replace, at least in part, what would otherwise be mutually destructive competition or conflict or can otherwise create a more predictable environment for the participating unit. Examples are umbrella units that form among populations of special collectivities facing unpredictability in “turbulent environments” (cited by Scott 1987, pp. 122–123), even if they serve as no more than clearinghouses for information. All things being equal, ethnic pluralism—that is, subdivision into collectivities having different histories and life-styles—is another illustration of segmentation.

Stratification. For present purposes, stratification means the ranking of units or sets of units in their capacities to affect the existence and activity of other units or sets by controlling resources. This occurs through manipulation or struggle, as a result of competition or exchange, or voluntarily. Stratification and segmentation can co-occur. Where agriculture is the main economic activity, for example, it has been observed that rank tends to be associated primarily with size of landholding, if any; and where land ownership is also associated with other ranking criteria, as in earlier India, it is likely to serve as a basis either for strata (layers) or for collectivities of same-rank kinship units (Landecker 1981, pp. 33–34, 97). More complex social organization can consist of stratification among units that are themselves stratified. For example, it has been shown that the nations of the world are both internally stratified and stratified vis-à-vis one another (Wallerstein 1979), although effects of the one structure on the other are variable (see, e.g., Evans and Stephens 1988).

Specialization. In its pure sense, specialization refers to composition of unlike units that only taken together can accomplish all that is deemed significant. As a division of labor (Smith [1789] 1976; Durkheim [1902] 1964; Rueschemeyer 1986), specialization is characterized by greater interdependence—facilitative *or* inhibitory—than in the cases of simple segmentation or stratification. Segments can be added or lost with little effect; specialties cannot. Specialization ranges from little more than by age and sex in hunting and gathering societies, possibly with part-time political and religious leadership, to thousands of occupational specialties and nonoccupational roles in industrial and postindustrial societies (Lenski 1975, 1979; Hawley 1986, pp. 31–37, 64–67).

Generally also stratified, this form of social organization has been called corporate in distinction to categoric (Hawley 1986, pp. 68–69). The specialized units can be individuals or certain of their roles, as in a family, a small commune, or a small business enterprise; or they can themselves be segmented, stratified, or specialized internally.

Scale. Frequently associated with other aspects of social organization is its scale, variously specified as, for example, the number of units encompassed; the number of levels at which units are nested into progressively more comprehensive

units; or lengths of chains in the modification and flow of materials and services, information, influence, or command.

Contrasted with today's enormous urban settlements and nation-states are the unspecialized and unnested bands of twenty-five to forty or so hunters and gatherers (Lenski 1979). Specific examples of nesting—often accompanying or accompanied by stratification and one type of chain—are world system, country, province, and locality; Catholic Church, archdiocese, diocese, parish, and priest or parishioner; corporation, division, department, and job. Nesting is bypassed when, for example, transnational corporations become disassociated from local, provincial, or national jurisdictions; when religious ties crosscut nation-states; or when staff activities or occupational associations occur irrespective of level (Turk 1977, pp. 923–224; Tilly 1984, p. 136; Hawley 1986, p. 104).

The more activities become organized into large, specialized, but unnested units at higher levels of social organization, according to one body of theory, the less likely are the constituent units to be interconnected (references cited by Turk 1977, p. 65; McAdam et al. 1988). Each of the aggregates that result, sometimes the set of all such aggregates, is called a mass. An example is loss of relationships based on common residence to the extent that the local community is penetrated by specialized large-scale nonlocal collectivities called organizations (e.g., Turk 1977, pp. 65–66, 208–209).

Endurance. An important basis of classifying structure—or, for that matter, any complex unit or relationship that comprises structure—is by the extent to which it predates and outlives, or is otherwise independent of, specific units. Factory workers and managers are relatively replaceable, but a marriage does not substitute a new spouse for one that has been lost without becoming a different marriage. A market can be independent of particular producers and consumers, but a partnership or international bloc is not. Moreover, general features of factory, family, market, partnership, or bloc—or the means of generating these—tend to predate and survive as prototypes any of their specific instances (see, e.g., Jackson 1990).

Combinations. Hybrid forms, some of them complex, occur when segmentation, stratification,

specialization, and nesting are considered with respect to one another or with respect to markets, arenas, collectivities, and aggregates. Further, units can themselves be composed of other units in ways other than by nesting, or they can themselves be patterned. A few illustrations follow.

Organizations are specialized collectivities. Defined as complexes of more or less cooperative relations directed toward more or less specific objectives, these units have been said to occur in every known society as “the major vehicle through which concentrated goal-directed effort takes place” (Udy 1979). They, the aggregates they comprise, and relations among them—including organizations of organizations—are considered to be primary units of social organization, at least in industrial and postindustrial communities and nations (see, e.g., Turk 1977, 1985; Skocpol 1979; Perrow 1986; Evans and Stephens 1988; Perrucci and Potter 1980; Coleman 1990).

Markets and arenas generally affect and are affected by collectivities—including ones that they nest or in which they are nested, that they constrain or by which they are constrained—shaping units so they can compete, exchange, struggle, or ally themselves with one another (see, e.g., Stinchcombe 1986; Coleman 1990, esp. pp. 266–321, 371–396, 689). Indeed, organizations and other kinds of collectivities can affect the conditions under which other organizations are formed in substitution for markets (Williamson 1990). Clearly, positions within the organizational substitutes may be filled in turn by labor markets (Stinchcombe 1986; Granovetter and Tilly 1988).

Sizes of aggregates can affect social organization (see citations by Eisenstadt 1968). Sheer numbers make it impossible for each unit to have relations with each other one. This affects the probabilities of positions, networks, or organizations that channel and mediate social relationships (research stimulated by Simmel 1908, pp. 55–56). More recent work shows how specific interconnections, such as marriage or crowd behavior under conditions of threat, can be affected by aggregates, by their relative sizes and other properties, and by relations among these properties (e.g., Blau 1987, Coleman 1990).

Network analysis has added precision to the measurement of form—say, of stratification or of degrees of interconnectedness—by detailing the

connections (links) among units and the patterns that these provide (see, e.g., Cook 1977; Leinhardt 1977; Burt 1982; Turner 1986, pp. 287–305). Its techniques are uniquely suited to the chains, clusters, and sequences of exchange, cooperation, alliance, or command over which goods, services, money, information, or influence flow. Associated with scale, for example, can be the number of points between origin of flow and its completion. Network formulations have also proven especially useful in identifying relations among organizations that affect concerted action locally (Turk 1977; Galaskiewicz 1989) and ones that affect it nationally (Laumann and Knoke 1989).

Complexity. The very complexity of social organization—the number and variety of units, levels, and interconnections—is itself an aspect of form. Though admittedly crude (Luhmann [1977] 1982, pp. 232–233; Tilly 1984, pp. 48–50; Rueschemeyer 1986, p. 168), this variable can be used to account for other aspects of social organization (e.g., Lenski 1075, 1979; Turk 1977; Habermas [1981] 1987, pp. 153–197; Luhmann [1977] 1982, pp. 229–254; Rueschemeyer 1986).

CONTENT

Classification of units—including complex units—is necessary for similarity, stratification, or specialization to signify more than simply differences in form. Among many, two bases of classification stand out. Sometimes applied jointly, the one emphasizes objective consequences—positive, negative, or neutral, and varying from 0 in degree—the other communicated, remembered, or recorded meanings and rules. Examples of the two bases follow.

Consequences. Substructure has been classified according to its consequences for stability and change in overall structure (e.g., Marx and Engels [1846] 1970; Marx [1859] 1971; Parsons [1966, 1971] 1977; Luhmann [1977] 1982; Habermas [1981] 1987; Hawley 1986). Among these, adaptation to the environment and of units to one another have been stressed (see, e.g., Duncan 1964; Lenski 1975, 1979; Parsons [1966, 1971] 1977; Habermas [1981] 1987; Luhmann [1974–1977] 1982; Hawley 1986), quite likely because socially organized life has been observed to be the major

adaptive means available to primates (e.g., by Lenski 1975).

Thus, the distinction is often made between (1) economic substructure affecting environmental adaptation for the generation and distribution of general resources (e.g., gross national product, homelessness) and (2) political substructure affecting the generation and distribution of general capacity to mobilize resources for concerted action, including action by opposing collectivities (e.g., national efforts, party campaigns, uprisings). Further distinction involves (3) substructure affecting the generation and distribution of general bonds or schisms that provide harmony or discord among units (e.g., community cohesion, solitary antagonism; see Parsons and Smelser [1956] 1965, pp. 48–49; Parsons [1966] 1977, pp. 135–140; Hawley 1986, p. 66; Coleman 1990, pp. 91–116, 175–196, 517–527) and (4) substructure affecting the generation, distribution, and maintenance of participation in structure: recruitment of units (including but not limited to procreation) and their training, allocation, motivation, and retention—in short, the populating and regulating of social structure.

Meanings and Rules. The classification of content can also rest on disputed or common meanings, understandings, purposes, or binding rules (including law) that are communicated about environment and structure. Communication can involve all kinds of participants or only certain ones and can be modified depending on the context (Goffman 1959). The products of communication vary in their permanence through repetition, recording, or recall; in their breadth of dissemination and acceptance; and in their association with sanction—that is, support by enforcement or other incentives to comply. They can, but often do not, coincide with the structure's objective consequences (Habermas [1981] 1987, esp. pp. 153–197) but can affect it.

Most theories of social organization allow for the effects on stability and change of sanctioned agreement, or of oppositions among sanctioned agreements, calling the product institutional or cultural. They differ in terms of the importance the institutional component is said to have for structure.

Near the one extreme, institutional rules are viewed as “higher level” determinants of social

organization (Parsons [1971] 1977, pp. 234–236), not only of relations among units but also of the units themselves (Meyer et al. 1987; Coleman 1990, pp. 43–44, 325–70). Here the rules governing specific structure are considered to be products of more inclusive structure, such as political state or church (Znaniński 1945; Turk 1977, pp. 210, 215–221), or to be elements of a world “culture pool” (Moore 1988; Meyer et al. 1987). Near the other extreme, meanings (“ideas”) are viewed primarily as by-products of the material relations of production (Marx and Engels [1846] 1970, pp. 57–60) or in terms of their significance for organized adaptive processes vis-à-vis the environment (e.g., Duncan 1964; Lenski 1975). Meaning, if the concept is employed at all, is restricted to the acting unit’s purposive rationality: its adoption, within the limits of error and imperfect knowledge or skill, of means that are appropriate to specified outcomes (see, e.g., Hawley 1986, pp. 6–7).

A second source of variability is the degree to which the institutional can be seen as analytically distinct from structure. Some consider the institutional to be an aspect of the environments of substructures and other units (Parsons 1968; Meyer and Rowan 1978; Hawley 1986, p. 79; Meyer et al. 1987; Coleman 1990, pp. 43–44). Others see it as relatively inextricable from structure (e.g., Giddens 1979, pp. 49–85), specifically where structure is viewed as formed and modified through interpretive interaction between persons or groups, in which interpretations are frequently but not always shared (Blumer 1969, pp. 86–88).

The third issue regards the degree to which structure is “spelled out” by the institutional. There can be precise rules that govern even the minutiae, as on an assembly line or in religious ritual. There are also general principles that reduce the number of structural alternatives without determining structure precisely (Parsons [1971] 1977, pp. 193–194), as in such ideals as freedom, rationality, retribution, obedience, protest, solidarity, revolution, contract, and property. Relatedly, there can be shared common-sense reasoning (Collins 1988, pp. 273–291 on Garfinkel) on the basis of which “sense” is made of structure. Or there can be broad myths that serve to provide accounts of social organization (Meyer and Rowan 1978, Goffman 1959) on the basis of which, rather than on the basis of performance, structure is justified.

Agency, as do most theories incorporating meaning, rests on the general idea of interest—variously called purpose, intention, motive, or goal and variably emerging during a course of action—and on the availability of action alternatives (e.g., Giddens 1979, pp. 55–56). Agency is the extent to which purposive action by and interaction among the units affect social organization. There is little need to consider what individual units contribute to organization or why (Hawley 1986, pp. 6–7). When structure, environment, or rule are viewed as an absolute constraint or as providing only limited choice (see, e.g., Blau 1987), or where social organization results from natural selection (Lenski 1975, 1979).

This is not the case where structure and culture simply set loose conditions for action and interaction. Important here for structural and cultural stability and change are the processes (1) by which interests are pursued under the influence and constraint of other actors (Homans 1975); (2) by which the conditions of action are interpreted through social interaction (Blumer 1969); (3) by which the acting unit monitors and adjusts the components of action, even intention, throughout (Giddens 1979, pp. 53–59); and (4) by which individual and collective actors choose means of implementing their interests (Coleman 1990). These processes are significant both to the reproduction and to the transformation of structure and institutional rule.

Classifications of meaning are numerous. Yet they frequently rest on one or more of the following variables (polar approximations in parentheses): (1) specificity: the scope of the relationship, from specific to diffuse content (e.g., organizations or special markets vs. unspecialized collectivities or conflict arenas); (2) universalism: the extent to which relationships hold for all units belonging to a category or only for particular ones from that category (e.g., upholding sovereignty of any nation or opposition toward all governments vs. a treaty or a declaration of war); (3) neutrality: the extent to which relationships are means to ends vs. ends in themselves (e.g., banking transactions or job competition vs. flag-raising or flag-burning ceremonies); and (4) performance: the extent to which relationships are based on what units do rather than on what they are (e.g., production relations or industrial conflict vs. aristocracy or racial conflict).

Concrete as well as abstract structures have been classified according to various combinations of values of these variables, leading to widely used typologies. More generally, any variables used to define content and form serve the analysis of overall structure by describing its various aspects or its different parts.

FORM AND CONTENT

Structure can vary in the extent to which substructures—such as the four whose consequences were noted—are abstractions, involving the same concrete units rather than different ones. At the low end of this continuum, the units comprise a single unstratified and unspecialized collectivity, approximated by a tribal society or a commune, in which each act affirms the totality (Durkheim [1902] 1964; Luhmann [1974] 1982, 1987, pp. 153–197), having every kind of consequence for it. In it myth tends to blur distinctions among the objective, social, and subjective worlds and between society and its natural surroundings (Habermas [1981] 1987, pp. 158–159), and there is comprehensive and detailed regulation of activity. The units not only resemble one another but also tend not to have separate identities. In short, relations tend to be particular to the given collectivity, not universal; affective, not neutral; ascriptive, not performance-based; and diffuse, not specific.

In examples of this noncomplex instance, economic and political organization tend to be extensions of family, extended family, religious group, and common territory, which overlap to considerable degrees. Commitment to any one aspect of social life tends to be supported and sanctioned within all of the others (Habermas [1981] 1987, pp. 156–157), and there are relatively few conflicting constraints, structural or cultural (Blumer 1969, pp. 87–88).

Compliance to one cluster of rules and understandings is approximated, with utility, sanction, attachment, and/or commitment as its basis or bases. Here change has been attributed, in the main, to changes in the environment or in ways of coping with it (e.g., Hawley 1986, pp. 15–18) or to ubiquitous “tension” between rules of action and the situation of the acting unit (e.g., Parsons and Smelser [1956] 1965, esp. pp. 50–51). There is little institutional provision for change.

With greater complexity, however, activities can be removed from these primordial units and assumed by large-scale economic, political, and other kinds of organizations (e.g., Lenski 1979; Coleman 1990, pp. 584–585). Varied organizational purpose as well as interaction among organizations can constitute bases of change that are themselves institutionalized.

Domination. Stratification implies domination—that is, setting the conditions of existence by certain units for other units through disposition over key resources; over the generation and selection of often self-serving meanings and rules (see, e.g., Landecker 1981); and over the means of securing compliance. Such disproportion is one of the most widely considered sources of strain, hence of change through conflict (see, e.g., the modifications of Marxian theory by Dahrendorf 1959 and Skocpol 1979).

Considered under various names (see, e.g., Marx and Engels [1846] 1970; Parsons and Smelser [1956] 1965; Dahrendorf 1959; Duncan 1964; Hawley 1986; Giddens 1985), domination includes disposition over means of coercion, material inducement, social support, or rules of command (adapted from Weber [1920] 1978, pp. 53–54; Hawley 1986, pp. 33–37). Domination reflects power, the capacity to affect action and its outcomes (Giddens 1979, pp. 88–94). Suggested by Weber ([1920] 1978, p. 53) as the probability that the acting unit can carry out its will despite resistance, power has also been defined as the structure’s capacity to mobilize resources in effecting outcomes through concerted action, such as the production of sustenance (or other ways of supporting units) and environmental control (Parsons and Smelser [1956] 1965, p. 48; Hawley 1986, pp. 36–37). This capacity is conceived to be distributed in different ways, depending on the structure under consideration (Hawley 1986, pp. 74–77), serving political relations as money serves economic relations (Parsons 1975).

Domination can effect both form and content. For example, domination can cause segmentation to give way to stratification, frequently as a result of conquest, as when multicomunal societies become kingdoms or empires (Lenski 1979) or numerous petty sovereignties are gathered under nation-states (Tilly 1984, p. 48). By setting the conditions for competition and exchange or more

directly by affecting concerted action that favors certain specialties or even by imposition, domination can also make specialization possible or influence its nature and degree (Habermas [1981] 1987, pp. 161–163; Hawley 1986, pp. 64–67, 91–95; Rueschemeyer 1986).

The resources on which domination is based need not only be material. They can be social—for example, active support, institutionalization by organizations and movements that generate and implement ideology or legality, and the absence of opposition. Generalized control over all manner of resources has been called hegemony, and political processes have been characterized as struggles for hegemony (Wallerstein 1979, 1984; Tuchman 1988). Domination has been conceived, in its extreme form, as rendering certain alternatives invisible (Giddens 1985, pp. 8–10) through taken-for-granted opposition by powerful units (Polsby 1980, pp. 189–218), lack of relevant language (Parsons 1975), absence of relevant substructures, agendas set by the mass media of communication (Tuchman 1988), and uncontested legitimacy—that is, common understandings as to what is valid or binding. The elementary stratified society is, by definition, hegemonic, since it is unspecialized in terms of the control of various types of resources.

Domination can be by one or more substructures over the others. History shows, for example, cases of kinship-based, religious, military, economic, and political domination (e.g., Tilly 1984; Evans and Stephens 1988). The hypothesis has been suggested that the greater the specialization, the less stable is domination through fusion of, say, political with economic activities (Parsons and Smelser [1956] 1965, p. 83). The expected trend is for substructures to become concretely separate. For example, underground markets arise as responses to shortages and bottlenecks in socialist societies, which are characterized by political domination of economic activity, or by the “informally” organized demands of their workers (Jones 1984).

Pluralism and Plasticity. The degree to which meanings are single or plural can be affected by segmentation or specialization. Different collectivities, constituted, say, on the basis of different fundamental beliefs, different descent, or different economic circumstances (Landecker 1981), coexist segmentally either by loose agreement or by coercive regulation, each with separate rules and un-

derstandings (Tenbruck 1989), or struggle with one another over which ones shall prevail (e.g., Landecker 1981, pp. 136–169; Wallace 1988).

The greater the specialization among units, all things being equal, the greater also is the plurality of interests, according to some models. A recurrent theme is that this form of pluralism affects the probabilities of different degrees of involvement by given units and of different alignments among units from one issue to the next. Such differential participation can have a negative effect on the probability of broad or intense conflict (Dahrendorf 1959, pp. 215–231; Polsby 1980, pp. 84–97, 122–138; Turk 1977, pp. 97–103, 1985; McAdam et al. 1988).

Specialized forms, including organizations, are by definition relatively indifferent to the activities or aspirations of supporting, component, or utilizing units in other social settings (Luhmann [1975] 1982, pp. 78–79; Labovitz and Hagedorn 1977, pp. 12–15). Entire areas of indifference are seen to result, for example, from “gaps” left between interests served by organizations (Luhmann [1975] 1982, pp. 79–80, 87, [1977] 1982, p. 237). The intrusion of, say, race and gender in contemporary labor markets suggests, however, that organizational indifference is a matter of degree (see, e.g., Stinchcombe 1986; Granovetter and Tilly 1988).

Accompanying segmentation or specialization, according to several theories, is plasticity: the probability of loose and variable connections among segments or among organizations subsumed by substructures like the four singled out. Here overall organization is limited to compatibility, falling short of the pursuit of unified or concerted outcomes across substructures (see, e.g., Luhmann [1975] 1982, pp. 78–79). Change is endemic in the absence of overall structure, save for markets and conflict arenas and rules that govern these (Luhmann [1977] 1982, pp. 238–242). It tends to occur as accommodation (1) through exchange, say, between segments or between political and economic substructures (Parsons and Smelser [1956] 1965), or (2) through new forms and modification of older ones in responses to changes elsewhere, as in the case of the family’s loss of economic activity in the United States but its growing importance in providing incentive for such activity (Schumpeter, cited by Suttles and Janowitz 1979).

The greater the segmentation or specialization, the more general the accommodative meanings and rules that encompass social organization overall—for example, the idea of tolerance and its enforcement, or of universal civility (Parsons [1971] 1977, pp. 182–193; Hawley 1986, p. 66). Another example is the idea of freedom in classic liberal society, implemented as economic *laissez faire*, religious autonomy, voluntary rather than arranged marriage, political competition for electoral support, and stratum membership on the basis of achievement rather than family (Gerth and Mills 1964, pp. 354–357).

There is disagreement about the extent of hegemony under conditions of specialization, even where, say, political or economic organizations overshadow other organizations in control over resources. At the one extreme incumbents of dominant positions within the various specialized organizations have been conceived as constituting a single elite capable of joint domination (e.g., Mills 1956) or as being generally dominant to the extent that they hold positions in multiple organizations (Perrucci and Pilisuk 1970). Relatedly, large organizations have been observed to divorce themselves from the interests they were established to represent—as, say, those of capital and labor—and strike bargains with one another (Evans and Stephens 1988). These conceptions of unified domination have partly been verified and partly refuted (e.g., by Lieberson 1971; Mizruchi 1982; Johnsen and Mintz 1989).

Specialized as they are, according to another partly verified view, the same set of organizations can facilitate one another in certain respects and be in mutual struggle in others, therefore resisting direct domination by any one or a few of their number (citations in Turk 1985). Under these conditions policy that is the basis for binding domination is formed through action by those masses or by those nonpermanent coalitions of public agencies and private organizations that are concerned with any particular matter (Turk 1977, pp. 136–205; Galaskiewicz 1989; Laumann and Knoke 1989).

Crosscutting the issue is the question of whether, given specialization, either an organized elite or an interorganizational coalition has the capacity for concerted action that transcends the substructures. Specialization can mean that, at the

most, even the most powerful organization is dominant only with respect to one or two issue areas (Luhmann [1975] 1982, pp. 76–89; Polsby 1980, pp. 122–128). However, even within organizations the normal decision process has been defined as organized anarchy by certain investigators (e.g., citations by Scott 1987, pp. 277–282; Meyer and Rowan 1978). Carried to an extreme, the question is one of the extent to which coordination by domination is haphazard, whether actual coordination might not result from the “invisible hand” of a market (Smith [1789] 1976, Vol. 1, pp. 477–478) or of an arena of conflict.

Standardization. Mitigating the diversifying possibilities of segmentation and specialization that have been noted are tendencies for units to become alike in certain aspects of form and content—that is, isomorphic (Hawley 1986, pp. 66–70; Udy 1979; Kerr 1983, pp. 85–89). This can be because units require similar internal arrangements for purposes of connection with one another (Hawley 1986, p. 70), or model themselves after other units in the preservation of competitive effectiveness (suggested by Aldrich and Marsden 1988, citing DiMaggio and Powell). It can also be through institutionalization by drawing upon a common “culture pool” available, say, to the countries of the world (Moore 1988) or through, say, political or religious imposition within a given society (Znaniecki 1945; Landecker 1981, p. 136) or by either (Hawley 1986, p. 66; Meyer et al. 1987).

Not only can there be standardization of form, there can also be standardization of process. For reasons of predictability and economy of effort, among others, the joint reproduction of habitual patterns has been considered to lie at the heart of social life (e.g., Berger and Luckmann 1966). This not only accounts in part for compliance with meanings and rules that standardize feeling, thinking, and acting in such relatively unspecialized settings as tribal societies, it also accounts for standardized, partly area-specific media and codes that symbolize and routinize all manner of activities and products where there is more specialization. Examples are language (Habermas [1981] 1987, pp. 56–57), money, property, prestige, influence, power, legality, administrative principles, criteria of truth (Parsons 1975, Habermas [1981] 1987, pp. 153–197, 367–373; Luhmann [1974] 1982, pp. 168–170), and credentialed expertise (Collins 1988, pp. 174–184; Luhmann [1976] 1982,

pp. 303–331; Bauman 1989). These standardize and objectify aspects of markets, conflict arenas, collectivities, or aggregates. Unless it fails noticeably, it is believed, routine tends not to be questioned, especially where relevant knowledge is not widely pursued and alternatives are not at hand.

Collective Agency. Mainly based on exchange, conquest, or revolution, change is seldom institutionalized in segmental or stratified society. Pluralism generally includes provisions for categorical organization in the form of mass action, say through referenda, or in the form of movement and interest organizations, which not only participate in the coalitions that seek to dominate given matters but also define matters for action by the mass. These institutionalized means of structural and cultural change through collective agency are thought to occur where pluralism means lack of overall institutional detail (e.g., Gusfield 1979). Recent investigations have not only examined their causes and effects but also their forms and ways of acting (Zurcher and Snow 1981; McAdam et al. 1988). Their efforts can be toward increasing the material and social resources controlled by given categories of units, as in the case of gay rights, or they can be directed toward broad structural changes or changes in meaning that occur for their participants and for nonparticipants alike, as in the case of civil liberties (Gusfield 1979). Like revolutions, movements have been considered to be processes that can begin by effecting transitional social organization and end with new institutionalized structure (Alberoni [1981] 1984).

Commitment and Trust. Commitment of units to one another and to their common structure is a widely recognized influence. The “we” that characterizes collectivities (Cooley 1902, 1916) or the “consciousness” that causes support of existing social organization or generates struggle within it (Marx and Engels [1846] 1970; Durkheim [1902] 1964) is seen as having either of two effects. It can be direct, producing commitment to the given structure, or indirect by habitualizing the commitment and trust that serves participation in a variety of settings, even ones that are specific and neutral (also see Coleman 1990, p. 297).

Increasing specialization and other forms of organizational complexity and increasing scale have been viewed as negative influences on commitment, even on commitment to disputing factions

or to revolutionary movements seeking structural change. Commitment to large-scale organizations comprising specialized substructure is generally considered less than to other kinds of collectivities because of anonymity among the constituent units, which are likely to have the characteristics of a mass, and because only part of the constituent is involved.

With complexity and scale, participation in one substructure is less contingent on participation in others, incurring separate, possibly conflicting obligations; indeed, everyday interactions that produce common meaning have been considered divorced from structure and rules (Luhmann [1974–1977] 1982, 1987; Habermas [1981] 1987, pp. 117, 153–197), and even everyday life is penetrated by the actions and generalized media controlled by organizations (e.g., legal and monetary), reducing its potential for social integration (Habermas [1981] 1987, pp. 267, 330–331, 367–373). Under these conditions the influence of trust on social organization is less likely (Coleman 1990, pp. 300–321), and benefits are more likely sought without corresponding contributions (Coleman 1990, pp. 650–655).

The greater the specialization and accompanying standardization, it has been observed, the more of the population can be included in whatever substructures comprise various areas of social life (Parsons [1966] 1977)—that is, the more universalistic, for example, are criteria for suffrage and military service, access to public facilities, mass education, and employment opportunity. One reason follows. The more social structure consists of aggregates of organizations whose concerted activities are narrowly focused on specialized consequences—meaning specific and neutral orientation toward performance—that tend to be unranked, the less relevant these aggregates are to one another as criteria of exclusion (Luhmann [1977] 1982, pp. 236–238). Examples can be found in references to “customer,” “patient,” “student,” or “defendant,” independently of the beneficiary’s other social attributes. At its extreme it can even lead to “the gall bladder in bed 27.” Aided by standardized media such as money, the result of inclusion can be the diminution of commitment and trust through the transformation of agents into commodities for exchange (e.g., Marx [1859] 1971, pp. 78–84), or their more general removal

from meaningful communicative interaction (Habermas [1981] 1987, e.g., p. 343).

The other side of inclusion is regulation. The more central that large, specialized organizations are to social structure, it has also been claimed, the less social organization depends on commitment and the greater is the shift from mutual trust to trust in expertise. The state, for example, is said to require less legitimacy as its expert-driven political technology provides, say, surveillance, "correction," welfare supervision, "medicalization," or "psychiatrization" (Bauman 1989). Indeed, the electorate's growing cynicism about government (e.g., Institute for Social Research 1979) has had little apparent effect on political structure in the United States.

SOCIAL PERCEPTION

Social perception theories and investigations deal with the nature, causes, and consequences of perceptions of social entities, including one's self, other individuals, social categories, and aggregates or groups to which one may or may not belong. The content of a perception can be virtually any property. Individual attributes may include personality traits, behavioral dispositions, physical characteristics, and ability evaluations. Group attributes can include properties such as

size, cohesiveness, cultural traits, stratification patterns, network patterns, legitimacy, and historical elements. With some notable exceptions, however, the field of social perception traditionally has emphasized the micro side, focusing on individual inferences regarding one individual or a very small number of other individuals.

Social perception is best viewed as an umbrella label that covers a range of loosely related and usually loosely formulated theoretical conjectures and associated research. Today “social cognition” may be the more popular label, subsuming theory and research indexed under numerous other headings: person perception, social judgment, social representation, schema theory, reference group theory, impression formation, attribution theory, and more. Little of this work will be discussed here, although most of it is easy to access. Reference lists in books, chapters, and articles under the various headings tend to intersect rather than be isolated. Review articles have appeared with regularity, and so it is relatively easy to locate the seminal, general, or esoteric references one seeks.

This article provides an introduction and selective overview of the social perception area, with additional attention to some threads that have been or could be of particular interest within sociology. First there is a brief discussion of perception in general, followed by sections that divide the field into three major realms: self-perception, person perception, and group perception.

PERCEPTION

Social perception is only one manifestation of the general phenomenon of human perception. All perceptions begin with energy-producing events, either inside people or from the environment. Each of the senses operates as a “transducer,” encoding a particular form of energy (e.g., radiant, kinetic, chemical) into neurological signals that are carried to the brain as complex, parallel streams of bioelectrical impulses. In the brain, these streams of information are filtered and transformed through several stages, producing dynamic neural representations almost instantaneously. Depending on anatomic factors, prior experiences, and the nature of the signals, these representations may or may not reach the level of conscious awareness.

When sensations survive this elaborate preprocessing and exceed sensory thresholds, however, they break through into a person's conscious awareness, appearing as coherent and meaningful perceptions: hunger pangs, one's reflection in the mirror, a smile from a friend. These perceptions seem to capture all the essential properties of the events that instigated them.

Roughly speaking, then, people acquire energetic impulses from internal and external environments that, in turn, impinge on the sensory apparatuses as sensations and are transformed by the brain into perceptions. This suggests a close relationship between the perceptions that are formed and the subsequent actions taken on their behalf. For instance, on the basis of perceptions of the personal qualities of others (and perceptions of others' perceptions of those qualities), people make judgments about those qualities (e.g., good or bad); on the basis of those judgments, people formulate intentions about how they will behave toward others (e.g., plan to engage with them or avoid them); on the basis of those intentions, the actions of others, the prevailing context, and so on, people enact their impressions and intentions in social interactions.

Three qualities of perceptions bear further elaboration: *Structure*, *stability*, and *meaning* are definitive subjective properties (Schneider et al. 1979). A fourth quality—*accuracy*—is best understood as an objective property of perceptions, at least in principle. Accuracy and bias in social perception are addressed later in this article.

Structure. Humans experience the world as structured. Rather than seeming chaotic and unpredictable, elements and events generally appear to correspond to one another in patterned ways. Things seem to happen for reasons. Much of this patterning is imposed, however, and one person's perceptions may be very different from those of others, even under identical conditions. This is especially relevant in regard to the interpretations people impose on complex phenomena. For instance, people tend not to be aware of how differences in the expectations they bring to a situation color their perceptions. People cannot take in information on everything around them and those expectations direct a person to attend selectively to the available stimuli in a situation. This biasing of attention can have a tremendous influence on

interpretations of the situation. Moreover, each person may impose a unique subjective structure on the same objective reality. Every sports fan has experienced the perception that compared to the opponent, his or her favored team is consistently the victim of "bad calls" by the officials. Supporters of the opponent generally disagree, and rarely does one perceive the opposition to have been treated unfairly by officials. What fans actually "see" are slices of reality unconsciously chosen to conform with their beliefs and expectations.

Stability. Different sports fans may see different things, but if pressed, they probably could identify broad areas of the game they agree about and take for granted. They would agree that there were no sudden changes in the sport they were watching; they would profess not to have seen players on the field dematerializing in one place and rematerializing elsewhere; the ball appears to stay the same size and shape even as it moves nearer to and farther from the fans' points of view. In general, while observers may disagree on some points, most of what is observed has an underlying sense of continuity. Indeed, among the myriad sensations to which one might attend in a given situation, the bias is toward those which engender a sense of stability—a sense of the temporal endurance of these patterned sensations.

Meaning. If structure and stability were the only properties of experience, the world would appear merely as successions of discrete, insignificant objects and events, each with no particular import transcending the moment. In contrast, most perceptions seem meaningful. That is, perceptions are conceived of as threads in a larger fabric. Through their interconnections and the patterns they form, they seem to have significance, purpose, causes, and consequences beyond their own existence. With cognitive development comes the ability to recognize and select impressions and events that are significant in terms of the information they convey. As will be discussed below, meaningfulness and significance do not imply accuracy. Perceptions—especially social perceptions—are imperfect representations that can be highly misleading.

Among the variety of ways in which one could organize the social perception literature, one of the simplest and most useful proceeds from the individual perceiver, to perceptions of other individuals, and finally to group perceptions. These

categories define the three sections below, which are followed by some remarks about future directions.

SELF-PERCEPTION

Self-perception is social perception with the self as the object. Through introspection and information from others, people develop beliefs about their many qualities: personality, physical appearance, behavioral tendencies, moral stature, athletic prowess, and the like. "Self-concept" is the general term for the system of beliefs about the self. Although introspection is a source of self-knowledge (Andersen and Williams 1985), mounting evidence suggests that it is not the predominant source that people used to believe it is and that it is generally biased and inaccurate (Nisbett and Wilson 1977; Wilson et al. 1981).

One major branch of self-perception research focuses on inaccuracies in self-knowledge, and a second on how information from others shapes the self-concept. An example of work in the first branch is a review by Greenwald (1980) of evidence of three types of self-conceptual biases: (1) *egocentricity*: the anchoring of judgments, recollections, thought experiments, and attributions about others with reference to the self, (2) *benefactance*: the tendency to perceive the self as generally efficacious, and (3) *cognitive conservatism*: a resistance to cognitive change. Bem's influential self-perception theory (1972) asserts that in conditions of uncertainty, people use their own behavior as a guide to inferences about their inner selves. Later approaches to the self-concept focus on structures such as category systems, conceptual networks, and complex schemas that can represent explicit connections and nonconnections among elements of the self-concept (Greenwald and Pratkanis [1984] provide a review).

The early insights of Cooley (1964[1902]) and Mead (1934) still guide sociological theory and research on the social origins of the self-concept, the second branch mentioned above. Cooley described the "looking-glass self" as the use of others' appraisals as mirrors of the "true" self. Mead noted that the images people form of themselves are greatly affected by how they imagine significant others would respond to and evaluate them. Social comparison theory (Festinger 1954; Suls and Miller 1977) deals with, among other issues, the question of whom one refers to when seeking

comparative self-knowledge and the effects of the various available social referents on one's self-concept and behavior.

Under the rubric of self-perception also are found topics such as self-efficacy, self-evaluation, self-esteem, and self-identity. Self-efficacy is the perception of one's competence with respect to specific tasks (Bandura 1986; Cervone and Peake 1986). Self-esteem is the extent to which one thinks positively about oneself (Rosenberg 1979). The concept of self-evaluation, when distinguished from efficacy and esteem, has been used in theory and research on how the characteristics of evaluators affect self-evaluations in specific, collective task situations (Webster and Sobieszek 1974). There are two major approaches to self-identity: identity theory (Stryker 1980; Burke 1991) and social identity theory (Hogg and Abrams 1988; Hogg et al. 1995). Although there are many shared concepts in these approaches, identity theory is distinguished by a greater emphasis on the performance of social roles as the source of self-definitions; in contrast, social identity theory emphasizes the ways in which self-categorizations hinge on salient properties of the groups with which individuals align themselves.

The more strongly a person's identity is tied to a particular social role or category, the greater is the extent to which that individual empathizes with other occupants of that role or category. It is as if the boundary between self and others became blurred, and the individual empathizes with similar others to whom good things and bad things happen. For instance, an experiment by Markovsky (1985) subtly emphasized self-identification versus group identification and created unjust reward allocations to both individuals and groups. The subjects responded more strongly to the type of injustice that corresponded to their identification.

PERSON PERCEPTION

The core of social perception theory and research addresses how people formulate impressions about the inner qualities and outward behaviors of other individuals. The focal points for this work include the properties of the people who are perceived and the characteristics of the situations in which a perception is developed, the logic by which basic sensations are integrated to form complex social perceptions, and the way in which perceptions, once formed, are affected by new information.

Attribution theories are concerned with how people form inferences about the causes of others' behaviors. The basic question in these approaches concerns the conditions under which another person's behavior is attributed to an internal disposition or to aspects of the situation in which it occurred (Jones et al. 1989). The so-called fundamental attribution error is the pervasive tendency for observers to underestimate the impact of situational factors on others' behavior (Ross 1977). In fact, people tend to make personal attributions for others' behavior and situational attributions for their own (Jones and Nisbett 1972). Gilbert (1989) has modified this question in a fruitful way by asserting that personal attributions occur automatically; situational attributions occur only as the possible result of an effortful search for additional information (Gilbert et al. 1988).

Although *schemas* could be discussed under the "self-perception" and "group perception" headings, most often they are invoked in theory and research on person perception. Schemas are organized structures of cognitions pertaining to social objects such as the self, other persons, groups, roles, and events (Taylor and Crocker 1981). Thus, one's schema for "college professor" may include beliefs such as "intelligent" and "scattered," negative attitudes such as "inaccessible" and "too political," and expectations for behaviors such as "lecturing" and "conducting research." Schemas have a variety of effects on social perception. For instance, they induce people to attend to certain social and situational features, influence people's judgments by inducing particular expectations for the consequences of their actions, and affect how people recollect social events by making some pieces of information more salient than others. Schemas also transcend individuals by becoming cultural elements that can be communicated among group members or from parent to child.

Other approaches to person perception focus on the integration of bits of information associated with particular others. Information integration theory (Anderson 1981) provides rigorous mathematical models of how an observer employs weighted combinations of another individual's traits to form an overall impression. Social applications of psychophysics (Stevens 1975; Lodge 1981) apply a magnitude scaling technology first developed for expressing judgments of physical properties (e.g., weight, brightness, numerosity, sound pres-

sure, saltiness) to the quantification and validation of judgments of personal or social properties (e.g., competence, fairness, attractiveness). Status characteristics theory (Berger et al. 1985) explains the emergence of status and influence hierarchies in collective, task-performing groups on the basis of individuals' relative standings on combinations of salient characteristics that can order interaction whether or not they are explicitly relevant to a task.

The accuracy of social perceptions was an early research focus but languished for years because of conceptual and methodological roadblocks (Cronbach 1955; Zebrowitz 1990; Fiske 1993). One problem is that determining accuracy requires the existence of a criterion against which a social perception is judged. Often, however, there is no assurance that the criterion is accurate because it may be arbitrary, subjective, or biased. Research in this area has seen a resurgence in recent years, however, partly as a result of approaches like Kenny and Albright's (1987) social relations model. That approach measures the accuracy of judgments of a given characteristic by using multiple observers and targets, permitting the researcher to control for observers' response sets, targets' attributes, and other aspects of the relationships between observers and targets. A mere recent trend is to attempt to disentangle the combined effects of observers' expectancies and targets' characteristics, specifying the conditions under which either set of factors predominates in determining social perceptions.

In a related vein, attributional and social perceptual biases constitute a vast field of inquiry. In recent years, a number of universal human perceptual inclinations have been cataloged that are capable of generating perceptual biases. Many perceptions depend on the ability to gauge one's relevant behaviors and characteristics, yet people often have difficulty assessing their own qualities and properties in an absolute way (Bem 1972). Preconceived notions powerfully influence subsequent perceptions by inducing selective perceptions. Once an idea is accepted, falsifying information is discounted and verifying information is accepted uncritically. People not only are subject to such errors of perception, they also underestimate the degree to which this is so. They are overconfident in their judgments; employ useless, distracting, and unrepresentative information contained in anecdotes; and infer illusory covariations among

social characteristics. In recent years, cognitive and social psychologists have begun to identify and systematically examine these and other types of social perceptual biases. (For some examples, see Taylor and Fiske 1978; Taylor et al. 1978; Nisbett and Ross 1980; Kahneman et al. 1982; and Goldstein and Hogarth 1997.)

GROUP PERCEPTION

Two sets of approaches to group perception predominate: those concerned with reference group choices and effects, and those addressing social categorization processes. A reference group is a set of individuals whose standing or perspective is taken into account by an actor in selecting a course of action or making a judgment about a specific issue (Farmer 1992).

Research on reference group phenomena represents one of the first and longest-lived attempts in sociology and social psychology to understand how individuals orient themselves to groups, which groups they choose, and the consequences of their choices. (See the early work of Newcomb [1943] and Merton and Rossi [1968] and the more recent review by Singer [1981].) Among the functions of reference groups are providing sources for normative information and offering bases for social comparisons (Gecas 1982). Normative information dictates ostensibly correct and incorrect courses of action and positive and negative values. For example, people may adopt as their own the expressed values of respected members of the community or may assert a position opposite to that held by a disrespected group. In a similar way, social comparisons with reference groups provide bases for evaluating one's beliefs, actions, and accomplishments. For instance, without making reference to the set of people with incomes comparable to one's own, it is impossible to gauge one's level of generosity in donating money to charitable organizations. Three hundred dollars donated in a year may seem high until one discovers that the average donation of people in one's income bracket is ten times that amount.

Although virtually everyone makes use of reference groups, *which* reference groups one selects for one's comparisons and what consequences follow from those selections are more complex issues. Reference group choices have been shown in both natural and experimental settings to be

influenced by numerous factors, including attitude similarity, structural inducements, and normative prescriptions. The consequences of referential comparisons that have been studied include the treatment of social deviants and the emergence of negative social evaluations, changes in self-esteem, and feelings of relative deprivation, gratification, or inequity. Although a good deal of interesting research and many theoretical conjectures have been associated with this area of inquiry, as Singer (1981) noted, there is no reference group theory per se, and the explanatory promise of this area remains unfulfilled. However, many of the research lines spawned by interest in reference groups remain active.

The reference group literature takes as given the existence of groups and the issue of which people are and are not members. Social categorization approaches (Tajfel 1981; Wilder 1986; Abrams and Hogg 1999) are closely related to the social identification literature noted earlier and view the perception of membership versus nonmembership as problematic. In general, people say that they detest being categorized and avoid categorizing others. However, social categorization is a manifestation of a perceptual process that is fundamental to survival. Everyone does it, consciously or not. By learning to recognize and categorize elements of their environments, humans are able to distinguish nutriment from poison and ally from adversary.

Despite its indispensability, the categorization process has side effects in the social realm. The most important and robust of these effects is the tendency for people to overestimate differences between groups and underestimate differences among group members. "They" appear uniform, but "we" are individuals (Quattrone 1986). This phenomenon lies at the heart of stereotyping: the overgeneralization of perceived group attributes (Stangor and Lange 1994). Once formed, stereotypes are maintained by virtue of the types of perceptual biases previously noted, such as forming illusory correlations and relying on anecdotes. A classic finding in research on social identity (Tajfel 1982; Turner 1987) demonstrated that arbitrary we-they distinctions created by random assignments to groups in a laboratory setting were sufficient to produce in-group favoritism and a variety of negative attributions regarding the out-group.

Discrimination—the differential treatment of others solely on the basis of their group memberships—and prejudice—negative attitudes toward certain groups and their members—are common behavioral manifestations of perceptual stereotyping. In American society and in the social and behavioral sciences, gender- and race-based forms of discrimination and prejudice have received the most attention (Eagly 1987; Dovidio and Gaertner 1986, respectively), although the list of bases for discrimination is probably as long as the list of conceivable social characteristics.

FUTURE DIRECTIONS

Social perception theory and research embrace multiple levels of analysis: cognitive processing, individual and interpersonal behavior, perceptions of groups, and group behavior. The social perception theories that may hold the greatest promise for the future are those amenable to integrating explicit formulations developed within these different levels of analysis. Undoubtedly, much social perception research in the near term will be business as usual, identifying new theoretical contingencies and empirical patterns. However, social and behavioral scientists are developing new approaches to modeling social and social psychological phenomena that may prove fruitful in social perception research.

Burt (1982) integrated a psychophysical model of human perception with explicit models of social network structure. The result is a conceptualization of social groupings at any scale in which network members (1) receive information about certain properties of others (e.g., resource holdings, attitudes), (2) take into account structural information about those others (e.g., the patterns of their social relations and of their relations' relations), (3) evaluate and combine the information received, and (4) make self-referential comparisons involving the information obtained from the network (e.g., relative resource holdings). The models show precisely how structural configurations of social relationships, in combination with individually based social perception and comparison processes, can theoretically account for a far broader class of phenomena than can either individual-level theories that do not consider structures or structural theories that do not consider individuals. Unfortunately, this formulation has

not inspired a corresponding program of research, and the potential contributions of this innovative approach have not been tapped.

Significant progress has been made, however, using network models of a different sort. Within a broader class of approaches known as complexity theory (Eve et al. 1997), neural network models (Read and Miller 1998) and related alternatives (Carley and Svoboda 1996; Macy and Skvoretz 1998; Gilbert and Conte 1995) are beginning to account for social perception phenomena using parallel distributed processing models. This is a type of computer simulation in which numerous interconnected elements (e.g., neurons or agents) repeatedly receive, process, and respond to information from their environments, which may consist largely of similar elements. For example, using this approach, Smith and DeCoster (1998) devised a unified computational model that accomplishes several feats: It learns the social characteristics it “perceives” in individual cases and recognizes those characteristics from partial cues, learns stereotypes from exposure to multiple cases and recognizes those stereotypes from partial cues, and develops novel concepts from old ones. Although so-called connectionist approaches are relatively new, findings such as these bode well for further investigations.

There is no lack of good ideas in the social perception field, and this area may well play a central role in future attempts to integrate micro and macro sociology. Lacking, however, are concerted, programmatic efforts to develop and test explicit and rigorous social perception theories. Some exceptions were noted above. For the most part, however, the absence of explicitness and rigor has resulted in a minimal level of competition among different approaches, virtually no critical testing between formulations, and few time-tested conceptual and methodological refinements. However, this area remains attractive to a large number of psychologists and sociologists, in part because of its many unanswered questions and the ubiquity of its phenomena.

SOCIAL PHILOSOPHY

American sociology, with the significant exception of symbolic interactionism, generally has turned to Europe for a philosophical grounding. The years after World War II, when Talcott Parsons at Harvard and Paul Lazarsfeld and Robert Merton

at Columbia dominated the field, were no exception. Parsons had studied in Germany and had translated Weber; Lazarsfeld brought to the United States an Austrian philosophical heritage; Merton was a specialist in the philosophy and sociology of science. Under the guidance of these three men, American sociology was strongly influenced by the philosophers of the Vienna Circle, especially Carnap and Popper, and to a lesser degree by British logical positivism.

The common ingredient in this philosophical heritage was the notion that there were few obstacles to the creation of a science of human behavior modeled on the natural sciences. A great deal of attention was paid to hypothesis testing, criteria for evidence, and the nature of statistical proof. Most important, this way of thinking assumed that there was a social reality that would prove to have the same nature as physical reality. A predictive science of human behavior was possible because the social world was assumed to work in lawlike ways. The problems of the social sciences lay in discovering reality, not in the nature of reality.

This assumption would be shaken from two different directions. On the one hand, in many cases sociologists would lose their faith in the natural science model as the most appropriate way to think about society. In part as a result of the political upheavals of the 1960s, adherence to the patient accumulation of facts to verify what Merton called "middle level" theories about the world was difficult to maintain. On the other hand, philosophers increasingly came to question the epistemology associated with the natural science model. Kuhn's thesis that scientific insight resulted from a new paradigm had a stunning effect on social science, while Polanyi argued for a more "artistic" and "sociological" conception of scientific inquiry (Kuhn 1970; Polanyi 1968). As epistemological skepticism invaded the natural sciences, its implications for the social sciences became even more serious.

One of the first consequences of this increasing skepticism was the discovery in America that the European philosophical heritage was far broader than it first had appeared. Weber, for example, had been influenced strongly by Nietzsche, yet Parsons's interpretation of Weber downplayed the significance of heroism, irrationality, and cultural pessimism and presented Weber as an American

pluralist. The two philosophers who perhaps had the greatest influence in Europe during and after Parsons's visits to Germany were Heidegger and Husserl, and neither played a significant role in Parsons's outlook. The late Wittgenstein was discovered to be quite different from the earlier one, who had been convinced that pure logic would make philosophy unnecessary. French existentialism would become prominent in the 1960s, yet its dominance would not last, and its influence on American sociology was minimal. What had been a selective and partial reading of European philosophy by American sociologists could no longer last.

Even during the years when Parsons was the leading American sociologist, alternatives had existed. Husserl's phenomenology was one. As brought to the United States and applied to sociology in the work of Schutz (1967), phenomenology argued for the importance of the "life-world," the everyday events out of which people's understanding of the world around them becomes possible. Schutz was unable to convince Parsons of the importance of phenomenology (Schutz 1978), but he did influence one of Parsons's most brilliant students, Garfinkel (1967). Ethnomethodology became the most important alternative to structural functionalism in the 1960s and 1970s. The legacy of phenomenology also could be seen in the work of other sociologists, such as Berger and Luckman (1967). Other alternative traditions, such as the influence of Wittgenstein, also existed during this period, especially in Great Britain. Finally, among Marxists, the traditions of the Frankfurt School and the legacy of Lukacs constituted an important basis for social science theorizing (Arato and Gebhart 1977).

As the wide variety of ideas associated with European philosophy became increasingly known to sociologists, confidence in the natural sciences as a model for the social sciences gave way to far more nuanced approaches. No theorist in contemporary sociology was more aware than Habermas (1987) of the necessity of incorporating insights from a wide variety of philosophical traditions. Not only did Habermas bring to the task of sociological theorizing his background in Frankfurt School Marxism, plus a far more realistic reading of Weber than the one offered by Parsons, he also grounded his work in British linguistic philosophy, the Schutzian life-world, and American pragmatism. To read Habermas was to learn about

those whom Habermas had read, bringing wide swaths of European philosophy to the attention of many American readers. Habermas was not alone in trying to synthesize philosophical traditions with the social sciences. Bourdieu (1984) in France was equally influential in sociology; his combination of theoretical insight, empirical investigation, and concern with how knowledge is produced made him a major figure in American sociology (Bourdieu and Waquant 1992; Lamont and Fournier 1992).

Habermas in particular argued for the importance of modernity, for the possibility of using rationality as a standard by which communicative utterances could be judged, thus making possible a social order held together by norms that lay outside the purely subjective preferences of the individuals who constituted that social order. This belief in reason would lead others to criticize Habermas as excessively rationalistic and therefore too close to the assumptions of a nonproblematic reality that had guided Parsons (Lyotard 1984). Postmodernism would become the most radical challenge imaginable to the earlier Parsons's faith in a scientific model for the social sciences.

With postmodernism, the philosophers once ignored by American social science became the most important ones to read. Foucault (1971), under the influence of Nietzsche, argued that knowledge is the product of a general *episteme* that in itself is not a reflection of a reality in the world but the product of a particular historical period and its self-understanding. Lyotard (1984), borrowing from Wittgenstein, viewed science as a "language game" preoccupied with strategy and tactics, anything but a dispassionate and objective search after truth. Derrida (1978), under the influence of Heidegger, argued for the indeterminacy of concepts such as truth, justice, and morality. Philosophers could not seek fixed universals; they were engaged in the practice of rhetoric, defending or attacking contingent, local, and socially constructed practices that defined truth, justice, and morality in the interests of certain groups and against the interests of others.

Postmodernism has not had the impact in sociology that it has had in literary criticism, history, and law. Numerous sociologists continue to study the empirical world by testing various hypotheses on the basis of evidence collected through

surveys, demographic data, and other essentially quantitative methods. However, the postmodern challenge to normal science is likely to prove to be significant. Postmodernism is the culmination of all the challenges to the Parsonian consensus that once existed in the field; it represents what seems to be an end point to the process of questioning the existence of a nonproblematic social reality that can be understood by an observer standing outside that reality.

The question raised by the varieties of epistemological skepticism currently prevalent in the humanities is whether any science, let alone a social science, is possible. Just as some scientific fields seek to reduce the laws of one field, such as biology, to those of another, say, biochemistry, postmodernism argues that all fields of inquiry can be reduced to the study of rhetoric. In a perhaps unintended fashion, the implication of this argument is a hegemonic one: The rhetorical methods associated with literary criticism will become the model for all inquiry, just as science was once understood to be.

The rhetorical issues involved in social science theorizing have been analyzed in the case of economics by McCloskey (1985). In addition, some work in the sociology of science has made it clear that scientists have strategies by which they present themselves to the world and hope to gain acceptance (for an example, see Latour [1987]). However, does it follow that there is no grounding for social science, no Durkheimian facts in the world to which one can appeal to resolve disputes about knowledge? There is, of course, no way to answer such a large question satisfactorily in a brief article, but it is possible to offer the hope that both science and rhetoric can play a role in the sociological enterprise.

Sociology began, as Lepenies (1988) has argued, "between science and literature." Its most important theorists were attracted to positivistic understandings of knowledge, but they were also essayists dealing with some of the most significant issues in the moral philosophy of their time. One could argue that this "ambivalence" between fields has consistently characterized sociology at its best (Merton 1976). Merton, for example, though engaged in what he called the "systematics" of theory, was also a historian of science, wrote with

reference to the entire Western tradition of philosophy and literature, and was very much part of the milieu of the New York intellectuals of his day (Merton 1967, pp. 1–37).

The fate of sociology may lie in finding a balance between a scientific grounding in fact and an appreciation of how rhetorical strategies affect the ways in which scholars argue about facts. Unlike earlier sociologists, sociologists today cannot be confident that there will exist a one-to-one relationship between social reality and its representations; we must always be skeptical about the likelihood that the indicators we use actually measure the real world. But this does not mean that sociologists should give up collecting evidence, testing hypotheses, or trying to establish facts. It means only that the truths uncovered by these methods are not universals that exist for all time but are contingent on historical periodization and location.

From this perspective, the question becomes one of the length of the historical periods and the width of the locations by which we can judge the truths we discover. If we could determine that it is possible to discover regularities in, for example, the way liberal democracies have organized themselves over the past 200 years, that would be a significant and important accomplishment. It would mean neither that we had discovered an unchanging reality nor that our discoveries are simply part of a rhetorical strategy. A sociology that modeled itself neither on physics nor on literary reading, but combined elements of both would be a sociology more chastened than Parsonianism but more hopeful than postmodernism.

SOCIAL PROBLEMS

The discipline of sociology was born during a century of rapid social change attributable largely to the Industrial Revolution. Social theorists in nineteenth-century Europe devoted much of their attention to the institutional consequences of the erosion of the old social structure. American sociologists in the late nineteenth and early twentieth centuries, especially at the University of Chicago, added an intellectual orientation derived from the political idealism and meliorist pragmatism then fashionable in this country. "Social problems" generally were understood to be conditions that disrupted peaceful social life (e.g., crime) or produced obvious human misery (e.g., poverty) and that could be eliminated or alleviated by means of enlightened social policy and effective social engineering. Nearly all the conditions envisioned as social problems were associated with burgeoning cities and the dispossessed immigrants (foreign and domestic) they attracted. Few scholars doubted that these problems could be objectively diagnosed and treated, much like a malady in the human body.

By midcentury, however, American sociology was influenced increasingly by the functionalism and positivism of some of the earlier European intellectuals, whose major works had only recently been translated into English. Under this influence, sociologists assumed a more detached and value-neutral posture toward traditional social problems. While still acknowledging certain social conditions as problematic, most sociologists limited their responsibilities to scientific analysis of problems and their causes, leaving meliorist activism to politicians, social workers, and interest-group partisans. A split within the American Sociological Association between the more detached and the more activist visions of the discipline led to the formation in 1952 of the Society for the Study of Social Problems, which generally favors a more actively meliorist role for sociology. Since its inception, that society has published the quarterly *Social Problems*, the journal that most defines the

content and direction of social problems theory and research in American sociology.

THE TRADITIONAL PARADIGM

Historically, the reigning paradigm in the sociology of social problems has properly been called an *objectivist* one. From this perspective, social problems are conditions that (1) are in some sense undesirable to any trained and objective observer and (2) are in one way or another amenable to alteration. Interest-group differences are acknowledged in regard to how the problems should be defined and corrected, but it is taken for granted that the problems themselves exist as objective realities in the form of structural arrangements, material conditions, institutional processes, interactional patterns, and the like. In much of the literature on social problems, especially textbooks, there is an implicit analogy to medical diagnosis; that is, a social problem is to society as a disease is to the body, an objective reality apart from popular opinion. Often conventional medical terms are even used, such as *pathology* (or *social pathology*), *epidemiology*, and *etiology*, not only for social problems that might be quasi-medical in nature (such as alcoholism and mental illness) but even for those which are entirely societal (such as poverty and juvenile delinquency). From this point of view, social problems require the investigation of diagnostic experts (social scientists) who can objectively discern the nature of a problem and the most effective way of addressing it and thus enhancing the welfare of people and society.

These diagnostic experts also come from different schools of thought, as is often the case in other disciplines. Two theoretical orientations have tended to dominate the diagnosis and analysis of social problems by sociologists who work within the traditional paradigm. The first is functionalism in one version or another. From a functionalist perspective, society is seen as a more or less organic entity made up of interdependent parts (i.e., institutions). Breakdowns occasionally occur, but the whole generally succeeds in maintaining its natural state of equilibrium. These breakdowns (also called *dysfunctions* or *social disorganization*) are social problems; once they are fixed, the social system can return to a normal state of functioning. This perspective has been criticized by activists as being informed by the conservative assumption

that the existing social system is acceptable as it is, with only meliorative adjustments needed to deal with the occasional breakdown.

The second school of thought within the traditional paradigm, one generally preferred by activists and derived mainly from the Marxist heritage, is a more radical theoretical perspective sometimes called *critical theory*. From this perspective, social problems are the inevitable and endemic characteristics of a capitalist system. Efforts to deal with social problems in such a system can never produce more than temporary palliation, or, worse still, only co-op discontent and protest in the class interests of the dominant and oppressive establishment. Therefore, only the drastic overhaul or total overthrow of the capitalist system can produce a society free of social problems. This radical perspective shares with its more conservative functionalist counterpart the premise that social problems can in principle be objectively identified, diagnosed, analyzed, and corrected.

The belief that social problems have objective bases, which is the foundation of the traditional paradigm, continues to inform public policy at local, state, and federal levels of government in the United States and elsewhere. Accordingly, public funding for research on and amelioration of conditions officially designated as social problems has helped promote the objectivist paradigm in sociology. In the war on poverty of the 1960s, the war on drugs of the 1990s, and the war on violence at the beginning of the twenty-first century, billions of dollars in government support have gone into research on the prevention and/or correction of the social problems deemed most prevalent and consequential in a given era. Both the objectivist paradigm and the professional careers of its proponents, including sociologists with an applied orientation, have been strengthened in the process.

THE EMERGENT PARADIGM

While the objectivist approach continues to dominate textbooks and policy-oriented sociology, the academic literature on social problems in recent decades, including much that has appeared in *Social Problems*, has provided a robust alternative theoretical paradigm. Generally called *subjectivist*, in contrast to its traditional counterpart, this paradigm derives from different epistemological pre-

ises. With roots in phenomenology and symbolic interactionism rather than in the positivism of the objectivist paradigm, the subjectivist approach to social problems in its original formulation is akin to what is sometimes called the *labeling* perspective in the study of crime and deviance. Intimations of this subjectivist paradigm can be found in some nineteenth-century European theoretical literature and even in the work of some American sociologists earlier in the twentieth century (Fuller 1937; Fuller and Myers 1941a, 1941b; Mills 1943; Waller 1936). The emergence of this paradigm into the mainstream of the discipline, however, has occurred mainly since the 1960s in the work of Becker (1966), Blumer (1971), and the team of Kitsuse and Spector (Kitsuse and Spector 1973; Spector and Kitsuse 1973, 1977). More recently, the paradigm has been promoted in the works of Best (1989, 1990) and the team of Holstein and Miller (1993; Miller and Holstein 1993a).

In the simplest terms, the subjectivist paradigm holds that a social problem lies in the eye of the beholder, not in objective reality. Certain social *conditions* may be real (e.g., deviance, inequality, depletion of the ozone layer, and natural disasters), but to term them *problems* requires an evaluative judgment not inherent in the condition itself; thus, there is a distinction between a (real or imagined) social condition and its acquisition of the standing as a recognized social problem. In this formulation, social problems are best seen as projections of collective sentiments and representations rather than as mirrors of objective conditions (Best 1989; Holstein and Miller 1993; Mauss et al. 1975; Miller and Holstein 1993a; Spector and Kitsuse 1977). Collective sentiments and representations reflect judgments emanating from the political, economic, cultural, moral, religious, and other interests of the persons who allege the existence of a problem. Accordingly, the subjectivist paradigm denies the analogy to medical diagnosis on the grounds that there are no generally accepted scientific standards in sociology, as there are in medicine, for judging what is “pathological.” For example, in the study of societies there is no counterpart to the medical standard that “normal” human body temperature is 98.6 degrees Fahrenheit (and that significant departures from that figure are symptomatic of pathology). Instead, the judgment that a social condition is undesirable or problematic in any sense is entirely

relative to cultural (or subcultural), generational, and many other social variables.

As evidence of relativity and variability in the definition of the term "social problems," subjectivists make at least two historical observations. First, social conditions once regarded as serious problems in the United States are no longer so regarded, whether or not they are still extant. One example is witchcraft, which now is considered never to have existed "in reality" but nevertheless was recognized as a major social problem in seventeenth-century Massachusetts and elsewhere. Other, more recent examples include miscegenation, which gave rise to a powerful eugenics movement early in the twentieth century; prostitution, which is now legal in some jurisdictions, and illegal in others but nowhere regarded as the national social problem that it was at one time; and homosexuality, which once rated attention, along with prostitution, in most social problems textbooks and even a listing as a disorder in the official diagnostic manual of psychiatry but now often is considered a legitimate lifestyle and is protected by civil rights legislation. In none of these examples has there been any evidence of a reduction in the *actual incidence* of the condition, and so the erosion in their status as "real" social problems can be attributed only to changes in public *perception*.

The second observation, related to the first, is that no consistent relationship is apparent between the waxing and waning of given social *conditions*, on the one hand, and the official or public designation of those conditions as problems, on the other hand. For example, the official and professional recognition of racial discrimination as a social problem in the United States came not while the Jim Crow regime was at its worst (before World War II) but only after the lot of African-Americans had begun to improve significantly. Similarly, it is only since the 1980s that so-called hate crimes (crimes motivated by bias based on race, religion, ethnicity, sexual orientation, gender, etc.) have entered into national discourse despite the fact that this type of intergroup violence is as old as humankind. In the opposite direction, the war on poverty of the 1960s was effectively dropped from the national agenda of social problems with no change in the actual incidence of poverty. Similarly, the national war on drugs was officially declared after more than a decade of *decline* in the incidence of alcohol and

drug use by both adults and youths in the United States.

This common and paradoxical lack of correspondence between *objective* social *conditions* and the ebb and flow of social *problems* means that the two phenomena can vary independently. From the subjectivist viewpoint, the traditional objectivist focus has made the mistake of studying not social problems but only certain social conditions. In evaluating these conditions as problems, objectivists have not assumed the positivist, value-neutral stance of science, as they have supposed; instead, they have unquestioningly accepted the transitory evaluative definitions of interest groups, government funding agencies, and a fickle public. If the objectivists have been studying the wrong thing, what *should* the focus be for sociologists of social problems?

From the subjectivist viewpoint, the sociological study of social problems, properly understood, is the study of the process by which putative social conditions come to be defined as social problems by governments and publics (Spector and Kitsuse 1977). In this formulation, social problems are reconceptualized in terms of discourse, interactions, and institutional practices by which only some social conditions are defined as social problems and given a place in the social problems marketplace (Best 1990; Hilgartner and Bosk 1988). The social conditions themselves can be left to sociologists with other specialties: Criminologists can and should study crime; family sociologists can and should study divorce, spousal conflict, and child-rearing stresses; environmental sociologists can and should study the ways in which the physical environment and the organization of social life interact; specialists in stratification can and should study inequality; and so on. None of this other work, however important, constitutes the sociology of social problems per se, for social problems do not originate in social conditions. They originate in *claims-making activities* of interest groups and partisans who undertake to gain political acceptance for their perceptions of certain conditions as "problems," after which those perceptions reflect the evolution of social problems construction (Spector and Kitsuse 1977; Jenness 1993). It is those claims-making activities, then, that should constitute the focus of study in the sociology of social problems. Put another way, the study of social problems is a study of the social construction of reality (Berger and Luckman 1966).

Thus, subjectivists who study social problems in this way also are called *social constructionists* (or simply *constructionists*).

To understand how social problems are constructed, Kitsuse, Spector, and their disciples focus primarily on claims-making activities. These activities consist of the usual tactics of interest groups in asserting claims and grievances, including boycotts, demonstrations, and lawsuits, as well as the strategic use of terms, labels, semantics, and other rhetorical devices, to win political and public support for definitions of certain putative social conditions as problems (Spector and Kitsuse 1977, pp. 9–21, 72–79; Schneider 1985, pp. 213–218, 224). The particular arena within which claims-making activities occur can be as large as American society or as small as a college campus, a corporation, or even a professional society. Whatever the arena, it is claims-making activities or “social problems work” that constitutes the appropriate focus of research in social problems (Miller and Holstein 1989).

While the subjectivist or social constructionist paradigm is relatively recent as a theoretical alternative to the positivist or objectivist tradition in the study of social problems, it is actually cognate to several other well-established lines of inquiry in sociology. One of these fields is *cultural analysis*, represented especially in the work of Douglas (1966; Douglas and Wildavsky 1982). Broadly defined, cultural analysis is the study of the production and distribution of culture (including popular culture). As applied to social problems, cultural analysis includes the assessment of risk as a cultural product, much like a religious ideology (Stallings 1990). Miller and Holstein (1989) see a parallel here to the early Durkheimian concept of *collective representations*, which they understand as a cultural product of social problems work (see also Gusfield 1981).

A second theoretical link can be made between the social constructionist approach to social problems and *conflict theory* (Pong 1989). Inspired partly by Marxism, conflict theory, like critical theory, rejects the functionalist assumption that the natural condition of society is a state of equilibrium among interdependent parts (institutions). Instead, it emphasizes the naturally conflicting tendencies in society among economic, political, religious, and other interest groups (Eitzen and

Zinn 1988; Skolnick and Currie 1985). While the objectivist tendency in the way conflict theory defines social problems does not accord well with the social constructionist paradigm, the claims-making activities that are so important in that paradigm are classical examples of the political struggle and agitation that constitute the typical focus of conflict theorists and, more recently, of the critical theorists working in the deconstructionist (Michaelowski 1993; Pfohl 1993), feminist (Gordon 1993), postmodernist (Agger 1993), and poststructuralist (Miller 1993) traditions. These recent critical challenges “represent promising opportunities to reconsider assumptions, distinctions, and categories on which social constructionism and social problems theory rests” (Miller and Holstein 1993c, p. 536).

The social constructionist perspective converges perhaps even more closely with a third important preoccupation of sociology: *social movement theory*. The claims-making activities that are the principal focus of the constructionist approach are also the classical tactics and strategies of social movement activists. This would include both rhetorical products, such as ideology and propaganda, and mobilizing activities, such as demonstrations, agitation, and political organization (Hilgartner and Bosk 1988; Mauss et al. 1975; Mauss 1989). The “resource mobilization” approach to social movements that has gained currency in recent years seems especially close to the claims-making focus of the subjectivist or constructionist perspective on social problems (Zald and McCarthy 1987; Turner 1981).

At least in part because of the many ways in which the subjectivist approach to social problems has converged with other literatures in the social sciences, it has come to dominate scholarly approaches to social problems theory. Indeed, by the mid-1980s Schneider, a former editor of *Social Problems*, concluded in the *Annual Review of Sociology* that “over the last two decades the constructionist approach to social problems has constituted the only serious and sustained recent discussion of social problems theory” (Schneider 1985, p. 210). By the mid-1990s, it had produced “a torrent of empirical studies” (Miller and Holstein 1993b, p. 3) that focus on diverse social conditions and activities, including alcohol and driving (Gusfield 1981), hyperactivity (Conrad 1975), child abuse (Best 1990), AIDS (Albert 1989), alcoholism

(Schneider 1978), cigarette smoking (Markle and Troyer 1979), crime (Fishman 1978), rape (Rose 1977), homosexuality (Spector 1977), hate crime (Jenness and Broad 1997), premenstrual syndrome (Rittenhouse 1992), chemical contamination (Aronoff and Gunter 1992), drugs (Orcutt and Turner 1993), satanism (Richardson et al. 1991), prostitution (Jenness 1993), and even earthquakes (Stallings 1995). True to the constructionist perspective, this work has been sustained by research questions and procedures focused not on social conditions but on the full range of political and claims-making activities that cause these activities to be understood as social problems.

As demonstrated by Mauss (Mauss et al. 1975; 1989) these are also the activities typically associated with social movements. Accordingly, an issue among subjectivists and their allies is the question of whether the constructionist approach to social problems is equivalent to the study of social movements. The 1985 and 1989 annual meetings of the Society for the Study of Social Problems featured the theme of social problems as social movements. At those meetings and in subsequent publications, proponents of the subjectivist perspective have not agreed on whether the study of social problems should be subsumed by social movement theory or, alternatively, should be approached as a theoretically distinct field of study. Some would say that the dominant way in which social conditions come to be seen as social problems is through the work of social movements (Gerhards and Rucht 1992; Mauss 1989; Troyer 1989; Holstein and Miller 1993; Miller and Holstein 1993a). As early as 1975, Mauss (p. 38) presented the case for considering "social *problems* as simply a special kind of *movement*." This case rests largely on the proposition that the characteristics of social problems are typically those of social movements and that social problems are always outcomes of social movements. In this formulation, the study of social movements and the study of social problems are rendered compatible through an examination of the genesis of social problems movements, the organization and mobilization of social movements, the natural history of social movements, and the decline and legacy of a social problem. More recently, Bash (1995, pp. xiii-xiv) argued "that what is addressed as the Social Movement, in the one instance, and what is targeted as a host of social problems, in the other, may not reflect *distinctive*

sociohistorical phenomena at all." In contrast, Troyer (1989) has noted the similarities *and* differences between the definitional approach, the standard structural approach, and the more recent resource mobilization approach to social movements (Zald and McCarthy 1987). More recently, Klandermans (1992, p. 77) has observed that "many situations that could be considered a social problem never become an issue, even though they may be no less troublesome than situations that do become a rallying point. Further, a social problem does not inevitably generate a social movement" (he does not cite any examples).

A more vigorous debate among subjectivists began with the provocative critique offered by Woolgar and Pawluch (1985) of the "ontological gerrymandering" they attributed to the constructionist analysis of social problems. A successful constructionist explanation for social problems, they argued, "depends on making problematic the truth status of certain states of affairs selected for analysis and the explanation, while backgrounding or minimizing the possibility that the same problems apply to assumptions upon which the analysis rests" (Woolgar and Pawluch 1985, p. 216). Since constructionist analysis is itself a claims-making activity, these authors observe, it involves selective relativism and theoretical inconsistency: Constructionists invoke subjectivist assumptions about the phenomena under study but at the same time present their claims as objective facts.

In an attempt to rescue the constructionist paradigm from this apparent inconsistency, Ibarra and Kitsuse (1993, p. 26) have proposed replacing the term "putative condition" with the term "condition-category" as the appropriate focus of study. Mauss (1989, pp. 36-37, notes 1 and 2), however, implicitly rejects the entire issue raised by Woolgar and Pawluch by insisting that constructionists need not question the objective reality of "putative conditions" any more than that of any of the other elements in the construction of social problems but should focus only on the process by which those conditions come to be defined as problems. Yet if the issue of "ontological gerrymandering" has stalled the theoretical development of the constructionist perspective, as is feared by Ibarra and Kitsuse (1993), at least that argument has required of subjectivists more awareness of their own potential biases.

The position advocated by Mauss might be called “strict constructionist,” an example of which can be found in the work of Jennes and Broad (1997) on the anti-hate crime movement in the United States. In this work, the authors do not attempt to evaluate the accuracy or “objective” reality of the claims made by the women’s movement or gay/lesbian movement in the efforts of those movements to define violence as a social problem. In contrast, a somewhat nuanced approach, that might be called a “contextual constructionist approach” includes the evaluation of claims by interest groups as an important part of the analysis of the development of a social problem. For example, Best (1993), in his work on threats to children, relies on statistical and other data to assess the claims he describes. Calling a statement a “claim” does not discredit it, according to Best, who calls for social scientists to “worry a little less about how we know what we know, and worry a little more about what, if anything, we do know about the construction of social problems” (Best 1993, p. 144).

THE CURRENT INTELLECTUAL STATE OF AFFAIRS

In effect, two paradigms for understanding and explaining social problems have historically defined the sociological study of social problems. The traditional objectivist paradigm, which dominates textbooks and anchors policy-relevant research, evaluates certain social conditions as problems by definition. In this conceptualization, there is an implicit analogy to a cancer or another disease in the human body. That is, a social problem is understood as an objectively real and undesirable condition in society that should be diagnosed and treated by experts (especially sociologists). The more recently developed subjectivist paradigm, in contrast, denies that any social condition can be defined objectively as a social problem, for such a definition depends on the evaluation and claims-making activities of interest groups. Those groups organize and mobilize social movements in an attempt to gain general political acceptance of certain “undesirable” conditions as “social problems.”

Despite the growing prominence of the subjectivist approach in academic debates, at the level of social policy and undergraduate teaching the objectivist paradigm is likely to remain dominant.

One reason for this dominance in the public policy arena is the objectivist bias in the political culture of North America, in which public opinion has traditionally taken for granted the amenability of social ills to objective diagnosis and the responsibility of the political system to ameliorate those ills. As for undergraduate teaching, the lack of intellectual sophistication typically found at the freshman and sophomore levels of college education, where most courses in social problems are taught, makes teaching the subjectivist position difficult. The phenomenological epistemology of the subjectivist paradigm may be too abstract for most college students. Thus, the overwhelming majority of social problems textbooks continue to be organized around one or both versions of the traditional objectivist paradigm insofar as they assume that select social conditions—most frequently things such as crime, mental illness, poverty, environmental degradation, and suicide—are inherently social problems. It is rare to find a textbook that is organized around subjectivist concerns (but see Best 1995).

The emergent subjectivist paradigm is likely, however, to continue to provide the basis for the most novel and creative scholarly and professional literature on social problems. This is the case because its epistemology and methodology leave much room for development, in comparison with objectivism and positivism. Some scholars have even attempted to reconcile the objectivist and the subjectivist paradigms (e.g., Jones et al. 1989), but such attempts are most often made in textbooks, which are notorious for their sacrificing of theoretical focus in favor of eclecticism. Ultimately, the two paradigms probably cannot be reconciled, since they proceed from different epistemologies and study different topics. Objectivism focuses on certain social conditions, such as inequality and deviant behavior, taking for granted the evaluation of those conditions as problems. Subjectivism focuses on the *political players and processes* by which those conditions come to be defined as problems.

SOCIAL PSYCHOLOGY

Social psychology is the study of individual behavior and psychological structures and processes as both outcomes of and influences on interpersonal relationships, the functioning of groups and other collective forms, and culturally define macrosocial structures and processes. Social psychologists vary in the theoretical orientations and methods they use, the conceptual distinctions they draw, and the substantive causal linkages they study. Much of the variability in these areas is accounted for by the

academic tradition in which a social psychologist has been trained.

Contemporary social psychology has intellectual roots in both psychology and sociology. Psychological social psychologists are guided by social learning theory as well as by orientations such as exchange and role theories. For the most part, their methods consist of laboratory and field experiments, and data analysis is accomplished with quantitative techniques. They discriminate between individual behavior and psychological structures and processes and interpersonal settings. The primary interest of psychological social psychology is the influence of the perceived social environment on individual cognitive, affective, and behavioral responses (Gilbert et al. 1998).

Contemporary sociological social psychology encompasses two major perspectives: symbolic interactionism and personality and social structure. Within symbolic interactionism, other distinctions are drawn according to the degree to which the proponents emphasize consistencies in human behavior as opposed to creative and emergent aspects of behavior, the influence of social structure in placing constraints on social interaction through which concepts of the self and others are formed, and the relative merits of qualitative and quantitative research methods. Considering these perspectives together, sociological social psychologists are influenced most frequently by symbolic interactionism, role theory, and exchange theory. They employ a range of research methods, including social surveys, unstructured interviews, observational techniques, and archival research methods; laboratory and field experiments also are used on occasion. Data analysis is accomplished with both qualitative and quantitative techniques. Distinctions are drawn between individual behaviors, psychological structures, groups and other interpersonal systems, and culturally defined macrosocial structures and processes. Sociological social psychologists focus on the reciprocal causal influences between individual psychological structures and macrosocial structures and processes or those between psychological processes and ongoing interpersonal systems (Cook et al. 1995; Michener and DeLamater 1994).

Implicit in the explanatory constructs sociologists use in investigating patterns of social behavior are individual-level psychological constructs.

The concept of culture, for example, frequently is defined in terms of shared normative expectations that are learned and transmitted in the course of social interaction. This definition implies subjective probabilities, evaluative judgments, and processes of symbolic communication through which normative expectations are transmitted and shared. Further, the substantive referents of culture relate to individual-level phenomena such as systems of values, beliefs, and perceptual orientations. In short, definitions of sociological explanatory constructs and the substantive referents of those constructs tend to be abstractions from individual-level psychological responses and systems, including those relating to cognition, affect, and goal orientation. A full understanding of most, if not all, sociological constructs depends on comprehension of the psychological responses and systems that the sociological constructs connote and from which the sociological concepts can be generalized.

The current state of social psychology is best understood through a description of the range of theoretical orientations and research methods used, the conceptual distinctions that are drawn, and the causal linkages that are investigated by representatives of the two social psychological traditions.

THEORY AND METHOD

Social psychologists use a broad range of theoretical perspectives and research methods to study the reciprocal causal linkages between individual-level and social-level variables.

Theoretical Perspectives. Among the more frequently used theoretical perspectives are symbolic interactionism, role theory, exchange theory, and social learning theory.

Symbolic interactionism. From this perspective, people are perceived as acting toward others on the basis of the meaning those others and their behaviors have for the actors. Those meanings are derived and modified during social interaction in which people communicate with one another through the use of shared symbols. Symbolic interactionism encompasses the notion that people's ability to respond to themselves as objects permits them to communicate to themselves, through the use of symbols, the meanings that are given to people and objects by the persons who

perceive them. Thus, people interpret the world to themselves and respond according to that interpretation. The interpretation of a situation occurs in the course of ongoing social interaction. In short, persons become objects to themselves, interact with themselves, and interpret to themselves ongoing events and objects in the environment.

Proponents of symbolic interactionism vary in the extent to which they focus on the influence of a stable social structure on these processes. Those who deny the significance of a social structure concentrate on the process of cognitive interpretation and the creative construction of behavior that grows out of a person's interpretation of the ongoing interactive situation. Appropriate to this emphasis, empirical investigations employ observation and in-depth interviewing to the exclusion of experimental and quantitative, nonexperimental methods (the Chicago School). Derivatives of this approach to symbolic interactionism include the dramaturgical school, in which the metaphor of the theater is used to study how people create impressions of themselves during face-to-face interaction, and ethnomethodology, in which theoretical perspective students study the implicit rules governing interaction in particular situation to understand how people construct reality through social interaction.

For those who focus on the significance of social structures to symbolic interaction, the meanings of the behaviors in social interaction depend on the relevance of those behaviors for the social-identity-related standards by which people evaluate themselves. Individuals interact within a framework that defines the social identities of the interacting parties and the normative expectations that are applicable to each identity as it relates to the other identities in that situation. The behaviors that have the most meaning are relevant for highly placed standards in a person's hierarchy of values. The more a behavior of a person or the others with whom he or she is interacting validates or contradicts the social identity (male, father) that is important to that person, the more meaningful that behavior will be to him or her. To the extent that the behaviors of others toward a person signify evaluatively significant aspects of the self, it is important to anticipate responses from others. The others whose responses are more likely to signify evaluatively relevant information about the self are significant others (Charon 1998; Couse

1977; Kaplan 1986; Michener and DeLamater 1994; Stephan and Stephan 1990).

Role theory. From this perspective, human social behavior is viewed in the context of people playing roles (that is, conforming to normative expectations) that apply to people who occupy various social positions and interact with people in complementary social positions. As individuals change from one social position to another in the course of a day, they play different roles (as a father, for example, and then as an employer). The roles individuals play also change as they interact with people in different positions (a professor interacting with a colleague, with the dean, and with a student). As people shift roles, they also change the ways in which they view the world, the attitudes they hold toward different phenomena, and their behaviors. Although people identify more with some roles than with others, their ability to play their preferred roles is limited by the contradictory demands made on them by the other roles they are called on to play (Biddle 1986; Turner, 1990).

Exchange theory. This perspective is relevant to the investigation of the conditions under which individuals enter into and maintain stable relationships. One is most likely to do this when the rewards gained from the relationship are perceived as high, the costs are low, and the reward-cost differential is favorable compared with the perceived alternatives. Rewards (power, prestige, material goods) and costs (interpersonal hostility, great expenditures of money, long hours of work) are defined by personal values. Attraction to relationships is also a function of the extent to which the participants perceive each other as receiving outcomes (rewards) that are appropriate to their inputs (costs). In the absence of such equity, the participants adjust their behavior or way of thinking in an attempt to restore the fact or appearance of equity in a relationship (Molm and Cook 1995; Stephan and Stephan 1990).

Social learning theory. This orientation addresses how individuals learn new responses that are appropriate in various social situations. The primary processes through which social learning occurs include conditioning, by which one acquires new responses through reinforcement (that is, the association of rewards and punishments with particular behaviors), and imitation, by which one

observes the reinforcement elicited by another person's behavior (Bandura 1986; Taylor 1998).

Methods. Social psychological research employs a variety of methods, including social surveys, naturalistic observation, experiments, and analysis of archival data. Social surveys may be conducted by personal or telephone interviews or by self-administered questionnaires. For the most part, naturalistic observation involves observing ongoing activity in everyday settings (that is, field studies); in participant observation, the investigator plays an active role in the interaction. Experimental research involves the manipulation of independent variables to assess their effects on outcomes. Subjects are assigned at random to the independent conditions. The experiments may be conducted in the laboratory or in natural settings; in the latter case, the experimenter has less control over theoretically irrelevant variables but the experimental conditions are more realistic for the subjects. Archival research involves the use of existing data to test hypotheses. In some instances, the data can be used exactly as they appear, as with some statistical data. In other instances, such as newspaper stories, the data must be converted into another form, for example, for use in content analysis, which involves categorizing and counting particular occurrences (Cook et al. 1995; Gilbert et al. 1998; Michener and DeLamater 1994).

CONCEPTUAL DISCRIMINATIONS

The pursuit of the goals of social psychology by scientists from psychological and sociological traditions has entailed the differentiation between concepts at the individual level and the social level.

Individual-Level Concepts. Social psychologists have focused on dynamic psychological structures, intrapsychic responses, and individual behaviors as outcomes of or influences on social structures and processes.

Psychological structures. At the individual level, psychological structures have been represented as dynamic organizations of dispositions to respond at the intrapsychic level or the behavioral level. More inclusive concepts, such as the personality, reflect the organization of psychological dispositions in terms of a structure of relatively stable cognitive, evaluative, affective, and behavioral tendencies. The concept of the person has been under-

stood in terms of a structure of predispositions to respond at the intrapsychic or behavioral level that are organized around a hierarchically related system of situationally defined social identities. The self has been treated as an inclusive structure of dispositions to respond reflexively at the cognitive, evaluative, affective, and behavioral levels. Less inclusive structures refer to organizations of particular psychological dispositions, such as personal value systems, treated as the hierarchy of situationally applicable criteria for self-evaluation; the structure of attitudes or generalized evaluative responses; and the system of concepts and schemas (structures of related concepts) a person uses to order stimuli (Kaplan 1986).

These structures are treated as components that are related to one another in a stable dynamic equilibrium and at the same time as having the potential to change. The structures of predispositions, when stimulated by internal or external cues, respond at the intrapsychic level or the behavioral level. The predispositions are inferred from the observed behaviors and self-reports of intrapsychic responses to recurrent stimuli in particular situations.

Intrapsychic responses. These are cognitive (including awareness and conceptual structuring), evaluative, and affective (or emotional) responses to contemporary stimuli, including one's own or others' behaviors in particular situational contexts. The current situation may stimulate one to attend to particular aspects of oneself, classify others in terms of group-membership concepts, attribute others' failures to external rather than internal causes, evaluate oneself as a failure, or experience attraction to other people. Intrapsychic responses are inferred from one's perceptible behaviors or self-reports of percepts, beliefs, attitudes, and feelings relating to the current situation.

Behavior. Individual behavior refers to the class of responses that are perceptible to others as well as to oneself. Behavior is distinguished from intrapsychic responses and the stable organization of dispositions to respond (person or personality) that are perceptible only to the self. Behavior includes purposive or unintended communications about oneself or others, helping and hurtful responses, affiliation and disaffiliation with other individuals or groups, conformity to or deviation from one's own or others' expectations, coopera-

tion and competition, positive and negative sanctioning of one's own or others' behaviors, and the myriad other perceptible responses one may make to oneself, others, or other aspects of one's environment (Kaplan 1986; Michener and DeLamater 1994; Stephan and Stephan 1990). Behavior is conceptualized as the outcome of socially influenced psychological structures and intrapsychic processes and as influencing social-level variables.

Social-Level Concepts. These concepts include interpersonal systems and culturally defined macrosocial structures.

Interpersonal systems. Interpersonal systems are defined as those in which two or more individuals interact with each other or otherwise influence each other over a brief or extended period. The interaction or mutual influence is governed by shared normative expectations that define appropriate behavior for individuals who occupy complementary or common social positions in the course of the interaction or mutual influence. The shared expectations may exist before participation in the interpersonal system and reflect the common culturally defined macrosocial structure or may be refined or emerge during the ongoing social interaction or mutual influence in response to the unique characteristics of the interacting individuals or other situational demands. The social positions a person occupies and the interpersonal systems in which a person participates as a consequence may be given at birth or may be adopted later in life according to stage in the life cycle and current situational demands. Interpersonal systems include interpersonal relationships, groups, and collective forms.

Interpersonal relationships are those in which two individuals have an ongoing interaction that is governed by their shared normative expectations. These expectations are derived from social definitions that delineate appropriate behavior for people occupying the social positions that characterize the individuals and emerge in the course of the ongoing social interaction. For example, a married couple's shared expectations depend on a common understanding of the obligations and rights of a husband and a wife in relation to each other, and the same is true of friends; in addition, in the course of social interaction, specific evaluative expectations regarding what each person in the relationship will and should do in various

circumstances develop. Individuals may interact with one another in the capacity of having the same status (such as group member or friend) or complementary statuses (such as husband and wife) or in the capacity of representing conflicting or cooperating groups. Relationships develop through predictable stages. Intimate relationships develop from the awareness of available partners, to contact with those who are thought to be desirable, to various stages of emotional involvement. The accompanying increases in emotional involvement represent increases in self-disclosure, trust, and mutual dependence (Berscheid and Reis 1998; Michener and DeLamater 1994).

A group consists of a number of individuals in ongoing interaction who share a set of normative expectations that govern the behavior of the members in relation to one another. Normative expectations may refer uniformly to all group members as they interact with one another and with nongroup members or to different individuals in their various social relational contexts. Individuals share an identity as members of a group as well as common goals; these goals may include the personal satisfaction gained from the intrinsically or instrumentally satisfying intragroup relationship or from a group identity that evokes favorable responses from extragroup systems. Group members may share norms from the outset and refine or change their expectations over time, or the norms may emerge in the course of member interaction. Groups include friendship networks, work groups, schools, families, voluntary associations, and other naturally occurring or purposively formed ad hoc associations. Groups vary in size, stability, the degree to which interaction among the members is regulated by preexisting role definitions, and complexity of role differentiation as well as the extent to which a group is embedded in more inclusive groups. Groups also vary according to whether the gratifications achieved from participation in a group are intrinsic to the social relationships and are diffuse as opposed to instrumental to the achievement of other ends and delimited.

Over the course of time, groups develop structures characterized by status hierarchies and functional role differentiation, or those structures may be predefined for new members. Status hierarchies reflect the values placed by group members on positions within the group. The individuals who occupy those positions are more or less es-

teemed depending on the valuation (status) of a position. Individuals who have higher-status positions and are consequently more highly esteemed ordinarily receive greater rewards (as these are defined by group members) and exercise greater influence over group decisions. In formal groups, functional differentiation is indicated by the formal role definitions associated with the various social positions that make up a group. In informal groups, over time some individuals come to be expected to perform certain functions, such as leading the group toward solving a problem (the task leader) or accepting responsibility for relieving tensions and maintaining group solidarity (the social-emotional leader) (Levine and Moreland 1998; Ridgeway and Walker 1995).

Collective forms include publics, audiences, crowds, and social movements. Collective forms are characterized by the mutual influence of individuals in responding cognitively, affectively, and behaviorally to a common focus. Individuals are undifferentiated according to social position: They share the social position defined by their common attention to an idea, person, object, or behavior. The common stimulus, previously learned dispositions to respond to that stimulus, and mutual influences through social contagion, social observation, and emergent norms that govern mood, action, and imagery lead to collective behaviors. Collective behaviors by large numbers of individuals who are not physically proximate in response to mass media and interpersonal stimulation include mass expressions of attitudes (public opinion), attraction (fads, fashions, crazes), and anxiety (panics). Crowd behaviors are collective responses by large numbers of physically proximate individuals who are influenced by social contagion, observation, and the resultant emergent norms. Social movements are expressions of dispositions to behave similarly with regard to a social issue (Michener and DeLamater 1994).

Culturally defined macrosocial structures. The inclusive sociocultural structure provides shared meanings and defines relationships among individuals depending on their social positions or identities in a situation. The social structure is made up of the stable relationships between social positions or identities that are culturally defined in terms of the rights and obligations people who occupy one position have in interacting with people who occupy another position. In the course of

the socialization process, individuals learn the rights and obligations that apply to those who occupy the various social positions, and those rights and obligations constitute the role that defines a social position. The inclusive social structure is a system consisting of components that are related to one another in a relatively stable dynamic equilibrium but may change over time as changes in structural positions and their role definitions become prevalent in interpersonal settings throughout the society. The culturally defined inclusive macrosocial structure encompasses systems of stratification, social differentiation according to race or ethnicity, and major social institutions as well as other consensually defined social structures (Kerckhoff 1995).

CAUSAL RELATIONSHIPS

Within a social psychological framework, a person's psychological structure, intrapsychic responses, and behaviors are viewed in terms of the profound influence exerted on that person by his or her past and continuing participation in interpersonal and social systems. In turn, the person behaves in ways that have consequences for the interpersonal systems and social structures in which he or she participates. Implicit in this framework is a general causal model. Social structural arrangements define systems of shared meanings that in turn define the role expectations that govern behavior in interpersonal systems. A person is born into functioning interpersonal systems and throughout the life cycle participates in other interpersonal systems that together reflect culturally defined macrosocial structures and processes. In the course of a person's life in the context of dynamically evolving interlocking interpersonal systems, biogenetically given capabilities are actualized; the person learns to view the world through a system of concepts, internalizes needs, symbolizes those needs as values, accepts social identities, and develops emotional cognitive and behavioral dispositions to respond. These relatively stable psychological structures are stimulated by contemporary social situations that have symbolic significance for the individual and thus evoke predictable personal responses. Over time, the same social situations stimulate personal change.

The development of language skills, along with a person's experiences as the object of others'

responses to him or her in the course of the socialization process, influences the development of a person's tendencies to become aware of, conceive of, evaluate, and have feelings about herself or himself as well as dispositions to behave in ways that are motivated by the need to protect or enhance the self. The nature of a person's responses to herself or himself are influenced by past and present social experiences. Those responses in turn influence the relationships and groups in which a person participates and indirectly influence the more inclusive social system, thus intervening between social influences on the person and her or his influence on interpersonal systems and the culturally defined social structure (Corsaro and Eder 1995; Fiske et al. 1998; Elder and O'Rand 1995; Kaplan 1995; Kerckhoff 1995; Krauss and Chiu 1998; Maynard and Whalen 1995; Miller-Loessi 1995).

The substantive concerns of social psychological theory and research reflect detailed consideration of these general processes. These concerns address (1) the influence of culturally defined macrosocial structures and processes or interpersonal systems on psychological structures, intrapsychic responses, and individual behaviors or (2) the influence of psychological structures, intrapsychic responses, and individual behaviors on interpersonal systems and culturally defined macrosocial structures and processes.

Social Influences on Psychological Structures.

Substantive concerns with social influences on individual psychological structures, intrapsychic responses, and behaviors have focused on long-term social structural influences through socialization processes and contemporary interpersonal influences in interpersonal settings.

Social structural effects. Social structural arrangements define the content, effectiveness, and style of the socialization experience and thus influence a person's psychological structures. Individuals occupy social positions by being born into them or achieving them later in life. Each social position is defined in terms of role expectations that specify appropriate behavior for people who occupy that position in the context of particular relationships. As a result of occupying positions, people become part of interpersonal systems that consist of themselves and those who occupy complementary positions. In these relationships and groups people

become socialized. Socialization is the lifelong process through which an individual learns and becomes motivated to conform to the norms defining the social roles that are played or might be played in the future that individual and those with whom she or he interacts. Socialization occurs in a variety of social contexts, including the family, school, play groups, and work groups, through the experience of rewards and punishment consequent to performing behaviors, observation of the consequences of behaviors for others, direct and intended instruction by others, and self-reinforcement. The acquisition of language skills permits one to be rewarded and punished through the use of symbolic responses, communicate with others about the appropriateness of different responses, and reinforce responses through the process of becoming an object to oneself and disapproving or approving of one's past or anticipated behaviors. The cognitive structures used in coding and processing information about one's own behavior and the hierarchy of self-evaluative criteria also are learned in the course of socialization.

The content of role definitions and the centrality of particular roles for a person's identity structure depend on stage in the life cycle, role definitions associated with other social positions, and the historical era. The roles that are most central to a person's identity and contribute most to self-esteem depend on that person's position in the social structure, including age and gender. During a particular historical period, for example, men may base their self-esteem more on success in the occupational sphere whereas women in the same stage of life base theirs on adequate performance of family roles.

The effectiveness of the socialization process is influenced by more or less invariant developmental stages of cognitive and emotional development in interaction with the varying demands made on the individual at various stages in life as well as by discrepancies between the demands made on a person and the resources that would permit her or him to meet those demands (Corsaro and Eder 1995; Elder and O'Rand 1995; Miller-Loessi 1995).

The social structure affects the style of the socialization process as well. Higher-socioeconomic-status parents are more likely than are lower-class parents to base rewards and punishment on a

child's intentions than on actual behavior and to rely on reasoning and the induction of shame and guilt rather than physical punishment. As a family becomes larger, parents are more likely to exercise autocratic parenting styles, while children elicit less attention from parents and develop more independence (Michener and DeLamater 1994).

The end result of the social-structure-influenced socialization process is the development of psychological structures that are stimulated by social-identity-related situations or are evoked more generally in the course of social interaction. Depending on whether persons are born into male or female social positions, they develop different achievement orientations and evaluate themselves in accordance with the success their in approximating the standards of achievement they set for themselves. Individuals in higher socioeconomic classes tend to value a sense of accomplishment and family security more highly than do those with lower socioeconomic status, who tend to put more emphasis on a comfortable life and hope of salvation. More specifically, individuals who are born into a higher social class are more likely to be socialized to value educational achievement and aspire to higher levels of education. Those who achieve at higher levels in school are more likely to interact with others who respond to them in ways that reinforce academically oriented self-images and values that reflect an achievement orientation. Individuals whose occupational status involves self-direction tend to develop a high valuation of responsibility, curiosity, and good sense, while those in occupational positions characterized by close supervision, routine activities, and low levels of complexity in work tasks tend to develop a high valuation of conformity (Heiss 1981; House 1981; Kohn et al. 1983; Rokeach 1973; Sewell and Hauser 1980).

In general, in the course of socialization people become disposed to identify others in their environment, anticipate their responses, imagine aspects of themselves as eliciting those responses, behave in ways calculated to elicit those responses, and value the responses of others and the aspects of the self that elicit those responses. Radical resocialization, by which an individual unlearns lifelong patterns and learns new attitudes, values, and behaviors, may occur in circumstances in which the agents of socialization have uniform and

total control over the individual's outcomes, as in some psychiatric hospitals, penal institutions, traditional military academies, and prisoner-of-war camps (Goffman 1961).

Interpersonal effects. The contemporary interpersonal context stimulates self-conceptions and self-evaluative, affective, and behavioral responses. Each social situation provides participants with physical cues that allow them to make inferences about the social identities of the other participants, the role expectations each person holds of the others, and the perceived causes of the behaviors of the interacting parties. These conceptions regarding the situated identities are in part responses to the demand characteristics of the situation and in part the outcomes of the need of one party to project a particular social identity on the other person so that the first party can play a desired complementary role (Alexander and Wiley 1981). The situational context provides symbolic cues that specify the relevance of particular traits, behaviors, or experiences for one's current situation; it also provides a basis for comparing one's characteristics with those of other people.

The current social situation defines the relevance of some self-evaluative standards rather than others. The presence of other people, cameras, or mirrors makes people more self-aware and thus stimulates their disposition to evaluate themselves. Certain responses of others (sanctions), in addition to constituting intrinsically value-relevant responses, communicate to persons the degree to which they have approximated self-evaluative standards. In the early stages of development of a group, individuals may be assigned higher-status positions on the basis of status characteristics (such as those relating to age, sex, ethnicity, and physical attractiveness) that have evaluative significance in the more inclusive society. Although these characteristics may not be relevant to the ability to perform the functions for which the group exists, the high valuation of these status characteristics may lead to the assignment of individuals to high-status positions in the group through a process of status generalization (Berger et al. 1989; Ridgeway and Walker 1995). As a consequence of culturally defined preconceptions regarding the merits of various status characteristics, persons with those characteristics are expected to perform better on a group task.

With regard to affective responses, social stimuli evoke physiological reactions that are labeled as specific emotional states, depending on the cues provided by social circumstances (Kelley and Michela 1980). In turn, individuals who label an experience as a particular emotional state selectively perceive bodily sensations as cues that validate that experience (Leventhal 1980; Pennebaker 1980). Social stimuli that evoke psychological distress include contexts in which a person is unable to fulfill role requirements because of the absence of personal and interpersonal resources and the presence of situational barriers to fulfilling the obligations associated with the social positions that person occupies. Other such stimuli are represented by intrinsically distressing aspects of social positions. People may be distressed not only because they cannot do their jobs well but also because of the absence of meaning that their jobs have for them and because of other noxious circumstances correlated with the position (time pressures, noise, lack of autonomy, conflicting expectations) (Kaplan 1996).

Situational contexts define expectations regarding appropriate and otherwise attractive behavior and thus stimulate behavior that anticipates fulfillment of the expectations and achievement of the goals (including avoidance of noxious states such as social rejection). In collective forms of interpersonal systems, emergent norms govern actions as well as moods and imagery for publics and crowds and so lead to mass behaviors such as crazes and panics and crowd behaviors such as rioting. The motivation for participation in social movements is influenced by expectations regarding the value and likelihood of the success of a movement (Michener and DeLamater 1994).

In interpersonal relationships as well, shared expectations govern attraction to others, helping behavior, and aggressive behavior. An individual tends to be attracted to those with whom interaction is facilitated, those who are characterized by socially appropriate and desirable traits (including physical attributes), those who share tastes with and are otherwise like that individual, those who manifest liking for him or her, and in general those who may be expected to occasion rewarding outcomes. Helping behavior is evoked by situational demand characteristics, such as role definitions that define helping behavior as appropriate for people who occupy particular social positions, or

by interpersonal expectations that helping behavior by the other person should be reciprocated. The likelihood of conforming to these situational demand characteristics increases when a person perceives that the rewards for doing so will be forthcoming (including personal satisfaction in helping others, a sense of fulfillment in doing what one is called on to do, and approval by others) and that failure to do so will bring negative sanctions (social disapproval, a self-evaluation of having failed to do the right thing). Conformity to demand characteristics that require helping behavior may be impeded if a person perceives that it would involve costs, such as hindering the achievement of other goals. The awareness of potential rewards or costs for engaging or failing to engage in helping behavior is facilitated by situational characteristics such as the presence of observers and circumstances that produce self-awareness. The need to help others is increased by experiences that evoke negative self-evaluations. The resulting negative self-feelings motivate helping behavior as a way of improving one's self-evaluation (Michener and DeLamater 1994).

Aggressive behavior may arise in response to situational demand characteristics such as perceiving oneself as playing a role that requires aggressive behavior either as a response to intentional aggressive behavior directed toward one by others or simply as a communication of an aggressive stance. Reinforcement by rewards increases the frequency or continuity of aggressive patterns. Rewarding outcomes of aggression include the related rewards of social approval, an improved position in the prestige hierarchy of the group, self-approval, and material gain. Individuals are inhibited from engaging in aggressive behavior when they perceive the act as contrary to normatively proscribed roles or otherwise anticipate adverse consequences of the behavior. These inhibiting effects may be obviated by the reduced self-awareness that results from being part of a crowd, for example, or by the administration of psychotropic drugs (Bandura 1973; Baron 1977; Kaplan 1972; Singer 1971).

In group contexts, role definitions and influences on self-awareness affect individual behavior. The assignment of individuals to higher-status positions in a group and concomitant expectations of higher levels of performance or of the adoption of particular functional roles frequently motivate peo-

ple to conform to those expectations or lead to the provision of resources that permit them to do so (Berger et al. 1989). When socially induced self-awareness causes people to attend to public aspects of themselves, they tend to be responsive to group influences. When self-awareness causes them to attend to their personal standards, they tend to direct their behavior to conform with those values even when they conflict with group standards. Thus, exposure to cameras induces public self-awareness and increases social conformity, while exposure to mirrors evokes private self-awareness and an increase in self-direction (Scheier and Carver 1983).

The effects of social stimuli on deviant, as opposed to conforming, behavior have been addressed from a variety of theoretical frameworks, including structured strain theory, differential association and deviant subculture theories, control theory, self-theory, and the labeling perspective. Attempts to integrate or elaborate any of these approaches encompass the following ideas (Gibbs 1981; Hollander 1975; Kaplan 1984; Messner et al. 1989; Moscovici 1985). First, individuals who experience rejection and failure in conventional social groups lose their motivation to conform to conventional norms and are motivated to deviate from those norms. At the same time, these individuals are disposed to seek alternative deviant patterns to attain or restore feelings of self-worth. Second, individuals who participate in groups that endorse behaviors that are defined as deviant in other groups (whether because they seek alternative deviant patterns through which they can improve self-worth or because of long-term identification with a deviant subculture) positively value the "deviant" patterns and are provided with opportunities and the resources to engage in the deviant behavior. Third, individuals with the motivation and opportunity to engage in deviant behavior are deterred by anticipated negative responses from groups that define that behavior as deviant and to which they remain emotionally bonded. Individuals tend to conform to the normative expectations of a group to the extent that they are made aware of the deviant nature of their behavior or attributes, are attracted to the group and therefore are highly vulnerable to the sanctions the group may administer for deviant behavior, are prevented from leaving the group and so freeing themselves from vulnerability to the group's

negative sanctions, identify with the group and thus adopt its normative standards, and internalize the normative standards and regard conformity as intrinsically valuable. Fourth, individuals who evoke negative social sanctions in response to initial deviance continue or increase the level of deviant behavior as a result of the effects of the negative social sanctions on increased alienation from the conventional group, increased association with deviant peers, and increased motivation to justify the initial deviance by more highly evaluating a deviant act. Continuity or escalation of deviant behavior also is likely to occur if motives that ordinarily inhibit the performance of deviant acts are weakened and if a person perceives an association between the deviant behavior and satisfaction of preexisting needs (including the need to enhance one's self-esteem).

Psychological Influences on Social Systems.

The consequences of socially influenced psychological processes may be observed at the interpersonal level and at the more inclusive, culturally defined macrosocial-structure level (Kaplan 1986).

Interpersonal systems. Intrapyschic responses and behaviors influence interpersonal systems in a wide variety of ways. Among the more salient consequences are those relating to the stability and functioning of groups, intragroup influences, group membership, and intergroup relationships.

Individuals affect both the *stability* and the *functioning* of their groups through their behavior. The stability of a group is enhanced to the extent that individuals conform to the expectations other people have of them and thus validate those expectations. An individual contributes to group functioning by playing the roles other people expect her or him to play in the group, permitting others to play their complementary roles. Conformity is influenced by the need for self-approval and the approval of others when the criteria for approval are the group standards. If personal and group standards reflect the value of scholarship, individuals may study hard; if approximation to the standards of a particular social identity (such as male) is a salient basis for self-evaluation, people strive to conform to what they perceive as the role expectations associated with that position. More generally, persons may evaluate themselves in terms of conforming to others' expectations. A salient value may be to evoke approving responses from

others. To that end, a person may behave in number of ways, including conforming to others' expectations and presenting oneself to others in ways calculated to evoke approving responses. However, a person will strive to conform to group standards in order to approximate self-values only to the extent that success or failure is attributed to the degree of personal effort rather than to circumstances (Kaplan 1995). Conformity is also an outcome of the need for others' approval. In a group in which the members are highly attracted to the group, conformity to group norms, including those related to productivity, is high. In such cohesive groups, members have greater power over one another than they do in groups where the individuals are less attracted to and dependent on the group (Cartwright and Zander 1968; Cialdini and Frost 1998; Hare 1976). The need for others' approval is reflected in the use of disclaimers and excuses to mitigate others' responses to personal behaviors (Hewitt and Stokes 1975; Karp and Ybels 1986; Spencer 1987). A perceived threat to the group increases members' attraction to the group and conformity to shared norms while decreasing tolerance of deviance.

Interpersonal influence occurs through the use of both overt and covert behaviors. Overt methods of persuasion include the use of information or arguments, the offering of rewards, and the threat of punishment. Covert attempts to influence others are reflected in self-presentation in order to create the impression of oneself as likable or in other ways to manipulate the impression others have of one. Attempts at persuasion are more or less effective depending on the characteristics of the source of the communication, the message itself, and the target of the communication. For example, communications are more persuasive if they come from a number of independent sources each of which is perceived to be expert, trustworthy, or otherwise attractive to the target of the communication, than they are if they occur in mutually exclusive circumstances. The effectiveness of threats and promises in influencing others depends on the magnitude and certainty of the proffered rewards and punishments. When the parties involved in the influence process all have the capacity to reward or punish one another, changes in opinions or behaviors are influenced by bargaining and negotiation processes. Among the possible outcomes, depending

on a number of circumstances, are mutual influence, escalation of conflict, accommodation of one person to the demands of the other, and failure of the parties to agree (Michener and DeLamater 1994). In the course of group interaction, individuals develop more extreme attitudes than they held as individuals. This may be due to the pooling of arguments, which adds new reasons for the initially held attitude, or to the social support provided by other group members, which permits the person to be more extreme in his or her opinions with less fear of group rejection (Brandstatter et al. 1982).

Persons are motivated to present themselves in ways that evoke desired responses from others. This is accomplished through a variety of tactics. A significant feature of self-presentation is an individual's social identity in a situation. By projecting a particular identity, the individual effectively imposes complementary identities on others; if the other people perform the roles associated with those identities, they in effect endorse the identity that the individual wishes to project. This imposition of social identities on others (altercasting) has the desirable effect of affirming the social identity the individual wishes to project. For example, by complying with a reason's demands or following her or his lead, the others affirm that person's position of authority or leadership. In addition, people's favorable responses are intrinsically valued, other rewarding outcomes are contingent on them, and they indicate to a person that her or his public image reflects her or his personal ideals. Self-presentation may be used to create false as well as true images of oneself. The creation of false images (impression management) also is used to evoke responses from others that serve one's personal needs. Tactics involving the false presentation of self include pretenses that one admires other individuals or share their opinions and presenting oneself as if one had admirable qualities that one does not in fact possess (Baumeister 1982; Tedeschi 1981).

The attraction and maintenance of group membership are a function of the perception by members that group participation is intrinsically desirable or instrumental to the achievement of shared or individually defined goals (Evans and Jarvis 1980). Relationships, as well as larger groups, grow and become resistant to dissolution as the partners become increasingly dependent on each other

for need satisfaction, which may lie in the relationship itself or in the role the partner plays in facilitating the satisfaction of other needs outside the relationship (that is, by providing social support). Primary relationships dissolve to the extent that the costs come to exceed the rewards—whether in absolute terms or relative to the cost-benefit ratio that may be obtained from alternative relationships—and to the extent that the costs of remaining in the relationship outweigh the costs (including social disapproval) associated with terminating it (Cialdini and Frost 1998; Kelley and Thibaut 1978; Kerckhoff 1974). Among the costs are perceptions of inequity. Group members tend to compare the relationship between their own contributions to the group and the rewards they receive with other members' contributions and rewards. Judgments of inequity are made when members perceive rewards to be out of proportion to contributions. Judgments that inequitable states exist stimulate responses to reduce the inequity or at least the perception of the inequity. The inability to redress or tolerate inequitable relationships may lead to eschewing membership in a group (Walster et al. 1978). In general, people select group memberships, when they have a choice, and maintain them in accordance with their value in facilitating self-approving responses. People maintain relationships by whose standards they may evaluate themselves positively and tend not to associate with groups by whose standards they would be considered failures (Kaplan 1986).

The nature of the responses *that groups evoke from nonmembers* is influenced by the nonmembers' perceptions, evaluations, and feelings toward themselves and others. Negative emotions, such as anger, and consequent aggressive behavior may be directed toward groups when individuals' interests cannot be served except at the cost of frustration of the objectives of another group or when individuals associate the other group with past experiences of failure. Among the benefits persons may experience at the cost of the other group's outcomes is increased self-esteem. Aggressive behavior directed toward others deflects anger that might have been directed toward oneself. When the basis of one's feelings of accomplishment are judged relative to the achievements of another group, aggressive behaviors that lead to the failure or destruction of the other group enhance feelings of pride in one's own group. Stronger

levels of identification with one's group or social category increase the need to enhance one's group identity at the cost of adverse outcomes for other groups (Bobo 1983; LeVine and Campbell 1972; Worchel and Austin 1986). The tendency to devalue others as they deviate from one's own group's standards increases the justification for negative attitudes and hostile actions toward the other group. The need to justify aggressive attitudes toward another group also frequently leads to biased perceptions that reinforce or validate preexisting attitudes toward that group. Reversal of the process is impeded by the decreases in communication that accompany negative attitudes toward that group. Frequent experiences of observing aggressive responses desensitize a person to the effects of these responses and establish a normative judgment that they are within the expected range of responses.

Other individuals or groups may be the objects of helping behavior, depending on the actor's intrapsychic responses. Negative affect (particularly negative self-feelings) decreases helping behavior by focusing attention inward and away from the plight of other individuals. Thus, some individuals are less likely to empathize with or even be aware of others' needs. At the same time, distressful self-feelings motivate an individual to behave in ways that will earn self-approval. Helping behavior may serve this function by fulfilling others' expectation that helping behavior be offered, conforming to role definitions of helping behavior as appropriate for particular social identities, and conforming to self-values regarding altruistic behavior and thus compensating for feelings of rejection and failure (Dovidio 1984).

Macrosocial structures. Psychological structures, intrapsychic responses, and behaviors influence the substance of the social structure at any given time and social change over time. Dimensions of personality that reflect evaluative standards affect the positions an individual has in the social structure. High value placed on educational attainment and achievement orientation lead ultimately to educational achievement and high occupational status. Similarly, studies of the relationship between the occupational structure and personality suggest that workers may be selected into jobs because of the fit between their personality characteristics and the requirements of the work situation (Kerckhoff 1989). Individuals who value self-

direction select occupations that permit the exercise of self-direction, that is, ones that involve less routine, more complex tasks, and low levels of supervision. Persons who place a high value on conformity tend to opt for occupations that are closely supervised, routine, and noncomplex.

The effects of persons as products of past socialization experiences and as stimulated by contemporary social situations on interpersonal social systems and the more inclusive social structure are mediated by the responses of those persons to themselves. An individual influences the current and future functioning of interpersonal systems by becoming self-aware and conceiving of the self in particular ways, evaluating the self as more or less closely approximating personal standards, and experiencing self-feelings that stimulate self-protective and self-enhancing responses, some of which directly and indirectly affect the functioning of the interpersonal or social systems in which that individual participates.

If a person fails to behave in ways that meet self-imposed demands, that person will experience negative self-feelings that motivate him or her to behave in ways that will reduce the self-rejecting feelings. If the person identifies the self-rejecting experiences with particular social identities, she or he may reject the group and define it as a negative reference group, overidentify with the group and reevaluate formerly denigrated attributes as desirable ones, or project undesirable characteristics onto other groups or social categories and act with hostility toward them. Negative self-feelings also may lead to reduced levels of socioeconomic aspirations, occupational change, withdrawal from political participation or association with political activism, and changes in patterns of religious affiliation and participation (Kaplan 1986; Rosenberg and Kaplan 1982). If the circumstances that hinder a person from behaving in ways that earn self-approval and the self-protective responses they stimulate are widespread, the inclusive social structure will be affected. The person's responses directly affect interpersonal systems, that is, individuals who interact in the context of social relationships and groups that are governed by shared situation-specific, identity-specific, or person-specific expectations. If the individual is motivated to withdraw from or otherwise disrupt the functioning of the interpersonal systems in which she or he participates, the function-

ing of the other individuals will be similarly disrupted, since others' performance is contingent on the individual's conformity to their expectations. However, the functioning of the interpersonal system will be facilitated if the individual is motivated to conform to the normative expectations that the participants in the interaction situation view as applicable to the person in that particular situational context. If the disposition to deviate from normative expectations is prevalent, disruptions of social relationships will be widespread and the social structure will be less resistant to changes in patterns of response over time. While widespread conformity to shared expectations in particular social contexts has stabilizing influences on the broader social structure, widespread innovation or deviation from them influences the development of new social structural arrangements and definitions.

HOWARD B. KAPLAN

SOCIAL PSYCHOLOGY OF STATUS ALLOCATION

The processes of status allocation are among the most important phenomena of societal stratification structures, along with the ways in which those structures vary over time and between societies and the causes and consequences of those variations (Haller 2000). Within these partly stable

structures, these processes include the formation of individuals' status aspirations, the effect of those aspirations on attained statuses, and the causes of status aspirations (Haller 1982), including those describing a person's social origins (Alwin 1989). One's social status is defined in terms of both ascribed and achieved characteristics. Unless the value or meaning of ascribed characteristics changes, it is only through change in one's achieved characteristics that one's status in society can change. In modern society, occupation, income, and education are the most common achieved characteristics that are studied within the framework of status attainment.

People tend to see themselves and others as occupying positions along hierarchical continua, with evaluations being associated with a person's location in the hierarchy. One's plan, however vague, to strive for a particular place in a status hierarchy is defined as one's level of aspiration. As a mediator of achieved characteristics, and perhaps of ascribed characteristics as well, one's levels of aspiration affect one's levels of attainment (Haller 1982).

Status attainment research is concerned with the process by which people come to occupy their positions in life, some higher and some lower. Through social policy and social practice, the social system provides the opportunity structure for status attainment. The interface between sociology's study of stratification and psychology's study of individual motivation and achievement is dealt with by the field of the social psychology of status attainment.

HISTORY OF THE THEORETICAL FIELD

From the 1960s to the early 1980s, the theory of status allocation developed vigorously, increasing its theoretical comprehensiveness while maintaining its conceptual parsimony and explanatory power (Sewell et al. 1969, 1970; Haller and Woelfel 1972; Haller and Portes 1973; Haller 1982). These developments were matched by similar improvements in methods for testing the hypotheses of the theory (Duncan 1968; Duncan et al. 1968; Van De Geer 1971; Hauser et al. 1983). The social psychological theory of status attainment is both coherent and comprehensive by current standards of social science theory. The theory emerged from two traditions: one sociological, focusing on social

stratification research, and the other from social psychology, focusing on the self-concept and its formation.

The modern study of social stratification began with the work of Sorokin (1927) and was continued by Svalastoga (1965), Duncan (1968), and Haller (1970), among others. Stratification theorists typically posit at least four classes of fundamental status variables, or status content dimensions. Those content dimensions reflect the societal rewards an individual receives and the means to obtain those rewards. Thus, they also may be seen as dimensions of power. Content dimensions are conceptualized as political status, economic status, social status, and informational status (Haller 2000). In status attainment research, educational attainment, occupational prestige, and income are examined as the main variables by which one can measure a person's positions on the content dimensions.

The social psychological tradition that influenced status attainment is based primarily on work by Mead (1934). Lewin (1939) and Heider (1958) influenced this tradition as well. This tradition suggests that status in open societies is earned as opposed to being bestowed by a person's lineage. Before persons assume their eventual statuses, they knowingly or unknowingly develop a level of aspiration for educational status, occupational status, income, and political influence. One's level of aspiration is formed in three ways: by the modeling of others who are present, by self-reflection, and by adopting the status expectations held for a person by others. One can model the behavior of another person whom one knows only through mediated communication (e.g., by learning about another person's behavior by reading about it in books, newspapers, or magazines or by observing that behavior on television or in movies). One also can learn about the status expectations that others hold for oneself through the media. There is evidence, however, that most sources of influence are not transmitted in this way but instead by the direct and indirect effects of "significant others" (Haller and Woelfel 1969, 1972; Haller et al. 1969).

Once formed, aspirations are difficult to change, and they guide the decisions one makes about life. Consequently, one's level of aspiration is a significant determinant of one's level of attainment (Haller 1982).

Since the early 1980s, much work on status attainment has not been systematic but instead directed by policy considerations (Haller 1982). Interestingly, in the last two decades, research on status attainment has grown more in other countries than it has in the United States. In the United States, approximately the same number of studies were conducted on status attainment in each year over the last two decades. However, studies in other countries have more than doubled, and for the first time since the inception of the field, more research is being conducted outside of the United States than within it.

STATUS ATTAINMENT MODELS

A complete model of the process of status attainment does not exist. However, many significant contributions to what is known about status attainment have come from just a few perspectives. The work of Blau and Duncan (1967) was significant for its careful operationalization of concepts and presentation of formal models subject to statistical analysis. Those authors presented an important model concerned with the effects of parents' status, one's own education, and one's first job, although their model had four flaws. First, it lacked indicators for wealth and power, two important status content dimensions. Second, it contained a relatively primitive theory of the mechanisms of status attainment. Third, it lacked a comprehensive set of exogenous variables, which were limited to the father's occupational and educational statuses. Fourth, much variance in educational and occupational statuses was not explained.

A more complete model of status attainment was introduced informally in 1967; a test of it appeared in Sewell et al. (1969). The conceptual system it embodied, however imperfectly, became known as the Wisconsin model. Path analyses emphasized the social psychological and social structural antecedents of educational and occupational attainment. This early form of the model assumes that all relationships between the key variables are linear and that social psychological variables mediate the process of status attainment. Status aspiration for education and occupation was found to be a powerful mediator of status attainment.

An important contribution of this research was the elaboration, both theoretical and meth-

odological, of the concept of the significant other's influence. One's set of significant others is often larger than one's referent group of parents and peers. This set was defined to include all those who serve as definers and models. *Definers* are those who communicate their expectations, *whereas* models are those who provide illustrations of their statuses and related behaviors; an individual can serve in both capacities. The Wisconsin model changed the conception of social influence used in the study of status allocation from a list of individuals to a set of social processes by which the individuals in one's environment help determine one's status destination.

Sewell et al. (1969) found that the social structural and psychological factors of socioeconomic status and mental ability affect the academic performance of youths and that significant others have great influence in the status attainment process. However, the sample on which their original model was tested was limited, and this was a drawback for evaluating the internal and external validity of their model. The original sample consisted of 929 Wisconsin students who completed a survey as well as a follow-up group of males studied in 1964 whose fathers had been farmers in 1957 (Sewell et al. 1969).

The original form of the Wisconsin model was modified slightly in a study by Sewell et al. (1970), who proposed small changes that would make it applicable to boys with different residential backgrounds. As in the 1969 versions, one's ability and one's significant others were shown to affect one's educational and occupational aspirations. In turn, those aspirations affected one's educational and occupational status attainment (Sewell et al. 1970). Most significant was the finding that the Sewell et al. (1969) model could be used with minor modifications for young men from a variety of backgrounds.

The Wisconsin model was refined in two significant ways by Haller and Portes (1973). First, the model was modified by clarifying and completing the set of content dimensions of status. Second, it was shown that each content dimension of status also is manifested in both of two social psychological isomorphs (status "mirror" images): a status aspiration variable of each focal person and a corresponding variable describing the status orientation levels each of the focal person's significant others expects of him or her (definers) or

illustrates to him or her (models). Third, the Wisconsin model incorporated structural dimensions of status. Two critical structural dimensions are status dispersion and status crystallization. Status attainment models were held to work best when status dispersion is wide, which means that inequality is great; there is little to learn about attainment in fairly homogeneous status systems. Status crystallization is the degree of correlation among status content dimensions (e.g., how one's wealth corresponds to one's power). When crystallization is high, a status attainment model is relatively simplified: It is as if the ultimate endogenous variable were an unobserved variable with many correlated indicators. In complex societies with moderate to high crystallization, status attainment models must be more complex, because the isomorphs of each status content dimension must be treated as separate endogenous variables in the model.

The Wisconsin model was retested in 1983 with more recently developed estimation procedures. It was found to be even more effective in explaining the process of educational and occupational attainment than it previously had been thought to be (Hauser et al. 1983). However, the model was not tested as a whole because not all the variables in the model were measured.

Concerns with Current Status Attainment Models. Research on status attainment models has not advanced much since the early 1980s, and flaws in the models of that time remain. More recent research has focused mostly on status inheritance, but the inheritance models are incomplete. None of these models has included measures drawn from the power dimension; indeed, none has seriously attempted to cover the entire range of variables implied by each of the four general status content dimensions (Haller 2000). In the models that have been tested, about 25 to 35 percent of the variance in attainment can be explained by parental status variables. The more nearly complete models explain much more than this.

The social psychological variables used in models today are virtually the same ones used twenty-five years ago. However, the world has changed drastically in the last twenty-five years, particularly with the advent of and pervasive use of communication technology. It is conceivable that mediated sources of influence play a greater role in status

attainment process, but it is impossible to know whether this is true. More generally, it is quite possible that the relationship among status attainment variables has changed, and there may be additional variables to consider.

Concerns with Current Status Attainment Research. The initial fifteen years of research from 1967 through 1982 were significant in terms of formulating theory, defining variables, and enlarging the subject populations to which the attainment model applied. Haller (1982) described four avenues of study that would advance status attainment research greatly.

First, there has not been a longitudinal study that followed a cohort sample and observed the influence of the variables in the model on status attainments beyond mid-career. For example, what influences the selection of a second occupation? In addition, how do one's high school occupational, educational, and income aspirations affect one's position and income thirty years or more after those aspirations are formed? Second, most earlier attainment research was restricted to high school students and their first positions after school. The development of status orientations among young children needs to be explored. Third, it is important to understand how status definers emerge in young children. Fourth, the mechanisms that activate the status attainment process have to be explicated.

Above all, the full panoply of variables specified in Haller (1982) should be tested on today's youthful cohorts as they move through life.

THE STATE OF KNOWLEDGE

In status attainment research, the key variables that are feasible today are educational attainment, occupational prestige, and income. What is known about those variables?

Educational Status Attainment in the United States. *Young children and early teens.* The first longitudinal study of educational attainment conducted with young children spanned the period from fall 1985 to spring 1987. Achievement in the first grade was studied for minority groups, including African-Americans and Hispanics. Parental involvement, mobility, and motivation all had a direct influence on first-graders' outcomes. Interestingly,

at least two of the three variables—parental involvement and mobility—are under the direct control of the parents. Additionally, the cognitive readiness of children entering kindergarten was found to have an indirect effect on first-graders' outcomes. All the variables examined had a significant direct or indirect effects on those outcomes, including motivation, peer environment, parental involvement, readiness, and mobility (Reynolds 1989).

The second longitudinal study of educational attainment spanned a one-year period from fall 1987 to fall 1988, using a national sample of 3,116 youths. Data from this study were used to assess science achievement, attitude toward mathematics, and science and mathematics achievement in grades seven and eight. For young teenagers, prior achievement played a large mediating role in future mathematics and science achievement, but classroom context and parental involvement influenced their achievement as well (Reynolds 1991). Science achievement was directly affected by prior achievement, peer environment, and the amount and quality of instruction; mathematics achievement was most strongly influenced by prior achievement and the home environment (Reynolds and Walberg 1991, 1992).

Teenagers. Intelligence is a factor in predicting educational and occupational aspirations, but other variables appear to have a greater effect. There is a relatively small effect of parents' statuses on their children's but a relatively large effect of status aspirations and significant others' expectations on one's educational and occupational attainment. Thus, if one has significant others who expect one to go to college, it is more likely that one believes that going to college is possible and one is more likely to go.

Using annual data collected since 1975 for the Monitoring the Future survey, Morgan (1998) found that the educational aspirations of high school seniors increased between the late 1970s and the early 1990s. This effect was greater for white students than for African-American students. Morgan (1998) viewed aspirations as part of a cognitive process of continually calculating the costs and benefits of one's educational aspirations; this variable may influence the effects of significant others. The finding is consistent with the results of many early studies (Haller and Miller, 1963, Hypothesis 4, pp. 31, 41–45, 96), and is an expression of the

well-known Zeigarnik effect (Zeigarnik 1927, Lewin 1951).

The Wisconsin model from the 1970s worked well for the group of white males but not as well for others. With the addition of identity theory (Burke 1989) to the Wisconsin model, that model was found to work not only for white males but for African-American and white females as well. Identity theory suggests that one's identity originates from one's social interactions with others. When one's identity is established, one acts in ways that maintain and confirm that identity. White males and females and African-American females constructed an academic identity that directly influenced their college plans. In other words, if they constructed the meaning of going to college in terms of job-related reasons ("Going to college will help me get the kind of job I want"), they were more likely to go to college. However, the model's predictive ability for African-American males has been minimal. Preliminary research has indicated that one of the reasons for this may be that in that group there is insufficient correspondence between the constructs used in the modified Wisconsin model and the processes associated with African-American male attainment (Burke 1989; Burke and Hoelter 1988).

Education Outside the United States. *Australia.* In Australia, education is required for those aged 6–15. Thus, required education ends after the tenth year of school; however, students may elect to stay in the system for two more years. Students who left school after the tenth year earned less than did those who stayed the additional two years. Importantly, socioeconomic background, type of school attended, and career orientations appeared to be unrelated to the decision to leave school after the tenth year (Saha 1985).

Australian research sought to determine whether attending a private Catholic high school influenced attendance at college and the receipt of a college degree. Approximately two-thirds of those from public schools and two-thirds of those from private schools eventually obtain a college degree. However, only approximately 58 percent of those who receive a secondary degree from a Catholic school obtain a college degree (Williams and Carpenter 1990). Thus, receiving a private education results in the same chance of obtaining a college degree as does receiving a public school educa-

tion, but receiving a Catholic school education gives one a relatively lesser chance to obtain a college degree.

Young adult unemployment in Australia varied between 27 percent and 52 percent from the mid-1960s to the early 1980s. One might assume that most youths were encouraged to obtain further education, but that was not always the case. A revision of the Ajzen–Fishbein model of attitude–behavior relations (Carpenter et al. 1989) was used to assess youths’ intentions toward entering the workforce immediately after high school; the influence of economic conditions also was considered in this model. Parental and peer influence played a powerful role in molding a youth’s intentions; however, the youth’s decision to transform the intention into action was mediated by his or her self-perception of past academic performance.

Greece. A Greek study (Kostakis 1992) examined information and occupational demands in terms of the specific sources Greek students might use to influence their decisions about the future. How and from whom one gains information was considered a socially determined process. An individual’s significant others, consisting of friends and relatives, appeared to be the most important source of information for all groups; however, significant others were more available to higher-status individuals. Considered as an information source for vocational occupations, schooling was relied on by lower-status youths, rural youths, and girls.

Israel. In many studies, teachers were viewed as significant others, but their influence on status attainment did not appear to be large. However, little was known about a teacher’s long-term influence on status attainment. A national representative sample of 834 Israeli adults aged 21–65 was studied to ascertain the effect of the influence of a former teacher (Enoch et al. 1992). The group was divided into two cohort groups: older (ages 40–65) and younger (ages 21–39). Perceived teacher influence was found to be a determining factor in respect to occupation only for the older group. Furthermore, it was found that the Oriental (Sephardic) older group perceived teacher influence as being greater than did any of the other groups in terms of occupational attainment, whereas the older Ashkenazic group identified perceived

teacher influence as a significant variable in educational attainment.

Occupational Status Attainment in the United States: The Role of Gender. Typical status attainment models account for more variance in male occupational attainment than in female occupational attainment. A possible reason is that typical occupational status attainment models view occupations as discrete categorical variables as opposed to preferences along a continuum. When occupational titles were measured as a continuous variable, as was done by the Wisconsin researchers, it was found that a student’s gender and a family’s socioeconomic status were related to occupational choice. Additionally, significant others’ expectations for a student played a role in determining aspirations. Significant others’ expectations appeared to be affected most by gender as opposed to aptitude or ability. Thus, males and females may have their aspirations influenced by significant others who seem to choose traditional gender occupations for them (Saltiel 1988).

After the 1960s and 1970s, occupational status attainment research in the United States focused on gender differences in attainment, perhaps because changes in gender roles accelerated at that time. More women have chosen to pursue higher education and enter male-dominated careers than ever before. How will the increasing diversity of occupations open to women affect women’s aspirations and eventual occupational attainment?

There were no significant differences in levels of occupational aspiration between boys and girls and in different high school grades in the early 1960s (Haller et al. 1974). However, little research examining gender differences was conducted in the 1970s and the early to middle 1980s to determine whether aspirations affected occupational attainment.

Consistent with the Wisconsin model, women in the 1980s who pursued male-dominated careers such as business, engineering, and law were found to be subjected to a network of influences, as opposed to a single influence. Parents’ educational level was acknowledged as an influence in typical status attainment research, but until the late 1980s, the specific effect of parents’ possession of a college degree on their children was not considered. For both African-American and white women, parental income was found to have a

significant indirect effect on women's educational attainment. Furthermore, for white women only, the father's and mother's education proved to have significant indirect effects (Gruca et al. 1988).

Women recently have been receiving approximately 50 percent of the bachelor's degrees in life sciences and mathematics, but they are significantly underrepresented in science and mathematics occupations (National Research Council 1991). If women are attaining initial degrees in the same numbers as men, why are they not represented equally in the fields to which those degrees lead?

For women, significant factors associated with persistence in scientific and mathematical careers after college include receiving encouragement from teachers and parents, particularly the mother (Rayman and Brett 1995). Those who stay in science and mathematics careers after graduation do not necessarily believe that their current occupation is compatible with family life; however, the majority of these women have not been affected by family needs. Those who changed careers from a mathematics- or science-related occupation to one not oriented in those directions were more likely to believe that family need plays a role in occupational attainment. Over 50 percent of this group had taken time off from work, refused promotions, reduced their work schedules to part-time, or changed location because of family need. Grades in science and mathematics courses did not significantly affect attitude and achievement in science and mathematics. Additionally, self-esteem and perceived self-confidence did not play a role in deciding who stayed with scientific and mathematical careers and who did not (Rayman and Brett 1995).

Occupational Status Attainment outside the United States. *Canada.* The Canadian Mobility Study (Boyd et al. 1995) was directly influenced by the 1962 Occupational Change in a Generation Study in the United States. Using data from the early 1970s, this study showed that great inequalities exist in income, assets, and educational attainment between genders and among those with various ethnic origins (Porter 1995, p. 61). Preliminary research indicated that motherhood, as opposed to or in addition to being married, was the most significant variable determining the occupational status attainment of native-born Canadian

women (Boyd 1995a, p. 284). This finding makes sense, as motherhood, as opposed to marriage, generally requires time off from work. Some women choose to stay at home to raise a child; even if this time off from work is brief, by affecting continuity of employment, it affects one's advancement potential.

Interestingly, occupation and status seem to be consistent from generation to generation (McRoberts 1995, p. 98). One of the reasons for this is that the advantages of background often are passed on to children. For example, wealthy parents are more likely to have received higher education and are better able to afford to have their children receive higher education. Although it is not impossible for a child from a lower-income family to attend an institution of higher education, it is not as likely. This conclusion comes from a study of Canadian-born males in 1973 whose occupations were compared with those of their fathers.

Also of interest is the role of immigrants in status attainment levels in Canada. Native-born Canadian men have an average occupational status lower than that of American-born, German-born, and United Kingdom-born male immigrants and an average occupational status higher than that of immigrants from Poland, Italy, Greece, and Portugal (Boyd 1995b, p. 440). Much of the inequality between the Canadian-born and non-Canadian-born men results from differences in family origin and education.

Similarly, non-Canadian-born women tend to have an average occupational status lower than that of Canadian-born women, but non-Canadian status seems to have less of an impact on female immigrants from the United States and the United Kingdom. As in the United States, females have a lower average occupational status than do males (Boyd 1995b, p. 441).

Taiwan. Taiwan consists primarily of three ethnic groups: the aborigines, the Taiwanese, and the mainlanders. Although the Taiwanese account for slightly more than 85 percent of the population, the mainlanders, who account for approximately 12 percent, hold the political power. A study involving 3,924 men from the three ethnic groups determined that the mainlanders had an average occupational status higher than that of the Taiwanese or the aborigines (Tsai 1992).

The father's occupation was found to be the determining factor for first occupation among aborigines over 35 years old. However, for those under 35 years of age, residence and educational attainment were found to be significant influences on the first occupation. This result was different for the Taiwanese and the mainlanders, for whom the most important determinant of first occupation was their level of educational attainment (Tsai 1992).

Israel. In Israel, a better education does not necessarily predict better occupational attainment (Semyonov and Yuchtman-Yaar 1992). It once was believed that as Arabs became increasingly integrated into the general Jewish population in Israel, educational attainment and status attainment would become more equal between those two groups. From 1972 through 1983, the Arab population increased its average educational attainment level; however, its average occupational attainment declined. Market discrimination was estimated to account for 6.5 percent of the occupational gap between Jews and Arabs in the highest age group (ages 54–65), but its effect increased to nearly 25 percent in the youngest age group (ages 25–36). Clearly, there are social variables at work here that are not included in traditional status attainment models.

Political and Economic Status. Little research has been conducted in the areas of political and economic status. The link of economic status to the prior generation is much weaker than are educational and occupational links that generation. There are a number of reasons why economic status is much more difficult to study than are the educational or occupational variables. Many studies rely on participants to report information for their parents, and although occupational and educational attainments generally are known to family members, specific income information, particularly over a life span, is not. Also, the fluctuating rate of inflation makes it difficult to compare incomes directly across generations. Additionally, an economy's supplies and demands vacillate and ultimately determine an occupation's worth at a given moment. Thus, although the prestige of occupations may not change much, the income associated with those positions may change a great deal, in part as a result of market forces. Finally, the range of incomes today is greater than ever before. Chief executive officers, entertainment

performers, and professional athletes command high incomes. With more income "outliers" today, reliably measuring income and incorporating it into status attainment models are difficult. As a result of these factors, less is known about income status attainment than about educational or occupational attainment.

Similarly, little is known about political status attainment. Political status originally was defined as influence, authority, coercion, and power. Unlike occupational and educational achievement, which have been relatively well defined, there is little agreement on a person's political status.

In a study involving sports teams across cultures, age, experience, and performance were deemed to be the most significant factors in defining status in Canada and India (Jacob and Carron 1996). Both cultures gave more importance to achieved sources of status, such as experience and performance level, than to ascribed status, such as religion, race, and parental occupation. Surprisingly, age was found to be a significant determinant of status, apparently because it serves as an indicator of experience.

CONCLUSION

Some analysts, including Breiger (1995) and Ganzeboom et al. (1991), believe that theory formulation has become very narrow in social attainment research. However, there are several directions future research can take. First, status allocation research can increasingly feature the systematic incorporation of societal factors considered from the perspective of the individual. For example, advances in network analysis will allow measurement of extended networks and the influences of their members (Wasserman and Faust 1994). Similarly, simulation can provide a method to test models of social influence posited in status allocation models, allowing the investigation of the stability, equilibrium, rate of change, and other qualitative features of status dynamics in a social group (see Gilbert and Doran 1994; Jacobsen and Bronson 1995; Latané 1996). Finally, more extensive measurement of the multidimensional features of occupations and the related variables will allow the creation of models of greater complexity, for example, reflecting nonprestige or nonhierarchical features of status allocation (see Woelfel and Fink 1980).

This article makes it evident that researchers need to focus anew on conceptual clarity and theoretical parsimony. In the future, it is important that new research be executed with variables that include all that have been specified as crucial, along with the causal lines that were so specified, as elements of the theory referred to as the Wisconsin model (Haller 1982). As implied here, this should be done for both males and females in different decades and in societies with differing stratification structures.

SOCIAL RESOURCES THEORY

NOTE: Although the following article has not been revised for this edition of the *Encyclopedia*, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.

This article introduces the theory of social resources (Lin 1982, 1983). It describes the fundamental propositions of the theory and reviews empirical research programs and results pertaining to the theory. It concludes with a discussion of some issues regarding extensions and modifications of the theory.

Resources are goods, material as well as symbolic, that can be accessed and used in social actions. Of particular interest are the valued resources—resources consensually considered as important for maintaining and improving individuals' chances of survival as they interact with the external environment. In general, valued resources are identified with indicators of class, status, and power in most societies. In the following discussion, resources refer to valued resources.

Resources can be classified in two categories: personal resources and social resources. *Personal resources* are resources belonging to an individual; they include such ascribed and achieved characteristics as gender, race, age, religion, education, occupation, and income as well as familial resources. These resources are in the possession of the individual and at the disposal of the individual. *Social resources*, on the other hand, are resources embedded in one's social network and social ties. These are the resources in the possession of the other individuals to whom ego has either direct or indirect ties. A friend's car, for example, may be ego's social resources. Ego may borrow it for use and return it to the friend. Ego does not possess the car, and accesses and uses it only if the friend is willing to lend it. The friend retains the ownership. Similarly, a friend's social, economic, or political position may be seen as ego's social resources. Ego may seek the friend's help in exercising that resource in order for ego to obtain or achieve a specific goal.

Much of sociological research focuses on personal resources. While social network analysis has been a long-standing research tradition in sociology and psychology, attention had been given to

the structure and patterns of ties and relations. Only recently, in the past two decades, sociologists and anthropologists have explored the theoretical significance of the resources brought to bear in the context of social networks and social ties. The theory of social resources makes explicit the assumption that resources embedded in social connections play important roles in the interaction between social structure and individuals. More specifically, the theory explores how individuals access and use social resources to maintain or promote self-interests in a social structure that consists of social positions hierarchically related and organized in terms of valued resources. It has been argued that social resources are accessed and mobilized in a variety of actions by an individual to achieve instrumental and/or expressive goals.

Two terms need some clarifications here. I assume that a social structure consists of different levels, each of which can include a set of structurally equivalent positions. They are equivalent primarily on the basis of levels of similar valued resources, and secondarily, similar life-styles, attitudes, and other cultural and psychological factors. For the purposes here, the terms, "levels" and "positions," are used interchangeably. Also, status attainment is assumed to refer to the voluntary aspect of social mobility. Involuntary social mobility, due to job dissatisfaction, lack of alternatives, or other "pushing" or forced factors, is excluded from consideration. As Granovetter (1986) pointed out, voluntary social mobility generally results in wage growth. Likewise, it is argued that voluntary social mobility accounts for the majority of occurrences in status attainment.

THEORY OF SOCIAL RESOURCES AND SOCIAL ACTIONS

Attention in this article will be given to the theory of social resources as it is applied to the context of instrumental actions. Instrumental actions are a class of actions motivated by the intent to gain valued resources (e.g., seeking a better occupational position). In contrast, expressive actions are a class of actions motivated by the intent to maintain valued resources (e.g., seeking to maintain a marital relationship). Social resources have broad implications for both types of social actions (Lin 1986). However, for the present discussion, social resources will be considered in the perspective of

instrumental actions only. To carry the discussion at a more concrete level, attention will be given to the status attainment process, which can be seen as a typical process focusing on an instrumental goal. In the following material, the propositions of the theory of social resources will be presented in the specific framework of the status attainment process, to illuminate clearly and concretely the theoretical implications in a specific research tradition.

I have specified three hypotheses (Lin 1982): the social resources hypothesis, the strength-of-position hypothesis, and the strength-of-ties hypothesis. The *social resources hypothesis*, the primary proposition of the theory, states that *access to and use of better social resources leads to more successful instrumental action*. In the case of status attainment, it predicts that job-seekers are more likely to find a better job (in terms of prestige, power, and/or income) when they are able to contact a source with better resources (in terms of occupation, industry, income, etc.).

The other two hypotheses identify factors that determine the likelihood of access to and use of better social resources. The *strength-of-position hypothesis* stipulates that *the level of original position is positively associated with access to and use of social resources*. For the process of status attainment, it suggests that the original social position of a job-seeker is positively related to the likelihood of contacting a source of better resources. Position of origin can be represented by characteristics of ego's parents or previous jobs.

The *strength-of-ties hypothesis* proposes that *use of weaker ties is positively related to access to and use of social resources*. For status attainment, it states that there is a positive relationship between the use of weaker ties and the likelihood of contacting a source of better resources. For the formulation of the strength of weak ties argument, see Granovetter (1973, 1974).

Thus, the theory contains one proposition postulating the effect of social resources and two propositions postulating causes of social resources. The strength-of-position hypothesis implies an inheritance effect. A given position of origin in the hierarchical structure in part decides how well one may get access to better social resources embedded in the social structure. It is a *structural* factor and independent of individuals in the structure, although individuals may benefit. On the other

hand, the strength-of-ties hypothesis suggests the need for *individual action*. Normal interactions are dictated by the homophily principle, the tendency to engage in interaction with others of similar characteristics and life-styles. Going beyond the routine set of frequent interactants and seeking out weaker ties represent action choices beyond most of the normative expectations of the macrostructure (see Granovetter 1973, 1974).

It is true that the beginning of a job search often is unplanned. Many job leads become available through casual occasions (e.g., parties) and through interactions with casual acquaintances. It is not necessarily the case that a job search always begins with the individual actively seeking out contacts for this purpose. However, this does not negate the basic premise that individuals are situated at different levels of positions in the structure and have, therefore, access to "casual" occasions involving participants of certain types and amounts of resources, including social resources. In fact, it has been empirically demonstrated (Campbell, Marsden, and Hulbert 1986; Lin and Dumin 1986) that higher-level positions have greater access to more diverse and heterogeneous levels of positions in the hierarchical structure than lower-level positions, therefore having greater command of social resources. Thus, it can be expected that "casual" occasions for the higher-level positions are structurally richer in job and other types of information and influence. Such structural advantage, deducible from the pyramidal assumption of the theory, has distinct effect when a job search is eventually launched by the individual. *In relative terms, the strength of position should have stronger effects on social resources than the strength of ties*. This statement recognizes the significance of structural constraints everywhere in the social structure. In empirical systems, both factors are expected to operate, even though their relative effects may vary.

EMPIRICAL RESEARCH AND THEORETICAL EXTENSIONS

Research programs examining the theory of social resources in the context of socioeconomic attainment have been carried out in North America (Ensel 1979; Lin, Ensel, and Vaughn 1981; Lin, Vaughn, and Ensel 1981; Marsden and Hulbert 1988), in West Germany and the Netherlands (Flap and De Graaf 1988; De Graaf and Flap 1988;

Sprengers, Tazelaar and Flap 1988; Boxman, Flap, and De Graaf 1989; Wegener 1991), in Taiwan (Sun and Hsiong 1988), and in China (Lin and Bian 1990). Thus far, evidence strongly supports two of the three hypotheses: the social-resource hypothesis and the strength-of-positions hypothesis. Those with better origins tend to find sources for better resources in job-seeking, while contacting a source of better resources increases the likelihood of finding a better job. These relations hold even after the usual status attainment variables (e.g., education and first-job status) are taken into account. These results, as Marsden and Hulbert showed, are not biased by the fact that only those contacting interpersonal sources in job-seeking are selected for study.

However, evidence is equivocal on the strength-of-(weak) ties hypothesis. For example, Lin and associates have found evidence that weaker ties linked job-seekers to contacts with better resources, whereas Marsden and Hulbert (1988) did not. The different findings may be due to the interaction between the two exogenous variables: the strength of position and the strength of ties. Lin and others have found that the advantage of using weaker ties over the use of stronger ties decreases as the position of origin approaches the top of the levels. Lin, Ensel, and Vaughn (1981) hypothesized a ceiling effect for weak ties. At the top of the hierarchical structure there is no advantage to using weak ties, since such ties are likely to lead to inferior positions and therefore inferior resources. They did not anticipate similar ineffectiveness of weaker ties toward the bottom of the structure. Marsden and Hulbert (1988), however, also found that those with the lowest origins did not benefit more from contacts with weaker ties in gaining access to better resources than from contacts with stronger ties. One speculation is that those at the lower positions have more restricted range of contacts (Campbell, Marsden and Hulbert 1986; Lin and Dumin 1986), rendering the weaker ties accessible less effective. Thus, a nonlinear relationship (interaction) between strength of ties and social resources may be involved (Wegener 1991).

Another elaboration concerns the distinction between two types of social resources: network resources and contact resources. Network resources refer to resources embedded in one's ongoing social networks and ties. In this conceptualization, the researcher is interested in identifying the on-

going social ties, and from these identified ties, exploring resources they have. These resources are seen as social resources to ego (Campbell, Marsden, and Hulbert 1986; Lin and Dumin 1986; Boxman and Flap 1990). Contact resources, on the other hand, refer to resources associated specifically with a tie or ties accessed and mobilized in a particular action. For example, the researcher is interested in identifying the contact ego used in a particular job-seeking situation and specifying the social resources in terms of what resources the contact possessed (Lin, Ensel, and Vaughn 1981; Marsden and Hulbert 1988; Sun and Hsiong 1988; Lin and Bian 1990). Recent research (Lai, Leung, and Lin 1990) shows that network resources and contact resources are two conceptually distinctive and causally related components of social resources. Network resources, reflecting resources in ego's social network, contribute to the access of contact resources in the context of a particular action (e.g., seeking a job). Each in turn contributes to the ultimate success of the action (e.g., getting a high-status occupation).

FURTHER RESEARCH ISSUE

Some theoretical and methodological issues remain in the extension and application of the social resources theory.

One issue concerns the cost of social resources. Unlike personal resources, which ego may use and dispose of relatively free of constraints, social resources are "borrowed" from one's social ties. Thus, there should be a cost attached to such access. In most cases there is an implied obligation of reciprocity—that is, ego is committed to offer his or her resources as social resources to the alter from whom resources have been borrowed. The problem arises when ego and the alter do not occupy similar social positions, thus possessing dissimilar resources. In the case of ego seeking help from the alter, in fact, the better the social position the alter occupies, the more effective it provides social resources to ego. It is conceivable that ego possesses other resources, which may provide to be useful to the alter in the reciprocity process. For example, a banker (ego) may seek political influence from a politician (the alter), who in turn may secure financial benefit with ego's help. Fair exchange of different valued resources occurs. There will also be situations where ego

with inferior resources gains as a result of help from an alter with superior resources (e.g., a graduate student getting a desirable job with the help of a professor), the reciprocity becomes more intricate. One way of reciprocity requires quantity in compensation of quality (e.g., willingness to put more effort into a research or writing collaboration). Another form of reciprocity requires efforts to increase the value of the alter's resources (e.g., citations to the professor's work in one's publications). Variations in such reciprocal uses of social resources and, therefore, in cost deserve further conceptualization and research.

Another area worthy of research attention is the use of social resources for expressive actions. It has been hypothesized that, in contrast to instrumental actions, expressive actions would be more effective if ego and the alter share similar traits and experiences. The argument is that homophily (sharing similar characteristics and life-styles) increases the likelihood of the alter understanding the emotional stress experienced by ego (Lin 1986). Thus, the expectation is that strong ties, rather than weak ties, may provide the more desirable social resources for expressive actions. However, reality is much less tidy than this conceptualization. In some expressive actions (e.g., seeking support in time of a divorce), both emotional and instrumental support are needed. Further complicating the situation is that often the strong ties (e.g., spouse) are the sources of stress, and expressive actions must by definition be provided by either weaker ties or surrogate strong ties (e.g., relatives or a friend or professional helper) (Lin and Westcott forthcoming). Much more conceptual and empirical work is needed to tease out these issues.

Finally, there is the intriguing question of whether the theory of social resources can help conceptualizing the interplays between social structure and social action. I argue that the theory of social resources makes two kinds of contributions toward an understanding of social structure and social action (Lin 1990a, 1990b). First, research on social resources has offered the plausibility that under structural constraints, individual choices (in terms of social ties and social contacts) may yield different and meaningful consequences. It has been shown that given two individuals with similar personal resources (including original social positions), they might experience different outcomes in instrumental actions, depending on social re-

sources they access and use. To an extent such different access is dictated by structural constraints. As mentioned earlier, original position affects the range of social ties in the social hierarchy and therefore the likelihood of accessing better social resources. However, after such structural constraints have been taken into account, there is evidence that some flexibility remains in the choice of social ties and use of social resources, and such choice and use yield meaningful and different results.

Second, much of past research on social structure as well as social resources has assumed that social structure has a priori existence and imposes constraints within which individuals conduct meaningful actions. The theoretical possibility that individual actions and choices may constitute fundamental driving forces in the formation and functioning of social structures has gained currency in sociology (Coleman 1986, 1988, 1990). Social resources, it is argued, may also contribute to this theoretical formulation.

One may assume that individuals strive to gain resources for the promotion and maintenance of one's survival and well-being. Personal resources may be preferred to social resources in this striving, since the former incur less cost and are more manipulatable. However, the speed of cumulation may differ for the two types of resources. Acquisition and cumulation of personal resources may be additive. On the other hand, acquisition and cumulation of social resources may be exponential, in that once a social tie is established, not only the tie's personal resources become social resources to ego, but the tie's social resources (through its ties) also become social resources. Thus, social ties, through their networking patterns and dynamics, accelerate one's social resources. While social resources come at a cost, as discussed earlier, it is to the benefit of ego to acquire as much social resources as possible. Thus, social resources constitute the fundamental motivation to networking in the promotion and maintenance of one's self-interest and well-being. Such networking constitutes the elementary blocks in the emergence of social structure. Subsequently, the management and manipulation of the constructed and extended network that contains increasingly heterogeneous participants with varying demands for secondary resources (e.g., quality of life considerations) dictate the development of hierarchical positions and

role expectations, which in turn reduce the range of possible individual action choices. Further theoretical work along these lines promises to contribute to the current interest and debate in the interrelationships between social actions and social structure.

NAN LIN

SOCIAL SECURITY SYSTEMS

In the United States, Social Security refers to a set of programs, including old-age, survivors, and disability insurance, for the elderly and their dependents. This particular use of the term "social security" relates as much to the special and delimited character of the welfare state in the United States as it does to the generally accepted meaning of the term. For organizations such as the International Labour Office and the International Social Security Association and for scholars concerned with comparative studies, the term refers to a wider variety of programs. For instance, in its volume *Social Security throughout the World*, the Social Security Administration states:

The term "social security" in the context of this report refers to programs established by government statutes which insure individuals against interruption or loss of earning power, and for certain special expenditures arising from marriage, birth, or death. (1985, p. ix)

The concept of social protection that underlies this definition includes unemployment programs to cover involuntary temporary loss of work, sickness programs to cover loss of income from sickness and the cost of medical care, disability or occupational injury programs to cover physical limitations on working, family allowances to cover loss of economic status from the addition of members to the family, and social assistance to cover circumstances such as family disruption that cause income to fall below specified levels. Protection of earning power from loss of work or health conditions associated with old age also remains crucial. Still, many of the other programs, more common in the advanced welfare systems of western European nations than in the United States, must be considered part of social security systems.

The relative size of programs devoted to the elderly perhaps warrants the special attention paid to old age in social security systems. Among all expenditures for education and social security programs, those for old-age pensions represent the largest component, averaging 36 percent across high-income nations in 1985 (Organization for Economic Cooperation and Development 1988, Tables 1 and 3). The next largest component, 22 percent, is devoted to health care, which also disproportionately benefits the elderly. Furthermore, the growth rate of programs for the aged has exceeded that for other programs, and in the future, expenditures for those programs will account for an even greater proportion of the total. Spending for unemployment, family allowances, and social assistance represents a relatively small part of social security programs. As Myles (1984) notes, the welfare state is primarily a welfare state for the elderly.

The need for collective protection for the aged or others stems from the existence of economic insecurity. Loss of earning power as a result of poor health, old age, or unemployment remains a possibility for nearly all the participants in a market economy but is uncertain enough to make it difficult to predict loss of income or future

savings potential. Traditional protection against such risk in preindustrial societies developed informally through the family. Under ideal circumstances, children and relatives could support parents who were unable to provide for themselves or wanted to step down from their economic role of provider. In premodern societies, social security thus took the form of an intergenerational contract, based on norms of filial piety and parental control over wealth, between children or other relatives and parents (Simmons 1960). Never a guaranteed source of protection, however, other family members became an even less reliable source of support with the decrease in family size, the increase in mobility, and the industrialization of labor that accompanied the demographic and industrial transitions. With the development of large-scale corporate capitalism in the late nineteenth and early twentieth centuries, the risks of forced retirement and unemployment grew. Systems of social security collectivized and formalized the relationship between young workers and elderly, unemployed, or disabled nonworkers. Workers would contribute support to certain categories of non workers in return for the expectation that they would be covered if they became unable to work. The state has always played a crucial role in this collectivized contract by making participation in the system compulsory for most workers. Voluntary programs of saving for unexpected contingencies are insufficient because many people are not rational in saving for events that may not occur or occur only in the far future. Private compulsory systems industries, unions, and businesses similarly face problems of incomplete coverage, financial insolvency, and job movement. In contrast, collectivizing social security provides for reliable funding, and it is easier to predict events for a group than it is for individuals.

Most nations provide for more than social security alone. The broader welfare state in capitalist societies also supports education, retraining, full employment, business regulation, price supports, infrastructure, and legal rights. In the former socialist societies of Eastern Europe, social security systems involved broader social protection through guaranteed employment; subsidized food, housing, and energy prices; and the reduced importance of market performance as the criterion for economic support. Recent market-oriented reforms in eastern Europe may expand the

emphasis on social security systems as they are typically and more narrowly defined in capitalist societies.

If motives of social protection are common to social security systems, the coverage of the population and the distribution of benefits vary widely. Benefits may be distributed on the basis of at least four criteria, each of which may be emphasized or deemphasized in particular systems. First, citizenship entitlement provides basic benefits—usually in the form of flat-rate cash payments—to individuals or families as a right of citizenship regardless of work history, contributions, or income. Second, employment-related criteria base eligibility on wage or payroll contributions made before the contingency that causes earnings to cease. As a form of public or social insurance, these benefits reinforce market criteria of income determination. Third, need-based criteria provide benefits by comparing resources with a standard that typically is based on subsistence needs. Means-tested or social assistance programs target benefits at the most needy, usually those not covered by citizenship or insurance programs. Fourth, entitlement sometimes is granted on the basis of marital or family status, usually to women and homemakers or families with young children.

To a large extent, nations mix their degrees of reliance on the different criteria. Nations that began with universal systems added earnings-based supplements (e.g., Sweden), and those which originally enacted earnings-based benefits have added universal benefits (e.g., Great Britain) or some form of minimum benefit (e.g., the United States). Similar claims have been made about the mix of public and private systems. To limit inequality, nations that traditionally relied on private systems (e.g., the United States) have increasingly expanded public system benefits, while nations that traditionally relied on public systems (e.g., West Germany) have increasingly expanded private benefits for high-income workers who want a higher return on their contributions.

Some argue that social citizenship remains the most important component of social protection because security is not complete until the state grants alternative means to economic welfare to the market (Esping-Andersen 1989; Korpi 1989). Because meager means-tested benefits are structured to avert work disincentive effects, they fail to

emancipate individuals from dependence on the market. Because social insurance benefits stem from labor-based contributions—that is, qualification based on previous contributions defines the right to receive benefits—they maintain links to the market. Because family benefits depend on the qualification of others by virtue of need or contribution, they also fail to detach distribution from the market mechanism. A definition of social security would thus require decommodifying labor or insulating workers from dependence on the market for economic support. According to Esping-Anderson, in decommodifying welfare states,

citizens can freely, and without potential losses of job, income or general welfare, opt out of work under conditions when they themselves consider it necessary for reasons of health, family, age or even educational self-improvement; when, in short, they deem it necessary for participating in the social community. (1989, p. 22)

Few, if any, nations meet the high standards defined by citizenship rights or decommodification. Nearly all nations rely at least partially on earnings-related benefits to supplement universal benefits; flat-rate benefits available to all are too expensive to provide generously for all elderly persons. Still, the trend is toward expanded social rights. Recent efforts to gain the right to protection from economic insecurity follow efforts in previous centuries to gain civil rights such as freedom of speech and equality before the courts and the political right to universal voting (Marshall 1964). This process highlights the dynamic meaning of social security and the continuing evolution of its definition.

Political debate over how far governments should extend definitions of social security to include citizenship rights reflects larger tensions between the relative roles in the market and the state in public policy (Myles 1984). On the one hand, inequality in earnings and contributions during work life means that the market retains a strong influence on social security benefits and the financial circumstances of nonworkers. On the other hand, equality of participation in the democratic political system provides impetus for equality in benefits unrelated to the market. The underlying dynamics of market and democracy—differentiation versus equality—both show in varying degrees in the benefit structures of different systems and

debates over the definition of what social security should provide.

HISTORICAL BACKGROUND

A formal social security system was slow to come to the United States. The first public social security system (although limited in coverage and generosity) emerged in Bismarckian Germany in 1889 and was followed by systems in Denmark in 1891, New Zealand in 1898, Austria in 1906, and Australia and Great Britain in 1908 (Social Security Administration 1985). Legislation at the national level was not passed in the United States until 1935, and the first old-age pension was not paid until 1940. In part, the expansion of disability benefits to Civil War veterans (even if they had not been injured or seen combat) in 1890 provided a de facto pension system for northern whites but did not promote the implementation of a more general national pension system for nonveterans (Orloff and Skocpol 1984).

The reasons why Civil War pensions did not lead to a more comprehensive social security system have been examined extensively. The historical persistence of individualist, laissez-faire values obstructed public support for public programs (Rimlinger 1971). Big business preferred private negotiations with labor, and small business wanted to avoid the cost of social security provisions. Relative to a powerful business community, weak, decentralized labor unions were unable to agree on a common approach or push redistributive public programs as they did in several European nations (Stephens 1979). Relatedly, the United States did not have a socialist or social democratic party committed to labor goals, because regional, ethnic, and racial divisions split clearly defined class interests in support of social legislation. Southern congressional representatives, who wanted to maintain cheap agricultural (particularly black) labor in their region, used their power in a committee-dominated federal government to block legislation (Quadagno 1988). Finally, the lack of a professional civil service bureaucracy to administer the program and the existence of often corrupt patronage politics at the local level might have limited public support for a large public social security system (Skocpol and Ikenberry 1983). All these forces played a role in blocking attempts in the first several decades of the twentieth century to

expand protection beyond the veterans' pension and partial state-based programs for mothers' pensions or industrial accident insurance.

The impetus for the passage of old-age and unemployment social security came from the Great Depression. The rapidly expanding costs of private pensions and a crisis of capitalist growth lessened opposition of big business to federal pension legislation and a more general role of the government in the capitalist economy (Jenkins and Brents 1989). Southern congressmen were persuaded to support legislation that excluded agricultural and domestic workers and insisted that means-tested levels for old-age assistance be set at the state level; both factors would limit the disruption of the low-wage southern economy. Popular demands in the early 1930s by several hundred thousand supporters of the Townsend movement for a federal government pension for every citizen over age 60 may have hastened enactment (Williamson et al. 1982). Ultimately, the goal of reducing unemployment by removing older workers from the labor force and supporting at least temporarily those who were unemployed proved crucial in passing the initial legislation in 1935 (Schulz 1988; Graebner 1980).

The original 1935 Social Security Act mandated only limited coverage and benefit levels for old-age retirement. Only 60 percent of the workforce was covered: Agricultural, domestic, and self-employed workers; military personnel; federal, state, and local employees; and employees of nonprofit, tax-exempt organizations were all excluded. Moreover, benefit levels were quite low: Policymakers intended not to replace work income fully or assure the maintenance of workers' preretirement standard of living but instead to supplement private sources of retirement income with minimal public benefits (Achenbaum 1986). Social Security benefits alone would hardly meet what would be considered poverty levels in many states at the time (Quadagno 1984).

The initial structure of the social security system, along with the incremental changes made in the following decades, was for the most part market-conforming. Early debates about the degree to which the program should redistribute income across classes were settled in favor of those who wanted to maintain the connection between contributions and benefits (Cates 1983). Funding from

general revenues was rejected in favor of contribution-based financing, reinforcing the view of the system as an insurance system. Flat-rate benefits were rejected as unsuitable for a nation with such regional and social heterogeneity; instead, benefits would reflect preretirement income levels. A cap placed on taxable wages, which ostensibly concentrated both contributions and benefits for ordinary middle-income wage workers, introduced some regressiveness into the formula. The major exception to this strategy was that benefits for low-wage workers were higher relative to contributions than were those for high-wage workers (Myers 1981). Also, provisions for unemployment benefits, aid to dependent children, and relief for the blind targeted modest benefits for needy groups (Achenbaum 1989). The system thus began as and remains a mixture of social insurance based on contributions and social adequacy based on social need (Munnell 1977).

Expansion of the system began before the first benefits were paid out and continued for several more decades. In 1939, dependents and survivors were made eligible for benefits. Coverage was extended in the 1950s to include most self-employed, domestic, and agricultural workers, and the participation of state and local employees was made elective (federal employees kept their own system until 1984). In 1956, actuarially reduced benefits were made available at ages 62–64 for women, and in 1961 the same option for early retirement was made available to men, an option now exercised by a majority of new beneficiaries. Also in the 1950s, benefits equal to those for retirees were added for disabled persons aged 50–64 and later for disabled workers of all ages. In 1965, Medicare for the elderly and Medicaid for the poor were added to provide protection against the high costs of medical care. Benefit and contribution levels also rose with extensions of coverage and disability. Ad hoc adjustments to benefit levels, which well exceeded inflation (Tomasson 1984), were common until 1972, when benefits were linked to yearly increases in the consumer price index. Payroll taxes and the maximum taxable wage also increased.

The growth of benefits and coverage nonetheless proceeded more quickly than did that of contributions, and by the late 1970s this situation resulted in funding problems. The concept of the accumulation of a reserve was replaced quickly by

a pay-as-you-go system in which current workers paid for current retirees (with enough of a surplus to cover year-to-year fluctuations). In the early years of the system, the ratio of one retiree to 120 workers made this system of funding workable. By the 1970s, the ratio of retirees to workers was one to five. Combined with increasingly high benefit levels, the growing dependency ratio resulted in payments that exceeded contributions. Amendments in 1977 “deliberated” benefits for the first time by, among other things, freezing minimum benefits and making the earnings test more stringent (Tomasson 1984). Far from sufficient to deal with the implications of higher benefits and an older age structure, these changes only delayed a more serious restructuring. A \$17 billion deficit in 1983 made further deliberalization necessary. In 1981, a Reagan administration proposal to lower benefits, change the retirement age, delay cost-of-living increases, and reduce family benefits for dependents and survivors was met with nearly universal opposition. To move the negotiations out of the public eye, where painful and politically unpopular choices could be agreed on, a bipartisan commission was appointed to develop proposals to deal with both short-term and long-term funding problems (Light 1985). The commission offered a compromise plan that was quickly passed by Congress and signed by President Reagan.

To summarize a complex 1983 amendment, a number of major changes were made in the direction the system was to take compared with previous decades. For the first time, Social Security benefits above specified levels were to be taxed. The age of eligibility for full retirement benefits would be extended gradually to 67 beginning in 1999, and payroll taxes would be increased along with the maximum taxable wage base. All these changes have had the desired effect: Contributions now exceed benefits paid. The long-run projection is that the surplus accrued during the next thirty years probably will balance the expected deficit when large baby boom cohorts reach retirement age (Social Security Administration 1989). The surplus, however, is by law used to purchase Treasury bonds, which fund deficits in general revenue spending. Since the bonds will have to be paid off by taxpayers through general income taxes later on, funding problems will not disappear.

The cumulative changes in the system now result in the coverage of over 90 percent of work-

ers, who qualify for benefits by accumulating forty quarters, or ten years, of covered employment. Besides the basic benefit, a minimum benefit is available for those with long-term covered employment at low wages, a dependent’s benefit at 50 percent of the spouse’s benefits is available to spouses, and a survivor’s benefit is available at 100 percent of the deceased spouse’s benefits. Supplemental Security Income (SSI) provides cash assistance—unrelated to contributions and funded from general revenues—for needy aged, disabled, and blind persons who meet the means test. Among the elderly, 38 percent of all income comes from Social Security, and a majority of elderly persons depend on Social Security for more than half their income (Sherman 1987).

The position of the U.S. Social Security system relative to those of other nations depends on how generosity is measured. As a percentage of gross domestic product (GDP), the U.S. systems ranks quite low. Considering pensions alone, however, a measure of the benefit of a new retiree as a percentage of the wage of the average manufacturing worker ranks the United States higher. The United States falls slightly below average for single workers and slightly above average for married workers (Aldrich 1982). Part of the discrepancy stems from the concentration of public spending on pensions in the United States to the neglect of other programs. The family allowance spending and free health care for the nonaged that are common in other advanced industrial democracies are absent altogether in the United States except for need-based public assistance such as Aid to Families with Dependent Children and Medicaid. The United States provides well for those whose contributions during their work lives are high—the average retiree, in other words—but spends less in the aggregate for those who are not covered. Finally, the low percentage of the aged in the United States relative to other advanced industrial nations makes it possible to replace an above-average proportion of preretirement wages while spending a below-average fraction of GDP.

COMPARATIVE PERSPECTIVES

Many developing nations have begun to implement more formal social security systems, primarily for the benefit of urban workers and civil

servants, but few of those countries have the economic resources needed to provide more than minimal coverage or protection from economic contingencies (Midgley 1984). Comparative studies have concentrated on the historical emergence and current policies of mature welfare states in advanced industrial nations.

Among the high-income democracies, substantial variation exists in spending levels and the structure of benefit distribution. Including pension, health care, occupational injury, unemployment, family allowance, public assistance, and related programs for civil servants and veterans, mean spending as a percentage of GDP in 1980 was 19 percent (International Labour Organization 1985). Nations that spend the most include Sweden (31.2 percent), the Netherlands (27.6 percent), Denmark (26.2 percent), and France (25.5 percent), and the nations that spend the least are Japan (9.8 percent), Italy (11.3 percent), Australia (11.6 percent), and the United States (12.2 percent). As was discussed above, countries also vary in the extent to which they rely on universal benefits relative to insurance or need-based benefits. According to Esping-Andersen (1989), Sweden and Norway in particular have the most equalizing social security programs; Finland, Denmark, Belgium, and the Netherlands also structure benefits on the basis of citizenship rights. The English-speaking nations and Switzerland tend to base their systems most on market-related criteria.

A comparison of the maximum and minimum benefit levels of pensions during the 1980s further illustrates important intercountry differences. In the United States, the difference between the maximum and minimum benefit is \$9,900; in West Germany, it is \$11,000 (Social Security Administration 1985). These figures contrast with those for nations with primarily flat-rate systems, such as Canada (\$500), Denmark (\$1,300), and the Netherlands (\$0). Nations also differ in the frequency of adjustment for the cost of living, the ages of eligibility for early or normal retirement, the degree of retirement required for the receipt of benefits on reaching retirement age (i.e., the existence of a retirement test), and the wage ceiling for social security taxation. Scales summarizing national differences on all these dimensions provide an overview of the divergence in pensions (Day 1978; Myles 1984).

In the 1950s and 1960s, scholars predicted convergence in social security systems as advanced industrial technology spread: The standardizing effects of technology would reduce preexisting cultural and political differences among the economically developed nations. The need for a recently trained, highly educated, and geographically mobile labor force in industrial economies would make older workers superfluous to the production process. Without means of employment, the elderly would depend on government programs for economic support. In this functionalist framework, the state meets the needs of business for a differentiated labor force while simultaneously meeting the financial needs of surplus workers unable to find employment (Wilensky 1975). Hence, retirement and social security grew rapidly among all developed nations, especially in the decades after World War II.

Similar convergence in social security systems is predicted by neo-Marxist theories of monopoly capitalism. Here the focus is on the requirements of the capitalist mode of production and the power of the capitalist elite. State-sponsored insurance subsidizes the costs of the production of capital, and state-sponsored social assistance helps maintain the legitimacy of the political and economic system in the face of discontent among the superfluous population (O'Connor 1973). The standardizing force is therefore the needs of increasingly monopolized capital to maintain high profit and investment, but the consequence is still the expansion of the state in similar forms among advanced industrial nations. Partisan democratic politics play a minimal role in either the industrialist or the capitalist logic.

The fact that in contrast to the predictions of convergence theories, expenditure levels have continued to diverge across nations over the last several decades has led more recently to a number of political explanations of variation in social security. The most common explanations focus on the differential political power of labor unions across the advanced industrial democracies. In places where labor is centralized and unions have high membership, labor gains power in negotiation with capital and also can contribute to the election of socialist, social democratic, and labor parties that represent its interests. As a result, social legislation decreasing the scope of the market and emphasizing distribution based on political power

emerges in areas where labor is strong and leftist parties have ruled for significant periods. In places where labor is weaker and more fragmented, rightist parties are more powerful and market-reinforcing programs with low benefits are common. Relatedly, the emergence of corporatist bargaining structures in which officially designated representatives of labor and capital negotiate economic policy with state managers has emerged in some nations—usually small nations with a strong political representation of labor. The corporatist bargain has been for labor to hold down wage demands in return for full employment and generous, redistributive welfare spending (Goldthorpe 1984).

Other theories agree with the importance of political forces in generating divergence but focus on the political activity of the aged as well as on classes (Pampel and Williamson 1989). Even among the advanced industrial nations, substantial differences in the percentage of the aged exist and appear to be related to welfare spending through both demographic and political channels. Given the same benefit level in 1980 as in 1960, aging of the population can account for only some of the observed increase in pension spending. However, the size of benefit increases over time correlates closely with the size of the elderly population. Beyond demographic effects, then, the elderly appear, at least in some countries, to be an influential political interest group in supporting higher pension and health care spending.

Others have emphasized the role of the state in divergent social security policies. Beginning with the assumption that public policies cannot be reduced to the demands and preferences of any single social group, state-based theories have examined how the structure of relatively autonomous state agencies and the interests of state managers can shape the way in which demands are expressed and translated into legislation. Qualitative studies have identified, within specific historical and national contexts, the state characteristics important for particular policy outcomes. The quantitative literature, however, has had less success relating state characteristics such as size and centralization to measures of social security spending or citizenship rights.

Any resolution of the theoretical debates and mixed empirical results will come from synthetic efforts at theory building and statistical analysis.

Class, status-demographic, political, productive, and state factors all may prove important for understanding social security system development once theories and models more clearly specify how one set of factors varies with the levels of the others. Efforts to estimate nonlinear, interactive models are under way and should prove crucial for future research (Hicks et al. 1989; Pampel et al. 1990).

CONSEQUENCES

The huge literature on the consequences of social security spending for social equality and social behavior is beyond the scope of this article. Controversy exists not so much on whether spending has an effect but on the kinds of social phenomena it most affects.

One view is that social security spending directly reduces economic inequality without substantially changing social behavior such as labor force participation, living arrangements, and savings. The major evidence in favor of redistributive consequences comes from studies that subtract transfers from total income and compare inequality with and without those transfers (Smeeding, et al. 1988). In the United States and a number of European nations, pretransfer inequality and poverty are higher than they are for posttransfer income distribution. According to the results of this methodology, expenditures for pensions are particularly egalitarian. However, advocates of this view have been less willing to accept the claim that transfers promote inequality by providing incentives to leave the labor force, in other words, by inducing behavior that indirectly contributes to higher rates of poverty and inequality. Implicitly, unemployment and low income are seen as the result of discrimination and lack of opportunities, situations that do not change with the receipt of benefits.

Other views weigh the behavioral responses to transfers as important relative to the redistributive consequences. If transfers induce labor force and living arrangement changes that make pretransfer income distribution less egalitarian than it would be if transfers were not present, the evidence of redistribution cited above would have to be seen as flawed (Danziger et al. 1981). For instance, pensions have the largest effect in reducing pretransfer inequality but also induce voluntary retirement

that lowers earnings relative to what they would be without pensions or retirement benefits. Similarly, transfers increase an individual's ability to afford independent living arrangements, and this makes pretransfer income figures misleading.

Trends in poverty and inequality do not provide unambiguous evidence for either view. Certainly, the absolute income of the elderly in the United States has risen with the growth of Social Security benefits. As Social Security benefits rose dramatically in the last several decades, poverty among the aged declined from 35 percent (compared with 22 percent for the general population) in 1960 to 12 percent (compared with 13 percent for the general population) by 1987 (U.S. Bureau of the Census 1989). However, the improved economic position of the elderly also stems from the fact that recent cohorts entering old age have been better off financially and more likely to have accumulated private pensions and savings to support themselves than were previous cohorts. For overall income inequality, the trend shows little change (at least until 1980) despite the massive growth of transfers (Levy 1987). Either transfers were not redistributive or pretransfer inequality increased. Perhaps household changes, in part an indirect response to transfers, balanced the direct effects of transfers on inequality (Treas 1983). After 1980, inequality grew, but again, it is difficult to separate the effects of changes in the occupational structure from changes in real Social Security benefits for the poor and unemployed.

Comparative evidence on the relationship between social security spending and inequality across advanced industrial nations is also mixed (compare Pampel and Williamson 1989 with Esping-Andersen 1985). Nations with high spending levels and benefit structures based on citizenship rights, such as those in Scandinavia, have always had lower levels of income inequality among both the aged and the general population. However, it is difficult to establish a causal association between those levels and social security benefits across nations that differ in so many other social and economic characteristics.

Given the mixed empirical evidence, views on the redistributive consequences of the welfare state reflect theoretical assumptions about the determinants of the levels and structure of social security spending. Neo-Marxist theories of monopoly capi-

talism, which assume that high inequality is an inherent and necessary feature of advanced capitalism, argue that social security systems help maintain that structure rather than change it. Interest-group and neopluralist theories see middle-class, politically powerful groups as the primary recipients of most spending, which limits the extent of redistribution to the poor. Other theories claim the opposite. In industrialism theories, spending is directed at the surplus workers who are most in need. In social democratic theories, spending is directed to the working class and the poor represented by leftist parties and unions. Still others claim that the state and institutional context shapes the ability of spending to reduce inequality. As in the study of the determinants of spending, interactive or contextual studies probably will be needed to make sense of the comparative experience.

ISSUES

A number of issues or problems face policymakers who deal with social security systems. A few of these issues are reviewed briefly below. Some apply especially or primarily to the United States, while others apply to all advanced industrial nations and third world nations.

First, concern has been expressed over the inequitable treatment of women in earnings-related social security systems. When receipt of benefits for women in old age depends on the benefits of their spouses, high rates of marital breakup and widowhood make reliance on this source of financial security risky. When receipt of benefits of women in old age depends on wage contributions, discontinuous labor force participation during the childbearing years penalizes women. Universal benefits provide some support for older women, but other policy options are emerging to deal more directly with the gender-based problems. Some nations give social security contribution credits to women who leave the labor force to raise children or split the earned credits of a couple equally between the spouses. Classification of welfare state regimes needs to consider gender as a component of social rights (Orloff 1993).

Second, the improved economic position of the elderly, declining poverty rates, and higher public benefits in the 1970s and the 1980s stand in contrast to the declining real level of benefits and

increasing poverty among children in the United States. The improved position of the elderly relative to children may stem from the increasing size and political power of elderly cohorts compared to the smaller cohorts of children (Preston 1984). The fact that benefits for children take the form of means-tested social assistance—a type of program that receives weak public support relative to pensions because it is not shared by large parts of the population—also contributes to this inequality. Other nations that have family allowance systems that provide cash benefits to all or nearly all parents have experienced little concern over generational equity.

Third, after decades of expansion, policymakers must face problems in balancing continued demands for more spending with limits on taxation. On the one hand, with the problems of support that still exist among vulnerable groups such as the oldest old, minority group members, and widowed women, more spending is needed. Increasingly expensive health and long-term care for the elderly and disabled add to the cost of social security systems. Despite the cost, support for pension and health care continues to be strong (Coughlin 1980). On the other hand, critics have argued that the rising costs of social security contribute to inflation and unemployment by reducing savings and productivity. Those who are more sociologically oriented suggest that high expenditures tend to weaken community and family bonds, which ultimately are the source of protection for those in need (Glazer 1988). Certainly, concern with high tax levels has led politicians to attempt to control spending and reduce taxes in nearly all advanced industrial democracies. Balancing these goals without resorting to deficit spending will remain the task of governments in the decades to come.

Fourth, concern over population aging relates to debates about controlling the cost of social security. The difficulties in meeting funding demands are likely to worsen in the next century with the entrance of large baby boom cohorts into old age. In part, this is a problem of declining fertility, which reduces the size of younger, working cohorts relative to older, retired cohorts. In the recent past, when the relative sizes of working and elderly cohorts were reversed, social security recipients were treated generously, receiving bene-

fits worth five to six times their contributions and the accrued interest (Wolff 1987). Future retiring cohorts are not likely to experience such high returns on their contributions and are sometimes skeptical of receiving any at all. Still, funding problems for aging populations are not insurmountable. Many European nations, whose fertility levels fell faster than those of the United States, already have aged populations as large as 17 percent of the total—levels that will not be reached for thirty years in the United States. Through appropriate political and economic policies, the United States can meet the needs of its elderly population (Aaron et al. 1989).

Finally, these issues are emerging as important in third-world nations. Although the percentage of the aged in those nations is small and social security remains primarily a family rather than a state responsibility, that situation can change quickly. Rapid declines in fertility sharply increase the percentage of the aged, make family care for the elderly difficult, and generate demands for public support. With scarce resources, the state may risk being overwhelmed by these demands. Public understanding of the process of building social security systems in those nations remains meager.

RECENT TRENDS

If they follow the trends of recent years, the first decades of the twenty-first century will see demands for both stability and change in social security programs in the United States. In terms of stability, major changes in the system have been difficult to legislate. In the late 1980s, Congress passed legislation to add coverage for catastrophic health care and prescriptions to Medicare by increasing taxes on the affluent elderly. The funding mechanism avoided cross-generational taxes on workers but concentrated the costs of the new benefits on a relatively small part of the aged population that already had supplemental private health care coverage. The vocal opposition of those paying the higher taxes for the new provisions led Congress to rescind the legislation shortly after the new program began. Concentrating the costs of expanded social security programs on a small group of beneficiaries did not prove successful; sharing the costs among persons of all ages

and among all the recipients appears crucial to the success of any changes in social security programs.

Another major social security initiative to improve health care in the early 1990s also failed. After entering office in 1993, President William Clinton proposed a form of national health care that represented the most substantial change in American social security protection since the 1960s. The proposal did not advance a single-payer model of national health care such as those used in Canada, the United Kingdom, and many other European nations but aimed to provide universal coverage through a complex system of public and private health care delivery. Reflecting in part the suspicions of citizens of a huge change in government's role in health care as well as resistance to the change from the health and medical care professions, Congress rejected the proposed legislation.

Just as efforts to expand social security programs have failed, so have efforts to cut benefits substantially. Proposals by Republicans to control Medicare, Medicaid, and Social Security costs have met with acute resistance that has essentially blocked legislation. These examples indicate the desires of citizens for stability in most social insurance programs. Social assistance programs have, however, undergone major changes. With bipartisan political support, Aid to Families with Dependent Children has been renamed Temporary Assistance to Needy Families and now contains a work requirement for the continued receipt of benefits. The lack of change in social insurance programs and the major change in social assistance programs reflect the broad-based support for the former relative to the latter. Means-tested programs have never had the public approval enjoyed by insurance programs (Marmor et al. 1990).

In terms of demands for change, much concern remains about the long-term future of social security programs even as citizens resist short-term changes. As the baby boom generation approaches retirement age and the expected future deficit in the Social Security Fund comes closer, worries about funding have reemerged. Some economists predict serious problems. Thurow (1996, p. 46) states, "Already the needs and demands of the elderly have shaken the social welfare state, causing it for all practical purposes to go

broke." Even if it is not broke, Social Security probably will provide returns on contributions to future generations of retirees that do not reach today's high levels. According to Kotlikoff (1992), those age 25 in 1989 will pay \$193,000 more in taxes than they will receive in government benefits over their lifetimes; in contrast, those age 75 in 1989 will receive \$42,00 more in benefits than they pay in taxes. Despite the uncertain assumptions about the future contained in these forecasts, they present a disconcerting picture. As a result of these sorts of claims, polls show that young workers doubt that Social Security will even exist when they retire (Kingson and Berkowitz 1993, p. 87).

Given future funding concerns, recent federal budget surpluses have generated a desire to "save" Social Security. Ironically, the surplus results in large part from Social Security revenues that exceed current payments and thus mask deficit spending in other parts of the government, yet the surplus has produced debate about how to proceed. Some want to return the surplus to taxpayers in the form of tax cuts that, under the assumptions of supply-side economics, will generate economic growth and make it easier to support the large baby boom population of retirees in the decades to come. Others want to use the surplus to invest in Social Security by paying off current government debt that in future decades would aggravate the problem of funding retirement benefits. No legislation has passed yet, and policies change quickly with economic and political circumstances. The consensus seems to be to use part of the federal surplus for debt reduction toward the goal of Social Security solvency. However, unexpected military costs, such as those for the Serbian-Kosovar conflict, can reduce the surplus and eliminate its use for Social Security.

An alternative approach to improving Social Security solvency in the twenty-first century is to privatize contributions. An extreme version of privatization would follow the lead of Chile in allowing individual workers to invest their contributions in private accounts that fund their own retirement. The shift from a pay-as-you-go program to a funded program would involve an enormous change in the nature of old-age benefits that would create numerous risks (Williamson 1997). A less extreme version recommended by a recent commission on Social Security would allow the

government to invest some contributions in stock funds. The stunning upward movement in the stock market in the mid-1990s brought enormous returns to those with private pension investments and highlighted the low returns provided by the current system of using surplus contributions to buy government bonds. Controversy over government involvement in the stock market has, however, slowed action on the commission's recommendations.

Economists have taken the initiative in making policy recommendations for social security, while sociologists have aimed more to defend the current system against attacks. More than sociologists, economists tend to view the low rates of return on old-age contributions and the work disincentive effects of social assistance with alarm. Sociologists, in contrast, highlight the threats of privatization to social equality and universalism in public benefits (Minkler and Estes 1991), the government's role in social protection (Quadagno 1996), and the widespread sense of generational solidarity that citizens share in their attitude toward Social Security (Bengtson and Achenbaum 1993). Their contribution will continue to come from studies of the consequences of varied social security policies across the high-income nations for social equality (Esping-Andersen 1990; Korpi and Palme 1998), generational relations (Cohen 1993; Marmor et al. 1994; Myles and Quadagno 1991; Pampel 1994), and economic well-being (Rainwater and Rein 1993; Crystal and Waehrer 1996).

FRED C. PAMPEL

SOCIAL STRATIFICATION

In all complex societies, the total stock of valued resources is distributed unequally, with the most privileged individuals and families receiving a disproportionate share of power, prestige, and other valued resources. The term “stratification system” refers to the constellation of social institutions that generate observed inequalities of this sort. The key components of such systems are (1) the institutional processes that define certain types of goods as valuable and desirable, (2) the rules of allocation that distribute those goods across various positions or occupations (e.g., doctor, farmer, “housewife”), and (3) the mobility mechanisms that link individuals to positions and generate

unequal control over valued resources. The inequality of modern systems is thus produced by two conceptually distinct types of “matching” processes: The jobs, occupations, and social roles in society are first matched to “reward packages” of unequal value, and the individual members of society then are allocated to the positions defined and rewarded in that manner.

There are, of course, many types of rewards that come to be attached to social roles (see Table 1). The very complexity of modern reward systems arguably suggests a multidimensional approach to understanding stratification in which analysts specify the distribution of each of the valued goods listed in Table 1. Although some scholars have advocated a multidimensional approach of this sort, most have opted to characterize stratification systems in terms of discrete classes or strata whose members are similarly advantaged or disadvantaged with respect to various assets (e.g., property and prestige) that are deemed fundamental. In the most extreme versions of this approach, the resulting classes are assumed to be real entities that predate the distribution of rewards, and many scholars therefore refer to the “effects” of class on the rewards that class members control (see the following section for details).

The goal of stratification research has thus devolved to describing the structure of these social classes and specifying the processes by which they are generated and maintained. The following types of questions are central to the field:

1. What are the major forms of class inequality in human history? Is such inequality an inevitable feature of human life?
2. How many social classes are there? What are the principal “fault lines” or social cleavages that define the class structure? Are those cleavages strengthening or weakening with the transition to advanced industrialism?
3. How frequently do individuals cross occupational or class boundaries? Are educational degrees, social contacts, and “individual luck” important forces in matching individuals to jobs and class positions? What other types of social or institutional forces underlie occupational attainment and allocation?

Types of Assets, Resources, and Valued Goods Underlying Stratification Systems

Asset Group	Selected Examples	Relevant
1. Economic	Ownership of land, farms, factories, professional practices, businesses, liquid assets, humans (i.e., slaves), labor power (e.g., serfs)	Karl Marx, Erik Wright
2. Political	Household authority (e.g., head of household); workplace authority (e.g., manager); party and societal authority (e.g., legislator); charismatic leader	Max Weber, Ralf Dahrendorf
3. Cultural	High-status consumption practices; "good manners"; privileged lifestyle	Pierre Bourdieu, Paul DiMaggio
4. Social	Access to high-status social networks, social ties, associations and clubs, union memberships	W. Lloyd Warner, James Coleman
5. Honorific	Prestige; "good reputation"; fame; deference and derogation; ethnic and religious purity	Edward Shils, Donald Treiman
6. Civil	Rights of property, contract, franchise, and membership in elective assemblies; freedom of association and speech	T H. Marshall, Rogers Brubaker
7. Human	Skills; expertise; on-the-job training; experience; formal education; knowledge	Kaare Svalastoga, Gary Becker

Table 1

4. What types of social processes and state policies maintain or alter racial, ethnic, and sex discrimination in labor markets? Have these forms of discrimination been weakened or strengthened in the transition to advanced industrialism?
5. Will stratification systems take on new and distinctive forms in the future? Are the stratification systems of modern societies gradually shedding their distinctive features and converging toward a common (i.e., postindustrial) regime?

These questions all adopt a critical orientation to human stratification systems that is distinctively modern in its underpinnings. For the greater part of history, the existing stratification order was regarded as an immutable feature of society, and the implicit objective of commentators was to explain or justify that order in terms of religious or quasi-religious doctrines. During with the Enlightenment, critical "rhetoric of equality" gradually emerged and took hold, and the civil and legal advantages of the aristocracy and other privileged status groupings were accordingly challenged. After these advantages were largely eliminated in the eighteenth and nineteenth centuries, that egalitarian ideal was extended and recast to encompass not only such civil assets voting rights but also economic assets in the form of land, property, and the means of production. In its most radical form,

this economic egalitarianism led to Marxist interpretations of human history, and it ultimately provided the intellectual underpinnings for socialism. While much of stratification theory has been formulated in reaction against these early forms of Marxist scholarship, the field shares with Marxism a distinctively modern (i.e., Enlightenment) orientation that is based on the premise that individuals are "ultimately morally equal" (see Meyer 1994, p. 733; see also Tawney 1931). This premise implies that issues of inequality are critical in evaluating the legitimacy of modern social systems.

BASIC CONCEPTS

The five questions outlined above cannot be addressed adequately without first defining some of the core concepts in the field. The following definitions are especially relevant:

1. The degree of *inequality* in a given reward or asset (e.g., civil rights) depends on its dispersion or concentration across the individuals in the population. Although many scholars attempt to capture the overall level of societal inequality in a single parameter, such attempts obviously are compromised insofar as some types of rewards are distributed more equally than others are.

2. The *rigidity* of a stratification system is characterized by the continuity over time in the social standing of its members. If the current wealth, power, or prestige of individuals can be predicted accurately on the basis of their prior statuses or those of their parents, then there is much class reproduction and the stratification system is accordingly said to be rigid.
3. The process of stratification is *ascriptive* to the extent that traits present at birth (e.g., sex, race, ethnicity, parental wealth, nationality) influence the subsequent social standing of individuals. In modern societies, ascription of all kinds usually is seen as undesirable or “discriminatory,” and much state policy is therefore directed toward fashioning a stratification system in which individuals acquire resources solely by means of their own achievements.
4. The degree of *status crystallization* is characterized by the correlations among the assets listed in Table 1. If these correlations are strong, the same individuals (i.e., the “upper class”) will consistently appear at the top of all status hierarchies, while other individuals (i.e., the “lower class”) will consistently appear at the bottom of the stratification system.

These four variables can be used to characterize differences across societies in the underlying structure of stratification. As the discussion below reveals, there is great cross-societal variability not only in the types of inequality that serve as the dominant stratifying forces but also in the extent of such inequality and the processes by which it is generated, maintained, and reduced.

FORMS OF STRATIFICATION

It is useful to begin with the purely descriptive task of classifying the various types of stratification systems that have appeared in past and present societies. Although the staple of modern classification efforts has been the tripartite distinction between class, caste, and estate (e.g., Svalastoga 1965), there is also a long tradition of Marxian typological work that introduces the additional categories of primitive communism, slave society, and socialism (Marx [1939] 1971; Wright 1985). As is shown in

Table 2, these conventional approaches are largely but not entirely complementary, and it is therefore possible to fashion a hybrid classification that incorporates most of the standard distinctions (see Kerbo 1991 for related work).

For each of the stratification forms listed in Table 2, it is conventionally assumed that certain types of assets emerge as the dominant stratifying forces (see column 2) constitute the major axis around which social classes, strata, or status groupings are organized (see column 3). If this assumption holds, the rigidity of stratification systems can be indexed by the amount of class persistence (see column 5) and the degree of crystallization can be indexed by the correlation between class membership and each of the assets listed in Table 1 (see column 6). The final column in Table 2 rests on the further assumption that stratification systems have reasonably coherent ideologies that legitimate the rules and criteria by which individuals are allocated to positions in the class structure (see column 7).

The first panel in Table 2 pertains to the “primitive” tribal systems that dominated human society from the beginning of human evolution until the Neolithic revolution of 10,000 years ago. Although tribal societies assumed various forms, the total size of the distributable surplus was in all cases limited, and this cap on the surplus placed corresponding limits on the overall level of economic inequality. Also, customs such as gift exchange, food sharing, and exogamy were practiced commonly in tribal societies and had some redistributive effects. In fact, many observers (e.g., Marx [1939] 1971) treated these societies as examples of “primitive communism,” since the means of production (e.g., tools and land) were owned collectively and other types of property were distributed evenly among tribal members. This does not mean that a perfect equality prevailed; after all, the more powerful medicine men (i.e., shamans) often secured a disproportionate share of resources, and the tribal chief could exert considerable influence on political decisions. However, these residual forms of power and privilege were never inherited directly and typically were not allocated in accordance with such simple ascriptive traits as ethnicity, race, or clan. The main pathway to political office or high status and prestige was through superior skills in hunting, magic, or leadership (see Lenski 1966 for further details). While

SOCIAL STRATIFICATION

Basic Parameters of Stratification for Eight Ideal-Typical Systems						
System (1)	Principal Assets (2)	Major Strata or Classes (3)	Inequality (4)	Rigidity (5)	Crystallization (6)	Justifying Ideology (7)
A. Hunting and gathering society 1. Tribalism	Human (hunting and magic skills)	Chiefs, shamans, and other tribe members	Low	Low	High	Meritocratic selection
B. Horticultural and agrarian society 2. Asiatic mode	Political (i.e., incumbency of state office)	Officeholders and peasants	High	Medium	High	Tradition and religious doctrine
3. Feudalism	Economic (land and labor power)	Nobility, clergy, and commoners	High	Medium-high	High	Tradition and Roman Catholic doctrine
4. Slavery	Economic (human property)	Slave owners, slaves, "free men"	High	Medium-high	High	Doctrine of natural and social inferiority (of slaves)
5. Caste society	Honorific and cultural (ethnic purity and "pure" lifestyles)	Castes and subcastes	High	High	High	Tradition and Hindu religious doctrine
C. Industrial society 6. Class system	Economic (means of production)	Capitalists and workers	Medium-high	Medium	High	Classical liberalism
7. State socialism	Political (party and workplace authority)	Managers and managed	Low-medium	Low-medium	High	Marxism and Leninism
8. "Advanced" industrialism	Human (i.e., education, expertise)	Skill-based occupational groupings	Medium	Low-medium	Medium	Classical liberalism

Table 2

meritocratic forms of allocation often are seen as prototypically modern, they were present in an incipient form at very early stages of societal development.

With the emergence of agrarian forms of production, the economic surplus became large enough to support more complex systems of stratification. The "Asiatic mode," which some commentators regard as a precursor of advanced agrarianism, is characterized by (1) the absence of strong legal institutions recognizing private property rights (with village life taking on a correspondingly communal character), (2) a state elite that extracts the surplus agricultural production through rents or taxes and expends it on "defense, opulent living, and the construction of public works" (Shaw 1978, p. 127), and (3) a constant flux in elite personnel

resulting from "wars of dynastic succession and wars of conquest by nomadic warrior tribes" (O'Leary 1989, p. 18). This mode thus provides the conventional example of how a "dictatorship of officialdom" can flourish in the absence of private property and a well-developed proprietary class. The parallel with modern socialism looms so large that various scholars have suggested that Marx downplayed the Asian case for fear of exposing it as a "parable for socialism" (Gouldner 1980, pp. 324-352).

Whereas the institution of private property was underdeveloped in the East, the ruling class under Western feudalism was very much a propertied one. The distinctive feature of feudalism was the institution of personal bondage; that is, the nobility not only owned large estates, farms, or

manors but also held legal title to the labor power of its serfs (Table 2, line B3). If a serf fled to the city, this was considered a form of theft: the serf was stealing the portion of his or her labor power owned by the lord (Wright 1985, p. 78). As such, the statuses of serf and slave differ only in degree, with slavery constituting the "limiting case" in which workers lose all control over their own labor power (line B4). At the same time, it would be a mistake to reify this distinction, since the history of agrarian Europe reveals "almost infinite gradations of subordination" (Bloch 1961, p. 256) that blur the conventional dividing lines between slavery, serfdom, and freedom. While the slavery of Roman society provides the best example of complete subordination, some slaves in the early feudal period were bestowed with "rights" of real consequence (e.g., the right to sell surplus product), and some nominally free men were obliged to provide rents or services to a manorial lord. The social classes that emerged under European agrarianism thus were structured in quite diverse ways, but in all cases rights of property ownership were firmly established and the life chances of individuals were defined largely by their control over property in its differing forms. Unlike the ideal-typical Asiatic case, the nation-state was peripheral to the feudal stratification system, since the means of production (i.e., land and humans) were controlled by a proprietary class that emerged independently of the state.

The historical record shows that agrarian stratification systems were not always based on strictly hereditary forms of inequality (Table 2, panel B, column 5). The case of European feudalism is especially instructive in this regard, since it suggests that stratification systems often become more rigid as the underlying institutional forms mature and take shape (Mosca 1939; Kelley 1981). Although it is well known that feudalism after the twelfth century (i.e., "classical feudalism") was characterized by a "rigid stratification of social classes" (Bloch 1961, p. 325), the feudal structure appears to have been more permeable in the period before the institutionalization of the manorial system and the associated transformation of the nobility into a legal class. In this transitional period, access to the nobility was not legally restricted to the offspring of nobility and marriage across classes or estates was not prohibited, at least not formally. The case of ancient Greece provides

a complementary example of a relatively open agrarian society. As Finley (1960) and others have noted, the condition of slavery was heritable under Greek law, yet manumission (the freeing of slaves) was so common that the slave class had to be replenished constantly with new captives secured through war or piracy.

The most extreme examples of hereditary closure are found in caste societies (Table 2, line B5). While some scholars have argued that American slavery had "caste-like features" (Berreman 1981), it is Hindu India which clearly provides the defining case of caste organization. The Indian caste system is based on (1) a hierarchy of status groupings (i.e., castes) that are ranked by ethnic purity, wealth, and access to goods or services, (2) a corresponding set of "closure rules" that forbid all forms of intercaste marriage or mobility and thus make caste membership both hereditary and permanent, (3) a high degree of physical and occupational segregation enforced by elaborate rules and rituals governing intercaste contact, and (4) a justifying ideology (Hinduism) that successfully induces the population to regard such extreme forms of inequality as legitimate and appropriate. What makes this system distinctive is not only its well-developed closure rules but also the fundamentally honorific (and noneconomic) character of the underlying social hierarchy. As is indicated in Table 2, the castes of India are ranked on a continuum of ethnic and ritual purity, with the highest positions in the system reserved for castes that prohibit behaviors that are seen as dishonorable or "polluting." In some circumstances, castes that acquired political and economic power eventually advanced in the status hierarchy, yet they usually did so after mimicking the behaviors and lifestyles of higher castes.

The defining feature of the industrial era (Table 2, panel C) has been the emergence of egalitarian ideologies and the consequent "delegitimation" of the extreme forms of stratification found in caste, feudal, and slave systems. This can be seen in the European revolutions of the eighteenth and nineteenth centuries that pitted the egalitarian ideals of the Enlightenment against the privileges of rank and the political power of the nobility. In the end, these struggles eliminated the last residue of feudal privilege, but they also made new types of inequality and stratification possible. Under the class system that ultimately emerged (line C6), the

estates of the feudal era were replaced by purely economic groups (i.e., “classes”) and the old closure rules based on hereditary principles were supplanted by formally meritocratic processes. The resulting classes were neither legal entities nor closed status groupings; consequently, the emergent class-based inequalities could be represented and justified as the natural outcome of economic competition among individuals with differing abilities, motivation, or moral character (i.e., “classical liberalism”). This class structure had such a clear “economic base” (Kerbo 1991, p. 23) that Marx ([1894] 1972) of course defined classes in terms of their relationship to the means of economic production. The precise contours of the industrial class structure are nonetheless a matter of continuing debate; for example, a simple (“vulgar”) Marxian model focuses on the cleavage between capitalists and workers, whereas more refined Marxian and neo-Marxian models identify additional intervening or “contradictory” classes (Wright 1985) and other (non-Marxian) approaches represent the class structure as a continuous gradation of socioeconomic status or “monetary wealth and income” (Mayer and Buckley 1970, p. 15).

Regardless of the relative merits of these models, the ideology underlying the socialist revolutions of the nineteenth and twentieth centuries was explicitly Marxist. The intellectual heritage of these revolutions and their legitimating ideologies ultimately can be traced to the Enlightenment; that is, the egalitarianism of the Enlightenment was still very much in force, but now it was deployed against the economic power of the capitalist class rather than against the status and honorific privileges of the nobility. The evidence from eastern Europe and elsewhere suggests that these egalitarian ideals were only partially realized. In the immediate postrevolutionary period, factories and farms were collectivized or socialized and fiscal and economic reforms were instituted expressly to reduce income inequality and wage differentials among manual and nonmanual workers. Although these egalitarian policies subsequently were weakened or reversed through the reform efforts of Stalin and others, this does not mean that inequality on the scale of prerevolutionary society was ever reestablished among rank-and-file workers. At the same time, it has long been argued that the socialization of productive forces did not have the intended effect of empowering workers,

since the capitalist class was replaced by a “new class” of party officials and managers who continued to control the means of production and allocate the resulting social surplus. This class has been variously identified with intellectuals or the intelligentsia (e.g., Gouldner 1979), bureaucrats or managers (e.g., Rizzi 1985), and party officials or appointees (e.g., Djilas 1965). Whatever the formulation adopted, the assumption is that the working class ultimately lost out in contemporary socialist revolutions, just as it did in the so-called bourgeois revolutions of the eighteenth and nineteenth centuries.

Whereas the means of production were socialized in the revolutions in eastern Europe and the former Soviet Union, the capitalist class remained largely intact throughout the process of industrialization in the West. The old propertied class may, however, be weakening in the West and the East alike as a postindustrial service economy diffuses and technical expertise emerges as a “new form of property” (Berg 1973, p. 183). It follows that human and cultural capital may be replacing economic capital as the principal stratifying force in advanced industrial society (Table 2, line C8). According to Gouldner (1979) and others (e.g., Galbraith 1967), a dominant class of cultural elites is emerging in the West, much as the transition to state socialism allegedly generated a new class of intellectuals in the East. This does not mean that all theorists of advanced industrialism posit a grand divide between the cultural elite and a working mass. In fact, some commentators (e.g., Dahrendorf 1959, pp. 48–57) have argued that skill-based cleavages are crystallizing throughout the occupational structure, resulting in a continuous gradation or hierarchy of socioeconomic classes. In nearly all models of advanced industrial society, it is further assumed that education is the principal mechanism by which individuals are sorted into such classes, and educational institutions thus serve in this context to “license” human capital and convert it to cultural currency.

SOURCES OF STRATIFICATION

Although the preceding sketch indicates that a wide range of stratification systems emerged over the course of human history, it remains unclear whether some form of stratification or inequality is an inevitable feature of human society. In ad-

addressing this question, it is useful to consider the functionalist theory of Davis and Moore (1945), which is the best-known attempt to understand “the universal necessity which calls forth stratification in any system” (p. 242). The starting point for any functionalist approach is the premise that all societies must devise some means to motivate the best workers to fill the most important and difficult occupations. This “motivational problem” can be addressed in a variety of ways, but the simplest solution may be to construct a hierarchy of rewards (e.g., prestige, property, power) that privileges the incumbents of functionally significant positions. As noted by Davis and Moore (1945, p. 243), this amounts to setting up a system of institutionalized inequality (i.e., a “stratification system”), with the occupational structure serving as a conduit through which unequal rewards and perquisites are disbursed. The stratification system therefore may be seen as an “unconsciously evolved device by which societies insure that the important positions are conscientiously filled by the most qualified persons” (Davis and Moore 1945, p. 243). Under the Davis–Moore formulation, it is claimed that some form of inequality is needed to allocate labor efficiently, but no effort is made to specify how much inequality is sufficient for this purpose. The extreme forms of stratification found in existing societies may well exceed the “minimum . . . necessary to maintain a complex division of labor” (Wrong 1959, p. 774).

The Davis–Moore hypothesis has come under criticism from several quarters. The prevailing view among postwar commentators is that the original hypothesis cannot adequately account for inequalities in “stabilized societies where statuses are ascribed” (Wesolowski 1962, p. 31). Whenever vacancies in the occupational structure are allocated on purely hereditary grounds, there is no need to attend to the “motivational problems” that Davis and Moore (1945) emphasized, and one cannot reasonably argue that the reward system is serving its putative function of matching qualified workers to important positions. It must be recognized, however, that a purely hereditary system is rarely achieved in practice; in fact, even in the most rigid caste societies, talented and qualified individuals typically have some opportunities for upward mobility. Under the Davis–Moore formulation (1945), this slow trickle of mobility is regarded as so essential to the functioning of the

social system that elaborate systems of inequality have evidently been devised to ensure that the trickle continues. Although the Davis–Moore hypothesis therefore can be used to explain stratification in societies with some mobility, the original hypothesis becomes wholly untenable in societies with complete closure (if such societies could be found).

The functionalist approach also has been criticized for neglecting the “power element” in stratification systems. It has long been argued that Davis and Moore (1945) failed “to observe that incumbents [of functionally important positions] have the power not only to insist on payment of expected rewards but to demand even larger ones” (Wrong 1959, p. 774). In this regard, the stratification system may be seen as self-reproducing: The holders of important positions can use their power to influence the distribution of resources and preserve or extend their own privileges. It would be difficult, for instance, to account fully for the advantages of feudal lords without referring to their ability to enforce their claims through moral, legal, and economic sanctions. The distribution of rewards thus reflects not only the “latent needs” of the larger society but also the balance of power among competing groups and their members.

Whereas the early debates addressed conceptual issues of this kind, subsequent researchers shifted their emphasis to constructing “critical tests” of the Davis–Moore hypothesis. This research effort continued throughout the 1970s, with some commentators reporting evidence consistent with functionalist theorizing (e.g., Cullen and Novick 1979) and others providing less sympathetic assessments (e.g., Broom and Cushing 1977). The 1980s was a period of relative quiescence, but Lenski (1994) recently reopened the debate by suggesting that “many of the internal, systemic problems of Marxist societies were the result of inadequate motivational arrangements” (p. 57). That is, Lenski argues that the socialist commitment to wage leveling made it difficult to recruit and motivate highly skilled workers, while the “visible hand” of the socialist economy could never be calibrated to mimic adequately the natural incentive of capitalist profit taking. These results lead Lenski to conclude that “successful incentive systems involve . . . motivating the best qualified people to seek the most important positions” (p. 59). It remains to be seen whether this reading of

the socialist “experiments in destratification” (Lenski 1978) will generate a new round of functionalist theorizing and debate.

THE STRUCTURE OF MODERN STRATIFICATION

The recent history of stratification theory is in large part a history of debates about the contours of class, status, and prestige hierarchies in advanced industrial societies. These debates may appear to be nothing more than academic infighting, but among the participants they are treated as a “necessary prelude to the conduct of political strategy” (Parkin 1979, p. 16). For instance, considerable energy has been devoted to drawing the correct dividing line between the working class and the bourgeoisie, since the task of identifying the oppressed class is seen as a prerequisite to devising a political strategy that might appeal to it. In such mapmaking efforts, political and intellectual goals are often conflated and debates in the field are accordingly infused with more than the usual amount of scholarly contention. While these debates are complex and wide-ranging, it will suffice here to distinguish between four major schools of thought.

Marxists and Post-Marxists. The debates within the Marxist and neo-Marxist camps have been especially contentious not only as a result of such political motivations but also because the discussion of class in *Capital* (Marx [1894] 1972) is too fragmentary and unsystematic to adjudicate between competing interpretations. At the end of the third volume of *Capital*, one finds the famous fragment on “the classes” (Marx [1894] 1972, pp. 862–863), but this discussion breaks off at the point where Marx appeared to be ready to advance a formal definition of the term. It is clear, nonetheless, that his abstract model of capitalism was resolutely dichotomous, with the conflict between capitalists and workers constituting the driving force behind further social development. This simple two-class model should be viewed as an ideal type designed to capture the developmental tendencies of capitalism; after all, whenever Marx carried out concrete analyses of existing capitalist systems, he acknowledged that the class structure was complicated by the persistence of transitional classes (i.e., landowners), quasi-class groupings (e.g., peasants), and class fragments (e.g., the lumpen

proletariat). It was only with the progressive maturation of capitalism that Marx expected these complications to disappear as the “centrifugal forces of class struggle and crisis flung all *dritte Personen* [third persons] to one camp or the other” (Parkin 1979, p. 16).

The recent history of modern capitalism suggests that the class structure has not evolved in such a precise and tidy fashion. As Dahrendorf (1959) points out, the old middle class of artisans and shopkeepers has declined in relative size, yet a new middle class of managers, professionals, and nonmanual workers has expanded to occupy the vacated space. The last fifty years of neo-Marxist theorizing can be seen as the intellectual fallout from this development, with some commentators attempting to minimize its implications and others putting forward a revised mapping of the class structure that explicitly accommodates the new middle class. In the former camp, the principal tendency is to claim that the lower sectors of the new middle class are in the process of being proletarianized, since “capital subjects [nonmanual labor] . . . to the forms of rationalization characteristic of the capitalist mode of production” (Braverman 1974, p. 408). This line of reasoning suggests that the working class may gradually expand in relative size and therefore regain its earlier power.

At the other end of the continuum, Poulantzas (1974) has argued that most members of the new intermediate stratum fall outside the working class proper, since they are not exploited in the classical Marxian sense (i.e., surplus value is not extracted). This approach may have the merit of keeping the working class conceptually pure, but it reduces its size to “pygmy proportions” (see Parkin 1979, p. 19), and hence dashes the hopes of those who see workers as a viable political force in advanced industrial society. There is, then, much interest in developing class models that fall between the extremes advocated by Braverman (1974) and Poulantzas (1974). For example, the neo-Marxist model proposed by Wright (1978) describes an American working class that is acceptably large (approximately 46 percent of the labor force), yet the class mappings in this model still pay tribute to the various cleavages and divisions among workers who sell their labor power. That is, professionals are placed in a distinct “semi-autonomous class” by virtue of their control over the work process, while upper-level supervisors are located in a “mana-

gerial class” by virtue of their authority over workers (Wright 1978). The dividing lines proposed in this model thus rest on concepts (e.g., autonomy and authority relations) that once were purely the province of Weberian or neo-Weberian sociology. As Parkin (1979) puts it, “inside every neo-Marxist there seems to be a Weberian struggling to get out” (p. 25).

These early class models, which once were quite popular, have been superseded by various second-generation models that rely more explicitly on the concept of exploitation. In effect, Roemer (1988) and others (Wright 1997; Sørensen 1996) have redefined exploitation as the extraction of “rent,” which refers to the excess earnings that are secured by limiting access to positions and thus artificially restricting the supply of qualified labor. If an approach of this sort is adopted, one can test for skill-based exploitation by calculating whether the cumulated lifetime earnings of skilled laborers exceed those of unskilled laborers by an amount larger than the implied training costs (e.g., school tuition and forgone earnings). In a perfectly competitive market, labor will flow to the most rewarding occupations, equalizing the lifetime earnings of workers and eliminating exploitative returns. However, when opportunities are limited by the imposition of restrictions on entry (e.g., qualifying examinations), the equilibrating flow of labor is disrupted and the potential for exploitation emerges. By implication, the working class can no longer be viewed as a wholly cohesive and unitary force, as some workers presumably have an interest in preserving and extending the institutional mechanisms (e.g., schools) that allow them to reap exploitative returns.

Weberians and Post-Weberians The rise of the “new middle class” has proved less problematic for scholars working within a Weberian framework. Indeed, the class model advanced by Weber suggests a multiplicity of class cleavages, since it equates the economic class of workers with their “market situation” in the competition for jobs and valued goods (Weber [1922] 1968, pp. 926–40). In this formulation, the class of skilled workers is privileged because its incumbents are in high demand on the labor market and because its economic power can be parlayed into high wages, job security, and an advantaged position in commodity markets (Weber [1922] 1968, pp. 927–928). At the same time, the stratification system is compli-

cated by the existence of “status groupings,” which Weber saw as forms of social affiliation that can compete, coexist, or overlap with class-based groupings. Although an economic class is merely an aggregate of individuals in a similar market situation, a status grouping is defined as a community of individuals who share a style of life and interact as status equals (e.g., the nobility, an ethnic caste). In some circumstances, the boundaries of a status grouping are determined by purely economic criteria, yet Weber notes that “status honor normally stands in sharp opposition to the pretensions of sheer property” (Weber [1922] 1968, p. 932).

The Weberian approach has been elaborated and extended by sociologists attempting to understand the “American form” of stratification. In the postwar decades, American sociologists typically dismissed the Marxist model of class as overly simplistic and one-dimensional, whereas they celebrated the Weberian model as properly distinguishing between the numerous variables Marx had conflated in his approach. These scholars often disaggregated the stratification dimensions identified by Weber into a multiplicity of variables (e.g., income, education, ethnicity) and then showed that the correlations between those variables were weak enough to generate various forms of “status inconsistency” (e.g., a poorly educated millionaire). The resulting picture suggested a “pluralistic model” of stratification; that is, the class system was represented as intrinsically multidimensional, with a host of cross-cutting affiliations producing a complex patchwork of internal class cleavages. While one critic has remarked that the multidimensionalists provided a “sociological portrait of America as drawn by Norman Rockwell” (Parkin 1979, p. 604), some post-Weberians also emphasized the “seamy side” of pluralism. In fact, Lenski (1954) and others (e.g., Lipset 1959) have argued that modern stratification systems can be seen as breeding grounds for personal stress and political radicalism, since individuals with contradictory statuses may feel relatively deprived and thus support “movements designed to alter the political status quo” (Lenski 1966, p. 88). This line of research died out in the early-1970s under the force of negative and inconclusive findings (Jackson and Curtis 1972). Although there has been a resurgence of theorizing about issues of status disparity and relative deprivation (e.g., Baron 1994), much of this work focuses on the generic proper-

ties of all “post modern” stratification systems rather than the allegedly exceptional features of the American case.

In recent years, the standard multidimensionalist interpretation of “Class, Status, and Party” (Weber 1946, pp. 180–95) has fallen into disfavor, and an alternative version of neo-Weberian stratification theory has gradually taken shape. This revised reading of Weber draws on the concept of social closure as defined and discussed in the essay “Open and Closed Relationships” (Weber [1922] 1968, pp. 43–46; 341–348). By social closure, Weber is referring to the processes by which groups devise and enforce rules of membership, typically with the objective of improving the position [of the group] by monopolistic tactics” (Weber [1922] 1968, p. 43). While Weber does not directly link this discussion with his other contributions to stratification theory, later commentators pointed out that social classes and status groupings are generated by simple exclusionary processes operating at the macro-structural level (e.g., Giddens 1973). Under modern industrialism, there are obviously no formal sanctions that prevent labor from crossing class boundaries, yet various institutional forces (e.g., private property, union shops) are quite effective in limiting the amount of class mobility over the life course and between generations. These exclusionary mechanisms not only “maximize claims to rewards and opportunities” among the members of closed classes (Parkin 1979, p. 44), but also provide the demographic continuity needed to generate distinctive class cultures and “reproduce common life experience over the generations” (Giddens 1973, p. 107). As is noted by Giddens (1973, pp. 107–12), barriers of this sort are not the only source of “class structuration,” yet they clearly play a contributing role in the formation of identifiable classes under modern industrialism. This revisionist interpretation of Weber has reoriented the discipline toward examining the causes and sources of class formation rather than the potentially fragmenting effects of cross-cutting affiliations and cleavages.

Gradational Status Groupings The theorists discussed above have all proceeded by mapping individuals or families into mutually exclusive and exhaustive categories (“classes”). As this review indicates, there continues to be much debate about the location of the boundaries separating these categories, yet the shared assumption is that fun-

damental class boundaries of some kind are present, if only in a latent or incipient form. By contrast, the implicit claim underlying gradational approaches is that such “dividing lines” are largely the construction of overzealous sociologists and that the underlying structure of modern stratification can be more closely approximated with gradational measures of income, status, or prestige. The standard concepts of class action and consciousness are similarly discarded; that is, whereas most categorical models are based on the (realist) assumption that the constituent categories are “structures of interest that provide the basis for collective action” (Wright 1979, p. 7), gradational models usually are represented as taxonomic or statistical classifications of purely heuristic interest.

This approach has been pursued in various ways, but typically not by operationalizing social standing in terms of income alone. It does not follow that distinctions of income are sociologically uninteresting; in fact, if one is intent on assessing the “market situation” of workers (Weber [1922] 1968), there is much to recommend a direct measurement of their income and wealth. The preferred approach has nonetheless been to define classes as “groups of persons who are members of effective kinship units which, as units, are approximately equally valued” (Parsons 1954, p. 77). This formulation was first operationalized in postwar community studies (e.g., Warner 1949) by constructing broadly defined categories of reputational equals (“upper upper class,” “upper middle class,” etc.). However, when the disciplinary focus shifted to the national stratification system, the measure of choice soon became occupational scales of prestige (e.g., Treiman 1977), socioeconomic status (e.g., Blau and Duncan 1967), or global “success in the labor market” (Jencks et al. 1988). Although there is much debate about the usefulness of such scales, they continue to serve as standard measures of class background in sociological research of all kinds.

GENERATING STRATIFICATION

The language of stratification theory makes a sharp distinction between the distribution of social rewards (e.g., the income distribution) and the distribution of opportunities for securing those rewards. As sociologists have noted, it is the latter

distribution that governs popular judgments about the legitimacy of stratification: the typical American, for example, is willing to tolerate substantial inequalities in power, wealth, or prestige if the opportunities for securing those social goods are distributed equally across all individuals. Whatever the wisdom of this popular logic, stratification researchers have long explored its factual underpinnings by describing and explaining the structure of mobility chances.

The study of social mobility is, then, a major sociological industry. The relevant literature is vast, yet much of this work can be classified into one of three traditions of scholarship.

1. The conventional starting point has been to analyze bivariate “mobility tables” formed by cross-classifying the occupational origins and destinations of individuals. These tables can be used to estimate the densities of occupational inheritance, describe patterns of mobility and exchange between occupations, and map the social distances between classes and their constituent occupations. Moreover, when comparable mobility tables are assembled for several countries, it becomes possible to address long-standing debates about the underlying contours of cross-national variation in stratification systems (e.g., Erikson and Goldthorpe 1992).
2. It is a sociological truism that Blau and Duncan (1967) and their colleagues (e.g., Sewell et al. 1969) revolutionized the field with their formal “path models” of stratification. These models were intended to represent, if only partially, the process by which background advantages can be converted into socioeconomic status through the mediating variables of schooling, aspirations, and parental encouragement. Under formulations of this kind, the main sociological objective was to show that socioeconomic outcomes are structured not only by “native ability” and family origins but also by various intervening variables (e.g., schooling) that are themselves only partly determined by origins, race and gender, and other ascriptive forces (Blau and Duncan 1967, pp. 199–205). This line of research, which

had fallen out of favor by the mid-1980s, has been rediscovered and revived as stratification scholars react to the now-fashionable argument (i.e., Herrnstein and Murray 1994) that inherited intelligence is increasingly determinative of stratification outcomes.

3. These “status attainment” models have been criticized for failing to attend to the social structural constraints that operate on the stratification process independently of individual-level traits. The structuralist accounts that ultimately emerged from these critiques amounted in most cases to refurbished versions of the dual economy and market segmentation models that were introduced and popularized several decades ago by institutional economists. When these models were redeployed by sociologists in the early 1980s, the usual objective was to demonstrate that women and minorities were disadvantaged not only because of deficient investments in human capital (e.g., inadequate schooling and experience) but also by their consignment to “secondary” labor markets that on average paid lower wages and offered fewer opportunities for promotion or advancement.

These three approaches to stratification analysis typically are implemented with quantitative models of the most sophisticated sort. In a classic critique, Coser (1975) suggested that stratification researchers were so entranced by quantitative models of mobility, attainment, and dissimination that “the methodological tail was wagging the substantive dog” (p. 652). This latter argument can no longer be taken exclusively in the intended pejorative sense because new models and methods have raised important substantive questions that previously had been overlooked. In this sense, the development of structural equation, log-linear, and event history models are properly viewed as watershed events in the history of mobility research.

ASCRIPTIVE PROCESSES

The forces of race and gender have long been relegated to the sociological sidelines by class theorists of both Marxist and non-Marxist persuasions. In most versions of class-analytic theory,

status groups are treated as secondary forms of affiliation, whereas class-based ties are seen as more fundamental and decisive determinants of social and political action. Although Race and gender have not been ignored altogether in such treatments, they typically are represented as vestiges of traditional loyalties that will wither away under the rationalizing influence of socialism, industrialism, or modernization.

The first step in the intellectual breakdown of this model was the fashioning of a multidimensional approach to stratification. Whereas many class theorists gave theoretical or conceptual priority to the economic dimension of stratification, the early multidimensionalists emphasized that social behavior could be understood only by taking into account all status group memberships (e.g., race, gender) and the complex ways in which they interact with one another and with class outcomes. The class-analytic approach was further undermined by the apparent reemergence of racial, ethnic, and nationalist conflicts in the late postwar period. Far from withering away under the force of industrialism, the bonds of race and ethnicity seemed to be alive and well: The modern world was witnessing a “sudden increase in tendencies by people in many countries and many circumstances to insist on the significance of their group distinctiveness” (Glazer and Moynihan 1975, p. 3). This resurgence of status politics continues today. In one last several decades, ethnic and regional solidarities have intensified with the decline of conventional class politics in central Europe and elsewhere, and gender-based affiliations and loyalties have strengthened as feminist movements diffuse throughout much of the modern world.

This turn of events has led some commentators to proclaim that the factors of race, ethnicity, and gender are now the driving force behind the evolution of stratification systems. In one such formulation, Glazer and Moynihan (1975) conclude that “property relations [formerly] obscured ethnic ones” (p. 16), but now it is “property that begins to seem derivative, and ethnicity that becomes a more fundamental source of stratification” (p. 17). The analogous position favored by some feminists is that “men’s dominance over women is the cornerstone on which all other oppression (class, age, race) rests” (Hartmann 1981, p. 12; see also Firestone 1972). This formulation

begs the question of timing; that is, if the forces of gender or ethnicity are truly primordial, it is natural to ask why they began expressing themselves with real vigor in more recent history. In addressing this issue, Bell (1975) suggests that a trade-off exists between class-based and ethnic forms of solidarity, with the latter strengthening whenever the former weaken. As the conflict between labor and capital is institutionalized (via “trade unionism”), Bell argues, class-based affiliations typically lose their affective content and workers must turn to racial or ethnic ties to provide them with a renewed sense of identification and commitment. It could be argued that gender politics often fill the same “moral vacuum” that this decline in class politics has allegedly generated.

It may be misleading to treat the competition between ascriptive and class-based forces as a sociological horse race that only one of the two principles can ultimately win. In a pluralist society of the American kind, workers can choose an identity appropriate to the situational context; a modern-day worker may behave as “an industrial laborer in the morning, a black in the afternoon, and an American in the evening” (Parkin 1979, p. 34). Although this situational model of status has not been adopted widely in contemporary research, there is some evidence of renewed interest in conceptualizing the diverse affiliations of individuals and the “multiple oppressions” (see Wright 1989, pp. 5–6) that those affiliations engender. It is now fashionable, for example, to assume that the major status groupings in contemporary stratification systems are defined by the intersection of ethnic, gender, and class affiliations (e.g., black working-class women, white middle-class men). The theoretical framework for this approach is not always well articulated, but the implicit claim seems to be that these subgroupings shape the “life chances and experiences” of individuals (Ransford and Miller 1983, p. 46) and thus define the social settings in which subcultures typically emerge. The obvious effect is to invert the traditional post-Weberian perspective on status groupings; that is, whereas orthodox multidimensionalists described the stress experienced by individuals with inconsistent statuses (e.g., poorly educated doctors), the new multidimensionalists emphasize the shared interests and cultures generated within commonly encountered status sets (e.g., black working-class women).

The sociological study of gender, race, and ethnicity has thus burgeoned. As is noted by Lieberman (1994, p. 649), there has been a certain faddishness in the types of research topics that scholars of gender and race have chosen for study, with the resulting body of literature having a correspondingly haphazard and scattered feel. The following research questions have nonetheless emerged as relatively central ones in the field:

1. How are class relations affected by ascriptive forms of stratification? Can capitalists exploit ethnic antagonisms and patriarchy to their advantage? Do male and majority group workers also benefit from stratification by gender and race?
2. What accounts for variability across time and space in ethnic conflict and solidarity? Will ethnic loyalties weaken as modernization diffuses across ethnically diverse populations? Does modernization instead produce a "cultural division of labor" that strengthens communal ties by making ethnicity the principal arbiter of life chances? Is ethnic conflict further intensified when ethnic groups compete for the same niche in the occupational structure?
3. What are the generative forces underlying ethnic, racial, and gender differentials in income and other socioeconomic outcomes? Do those differentials proceed from supply-side variability in the occupational aspirations or the human capital workers bring to the market? Alternatively, are they produced by demand-side forces such as market segmentation, statistical or institutional discrimination, and the seemingly irrational tastes and preferences of employers?
4. Is the underlying structure of ascriptive stratification changing with the transition to advanced industrialism? Does the "logic" of industrialism require universalistic personnel practices and consequent declines in overt discrimination? Can this logic be reconciled with the rise of a modern ghetto underclass, the persistence of massive segregation by sex and race, and the emergence of new forms of poverty and hardship among women and recent immigrants?

These questions make it clear that ethnic, racial, and gender inequalities often are classed together and treated as analytically equivalent forms of ascription. Although Parsons (1951) and others (e.g., Tilly 1998) have emphasized the shared features of "communal ties," such ties can be maintained (or subverted) in very different ways. It has long been argued, for example, that some forms of inequality can be rendered more palatable by the practice of pooling resources (e.g., income) across family members. As Lieberman (1994) points out, the family operates to bind males and females together in a single unit of consumption, whereas extrafamilial institutions (schools, labor markets, etc.) must be relied on to provide the same integrative functions for ethnic groups. If these functions are left wholly unfilled, one might expect ethnic separatist and nationalist movements to emerge. The same "nationalist" option is obviously less viable for single-sex groups; indeed, barring any revolutionary changes in family structure or kinship relations, it seems unlikely that separatist solutions will ever garner much support among men or women. These considerations may account for the absence of a well-developed literature on overt conflict between single-sex groups.

CONCLUSIONS

In recent years, criticisms of the class-analytic framework have escalated, with many scholars arguing that the concept of class is "ceasing to do any useful work for sociology" (Pahl 1989, p. 710). Although such postmodern accounts have taken many forms, most proceed from the assumption that social classes no longer definitively structure lifestyles and life chances and that "new theories, perhaps more cultural than structural, [are] in order" (Davis 1982, p. 585). In accounts of this sort, the labor movement is represented as a fading enterprise rooted in the old conflicts of the workplace and industrial capitalism, whereas new social movements (e.g., environmentalism) are assumed to provide a more appealing call for collective action by virtue of their emphasis on issues of lifestyle, personal identity, and normative change.

This argument has not been subjected to convincing empirical tests and may prove to be premature. However, even if lifestyles and life chances are truly "decoupling" from economic class, this should not be misunderstood as a more general

decline in stratification per se. The massive facts of economic, political, and honorific inequality will still be operative even if conventional models of class ultimately are found deficient in characterizing the postmodern condition. As is well known, some forms of inequality have increased in recent years (e.g., income inequality), while others show no signs of disappearing or withering away (e.g., political inequality).

This persistence and in some cases deepening of inequality is coupled with the continuing diffusion of antistratification values and a correspondingly heightened sensitivity to all things unequal. As egalitarianism spreads, the postmodern public becomes heavily involved in monitoring and exposing illegitimate (i.e., nonmeritocratic) forms of stratification, and even small departures from equality are increasingly viewed as problematic and intolerable (Meyer 1994). Moreover, because stratification systems are deeply institutionalized, there is good reason to anticipate that demands for egalitarian change will outpace actual changes in stratification practices. These dynamics imply that issues of stratification will continue to generate discord and conflict even in the unlikely event of a long-term trend toward diminishing inequality.

DAVID B. GRUSKY

SOCIAL STRUCTURE

“Social structure” is a general term for any collective social circumstance that cannot be altered by isolated actions and thus is fixed or given for the individual. It thus provides a context, environment, or fixed backdrop for action. The size of organizations, the distribution of activities in space, shared language, and the distribution of wealth all might be regarded as social structural circumstances that set limits on feasible activities for individuals.

Social structure is objective in the sense that it is the same for everyone and is beyond the capacity for alteration by any individual. Accordingly, social structure often is spoken of in the singular and as a thing apart, as if there were only one from whose effects no one can escape. This usage masks disagreement about the exact extension of the term but reflects the intention of authors to highlight abstract patterns as an inflexible collective circumstance to which individuals must adapt.

Social structure, or the weaker structural regularities, arises because of the prevalence of social routine. Many social patterns change very slowly either through unmotivated inertia, through willful efforts to renew or reproduce them, or as a collective consequence of individual efforts undertaken for independent reasons. An image or picture, such as a map colored by the linguistic practices of the inhabitants of geographic areas, will lose accuracy slowly and often would remain largely accurate after a century or more. Such substantial durability, along with the accompanying slow continuous change, suggests the possibility of regularities or even scientific laws governing the phenomena that underlie the description.

Routines endure and structural regularities persist for at least three general reasons. Social life is subject to physical constraints such as distance. Thus, most people live close to where they work or do both at one place. For related reasons, many persons maintain stable residences. Furthermore, many people need or desire the company or cooperation of representative social types, such as those who share their religious convictions, or particular work skills. Accordingly, one can associate social attributes with geographic maps. This was a central activity of the Chicago school of sociology (Park and Burgess 1924) and gave rise to the

perspective of human ecology (Hawley 1986). The specialization of social types and activities in space is subject to powerful incentives that induce similarity in the face of turnover among individuals. For example, ethnic concentrations result in specialized facilities, such as food shops, that attract replacements that conserve the ethnic character. Such patterns often persist beyond the lifetimes of the people who initiated them.

A second source of routine is limited learning capacity or the complexity of many social activities. Linguistic rules, moral codes, and work skills illustrate social capacities whose acquisition requires considerable time and effort. This socialization often requires extended exposure to others who know the routines well, especially when the delicate skills of interpretation are involved.

The difficulties of acquiring capacity can confound individual wills. Bernstein (1975) described how linguistic conventions acquired in the home reflect the conditions of adult work and render individuals unsuited for occupations that are not similar to those of their parents. In the same way, a New Yorker who wished to speak in Latin would have to make a huge investment in learning a novel linguistic code. However, this would not undo the investment in English by other New Yorkers, and thus Latin would be impractical for directing taxi drivers. Similar reasons impel the adoption of the abrasive social style of New Yorkers by newcomers. The general principle is that most people must adapt to many surrounding ways of doing things because those ways change so slowly.

A third source of structural regularity is laws governing averages. An example is the suicide rates studied by Durkheim. People commit suicide for a variety of personal motives and the act is never repeated by anyone, yet the frequency of the act is fairly stable over time and thus is stably different among different populations. This is the case because variable causes tend to average into stable totals whenever many instances are drawn from constant underlying conditions. Many of the rates that result are sufficiently stable to sustain plans and projections, which in turn can be embedded in routines, even though the underlying activity is very complex in its detailed causation.

The several sources of stable routines underlie the properties that frequently are associated with proposed structural regularities. Structural regu-

larities often are depicted as abstract, enduring, and operative across a large scale of units. These attributes reflect genesis, for many structural regularities ultimately stem from the long historical process of imposing routines that made a large scale feasible. For example, Tilly (1975) shows how the modern European state resulted from parallel decisions by state makers forced by military competition to pursue centralization by reordering the established routines of ordinary people. The history of collective contention (Tilly 1986) can be seen as the efforts of the victims to defend older patterns against intrusions by state agents such as tax collectors and against the vast reorganization of work and fortune implicit in the expansion of capitalism.

Mann (1986) argues that large-scale cooperation rests on enduring patterns of power. For example, shared religious ideology is a form of power because it makes people subject to claims on their activity. Rapid religious change is not infrequently the result of conquest. Once it has been established, religion is often compulsory. Coercion aside, religious conformity can provide insurance against the risks and pains of social isolation. Other large-scale patterns, such as the division of labor, are maintained in the face of considerable shifting by persons among different roles. This often is implemented by powerful actors who are motivated to induce (or coerce) approximate substitutes to fill in for those who withdraw (or die). In such terms, abstract stability, a large scale, and consequent duration often can be seen to be sustained through underlying causal regularities. In human terms, the reproduction of social structure consists of a myriad of modest efforts that sum to a stable result.

This interdependence underlies the transcendence of abstract structural regularity over individual will. Generally, one cannot learn more than locally applicable routines and must rely on others for critical needs. Thus, one assumes that the staff members in the emergency room will not all take the day off. This frees accountants from the necessity of acquiring medical skill to meet their own needs. As a result, the details of actual routines are known only locally, and the only possible knowledge of the overall pattern is coarse or abstract. Even accountants cannot count up the details they must count on. A further implication is that the alternatives to enacting the routines with which

one is familiar are often limited. It requires time on a historical scale to construct such a pattern. That history has happened, and if the conditions that made narrow, specialized learning practical suddenly came unglued most people would be in a terrible fix.

A special case of social routines consists of those worked out with others, who then are often hard to replace. Replacement is generally more troublesome as the duration is longer, such as many kinship bonds, which can be effectively irreplaceable for many adults. These social relations can be mapped as social networks describing the pattern of the links that surround individuals. The analysis of such patterns is not infrequently (or unreasonably) called "structural analysis," though it hardly exhausts the term.

Elaborate routines, especially social ties, are subject to pressures toward isomorphy, which is defined as a common anatomy or structure. An example is the formation of families, which are different in detail but share common features partly in response to common problems that must be solved within a shared environment. Goode (1970) analyzes the sources and consequences of such regularities. In modern societies, assumptions about such features often are written into administrative procedures such as tax codes, which provide further impetus for individuals to adopt a variant of the pattern defined as normal. Changing and varied individual desires are often in conflict with those pressures to cooperate in the reproduction of the supposedly "normal" pattern.

Emergent properties that apply to wholes but not to parts often are attributed to social structure. Some properties, such as size distributions and complexity, do not have direct individual analogues. Others arise because the net result of many partially independent actions can be different from the intentions of individuals. Thus, markets with many participants can experience crashes in value when many people try to sell in anticipation that others are about to do so, producing a result that no one desires. Kindleberger (1980) describes the recurrence of such crises. Routines are executed by fallible humans and are only locally adapted, somewhat independent, and imperfectly flexible. Many properties of the resulting averages or combinations do not follow from the components in any simple sense.

As the preceding analysis suggests, structural visions are various. One unifying theme is an appeal to abstract, extraindividual patterns that change slowly or not at all. A second unifying theme is that those regularities cause or condition many of the choices and behaviors of individuals. A final common theme is less unifying than divisive. Some structural visions are accompanied by claims of centrality. A particular array of simple elements is proclaimed, often on metatheoretical or philosophic grounds, to be the central deep structure whose inevitable unfolding underlies a vast array of surface appearances. Such comprehensive views have inspired competing, incompatible schools of thought on whose behalf a claim is sometimes made to *the* structural vision of society or the human condition.

Most of these structural visions are comprehensive worldviews that require detailed study in their own right. Among the most prominent are those of Marx and Freud, but there have been structuralist movements in nearly every field of social studies. Nearly all proceed from some highly abstract characterization of the human mind, laws of thought, or the human condition. All of social or mental life is viewed as a manifestation of the reproduction of such elements, often unfolding dialectically. This is presented as the inevitable underpinnings of individual or collective biographies. Piaget (1970) has provided an unusually concise description of an interdisciplinary structuralism based on mathematical progress; this description parallels his more famous theory of discontinuous advancement in human cognitive development. Originators and their descendants often delight in such subtle and insightful reductions of familiar patterns to the chosen central supports.

The term “structure” is most commonly employed in sociology without these all-encompassing ambitions. In empirical sociology, especially quantitative studies based on random samples of persons, the term is invoked for varied efforts to use the larger and often more durable features of social life as explanatory factors for individual conduct and outcomes. The most common contrast is with individual-level causes, including attitudes and aspirations. Sometimes attributes such as race, gender, and class are labeled structural to imply that the underlying mechanism is an exter-

nal force imposed on individuals independently of their wills.

The reasoning behind this is not always explicit, but the usage is justifiable. Generally, the factors labeled structural are alternatives among a differentiated array of possibilities to which individuals are confined for substantial periods. “Structure” then refers to the differentiating average conditions in which people live their lives. At least implicitly, such differences correspond to differences in the routines employed to adapt to local conditions as well as to resources that render routines practical. Classifying people by indicators of the local conditions that surround them reflects the opportunities they have for association and hence for processes such as influence, cooperation, and victimization. Some characterizations also correspond to labels, most notably race and gender, and broadly indicate common tendencies in routines of others to which one is likely to be exposed. Such differences are quite stable, impersonal, and hard to evade. Taken together, these differences in conditions contribute to differences in average responses or individual behaviors.

There is some confusion about the nature of such structural causation, which often is framed as an alternative explanation to individual choice. Persuasive force often comes from stories in which the predominant outcome is made to feel inevitable. This is at odds with the normal empirical result of a difference in tendency or proportion. Rules that hold without exception are rare. This should be expected. Structural abstractions mask much detail that varies. The implicit reference is to averages over multiple executions of complex routines. To take an obvious example, racial discrimination involving job applicants is not invariant but occurs often enough to lead to considerable differences.

Structural causes are not literally the antithesis of individual choice. More precisely, they reflect patterns over which individuals have limited control. The binding force of structural regularity is intrinsically probabilistic. People almost invariably have options, and exceptions to regularities are somewhere in reach. However, established structure—ultimately routines acquired over time, bonds developed to particular others, and the meshed ways of doing that result—exerts a frictional tug. Friction is implicit in the pain of for-

gone routines and the time required to work out new ones. Such pains may be amplified when those who benefit from regularities exert their power to maintain them. On any large scale, the path of least resistance consists of acting today nearly the same way as one acted yesterday. By no means does this rule out individual exceptions, resistance, or willful alterations to parts of the overall web, but friction is cumulative. For example, the rupture and replacement of one bond are quite different from the rupturing of all bonds at once. Similarly, any single person may change jobs, although in practice only to a very limited range of alternatives, yet if all jobs were randomly reshuffled one day, nearly all would go undone, for every job would be subject to the incompetence of the "first day on the job." In summary, the frictional forces of social structure do not rule out rare and/or modest exceptions but generally ensure that wholesale, simultaneous exceptions are rare to the vanishing point.

Empirical applications generally draw on fragments of social structure that are taken as conditioning factors for particular outcomes. The larger challenge is to translate the impersonal, durable complexity of stable differences in condition into a formal calculus, or a theory of social structure. Parsons's (1951) extensive analysis of the logic of social systems was an early and seminal attempt. His student Merton, under the banner of "theories of the middle range," provided a more easily applied set of general tools for structural analysis. Several of Merton's students, including Boudon, Blau, and Coleman, further developed formal calculi for social structure that benefit from the use of mathematical tools.

Parsons's complex system begins with the conditions for stabilizing interaction or, in current terms, meshing routines. Parsons characterizes the routines that govern choice as extended chains of logic linking means to ends. At their most abstract, those chains are anchored in ultimate ends, or values. Durable stability results from consensus on the values that are installed in individuals by more or less extended socialization.

In Parsons's view, the logical chains governing decision making are morally potent norms, or rules governing social conduct. The durable web that shapes individual choice is therefore the complex of norms animated by the anchoring ultimate

values. Parsons imposes on this a logical calculus of the different functions necessary for ensuring that the pattern is resistant to shocks that draw it away from equilibrium. A concomitant of this theme of differentiation is complementary specialization in distinct but interdependent expectations bundled into the social roles enacted by different players.

Parsons's calculus of the functional necessities of meshing differentiated normative specifications proved widely compelling but difficult to apply. His presentation is notoriously hard to read. Applications of the scheme usually consisted of classifying normative elements into taxonomies delimiting functional contributions. These qualitative operations were by no means mechanical or easily communicated as a stable procedure that would steer different investigators to identical results. This rendered moot the possibility of generating conclusions from initial conditions through the application of formal tools. In a similar way, while many were inclined to agree that Parsons's system illuminated how a social system governed by a logic over normative rules might work, it was less than evident that concrete social systems had such logical coherence.

Merton's (1968) "theories of the middle range" provided a more readily applicable set of tools. Like Parsons, Merton proposed that the enduring regularities that make up social structure are normatively defined. However, instead of attempting to calculate over extended normative webs, he drew attention to the implications of positions. Thus, he emphasized that roles place individuals in relations with concrete others or that membership in groups, both present and anticipated, provides reference points for calculating comparisons of expectations and outcomes. Unlike Parsons's more elaborate concerns, Merton's lent themselves to the construction and interpretation of surveys and other manageable research projects.

Merton did not assume, as Parsons did, that norms and roles can be divined from an overarching logic. More frequently, he treated contrasting norms as empirical counterparts of lay distinctions among different roles or group memberships. This can be viewed as a central motivation for the common use of the structural concepts outlined above. However, Merton more often used factual (or readily inferred) norms grounded in different

stable positions to highlight dilemmas. Concrete people could be understood as facing practical problems of resolving competing and often contrary normative standards. This strategy of framing the practical problem as the resolution of contrary expectations frequently leads to insight into choices that at first seem senseless or even self-defeating.

Merton's analyses rested on qualitative inferences, often turning on the meaning of norms. One of Merton's students, Boudon (1982), provides formulations in which social structure refers to numerically definite distributions so that the implications of such extraindividual constraints emerge from formal calculations. For example, he posits an array of young persons committed to personal advancement who make investments in education. However, when all do what is individually sensible, the collective result illustrates Merton's unintended consequences. If there is a fixed and therefore scarce supply of desired positions that will go to those who have the most education, many of those who invest will discover that their efforts are frustrated by the simultaneous striving of others. Boudon provides many illustrations of the perverse effects that can obtain when individual motive operates against a backdrop of a fixed system of positions.

Another of Merton's students, Blau (1977), presents a deductive structural theory based on the notion that social structure consists of arrays of positions, which he calls parameters. Blau divides differentiation into two types: among unranked or nominal categories such as religion and among continuous arrays of ranked positions that differ in their amounts of a scarce and valued resource. The distribution of individuals over positions gives rise to numerical properties of whole social structures, including the heterogeneity of nominal differences, inequality among ranks, and consolidation intersection, or the degree of correlation independence of positions on separate dimensions.

Blau's concept of social structure leads to differences in the sizes of collections of individuals occupying different positions. Size in turn strongly conditions the rate of interaction, or social association. More differentiated structures result in higher rates of intergroup association, and Blau argues that this leads to the successful meshing of routines, or social integration. The intersection of

different dimensions, which results in even smaller subgroups defined by multiple positions, also enhances social integration. Conversely, the consolidation of dimensions, homogeneity rather than heterogeneity, diminishes rates of intergroup contact and hence hinders social integration. Inequality emerges as a special case that illustrates Blau's taste for paradoxical results. Greater inequality leads to smaller strata and fosters intergroup relations, but those relations often take the form of interpersonal conflict, including crime (Blau and Blau 1982).

Blau's notions are particularly suitable for research application because his notion of structure more or less directly corresponds to widely used operationalizations such as gender, race, ethnicity, religion, occupational rank, and wealth. Of course, these are social constructs and in some final analysis are defined by norms and other ideal elements. At the same time, they are for most people most of the time subject to slow or even no change. This sustains the usefulness of a numerical calculus that rests on the notion that size is an objective, impersonal, and durable reality.

Coleman (1990) provides one of the most ambitious attempts to specify social structure as a mathematically tractable map of interdependence. He posits actors with rights of control over their own actions and over tangible things desired by others or resources. His actors maximize the achievement of their desires by exchanging their control in return for that which others control. The result in general is an equilibrium in which initial control in conjunction with the desires of others produces differential power. Within this apparatus, Coleman is able to provide a rigorous analysis of the emergence of larger-scale phenomena, including groups, norms, and corporate actors.

Although all these accounts lie along a single path of intellectual descent, there is a major divide with respect to the elemental nature of social structure. For Parsons, it is an interdependent complex of norms. Unfortunately, there does not exist at present any way to formalize or calculate the mutual implications in a web of symbolic elements. Later analysts who have gone much farther in rendering complexity calculable have done so from "hard" assumptions that take social structure from the outset as a set of objective positions (with objective properties) so that size,

distribution, rates of exchange, and so forth, can be treated mathematically.

More recent treatments have built on the rich, although eclectic, tradition of taking relations or social ties that are knitted into networks as fundamental. One point of departure is Granovetter's (1973) observation that weak ties are surprisingly efficacious in securing resources, notably access to better jobs. Weak ties are most likely to form bridges between clusters of interconnected and thus redundant strong ties. Burt (1992) generalizes this, suggesting that "structural holes," or gaps spanned by positions whose ties unite the otherwise disconnected, are a potent source of advantage. He was able to display supporting evidence from contexts as diverse as executives competing for promotion and sectors of an industrial economy. Burt's concepts are derivative in the best sense; that is, they are a conceptual refinement that moves on to novel terrain, building on what he can take as an established view of social structure.

Tilly (1998) has distilled from network concerns a potent challenge to much received thinking about stratification. He proposes that "durable inequality" reverberates from underlying schemas governing how networks are formed. Categorical divisions such as race, gender, nationality, and citizenship are embedded in widely shared, deeply learned propensities for action, or routines. Recurrent organizational problems, such as assigning work and dividing rewards, are most easily and durably resolved when they are consonant with widely shared assumptions about categorical differences. Somewhat like Burt, Tilly focuses less on origins and more on implications. He examines how relational considerations secure inequalities through persistent configurations of exploitation and resource hoarding that are diffused by emulation and ultimately underpinned by adaptation. In this view, social structure is not globally coherent or uniform but is, somewhat like DNA, a complex melange constructed from varying combinations of a few very simple elements.

A noteworthy gap here is that the proponents of formal theory (and those proposing building blocks) tend to posit or assume "hard" properties, giving limited attention to how or why the hypothesized elementary patterns emerged or became predominant. This leaves open issues of variability and interpretive options (or meaning)

that others see as fundamental. Indeed, some authors believe that human judgment is distinctive and that no mechanical analogue or simulation of human society (Habermas 1987) or human cognition, (Penrose 1989) will ever be possible.

In summary, there are no widely accepted sets of notions that capture all the properties that have been seen as fundamental to the concept of social structure. The huge catalogue of demonstrated effects of structural regularities cannot be organized in a tidy way. Enthusiasm for the different attempts to represent the concept in compact terms varies widely. Sufficiently close attention to the details of competing claims could convince one that no shared subject is really at issue. As in the analysis of social structure itself, it is necessary to carefully select the right degree of abstraction and appropriate pattern of highlighting to discern any common pattern in the competing pictures, but there is nevertheless a pattern to be found.

SOCIAL VALUES AND NORMS

Values and norms are evaluative beliefs that synthesize affective and cognitive elements to orient people to the world in which they live. Their evaluative element makes them unlike existential beliefs, which focus primarily on matters of truth or falsehood, correctness or incorrectness. Their cognitive element makes them unlike motives that can derive from emotions or psychological drives. Values and norms involve cognitive beliefs of approval or disapproval. Although they tend to persist through time and therefore foster continuity in society and human personality, they also are susceptible to change (Moss and Susman 1980; Alwin 1994).

The evaluative criteria represented in values and norms influence the behavior of subject units at multiple levels (e.g., individuals, organizations, and societies) as well as judgments about the behavior of others, which also can influence behavior. For example, values and norms affect the evaluation of individuals as suitable marriage partners and in that way influence marital behavior. Values and norms also affect evaluation of the governing policies and practices of societies and thus have an impact on diplomatic relations and the policies of one society's government toward other societies.

CONCEPT OF A VALUE

A value is a belief about the desirability of a mode, means, or end of action (Kluckhohn 1951; Schwartz and Bilsky 1987). It indicates the degree to which something is regarded as good versus bad. A value tends to be general rather than specific, transcending particular types of action and situations. As a general evaluative criterion, it is used to assess specific behaviors in specific situations.

The evaluative criteria represented by values derive from conceptions of morality, aesthetics, and achievement. That is, a mode, means, or end of action can be regarded as good or bad for moral, aesthetic, or cognitive reasons and often for a combination of those reasons (Kluckhohn 1951; Parsons and Shils 1951). For example, being considerate of others may be valued positively (i.e., be viewed as desirable or good) for moral reasons, neatness may be valued positively for aesthetic reasons, and intelligence may be valued positively for cognitive reasons. Since the distinguishing characteristic of a value is evaluation as good or bad, a value that has a cognitive basis is a function of cognitive appraisal based on competency and achievement rather than on scientific or utilitarian grounds. For example, the choice of steel rather than iron to construct a building is a decision based on scientific or utilitarian criteria rather than on values.

The concept of a value must be differentiated from other concepts that appear to be similar. One of those concepts is a preference. A value may be thought of as a type of preference, but not all preferences are values. The distinctive characteristic of a value is that it is based on a belief about what is desirable rather than on mere liking. A preference for an equitable rather than inequitable distribution of rewards is a value, but a preference for vanilla rather than chocolate ice cream is not.

The concept of a value also bears some similarity to the concept of an attitude. Some analysts have suggested that a value is a type of attitude (Fishbein and Ajzen 1975; Glenn 1980), but there are differences between the two concepts. An attitude refers to an organization of several beliefs around a specific object or situation, whereas a value refers to a single belief of a specific kind: a belief about desirability that is based in conceptions of morality, aesthetics, or achievement and transcends specific behaviors and situations. Be-

cause of its generality, a value occupies a more central and hierarchically important place in human personality and cognitive structure than does an attitude. It is a determinant of attitudes as well as behavior. Thus, evaluations of numerous attitude objects and situations are based on a relatively small number of values. Not all attitudes, however, derive from values. For example, an attitude toward skiing may be based on the extent to which that sport is found to be enjoyable rather than on a value. The concept of a value also differs from the concept of an interest in much the same way that it differs from the concept of an attitude, since an interest is a type of attitude that results in the directing of one's attention and action toward a focal object or situation. As is true of attitudes more broadly, some interests derive from values but others do not.

The concept of a value also can be distinguished from the related concept of a motive. The basic property of a motive is the ability to induce valences (incentives) that may be positive or negative. A value has a motive property, involving a predisposition to act in a certain way, because it affects the evaluation of the expected consequences of an action and therefore the choice among possible alternatives; however, it is a less person-centered concept than a motive, which also encompasses emotions and drives. A value is a particular type of motive involving a belief about the desirability of an action that derives from an evaluation of that action's expected consequences in a situation. A value is a distinctively human motive, unlike motives that operate at both the human and the infrahuman levels.

A value also differs from a need. Although both function as motives because of their ability to induce valences, a need is distinctive in being a requirement for the continued performance of an activity and the attainment of other valued outcomes (Emerson 1987). Some needs have a biological basis; others are psychological, often deriving from the persistent frustration of important goals. Although a value may arise from a need, becoming a cognitive transformation of that need, not all needs are transformed into values and not all values derive from needs. Needs also may derive from the structure of a situation, having a social or economic basis rather than a person-centered biological or psychological basis. For example, a need for income may cause an actor to

behave in ways that conflict with his or her values. A need differs from a value in that the continued functioning of the actor and the acquisitions of other valued outcomes are contingent on its being met. A need also differs from a value in that it implies a deficit that imposes a requirement, whereas a value implies motivation that is based on a belief about desirability.

Finally, a value can be differentiated from a goal. A value sometimes is thought of as a goal because goals are selected on the basis of values. However, some values focus on modes of action that are personal attributes, such as intelligence, rather than ends of action, or goals. Values are not goals of behavior. They are evaluative criteria that are used to select goals and appraise the implications of action.

CONCEPT OF A NORM

Like a value, a norm is an evaluative belief. Whereas a value is a belief about the *desirability* of behavior, a norm is a belief about the *acceptability* of behavior (Gibbs 1965; Marini 1984). A norm indicates the degree to which a behavior is regarded as right versus wrong, allowable versus unallowable. It is an evaluative criterion that specifies a rule of behavior, indicating what a behavior *ought* to be or *ought not* to be. A *prescriptive* norm indicates what should be done, and a *proscriptive* norm indicates what should not be done. Because a norm is a behavioral rule, it produces a feeling of obligation. A value, in contrast, produces a feeling of desirability, of attraction or repulsion.

A norm also differs from a value in its degree of specificity. A norm is less general than a value because it indicates what should or should not be done in particular behavioral contexts. Whereas a value is a general evaluative criterion that transcends particular types of action and situations, a norm is linked directly to particular types of action and situations. For example, there may be a norm proscribing the killing of other human beings that is generally applicable except in situations such as war, self-defense, capital punishment, and euthanasia. Situational variability of this type sometimes is referred to as the *conditionality* of a norm. A norm, like a value, is generally applicable to the *types* of action and situations on which it focuses, but it is less general than a value because it is less

likely to transcend particular types of action and situations.

Because norms often derive from values, they have their basis in conceptions of morality, aesthetics, and achievement and often in a combination of those conceptions. The basis of a norm tends to affect its strength, or the importance attached to it. For example, a norm based in morality that differentiates right from wrong is likely to be considered more important than a norm based in aesthetics that differentiates the appropriate from the inappropriate, for example, in matters of dress or etiquette. A norm, however, differs from a custom in much the same way that a value differs from a preference. A norm involves an evaluation of what an actor *should* do, whereas a custom involves an expectation of what an actor *will* do. It may be expected, for example, that people will drink coffee, but it is usually a matter of indifference whether they do. Drinking coffee is therefore a custom, not a norm; it is not based on a belief about what people ought to do.

THE STRUCTURE OF VALUES AND NORMS

Multiple values and norms are organized and linked in the cultures of human social systems and also are linked when they are internalized by individuals. Cultural “value orientations” organize and link values and norms to existential beliefs in general views that also might be called worldviews or ideologies (Kluckhohn 1951). They are sets of linked propositions embracing evaluative and existential elements that describe preferred or obligatory states. Values and norms are linked to and buttressed by existential beliefs about human nature, the human condition, interpersonal relations, the functioning of social organizations and societies, and the nature of the world. Since existential beliefs focus on what is true versus untrue, they are to some degree empirically based and verifiable.

In most of the early conceptual and theoretical work on values, values and norms were not differentiated clearly. Later, particularly as attempts to measure values and norms were made, the two concepts were routinely considered distinct, and studies focusing on them have been carried out separately since that time. As a result, the relationship between values and norms rarely has been analyzed theoretically or empirically.

Values and norms are closely related because values usually provide the justification for norms. As beliefs about what is desirable and undesirable, values often are associated with normative beliefs that require or preclude certain behavior, establishing boundaries to indicate what is acceptable versus unacceptable. For example, the positive value attached to human safety and security is supported by norms that proscribe doing harm to other persons and their property. Not all values are supported by norms, however. Displaying personal competence in a variety of ways is positively valued, but norms do not always require it. Similarly, not all norms support values. For example, norms in regard to dress and etiquette can be quite arbitrary. Their existence may support values, but the specific rules of behavior they establish may not.

Many cultural value orientations organize and link the values and norms that operate as evaluative criteria in human social systems. These orientations are learned and internalized by individuals in unique ways that vary with an individual’s personal characteristics and social history and the interaction between the two. Cultural value orientations and internalized individual value orientations are more comprehensive systems of values and norms than those activated as influences on particular types of behavior. The latent structure of values and norms that characterizes a social system or an individual can be thought of as a map or blueprint (Rokeach 1973). Only a portion of the map or blueprint that is immediately relevant to the behavioral choices being made is consulted, and the rest is ignored temporarily. Different subsets of values and norms that make up different portions of the map or blueprint are activated when different types of behavioral choices are made. For example, the values and norms relevant in choosing a mate differ from those relevant in deciding how to allocate one’s time among various activities.

The Object Unit. A characteristic of values and norms that is important for understanding their structure is the type of *object unit* to which they pertain, such as an individual, an organization, or a society. Values and norms establish what is desirable or acceptable for particular types of object units. For example, physical and psychological health are positively valued ends of action for individuals, and norms that proscribe or prescribe action to maintain or promote health gov-

ern individual action. Democracy, distributive justice, and world peace are positively valued ends of action for societies, and norms, usually in the form of laws, proscribe and prescribe certain actions on the part of a society's institutions in support of those values. Individuals may value democracy, justice, and peace, but these are societal values, not individual values, since they pertain to the characteristics of societies, not to those of individuals. Differentiating values by their object units is important in conceptualizing and measuring values relevant to the explanation of behavior because correspondence between the actor, or subject unit, and the object unit determines the extent to which behavior by the actor is relevant to achieving a particular end. Individuals differentiate between personal and societal values because they do not have direct influence over social values, thus distinguishing their beliefs on the basis of whether they think those beliefs will lead to action (Braithwaite and Law 1985).

The Basis of Evaluation. As evaluative criteria, values and norms have the ability to induce valences (incentives). They affect evaluation of the behavior of others and involve a predisposition to act in a certain way because they affect the evaluation of the expected consequences of action. The evaluation that occurs on the basis of values and norms derives from two structural properties: the polarity, or directionality, of the value or norm and the standard of comparison that is used.

Polarity. The polarity of a value or norm is the direction of its valence, or motive force, which may be positive or negative. In the case of a value, something that is evaluated as desirable will have a positive valence, whereas something that is evaluated as undesirable will have a negative valence. In the case of a norm, something that should be done will have a positive valence, whereas something that should not be done will have a negative valence.

Standard of Comparison. A value or norm also is characterized by a standard, or level, of aspiration or expectation. This evaluative standard is a reference point with respect to which a behavior and its consequences are evaluated. A subject unit's own action and that of others, as well as the ends that result or may result from action, are evaluated on the basis of whether they are above or below an evaluative standard.

In the case of a value, the evaluative standard determines the neutral point on the value scale at or above which a behavior or its consequences will be evaluated as desirable and below which a behavior or its consequences will be evaluated as undesirable. In both economics and psychology, it has been recognized that there is a utility, or value, function that should be considered nonlinear (Marini [1992] provides a discussion of these developments), and there is empirical evidence that it generally is appropriate to assume the existence of a reference point on a utility, or value, scale. This reference point plays a critical role in producing a nonlinear relationship between the value scale and the objective continuum of behavior and its consequences. It has been observed that value functions change significantly at a certain point, which is often, although not always, zero. In the prospect theory of Kahneman and Tversky (1979), outcomes are expressed as positive or negative deviations from a neutral reference outcome that is assigned a value of zero. Kahneman and Tversky propose an S-shaped value function that is concave above the reference point and convex below it but less steep above than below. This function specifies that the effect of a marginal change decreases with the distance from the reference point in either direction but that the response to outcomes below the reference point is more extreme than is the response to outcomes above it. The asymmetry of the value function suggests a stronger aversion to what is evaluated as undesirable, an asymmetry that is consistent with an empirically observed aversion to loss.

In the case of a norm, the evaluative standard is set by what is defined to be acceptable versus unacceptable. It is a level of expectation that is determined by the specific behaviors that are regarded as right versus wrong, appropriate versus inappropriate. An important difference between a value and a norm is that whereas there is a continuous, nonlinear relationship between a value scale and the objective continuum of behavior or its consequences above the neutral point set by the evaluative standard, this relationship is not expected between the scale of evaluation based on a normative criterion and the objective continuum of behavior. Because a normative standard establishes a boundary of acceptability or requirement that applies to all those covered by the norm, compliance with a normative expectation is not

evaluated as a continuous variable on the basis of variation in behavior above the reference point set by the normative expectation. However, violation of a normative standard is evaluated as a continuous variable on the basis of variation in behavior below the reference point set by the standard. Negative deviations from the standard are likely to be evaluated in much the same way as are negative evaluations from the reference point on a value scale, which is convex below the reference point. Because of the strong aversion to what is evaluated as being below the reference standard, behavior that violates a normative standard is likely to be eliminated from consideration as an option.

The level of aspiration or expectation that operates as an evaluative standard for an actor is socially determined to a large degree. It is a "comparison level" learned from others whom the actor takes as referents. As a result of variation in the characteristics of actors, the social environments to which they are exposed, and the interaction between those two factors, the evaluative standards associated with values and norms vary across actors. Even among actors in the same social environment, the evaluative standard is specific to the actor, although there may be a high degree of consensus about it in a social group.

The evaluative standards associated with values and norms are subject to change in an individual actor. An important source of change is experience that affects the level of ability, knowledge, or accomplishment of an actor. For example, the evaluative standard for achievement values is affected by an actor's level of achievement. There is evidence that people tend to raise their value standards with success and lower them with failure. Thus, as a worker learns a job, that worker's ability to perform the job increases, as does the worker's evaluative standard. A level of ability that once was aspired to and evaluated as "extremely good" may, after increases in the worker's ability, come to be viewed as "mediocre" and below the worker's current evaluative standard for expected performance. Experience also may affect the evaluative standard for norms. For example, there is evidence that the experience of divorce changes normative beliefs about divorce in the direction of increasing its acceptability (Thornton 1985). Another source of change in the evaluative standards associated with the values and norms of an actor is an increase in knowledge of the world that alters

the existential beliefs connected with values and norms.

The evaluative standards associated with values and norms vary not only among actors and over time for the same actor but also with the characteristics of other actors whose behavior is the object of evaluation. These characteristics may differentiate among actors or among the circumstances of the same actor at different times. For example, the value standard used by an adult to evaluate a child's knowledge will vary for children who have completed different amounts of schooling, such as an elementary school student, a high school student, or a college student: The amount of knowledge evaluated as "very good" for an elementary school student will differ from that evaluated as "very good" for a student at a more advanced stage of schooling. Different value standards will be applied to different students and to the same student at different stages of schooling. Similarly, in a work organization, the value standard used to evaluate performance may vary for different categories of workers: Those with more experience may be evaluated according to a higher standard. Again, these different standards may be applied to different workers who are in different categories or to the same worker as he or she progresses from one category to another.

Like a value standard, a normative standard may vary with the characteristics of other actors whose behavior is an object of evaluation. However, there is a difference between a value and a norm in this regard. Because a value is a continuous variable, variation in the value standard with the characteristics of the other actors whose behavior is being evaluated need not have implications for whether the value applies to those actors. In contrast, because a norm is a discrete variable that differentiates what is acceptable from what is unacceptable, variation in the evaluative standard of a norm with the characteristics of other actors whose behavior is being evaluated determines whether the norm applies to other actors with particular characteristics. This variability—that is, variability in whether a value or norm *applies* based on the characteristics of the actors being evaluated—is a dimension of the importance of a value or norm and is labeled its conditionality.

Dimensions of Importance. It is commonly recognized that values and norms differ in their

priority, or importance, and that those differences are another aspect of the structure of values and norms. Differences in priority produce a structure that is to some degree hierarchical. Recognition that not all values are of equal importance has led to the use of ranking procedures to measure values (Allport et al. 1960; Rokeach 1973). These procedures have been criticized for forcing respondents to represent their values in a ranked order that does not allow for the possibility that some values may be of equal importance (Alwin and Krosnick 1985; Braithwaite and Law 1985). Although there is a hierarchy among values, there may be sets of values that occupy the same position in the hierarchy. The priority of a value or norm not only has implications for its influence on behavior but also may have implications for the probability that it will change, since values and norms of high priority have been argued to be less likely to change than are those of low priority.

The priority, or importance, of a value or norm can be assessed on a number of dimensions: (1) strength, or intensity, (2) centrality, (3) range, (4) conditionally, and (5) intent. Although these dimensions are conceptually different, they are likely to overlap empirically to a considerable degree. The extent to which and ways in which they overlap in reflecting the importance of a value or norm are not known.

Strength. The *strength* of a value or norm can be defined as the maximum strength of the force field it can induce. The strength of the valence reflects its hierarchical position in the latent map or blueprint that characterizes the structure of values and norms for a social system or an individual. Although the strength of a value or norm is likely to display considerable stability, it is also subject to change. At the level of the social system, it may change as a result of long-term changes in social organization and aspects of culture as well as precipitating events. As the social system changes, socializing influences on individuals change. Changes in the values and norms of individuals occur both over the life course (Glenn 1980; Alwin 1994) and as a result of differences between those who are born and move through life in different historical periods. The motivational force of a value at a particular time, however, is not necessarily the maximum strength of its latent force field, because attaining a valued outcome may reduce the subjective utility of additional units of that outcome as a

result of diminishing marginal utility, or satiation. In the case of either a value or a norm, whether one attains an outcome also may alter the maximum strength of its latent force field. For example, if attainment is problematic, the importance of a value or norm may decline as a way of reducing cognitive dissonance.

Centrality. The *centrality* of a value or norm can be defined as the number and variety of behaviors or ends to which it applies. Because a central value or norm contributes more than does a peripheral one to the coherent organization and functioning of the total system, the disappearance of a central value or norm would make a greater difference to the total system than would the disappearance of a peripheral value or norm. A central value or norm is more resistant to change than is a peripheral value or norm; however, if change occurs, the more central the value or norm changed, the more widespread its repercussions (Rokeach 1973, 1985).

For individuals and even for social groups, concern and responsibility for the well-being of others is a central value that pertains to a large number and variety of specific behaviors and ends. It is supported by a central proscriptive norm that one should not harm others and a central prescriptive norm that one should help others, particularly if they are in need. These norms pertain to a large number and variety of specific behaviors. In contrast, excitement and adventure are more peripheral values, affecting a smaller number and variety of specific behaviors and ends. In connection with these values, peripheral norms govern the carrying out of specific types of activities that may be sources of excitement and adventure, such as the rules governing sports and potentially dangerous recreational activities.

For individuals, life values that pertain to the overall ends, or goals, of life along with the norms that support them tend to be more central than are the values and norms that pertain to particular life domains or social roles. Part of the reason for this is that life values affect whether particular life domains or social roles are entered into and the amounts of time and energy a person spends in different domains and roles. They also affect an individual's domain- and role-specific values and norms. For example, life values include things such as attaining a high material standard of living, having meaningful family relationships and friend-

ships, making the world a better place, and having a good time. Life values of this type are among the factors that influence entry into various life domains and roles, the activities in those domains and roles, and how much investment is made in each one (e.g., marriage, parenthood, employment, friendships, leisure activities and hobbies, community activities, religion). Values and norms pertaining to each of the domains and roles are to some degree a function of overall life values. For example, if an individual places a higher priority on making the world a better place than on material well-being, that individual's employment values will place a higher priority on the possible influence and significance of the work performed than on the earnings derived from the work. Similarly, if an individual places a higher priority on meaningful relationships than on material well-being, marital values will place a higher priority on love and mutual respect than on the shared material standard of living.

Range. The *range* of a value or norm can be defined as the number and variety of actors of a particular type of object unit (e.g., individuals, organizations, and societies) to which it applies. Whereas the dimension of centrality focuses on the characteristics of action and its ends (i.e., the number and variety of behaviors or ends to which a value or norm applies), the dimension of range focuses on the characteristics of actors (i.e., the number and variety of individuals or larger social units to which a value or norm applies). The characteristics of actors used to define the range of a value or norm tend to be ascriptive or group-defining characteristics of individuals or larger social units. In the case of individuals, these are characteristics such as age, sex, nationality, race, and ethnicity. A value or norm with a broad range applies to all actors of a particular type of object unit, whereas a value or norm with a narrow range applies to a very restricted category of actors of that type. For example, concern about and responsibility for the well-being of others is a value with a broad range that applies universally to individuals throughout the world. In contrast, wisdom is a value with a narrower range because although it applies throughout the world, it applies primarily to people of older ages. Similarly, the norm against incest has a broad range because it applies universally to individuals throughout the world. In contrast, the norm prescribing paid employment has a

narrower range because it applies primarily to men in particular age categories.

Conditionality. The *conditionality* of a value or norm can be defined as the number and variety of situations to which it applies. Whereas the dimension of centrality focuses on the characteristics of action or its ends and the dimension of range focuses on the characteristics of actors, the dimension of conditionality focuses on the characteristics of situations, including a situation's actors. When conditionality pertains to the characteristics of a situation's actors, it usually refers to emergent or potentially changing characteristics of actors that define the situation rather than to ascriptive characteristics that define membership in social groups. Although values are less tied to specific types of situations than norms are, both values and norms vary in the degree to which they are conditioned on the characteristics of situations. For example, some values pertaining to modes of conduct, such as courtesy, cleanliness, and honesty, are applicable across most situations. Others are applicable in many fewer situations or may even be bipolar, with the polarity of the value being conditional on the situation. For example, aggressiveness is positively valued in some types of competitive situations, such as warfare and sports, but negatively valued in some types of cooperative situations, such as conversation and child rearing.

The conditionality of a value or norm is evident when a given subject actor who is evaluating a given type of action or end of action makes different evaluations in different types of situations, that is, when the evaluation varies with the characteristics of the situation. For example, friendliness is valued positively, but it is a value characterized by some conditionality, since it is valued negatively when exhibited toward strangers in dangerous environments. Killing other human beings is normatively proscribed in almost all situations, but the norm has some conditionality because killing is not proscribed in warfare, self-defense, capital punishment, and euthanasia. In capital punishment and some types of warfare, killing actually is proscribed. Abortion is believed by some people to be normatively proscribed, and whether it is normatively proscribed often depends on the characteristics of the situation, including how conception occurred, whether the mother's health is in danger, and whether the mother can care for

the child. Opposition to abortion is therefore a norm of higher conditionality than is the proscription against killing other human beings. The conditionality of a value or norm is defined by the number and variety of situations to which it applies *consistently*, that is, with the same polarity. A value or norm that has the same polarity across many and varied types of situations is a value or norm of low conditionality and therefore of high priority. A value or norm that has the same polarity in only a few similar types of situations is a value or norm of high conditionality and low priority.

Intent. Whether a value applies to a mode, means, or end of action has been labeled its intent (Kluckhohn 1951). Mode values pertain to the manner or style in which an action is carried out and refer to both the action and the actor. They pertain to qualities manifested *in* the act, and if such qualities are observed consistently over time for a type of action or for an actor, they are applied not just to a single instance of action but to a type of action or to an actor more generally. Adjectives such as “intelligent,” “independent,” “creative,” “responsible,” “kind,” and “generous” describe mode values. Instrumental values focus on necessary means to other ends. They refer to action that constitutes the means or from which the means are derived. For example, a job and the earnings it provides may be viewed as means to other ends such as acquiring the material resources necessary to sustain life. Goal values, in contrast, pertain to self-sufficient, or autonomous, ends of action. They are not subordinate to other values and are what an actor values most. Some analysts have argued that they can be defined as what an actor desires without limit. They focus on sources of intrinsic satisfaction or happiness but are distinguished from pleasures, which, except when elevated to become goal values, are satisfactions that are enjoyed incidentally and along the way. Pleasures are not necessarily based on beliefs about desirability, since they can be based on mere liking.

A norm may apply to a mode or means of action but not to an end of action. By requiring or prohibiting a way of acting or a type of action, norms limit the modes and means used in accomplishing ends. For example, the values of honesty and fairness govern modes and means of accomplishing ends, and associated with these values are norms that require honest and fair action.

Values and norms cannot always be identified as falling into a single category of intent. For some types of action, mode values and norms and instrumental or goal values and norms overlap; choosing an action as a means or to directly achieve an end actually defines the mode of action. For example, accomplishing a task by a means that shows concern for others defines a mode of acting that is kind, considerate, polite, and caring. Choosing to accomplish a task by honest means defines a mode of acting honestly. Acting to achieve an end that benefits others defines a mode of acting that is caring, giving, and generous. Mode values and norms and instrumental or goal values and norms do not always overlap, however. A given mode may be applied to a variety of means and ends, and choosing a means or acting to achieve an end does not necessarily imply or define a mode. For example, for modes that reflect ability or competence, as described by adjectives such as “intelligent,” “creative,” “efficient,” “courageous,” “organized,” and “self-reliant,” there may be no necessary connection or only a limited one between the values reflected in the mode and the values reflected in the acts undertaken as means or ends.

Differentiating between instrumental values and goal values is difficult because the two types are interdependent. Their relationship is not just one of sequence, since achieving particular ends may require the use of certain means (Kluckhohn 1951; Fallding 1965). Differentiating between instrumental values and goal values also requires reflection by the actor. An important concern of moral philosophy has been identifying the end or ends of action that ultimately bring satisfaction to human beings, that is, that have genuine, intrinsic value (Lovejoy 1950). The focus has been on identifying important goal values and distinguishing them from less important instrumental values. This means-end distinction is not as well developed in the category systems of all cultures as it is in Western culture (Kluckhohn 1951), and even among persons exposed to Western culture, it is not developed equally or similarly in all actors. Not all actors make the distinction or make it in the same way. What are instrumental values to some actors are goal values to others.

When mode, instrumental, and goal values are separable, they can all affect behavior. Sometimes they point to identical actions, and sometimes they do not. Similarly, when mode and

instrumental norms are separable, both can affect behavior. Among values that can pertain to either means or ends, the distinction between instrumental and goal values is a dimension of importance, with goal values being of higher priority than instrumental values (Fallding 1965; Braithwaite and Law 1985). However, values that can pertain only to a mode or means are not necessarily of lower priority than are values that can pertain to ends.

Interrelationships. Because social structure, as defined both organizationally and culturally, links sets of values and norms, there are patterned relationships among the sets of values and norms held by actors. These relationships can be seen as being influenced by conceptual domain, dimensions of importance, behavioral context, and interdependence.

Conceptual Domain. Values and norms that are conceptually similar are thought of as falling within the same conceptual domain, and a conceptual domain is identified by the observation of strong empirical relationships among sets of values or norms. Domains that are conceptually distinct also can have relationships to one another. Compatible domains are positively related, and contradictory domains are negatively related. Empirical research provides some evidence of the existence of conceptual domains of values and norms and the relationships among them. For example, in Western societies, a value domain emphasizing pleasure, comfort, and enjoyment has a negative relationship to a prosocial value domain that emphasizes concern and responsibility for others. Similarly, a value domain emphasizing the extrinsic attainment of power, money, and position has a negative relationship to the prosocial value domain (Schwartz and Bilsky 1987). Values appear to be organized along at least three broad dimensions: (1) emphasis on the self versus others, (2) emphasis on achievement versus pleasure, and (3) emphasis on the external versus the internal. Although there has been less research on the pattern of interrelationships among norms, evidence indicates that norms fall into conceptual domains. Norms pertaining to honesty, for example, are conceptually separable from norms pertaining to personal freedom in family matters, sexuality, and mortality.

Dimensions of Importance. Interrelationships among values and norms also are affected by dimensions of importance, since these dimensions

affect their application across object units, social institutions, social roles, and behavioral contexts. Dimensions of importance such as centrality, range, and conditionality are linked to variability in application across object units, social institutions, and social roles. Values and norms that have high importance because they are broadly applicable are more likely to be interrelated than are values and norms that have low importance, which apply more narrowly. Values and norms that apply narrowly are related to each other and to values and norms that apply more broadly only under the conditions in which they apply.

Behavioral Context. Interrelationships among values and norms are influenced not only by conceptual domains and dimensions of importance but also by the behavioral contexts to which they apply. Values and norms that are relevant to the same or related behavioral contexts tend to be interrelated. For example, the values and norms that play a role in interpersonal relationships differ in some respects from those which play a role in educational and occupational performance. The value of concern for others and the norms that support it are of high priority in interpersonal relationships but can be of low priority in the performance of educational and occupational tasks.

Interdependence. Socially structured or otherwise necessary links among modes, means, and ends of action are a source of interdependence among values and norms. Mode values and norms and instrumental or goal values and norms can overlap, and instrumental and goal values are interdependent when achieving particular ends requires the use of certain means. This interdependence constrains the extent to which the relative priority of values can affect action. For example, attaining a less highly valued means cannot be forgone to attain a more highly valued end if the end cannot be attained without the means.

THE ORIGIN OF VALUES AND NORMS

Multiple values and norms are organized and linked in the cultures of human social systems, which are linked when they are internalized by human actors or institutionalized by corporate actors. *Social* values and norms, in contrast to *personal*, or *internalized*, values and norms refer to the values and norms of a social unit that encompasses more than one person. These may refer to the officially stated

or otherwise institutionalized values and norms of an organization or society, or to the collective, or shared, values and norms of the individuals who constitute a social unit such as an informal reference group, a formal organization, a society, or a societal subgroup defined by a shared characteristic. When a social value or norm refers to a collective property of the members of a social unit, it may be held with varying degrees of consensus by those who constitute that unit (Rossi and Berk 1985). An important difference between formal organizations and informal social groups or geographically defined social units is that formal organizations usually come into being for a specific purpose and are dedicated to particular types of activity and to achieving particular ends. As a result, their objectives are both narrower and more varied than those of other social units.

The Social Origin of Personal Values and Norms. The values and norms of individual persons derive from the social environments to which they are exposed. Through socialization, individuals become aware of and internalize social values and norms, which then become important internal determinants of action. An individual's internalized values and norms reflect the values and norms of the society and the various subgroups and organizations within that society to which that individual is exposed, particularly, although not exclusively, in the early stages of the life course. Once social values and norms are internalized, they can direct the behavior of individuals irrespective of external influences. Internalized values and norms are a source of *self-expectations* and a basis of *self-evaluation*, with the subjective response to an outcome ensuing from the self-concept. Adherence to self-expectations enhances self-esteem, producing a sense of pride and other favorable self-evaluations. Violation of self-expectations reduces self-esteem, producing guilt, self-depreciation, and other negative self-evaluations. To preserve a sense of self-worth and avoid negative self-evaluations, individuals try to behave in accordance with their internalized values and norms. Sociologists tend to see internalized values and norms as an important influence on human behavior, and this makes them see the social values and norms of society as governing and constraining the choices individuals make. Social values and norms also affect behavior because they are internalized by significant others and thus affect an

actor's perception of other people's expectations. To the extent that actors are motivated to comply with what they perceive the views of others to be, social values and norms become a source of external pressure that exerts an influence that is independent of an individual's internalized values and norms.

Although change in personal values and norms occurs over the life course, there is some evidence that levels of stability are relatively high (Moss and Susman 1980; Sears 1983; Alwin 1994). It has been argued that values and norms that are more closely tied to the self-concept and considered more important are more resistant to change (Rokeach 1973; Glenn 1980). Those values and norms may undergo less change because they are internalized through conditioning-like processes that begin early in life and are strongly linked to existential beliefs. They tend to be tied to shared mental models that are used to construct reality and become embedded central elements of cognitive organization with a strong affective basis. Some types of values, norms, and attitudes (for example, political attitudes) are quite malleable into early adulthood and then become relatively stable. After this "impressionable," or "formative," period when change is greatest, they are relatively stable in midlife, and this stability either persists or declines in the later years (Alwin et al. 1991; Alwin 1994).

The pattern of life-course change and stability described above has been argued to be due to a number of influences. One is the process of biological and psychological maturation with age, which is most rapid in the early stages of life. As functional capacity develops, influences at that time have the advantage of primacy, and when they are consistent over a period of years, affective "mass" is built up. Nevertheless, some types of values, norms, and attitudes remain malleable into early adulthood, and strong pressure to change or weak earlier socialization can lead to resocialization in late adolescence or early adulthood (Sears 1981; Alwin et al. 1991). It is likely that change declines after early adulthood in part because individuals tend to act on previously formed values, norms, and attitudes as they seek new information and experiences. This selective structuring of new inputs enhances consistency over time, since new inputs tend to reinforce rather than call into question earlier ones.

Another influence on life-course change and stability in values and norms is change in social experiences and roles over the life course (Wells and Stryker 1988; Elder and Caspi 1990). These changes are extensive during the transitional years of early adulthood and may increase after retirement. They represent opportunities for change because they bring the individual into contact with new individuals, reference groups, and situations, and change in values and norms is likely to occur through both interaction with others and adaptation to situations. Role change can produce change as a role occupant engages in new behaviors, is exposed to new circumstances and information, and learns the norms governing role behavior. After early adulthood, a decline in the number of changes in social experiences and roles leads to greater stability in values and norms.

Sources of Change in Social Values and Norms. Change in social values and norms occurs through a variety of processes. One influence is historical change in the conditions of life that occurs through technological innovation, alterations in economic and social organization, and change in cultural ideas and forms. Historical change by definition involves “period effects,” but because those effects tend to be experienced differently by different birth cohorts (i.e., those at different ages when a historical change occurs), the influence of historical change on social values and norms occurs to some degree through a process of cohort succession.

Change in social values and norms also occurs through change in the social values and norms of subgroups of social units. This change can be of several types. First, change in the presence and size of subgroups with different values and norms produces change in the collective values and norms of the group. For example, the presence of new immigrant groups with different values and norms or a change in the relative size of groups with different values and norms affects the values and norms of the collective unit. Second, change in the degree of similarity or difference in the values and norms of subgroups can produce change in overall values and norms. On the one hand, acculturation through intergroup contact and similar experiences will reduce the distinctiveness of subcultural groups; on the other hand, segregation and increasing divergence in the life experiences of subgroups will widen their cultural distinctiveness.

Third, some subcultural groups may be more subject to particular period influences than others are, and this differential responsiveness can increase or decrease differences in values and norms among subgroups.

Another source of change in social values and norms is change in exposure to social organizations that exert distinct socializing influences. For example, exposure to religious, educational, or work organizations may produce differences in values and norms between those with such exposure and those without it. The extent to which exposure to different organizational environments is likely to affect personal values and norms depends on the distinctiveness of those environments, which also is subject to change. Thus, social values and norms are affected by both changes in the exposure of the population to different organizations and changes in what is socialized by those organizations.

THE ROLE OF VALUES AND NORMS IN EXPLAINING BEHAVIOR

The ways in which values and norms influence behavior must be understood in a larger explanatory framework, and models of purposive action in all the social sciences provide that framework (Marini 1992). These models rest on the assumption that actors are purposive, acting in ways that tend to produce beneficial results. Although the models of purposive action that have emerged in various social sciences differ in the nature of the assumptions made about purposive action, they share the basic proposition that people are motivated to achieve pleasure and avoid pain and that this motivation leads them to act in ways that, at least within the limits of the information they possess and their ability to predict the future, can be expected to yield greater reward than cost. If reward and cost are defined subjectively and individuals are assumed to act in the service of subjective goals, this proposition links subjective utility, or value, to action. In sociology, a model of purposive action assumes the existence of actors who may be either persons or corporate actors. The usefulness of these models in sociology hinges on making appropriate connections between the characteristics of social systems and the behavior of actors (the macro–micro connection) and between

the behavior of actors and the systemic outcomes that emerge from the combined actions of multiple actors (the micro–macro connection).

In a model of purposive action, an individual actor (person or corporate actor) is assumed to make choices among alternative actions structured by the social system. Choices among those actions are based on the outcomes expected to ensue from those actions, to which the actor attaches some utility, or value, and which the actor expects with some probability. The choices of the actor are governed by beliefs of three types: (1) the perceived alternatives for action available, (2) the perceived consequences expected to result from each alternative, and (3) the perceived probabilities with which those consequences are expected to result. The choices of the actor also are governed by the actor's preferences, or the subjective utility (rewards and costs) of the consequences expected to result from each alternative. Values and norms are among the preferences of an actor that influence action. As evaluative beliefs that synthesize affective and cognitive elements, they affect the utility of the outcomes expected to ensue from an action. Action often results not from a conscious weighing of the expected future benefits of alternatives but from a less deliberate response to internalized or institutionalized values and norms (Emerson 1987). The actor's finite resources—the human, cultural, social, and material capital available to the actor that enables or precludes action—operate as influences on the choices made by the actor.

The component of a model of purposive action that makes the macro–micro connection links the characteristics of the social system to the behavior of actors and models the effects of social structure (both organizational and cultural) on the beliefs and preferences of actors as well as on the available alternatives for action and actors' resources. In this component of the model, characteristics of the micro model are taken as problematic and to be explained. These characteristics include: (1) the beliefs and preferences on the basis of which an actor makes choices, (2) the alternatives available to an actor, and (3) the resources available to an actor. A third component of a model of purposive action makes the micro–macro connection, linking the behavior of individual actors to the systemic outcomes that emerge

from the combined actions of multiple actors. This link may occur through a simple mechanism such as aggregation, but it is more likely that outcomes emerge through a complex interaction in which the whole is not just the sum of its parts. The action, or behavior, of the system is usually an emergent consequence of the interdependent actions of the actors that compose it.

MARGARET MOONEY MARINI

SOCIAL WORK

Social work has been defined as being "concerned with the interactions between people and their social environment which affect the ability of people to accomplish life tasks, alleviate distress, and realize their aspirations and values. The purpose of social work therefore is to (1) enhance the problem-solving and coping capacities of people, (2) link people with systems that provide them with resources, services, and opportunities, (3) promote the effective and humane operation of these systems, and (4) contribute to the development and improvement of social policy" (Pincus and Minahan 1973, p. 9). A key difference between social work and sociology lies in the emphasis placed on intervention in social work. A social worker expects to be actively involved in the amelioration of social problems, while a sociologist typically focuses on understanding the nature and extent of social issues. Social workers establish a helping relationship with a client system (individual, family, small group, community), using their assessment skills and knowledge of helping resources to identify alternatives that may improve a situation.

PROFESSIONAL ROOTS

Professional social work is historically tied to the emergence of social welfare as a social institution. Social welfare as it has come to be known, can be traced to society's numerous attempts to accommodate changes in economic and social relationships over time. The beginning of institutionalized social welfare is frequently ascribed to the English Poor Law of 1601. As the most critical part of modern social welfare's foundation, the Elizabethan poor laws were characterized by the articulation and promulgation of the principle of public responsibility and obligation for the economic well-being of the people. However, "the Poor Laws in England and in American communities were not primarily concerned with poverty and how to eliminate it. Instead, they were concerned with pauperism and the potential claims on community

funds, the danger that paupers might get by without working” (Dolgoff and Feldstein 1984, p. 80). This continuing tension between public obligation and social control is one of several dualities that characterize the context of professional social work practice. Institutionalized social welfare is the environment in which the profession of social work has developed. The history of social welfare is paralleled by and enmeshed with the increasing professionalism of those who administer social welfare programs.

Early social work was characterized by two streams of activity: social reform and direct assistance to individuals and families. The practice of friendly visiting and the development of both the Charity Organizations Societies and settlement houses illustrate both types of effort. Representatives of Charity Organization Societies, the so-called friendly visitors, engaged in social investigation and moral susasion improve the lives of the poor. The thrust of those encounters was to place responsibility on the persons or families for their economic and social status, what is known now as “blaming the victim.” The work of the Charity Organization Societies formed the origins of the social work method later known as social casework.

Residents of settlement houses, Jane Adams included, were friendly visitors who came to stay. A group of middle-class or upper-class individuals moved into residence in a poor area in an effort to study neighborhood conditions firsthand and work with neighborhood residents on solving neighborhood problems. While some settlement house efforts focused on assimilation, later programs focused on improving conditions in immigrant communities. In cities across the nation, settlement houses helped acculturate vast numbers of immigrants in the early part of the twentieth century. Settlement house activities emphasized teaching English, health practices, occupational skills, and environmental changes through cooperative efforts. Settlement house staff developed social group work, community organization, social action, and environmental change efforts. Furthermore, settlement house workers were active in the legislative arena, gathering and promulgating facts in order to influence social policy and legislation.

An early and continuing cleavage in the profession has its origins in differing explanations of social dysfunction. Some early social workers es-

poused the theory of the social causation of social problems and sought governmental actions to meet needs as well as developing coalitions for reform and institutional change. The educational foundation came from sociology, economics, and political science. Others emphasized individual causation of social problems, promoting an individually focused therapeutic approach to helping. These social workers identified the need to draw on psychological theory but emphasized the individual interacting with a social environment. These two primary orientations would feed the development of professional social work and provide the basis for conflict within the practice community and in professional social work education

PROFESSIONALIZATION

An issue throughout the development of professional social work has been the nature of its professional status. In 1915 Abraham Flexner critiqued the professional status of social work at the National Conference of Charities and Corrections. Although Flexner criticized social work as lacking a specific skill for a specific function, he also recognized its professional spirit. The ideal-type model of a profession has been the conception against which social work has measured itself through much of its history. Greenwood’s (1957) analysis examined the extent to which social work possessed five classic traits of a profession: systematic theory, authority, community sanction, an ethical code, and a professional culture. Characterizing social work as a less-developed profession, Greenwood concluded that it possessed these attributes to a moderate extent. The predominant direction of the field, however, has been to continue its professional development along all five dimensions. The recent emphasis on building the empirical base of practice coupled with more stringent licensure requirements by states are indicators of the continued progression of social work toward greater professional status. It would be incorrect to assume, however, that this direction is embraced by the profession as a whole. For those whose dominant professional identification is with the field’s social action tradition, increasing professionalization means being co-opted. Achieving the public acceptance accorded to a profession can distance social workers from their constituencies and limit confrontational strategies that are central to advocacy for the oppressed.

In the 1920s the practice of social work emerged in so-called fields of practice or settings: family and child welfare and medical, psychiatric, and school social work. Social workers defined their central problems and responsibilities as being characteristic of their particular fields. The concept of method also emerged during this period. Method developed first around casework and later in relation to both group work and community organization. Methods were based on selected theories of human behavior drawn from psychology and sociology. Setting referred to the organizational context within which services were delivered.

This combination of method and field of practice or setting fragmented professional social work, slowing the development of an integrated theoretical base for practice across methods and settings. Social casework theory and method developed to a large extent in isolation from group work and community organization. The curricula for professional social work education followed the same pattern, with separate tracks for each method. It took until the 1970s for the development of a conceptual approach based on the essential components of professional practice regardless of where a social worker was employed. Pincus and Minahan (1970) articulated a conceptual framework for generalist practice, that is, for social work service delivery across practice settings. This approach encompassed three major components: the *social systems* in relation to which a social worker carries out his or her role, the stages of *planned change* or problem-solving processes, and interactional and analytic *skills* for data collection, analysis, and intervention.

VALUES, ETHICS, AND THE BUREAUCRATIC CONTEXT

Since social work as a profession is concerned with social change and the improvement of the conditions in which people live, its orientation cannot be value-free or purely theoretical. A defining characteristic of social work practice is a fundamental commitment to knowledge, skills, and a core set of professional values to enhance the well-being of people and ameliorate environmental conditions that affect people adversely. Among the values and principles that guide professional practice are respect for individual worth, dignity, the right to self-determination, and active partici-

pation in the helping process; helping clients obtain needed resources; demonstrating respect for and acceptance of the characteristics of diverse populations; a commitment to the promotion of social change to achieve social and economic justice; an understanding of the dynamics of oppression and discrimination, along with attention to populations at risk; and a holistic view of the interactions between people and the complex environment in which they live. These values are embedded in the *Code of Ethics* of the National Association of Social Workers (1994). The code focuses on the conduct and comportment of a social worker as well as ethical responsibilities to clients, colleagues, employers, the profession, and society.

A distinguishing characteristic of social work is that the majority of its practitioners are employed by a variety of public and private social welfare agencies. Some social workers are employed by agencies that are sanctioned to function as agents of social control, while others have the authority to determine eligibility for benefits and services. The bureaucratic environment, however manifested, dramatically shapes the practice of social workers. The process of professional socialization is designed to instill a culture, a set of values and expectations, that may conflict with the work environment.

Professionals' autonomy can be circumscribed by organizational commitments, policies, and procedures. In these circumstances, just whose agent is the professional social worker: the agency's, the client's, the community's, or his or her own as an autonomous professional? In an organizational context, what form can a social worker's social action efforts take? How far can an employed social worker go in challenging an agency's priorities, policies, and procedures before his or her services are no longer desired? How long does it take before a professional social worker starts to identify more as an agency employee than as an autonomous professional? Given the range of practice settings and the variety of roles of social workers, there are no easy answers to these questions. These realities can produce a conservatizing effect on social work, limiting many workers' willingness or ability to take risks as autonomous professionals in the name of social justice and reform. In these circumstances, one can see how theories of individual causation can prevail over

explanations that invoke the influence of larger social forces in the creation and amelioration of social problems. This tension, with its roots in the origins of the profession, continues, as demonstrated by the overwhelming preference of students and professionals for work with individuals and families, mostly in the psychotherapeutic model.

THE KNOWLEDGE BASE AND EMPIRICALLY BASED PRACTICE

The creation of a systematic body of theory has been under development from the early days of the profession. Richmond's *Social Diagnosis* (1917) organized the contemporary theory and method of social work and formulated a data collection approach designed to serve as the foundation for diagnosis. Richmond organized and analyzed the naturalistic observations she made while working with individuals and families. Her work is the origin of psychosocial history taking and treatment plan development and perhaps the core of social casework practice methods. Richmond's contribution to the organization of what eventually would become social casework practice is legendary, forming the bedrock of clinical social work. Her approach, later to be known as empirically based practice, represents one of the two major streams of knowledge and theory development in social work. The other major focus has relied heavily on the application of social science (primarily sociological and psychological) theory to the explanation of social problems and the development of interventions to ameliorate those problems.

The breadth of social work practice (encompassing work with individuals, families, groups, and communities and including social work program administration, public policy development, and social planning) provides a rich and continually changing field for exploratory, descriptive, and explanatory empirical efforts. The early 1970s was a benchmark in the development of the profession's knowledge base. Along with the massive investment in social programs of the 1960s came the realization that good intentions and humane values are not enough. Funders focused increasingly on outcomes. Attention was shifted to the development of empirically based justifications for programs, services, and budgets. Program evaluation became the dominant focus of much of

social work research during this period, including methodology, design, outcomes, and professional accountability. This direction came to be known as the practice effectiveness movement. As articulated by Fischer, the question became, "Is Case-work Effective?" (Fischer 1973; Fischer and Hudson 1976).

During this period, a study of the effects of adult protective services by Blenkner et al. (1971) at the Benjamin Rose Institute in Cleveland created a furor. An early social experiment, this demonstration program, which employed skilled caseworkers, was reported to be associated with more negative effects than was the control program, which employed less highly trained workers. After one year, the findings were alarming. The experimental group manifested higher death rates, higher utilization of protective services, higher rates of institutionalization, a nonsignificant increase in contentment, and a nonsignificant decrease in symptoms of emotional disturbance. The authors concluded that the "effect of more skilled social workers on the clients was to 'overdose' them with help. This led to more concrete assistance, including institutionalization, which in turn was responsible for the higher death rate. . . . More highly trained social workers were apparently more lethal" (Tobin 1978). These findings could not demonstrate the effectiveness of professional social work intervention, illustrate accountability, or be used to justify program expenditures.

This study and the controversy it generated shifted attention from program description to research design, sampling, and data analysis. Investigators (Berger and Piliavin 1976; Fischer and Hudson 1976) reanalyzed the data in an attempt to discover alternative explanations for the findings. Berger and Piliavin argued that although randomization had been used to assign clients to groups, the experimental group was older and more mentally and physically impaired than were the controls. Fischer and Hudson (1976) challenged the sample size used in Berger and Piliavin's regression analysis and demonstrated that age, mental status, and physical status, although separate variables, produced an additive effect. The nature of the debate had shifted: Methodological issues had become the basis of discussion. Values and good intentions alone would no longer be sufficient grounds for justifying programs or demonstrating professional accountability.

THE PRACTITIONER-RESEARCHER

Concern with the outcomes of social work interventions led to the concept of the social worker as both practitioner and researcher. From this perspective, social workers are seen as having the opportunity and responsibility to develop methods and skills from an empirical base, from the experience provided in their own practice to develop, test, and refine practice innovations. Embedded in this movement toward practitioner-based empirical practice was the notion that evaluation and research were too critical to leave in the hands of a group of research “specialists.” Perhaps more fundamental is the belief that social work research is too important to leave in the hands of those who are not social workers: “It is the practicing professional who encounters and struggles with current issues and who is most sensitive to the critical knowledge gaps in the field. Thus social workers are in the best position to formulate and conduct the needed research and evaluation and they must be committed to acquiring the understanding required to direct the helping effort” (Grinnell 1996, p. 5)

These developments coincided with the expansion of doctoral education in social work. While past doctoral preparation often focused on the development of advanced clinical skills, contemporary training at the doctoral level is almost exclusively research-based, designed to provide students with the skills needed to contribute to the empirically anchored knowledge base of the profession. As a result, a cohort of social work researchers has been trained over the last twenty years, and this group has developed a body of theory and knowledge that has been generated directly as social work research. Social work no longer defers to sociology for the methodological sophistication to evaluate its programs and practice outcomes.

SOCIOLOGY AND SOCIAL WORK

Over time the link between social work and sociology has been strong, although the two fields have grown increasingly distant. There can be little doubt, however, regarding the importance of sociological theory and research for the development of the knowledge and theoretical base of social work practice. For example, social stratification, conflict theory, deviance, organizational

theory, community development and dynamics, family studies, occupational sociology, criminology, and life-span theories are only a few areas of sociological theory development and research that have informed and directly influenced both the theory and the practice of social work. Landmark social program evaluation studies were undertaken by sociologists, some of whom were members of faculties of social work, in the late 1950s and 1960s (Meyer and Borgatta 1959; Meyer et al. 1965).

Clearly, social work and sociology are related, although there are fundamental differences. Sociologists study and analyze social organizations and institutions. The emphasis has been on theory development, primarily through positivistic approaches, focusing on measurement and design issues. Although the development of grounded theory (Glaser and Strauss 1967) has been a major conceptual contribution in sociology, it has not been the dominant influence. Although there are reform-minded, “radical” sociologists, they are a minority. Sociologists are interested in understanding the “why” of human interaction. Sociology observes; it maintains a detached posture.

In contrast, social workers attempt to apply theories of social organization and interaction to improve social functioning. Social workers go beyond understanding social problems in their efforts to improve social functioning; social work intervenes. The goal is engendering progressive social change, improving social conditions, creating more humane delivery systems, and problem solving with individuals, families, groups, communities, and organizations and in public policy. Social workers develop and implement interventions in the form of programs, policies, and services in the context of public funding and demands for professional accountability. The orientation is toward outcomes, cost-effectiveness, and cost-benefit analyses.

There has been and continues to be tension in the relationship. Heraud notes that “the social worker may be able to participate actively in policy making through social science research; there is considerable need for research related to both intended and unintended consequences of social policy . . . there is considerable need in the initial stages of such research for intuition and speculation. Instead of only using the sociologist at this stage, who may be a distant figure, the social

worker may have an important role to play" (1970, p. 287). Several years earlier, Halmos noted that social workers could function "as an intelligence agent of the sociologist and of the policy maker, and a trusty pilot of the sociological researcher" (1961, p. 9). Although these attitudes may be antiquated, elements of such elitism remain, particularly in sociology's limited interest in applied social research.

Some attention has been paid to the development of so-called applied sociology. While the main body of sociological thought focuses on exploratory, descriptive, and explanatory theory; modeling; and empirical testing, "applied sociology" briefly emerged in response to the increasing interest in social program evaluation and the limited supply of trained methodologists who could design and execute well-formulated evaluative studies. Thus, applied sociology could provide an alternative, public-policy-oriented career path for sociologists, since the preferred, higher-status university-based employment opportunities were limited.

Over the last twenty five years, however, social work researchers have become key players in the design, implementation, and analysis of applied social research, particularly through their involvement in federally funded demonstration projects. During this period, there has been a proliferation of journals of social work, including research journals (*Social Work Research and Abstracts, Research on Social Work Practice*), as well as a range of specialty journals (*Gerontological Social Work, Health and Social Work, Child Welfare, School Social Work*), which provide publication outlets for researchers and practitioners.

At one time, social work education occurred within the social sciences, frequently attached to sociology. More recently, social work has emerged as an independent professional discipline, forming alliances with a variety of other professions, such as law, education, business, and nursing. Increasing numbers of pragmatic students have been attracted to social work because of the ability of graduates to find employment.

The undergraduate degree (BSW) offers a generalist foundation that is built on a set of social science prerequisites. The graduate degree (MSW), the terminal educational degree for the profession, is based on specialized courses that offer advanced theoretical content in fields of practice

and methodological approaches. The Council on Social Work Education (CSWE) has exercised a substantial influence in setting standards for social work education. Periodic accreditation reviews by the council assure uniformity and consistency in the required content. Particular attention has been paid to including content on minorities and oppressed populations. Accreditation by the CSWE is essential for the credibility of any social work education program in the United States.

Social work is an evolving profession, with its form and emphasis changing in response to the societal context within which social workers practice:

"Most social workers feel that although there are critical problems and pressures, numerous opportunities are available for the social work profession to move ahead on a sound basis, strengthening current delivery of services and innovating services that have been practically untouched to date. . . . Once thought of as a basket-on-the arm assistance for the poor, it is now a discipline, scientific in method and artful in manner, that takes remedial action on problems in several areas of society"
(Skidmore et al. 1997 pp. 376 to 3).

SOCIALISM AND COMMUNISM

What is socialism? According to a Hungarian joke made during the "gentle revolution" of 1989, it is the "longest and most painful road from capitalism to capitalism" (Garton Ash 1990). Although this biting definition was fashionably cynical about Soviet-type societies in the wake of their fall, it provides no substantive insights into one of the major social organizational forms of modern history.

The origins of socialism are obscure. Intellectual historians have traced its beginnings to the religious utopias of the Old Testament (Laidler 1968), the principles of Mosaic law (Gray 1963), the anti-individualism of the radical sects that emerged after the French Revolution (Lichtheim

1969), and the publication of the *Communist Manifesto* (Sweezy 1983). As well as can be determined, the term made its first appearance in Italian print in 1803, although its meaning at that time differed somewhat from the current interpretations (Cole 1959). For this reason, the origin of the term usually is attributed to the *London Co-Operative Magazine*, where it was used to designate followers of Robert Owen (Nuti 1981). The first French usage followed shortly thereafter when, in 1832, a French periodical, *Le Globe*, used it to characterize the writings of Saint-Simon (Bell 1968; Kolakowski 1978).

Despite its complicated origins, by 1840 the concept was used commonly throughout Europe and was making its way across the Atlantic to the United States. By the early 1920s, the Soviet Union had already claimed "socialism" as its overall organizing principle; ironically, at that time, over 260 definitions of the term were available in the social scientific literature (Griffith 1924), rendering its meaning somewhat ambiguous. Since then, further transformations of the concept have appeared; for instance, scholars now differentiate among Chinese socialism, corporatist socialism, democratic socialism, radical socialism, and Russian socialism.

The common core of socialist ideas is hard to define. To be sure, all socialists were critical of the competitive and unequal nature of capitalist society, and without fail, they championed a more egalitarian and just future. At the same time, their visions of the organization of a socialist future were sufficiently diverse to render a single definition of the term practically impossible. It is frequently assumed, for example, that all socialists wanted to establish communal ownership, yet many were content with the centralization of resources in the hands of the state (e.g., Bernstein 1961) and others actually protested the abolition of private property (e.g., Saint-Simon 1964). Battles also were waged over the role of the state: Some believed that centrally managed administrative organs would become superfluous under a socialist regime (Proudhon 1966), while others regarded those organs as essential for the management of community affairs (e.g., Cabet 1975). Many argued that the freedom of the individual must be guaranteed at all costs even under socialism (e.g., Fourier 1971), while others were willing to impose limitations on such freedom in the name of equality and

efficient production (Mao 1971). Finally, some believed that socialism could be realized through gradual reforms (Bernstein 1961), while others thought that it was possible only through a major revolution (Lenin 1971).

Because of the nontrivial nature of these differences, a single definition of socialism is likely to conceal more than it illuminates. For this reason, it is more productive to highlight features of the concept by examining separately some of the best known schools of socialist thought.

THE IDEA OF SOCIALISM

In the view of utopian socialists, socialism was a romantic vision whose purpose was not necessarily to be realized but to serve as an ideal against which the evils of capitalism could be compared. The specific content of this vision varied from author to author, but two central themes can be identified.

The ideal of community was the first of those themes. From Fourier to Cabet, through Owen and Saint-Simon, all utopian theorists championed a new social order organized around small communities. In most sketches of socialism, this vision was realized in an agrarian setting (e.g., Cabet 1975), although some required advanced industrial development (e.g., Saint-Simon 1964). In either case, however, it was assumed that those communities would be based on fellowship, harmony, and altruism—virtues that utopian theorists favored on moral grounds over bourgeois individualism.

Nostalgia for the past is the second common theme in utopian socialist thought. It frequently appeared in utopian novels and usually assumed one of two forms. In some versions, the protagonists in those novels were returned to a romanticized preindustrialism, while in others, they returned to an even more distant past, such as the Middle Ages (e.g., Morris 1970). Despite such variation in the settings of those novels, the message they sought to convey was more or less the same: In the transition to industrial capitalism, people abandoned the “golden age” of social harmony and replaced it with a fragmented and competitive social order that is unable to provide for the full satisfaction of human needs.

In the hands of scientific socialists, the idea of socialism represented more than just an attractive

dream (Marx and Engels 1968). Karl Marx, for example, considered it a historically possible future for capitalism, as he assumed that the internal contradictions of capitalism would create some of the preconditions for socialism. According to his theory of historical materialism, the demands made by capitalist development will create increasingly grave crises for the ruling class. He maintained that with the mechanization of production and the concentration of capital in the hands of a few, there will be greater polarization in terms of class inequalities and an increase in the degree of exploitation of the working class. As capitalism enters its advanced stage, the condition of the working class will deteriorate and the struggle over the quality of its existence will intensify. At first, the war between the “two hostile camps” of capitalist society (the bourgeoisie and the proletariat) will be waged within the boundaries of particular nation-states. However, as capitalism expands into new markets internationally, workers across the world will be forced to unite in their effort to overthrow capitalist society. Socialism, according to Marx, will emerge out of this final instance of class struggle.

It is ironic that the “father of socialism” never provided a detailed blueprint for his model of the future. It is evident from a number of passages, however, that Marx envisioned two stages in the evolution of socialism. In the lower stage (which he referred to as *socialism*, or the “dictatorship of the proletariat”), he foreshadowed major improvements in the human condition. He predicted, for example, that private property would be abolished, the forces of production would be nationalized and placed in the hands of the state, rights of inheritance would be eliminated, universal suffrage would be introduced, state representatives would be elected from among the working people, and education would become accessible to all. At the same time, because Marx expected this to be a transitional stage, he believed that some elements of capitalist society would continue to prevail. Specifically, he mentioned that income inequalities would continue to exist in the lower stage because workers would still be paid according to the amount of work they contributed to the social good.

At some point, according to Marx, this transitional phase in the development of human history would evolve into the higher stage of socialism, a

stage that he often referred to as *communism*, or the “realm of freedom.” Under communism, work would no longer be an obligation but a free and creative activity, alienation would be transcended, the production process would be under the direct control of the producers, and rewards would be distributed in accordance with the principle of “to each according to his need” rather than “to each according to his ability.”

Scientific socialism gained considerable popularity among French, German, and British socialists during the nineteenth century. Many agreed with Marx’s assessment of bourgeois society and were attracted to his vision of the future. As the century progressed, however, and the Marxist scenario still appeared to be far away, some began to raise questions about the continued relevance of scientific socialism in the modern age. The main protagonist in this debate was Eduard Bernstein, a leading advocate of democratic socialism.

Bernstein and his followers called into question various elements of scientific socialism, but they were especially concerned about Marx’s predictions concerning the development of industrial capitalism. On the basis of new empirical evidence, Bernstein (1961) noted that the standard of living at the turn of the century was improving rather than deteriorating, class inequalities were far from polarized, and the ownership of capital, rather than being concentrated in the hands of a few, was becoming diversified. In addition, he observed that general strikes were becoming less common and socialist parties were gaining considerable strength in the political organization of the state. In light of those findings, Bernstein called for a revision of the Marxist program and offered a new interpretation of socialism.

According to Bernstein, democracy was the most important feature of socialist society. He discouraged his confederates from describing socialism as a “dictatorship of the proletariat” and recommended that they acknowledge its fundamentally pluralist character. Of course, for Bernstein, the significance of democracy was not simply that it guaranteed the representation of minority rights under socialism; it was also that it assured a peaceful transition from capitalism through a series of parliamentary reforms. For many later socialists, this emphasis on reform came to represent the essence of democratic socialism; it was this

idea, in fact, that earned the “revisionist” label for this school of socialist thought.

Needless to say, Bernstein was not the only theorist to revise Marx’s ideas on socialism. In the early part of the twentieth century, Vladimir Ilyich Lenin (1971) also amended the concept by adding to it several new notions, some of which were derived from his experience with political organization in tsarist Russia. Taken together, these propositions constitute Russian socialism, also known as Bolshevik theory.

The best known contribution of this school of thought to socialist theory is the idea of the “vanguard party.” According to Lenin, Marx was unduly optimistic in his belief that the proletariat could develop the necessary class consciousness to overthrow capitalism. If left to their own devices, Lenin claimed, workers would defend only their immediate (i.e., economic or trade union) interests and would not know how to translate them into revolutionary action. To assist them in this task, he suggested that a vanguard party of intellectuals must be formed, the task of which would be to develop a revolutionary theory, “go among the masses,” and politically educate the proletariat. From the point of view of Bolshevik theory, therefore, the success of the socialist revolution depends not on the political maturity of the working class but on the strength of the vanguard party.

A second feature of Russian socialism that sets it apart from the Marxist scheme is grounded in its claim that the prospects of a proletarian revolution can arise not only in advanced industrial societies but also in precapitalist economic formations. Given the importance of the vanguard party in Lenin’s version of socialism, this idea makes perfect sense: As long as a country is equipped with a group of willing, dedicated, and professional revolutionaries, it should be able to make the transition to socialism without the benefits of advanced technology or without having passed through the capitalist stage.

Last but not least, Lenin took from Marx the idea that socialism will come in two stages. In terms of his scheme, however, the lower stage (the “dictatorship of the proletariat”) would not be a brief transitional period but would require a whole epoch in human history. During this time, the bourgeois state would be “smashed,” the class rule of the proletariat would be institutionalized, and

opponents of the socialist regime would be suppressed by the “special coercive force” of the proletarian state. The higher state of socialism (“communism”) would be realized once the socialist state had “withered away” and democracy had become a “force of habit.”

Russian socialism constitutes one of many indigenous graftings of the socialist vision. Another well-known attempt in this direction was made by Mao Zedong (1971), who accommodated the idea of socialism to the conditions of a peasant country. Those revisions led to the emergence of what is known as Chinese socialism or Maoism.

Unlike most interpretations of socialism, Mao’s is famous for its glorification of the peasantry. Earlier socialists, among them Marx and Lenin, were skeptical about the revolutionary potential of agricultural laborers. For the most part, they regarded them as inherently petty bourgeois and, consequently, as unlikely allies of the proletariat. Mao argued, however, that in a peasant country such as China, traditionally conceived paths to socialism are not viable because they require the mass mobilization of something that his type of country does not have: an industrial proletariat. He insisted therefore that the socialist revolution in China was a peasant revolution and had no reservations about organizing agricultural workers into a revolutionary force.

Another trademark of Chinese socialism is its lack of confidence in the guaranteed future of socialism. According to Mao’s writings, socialist victories are not everlasting; even as the dust from the revolution begins to settle, old inequalities can resurface and new ones may emerge. For this reason, the work of revolutionaries is never complete: They must be constantly on guard against opposition and be prepared to wage a permanent revolution.

THE REALITY OF SOCIALISM

During the nineteenth century, a number of communities were established to attempt the realization of the socialist vision, including Etienne Cabet’s Icaria in Illinois, Charles Fourier’s Brook Farm in Massachusetts, William Lane’s New Australia in Paraguay, and Robert Owen’s New Harmony in Indiana. In nearly all these cases, an attempt was made to isolate a small group of dedicated social-

ists from the rest of society and create a model environment for efficient production and egalitarian social exchange. The documented history of these communities suggests that they experienced varying amounts of success (Ross 1935). Some attracted a large number of followers (e.g., Icaria) and prospered for more than a decade (e.g., Brook Farm). Others were fraught with hardships from the beginning (e.g., New Australia), and some collapsed within a few years (e.g., New Harmony). In the end, however, all the utopian experiments failed: They suffered from lack of preparation and meager financial support, harsh living environments and a dearth of agricultural skills, heterogeneous membership, and a lack of long-term commitment to the socialist vision. The individuals who flocked to those communities were sufficiently adventuresome to embark on a project to build a new world but were not prepared for the trials of pioneering.

Experiments with socialism in the twentieth century were more successful and longer-lasting than their utopian counterparts. After the Russian Revolution, 1917–1923, the Soviet Union was the first country to call itself socialist. By the middle of the century, however, there were regimes in Europe, Asia, Latin America, Africa, and the Near East modeling themselves after the Soviet scheme (Hollander 1983). At the risk of oversimplifying, the following traits may be identified as the most important features of those “actually existing” (Bahro 1978) socialist societies: (1) They were characterized by a common ownership of the means of production and distribution. (2) Their economic activities were centrally planned by the state, and market forces played little or no role in the allocation of their resources. (3) One party ruled their political life and legitimated itself by reference to some version of Marxism and Leninism. (4) That party dominated their political culture with a unitary ideology and directed all their executive, legislative, and judiciary powers.

In their purest form, Soviet-type societies have secured a number of major achievements. Within decades of the revolution, they industrialized their outmoded economies (Berend and Ránki 1974), guaranteed full employment and attained price stability (Nove 1989), incorporated women into the labor force (Rueschemeyer and Szelényi 1989), developed their natural resources and advanced science and technology (Nutti 1981), strengthened

their military power (Starr 1988), and improved their educational, health care, and welfare systems (Ferge 1979). Along with those changes, socialist societies made a strong commitment to reducing income, educational, and occupational differentials after World War II (Szelényi 1998). Empirically, a number of studies have shown that those formally egalitarian policies have had impressive results: In nearly all these countries, inequalities in income have decreased (Matthews 1972; Walder 1989), educational opportunities have expanded (Lane 1976), and distinctions of prestige between manual and nonmanual occupations have narrowed (Parkin 1971; Giddens 1973). Policies also were implemented by socialist states to reduce the intergenerational transmission of social inequalities: Inheritance of wealth was eliminated, and quotas were imposed on educational and occupational recruitment to favor children from the working class and from peasant families (Simkus and Andorka 1982; Szelényi and Aschaffenburg 1993). Perhaps in part as a result of these changes, socialist societies carved out for themselves a position of considerable importance in the world system in the twentieth century. In the 1960s, for example, the Soviet Union competed directly with the United States in space exploration, the race for military power, and the development of science, technology, athletics, and the arts.

The economic and social miracles achieved by these countries in the years after World War II could not be sustained, however. By the early 1970s, centrally managed economies began to exhibit multiple signs of strain. Bureaucratic blunders on the part of state officials resulted in poor investment decisions (Nove 1983b), frequent bottlenecks created breakdowns in production (Bauer 1978), chronic shortages of consumer items provoked anger and dissatisfaction among the citizens (Kornai 1986), and curious managerial techniques (in the form of bribing, hoarding, and informal networking) had to be developed to mitigate the ineffective relationship between economic units and the state (Stark 1986).

Problems with central management, of course, were not restricted to the economic sphere. With a growing number of empirical studies during the 1970s (see Hollander 1983), the social and political consequences of Soviet-type planning became evident, although most scholars continued to be impressed by the initially positive outcome of

egalitarian state policies in socialist societies. At the same time, they soon began to realize that the quotas introduced after World War II were often applied inconsistently and in almost all circumstances disturbingly short-lived (Szelényi 1998). It is clear from these studies that the initial attempts to “build socialism” soon were overturned by a “second stage” in socialist development (Kelley and Klein 1986) that was marked by the crystallization of inequalities and the emergence of new privileges (Ossowski 1963; Nove 1983a). By the 1970s, many of those societies began to demonstrate substantial inequalities in their prestige hierarchies (Inkeles 1966), patterns of social mobility (Connor 1979), opportunities for educational attainment (Simkus and Andorka 1982), and distribution of monetary and nonmonetary rewards (Szelényi 1976; Walder 1986).

The political inequalities that characterized Soviet-type societies during their heyday are well documented in the literature. Many studies have shown, for example, that Communist Party functionaries and the so-called *nomenklatura* elite enjoyed definite social, political, and economic advantages: They attended party schools, shopped at special stores, vacationed at the most desirable holiday resorts, and had better access to decision-making posts (Szelényi 1987). In addition to those privileges, they were more likely to receive state-subsidized housing, purchase a car or vacation home, eat meat several times a week, and participate in cultural activities. Such differences in the allocation of goods and resources have led many to conclude that the political sphere was central to the stratification system of socialist societies (Goldthorpe 1966; Bauman 1974). Indeed, some scholars have suggested that the political elite may well have constituted a New (dominant) Class in socialist regimes (Djilas 1957; Konrád and Szelényi 1979).

In light of these problems as well as the apparent failure of the egalitarian experiment, socialist states made a number of attempts to reform their ailing economies. Yugoslavia began this trend by introducing a new economic program that combined free market principles with workers’ self-management; in 1949, Yugoslav leaders abandoned central planning, tied wages to the financial success of firms, and liberalized foreign trade (Sirc 1979). Hungary followed suit in 1968 by introducing its own version of market socialism (Hare et al.

1981), and China joined the trend in the late 1970s with similar economic reforms (Nee 1989).

Partial reprivatization, however, was not the only way for centrally managed economies to embark on the road to recovery. East Germany, for example, refused to combine planning with market reforms and chose to strengthen the operation of its central management (Szelényi 1989). In an effort to “scienticize” economic planning, East German leaders purchased state-of-the-art computers and sophisticated econometric programs to model the behavior of thousands of firms and anticipate the needs of millions of consumers. Cuba also refrained from market reforms in the late 1960s (Leogrande 1981). Hoping to prevent the restoration of capitalism in his country, Fidel Castro argued against the implementation of profit incentives to motivate workers. Instead, he introduced a rigorous political education program, the main purpose of which was to convince workers that they needed to expend maximum effort at work not for personal financial benefit but out of a moral commitment to socialism.

Despite those efforts to revitalize their economies, socialist societies were unable to recover from their experiences with overcentralization. Paradoxically, perhaps, reform plans were applied inconsistently, market rules were not followed rigorously, and the state continued its paternalistic practice of bailing out unsuccessful firms. Meanwhile, political opposition to those regimes continued to grow: Peasants asked for market reforms (Lewis 1979), workers demanded a say in management (Pravda 1979; Kennedy 1991), and intellectuals called for expanded political democracy and protection of their civil rights (Harman 1983). In the spring of 1989, many of those conflicts came to a head as a “gentle revolution” began to unfold in those countries. With a few exceptions, Soviet-type societies formally accepted the principles of multiparty democracy and announced their intention to move in the direction of a market economy.

THE LEGACIES OF SOCIALISM

If attempts to establish the socialist vision during the twentieth century were fraught with social and economic problems, efforts to undo the structure of existing socialist societies have proved equally challenging. Perhaps the biggest task facing postcommunist societies is to conquer the eco-

nomie legacies of socialism and make the transition to capitalism without the assistance of a capitalist class (Eyal et al. 1998). In this sense, the postcommunist revolution in Central Europe resembles the Russian Revolution. In 1917, a group of intellectuals constituted themselves as a political class in a peasant country to lead a “proletarian revolution” without a proletariat but with the express purpose of creating a proletariat. In 1989, a fraction of the intelligentsia seized power in Central Europe and sought to lead a “bourgeois revolution” without a bourgeoisie but with the objective of creating a bourgeoisie (Szelényi et al. 1995).

Needless to say, this objective was not an easy one. In all formerly socialist countries, the economic infrastructure was poorly developed and arguably deteriorating, the industrial firms of classical socialism were too large to be privatized easily, and the transition to a postindustrial service economy had not progressed very far (Böröcz and Róna-Tas 1995; Volgyes 1995). The distinctive feature of the transition is that despite such seeming homogeneity in the conditions of origin, there was great heterogeneity in the pathways to capitalism. For example, the East German model is one of centrally managed privatization in the context, of course, of West German “colonization.” By contrast, the Czech reformers acquiesced entirely to the “invisible hand” of capitalism, by which all workers were granted vouchers that could be redeemed for shares in any company. Finally, in Hungary, the transformation is best described as a form of “political capitalism” (Hankiss 1990; Staniszkis 1991), by which former communist bureaucrats used their political position to accumulate wealth and buy state companies. Where these privatization strategies will lead remains unclear, but one thing is certain: There is no single plan for designing capitalism, just as there was no simple blueprint for establishing socialism (Stark 1992).

Although most discussions of the transition to postcommunism have focused on the economic legacies of socialism, the political legacies are no less problematic as some form of successful marketization is sought. There are two political legacies of particular interest here. First, after forty years of communist rule and rampant political deception, the reigning view among East European workers involved considerable cynicism toward political elites, and such deep-seated cynicism

could not be overcome immediately even when new leaders were vying for power (Kovrig 1995). This cynicism undermined popular support for long-term sacrifices of the sort that all marketization strategies would necessarily entail. Second, the concept of marketization was not completely endorsed by the general population, as there was a long heritage of support for state paternalism in which basic needs, such as health care, education, and a living wage, were guaranteed (Szelényi et al. 1996). There was also widespread concern that marketization would increase inequality to levels that were unacceptably high. It has to borne in mind, then, that the transition to a market economy was undertaken simultaneously with a transition to political democracy. Democratic regimes, for all their possible virtues, are not necessarily well suited for revolutionary economic transformations and the popular sacrifice that such transformations typically imply (O'Donnell and Schmitter 1986).

Finally, the emergence of postcommunism is further complicated by the social legacies of communism. Most notably, the transition to the high-unemployment economy of postcommunism created special problems of legitimacy for a new market society, since Central Europeans had come to expect full employment from the state (Moskoff 1994). Similarly, one of the great successes of communism was its low levels of income inequality (relative to the capitalist alternative), and consequently, the sudden and visible increases in inequality in the postcommunist world were not readily accepted. It was all the more problematic that the prime beneficiaries of this growing wealth were in some instances the former communist elites themselves (Róna-Tas 1994; Fodor et al. 1995; Szelényi and Szelényi 1995). For all its economic failings and political repression, actually existing socialism was at least partially consistent with the original vision of social egalitarianism, and one cannot expect such success to be relinquished without a struggle.

THE FUTURE OF SOCIALISM

The question remains: Can the *idea* of socialism survive the *reality* of the past eighty years? For some, the answer to this question is in the negative, as the failings of socialism are so dramatic that the concept of socialism is inextricably associated with its particular realization, thus rendering it

effectively dead for all of history (Jowitt 1992). This is, then, a peculiar form of path dependency in which the possibly premature turn to socialism in the early twentieth century proved in the end to be its historical downfall. As a fallback position, one might argue that while socialism is perhaps dead in all the countries that experienced its "grief and shame" (Djilas 1998), it might nonetheless surface anew in countries that never underwent this premature experiment. Is there, in other words, a viable base for socialism in the Western world? The standard postmaterialist position on this score is that the base for socialism was at its strongest in the early twentieth century but has since dissipated with the decline in the size of the working class, the weakening of trade unions, and the associated rise of interest politics focusing on issues such as the environment, nuclear war, and gender politics (Inglehart 1983; Piven 1992). The implication is that socialism is dead not because of its tarnished history but because there is no longer a substantial base of working-class supporters.

This line of reasoning, for all its appeal, is not easily reconciled with the continuing support for social democratic policies and communist political leaders in formerly socialist countries. In many formerly communist societies, the initially extreme anticommunist sentiment weakened quickly, and the Communist Party was returned to power in the "second round" elections (Szelényi et al. 1996). Moreover, public opinion polls in those countries consistently reveal that the general population remains supportive of fundamentally social democratic policies even while disavowing support for highly repressive forms of communism of the sort that characterized Soviet-type societies. Under this formulation, a more mature civil society is in formation that probably will pursue a "Swedish form" of social democracy that maintains some elements of classical socialism (i.e., economic egalitarianism) yet abandons others (i.e., political inequality and repression).

SZONJA SZELÉNYI

SOCIALIZATION

Socialization has had diverse meanings in the social sciences, partly because a number of disciplines claim it as a central process. In its most common and general usage, the term “socialization” refers to the process of interaction through which an individual (a novice) acquires the norms, values, beliefs, attitudes, and language characteristic of his or her group. In the course of acquiring these cultural elements, the individual self and personality are created and shaped. Socialization therefore addresses two important problems in social life: societal continuity from one generation to the next and human development.

Different disciplines have emphasized different aspects of this process. Anthropologists tend to view socialization primarily as cultural transmission from one generation to the next, sometimes substituting the term “enculturation” for socialization (Herskovits 1948). Anthropological interest in socialization or enculturation coincided with the emergence of the “culture and personality” orientation of the late 1920s and 1930s, when the works of Mead (1928), Benedict (1934), and Malinowski (1927) focused on cultural practices affecting child rearing, value transmission, and personality development and helped shape the anthropological approach to socialization. Much

of the work in the culture and personality field was influenced by psychoanalytic theory. Contemporary cultural anthropology is guided less by psychoanalytic theory and more by social constructionist theories (such as symbolic interactionism), which view socialization as a collective and interpretive process of reality construction involving the reproduction of culture. This orientation has been shaped largely by the work of Geertz (1973), whose influence is also evident in sociological work on socialization, such as that of Corsaro and Eder (1995).

Psychologists are less likely to emphasize the transmission of culture and more likely to emphasize various aspects of individual development (Goslin 1969). There is considerable diversity within psychology in regard to the aspect of socialization studied. For developmental psychologists, particularly those influenced by Piaget (1926), socialization is largely a matter of cognitive development, which typically is viewed as a combination of social influence and maturation. For behavioral psychologists, socialization is synonymous with learning patterns of behavior. For clinical psychologists and personality theorists, it is viewed as the establishment of character traits, usually within the context of early childhood experiences. The subfield of child development is most closely associated with the topic of socialization within psychology, where socialization is largely equated with child rearing (Clausen [1968] provides a historical overview of socialization in these disciplines).

Political science has shown some interest in socialization, but in a limited sense. Its studies have not gone much beyond political socialization: the process by which political attitudes and orientations are formed. However, a different and more esoteric use of the term occasionally appears in this literature: socialization as “collectivization,” that is, the transformation of capitalism to socialism and/or communism.

Within sociology, there have been two main orientations toward socialization. One views socialization primarily as the learning of social roles. From this perspective, individuals become integrated members of society by learning and internalizing the relevant roles and statuses of the groups to which they belong (Brim 1966). This view has been present in some form from the beginnings of sociology as a discipline but has

been most closely associated with structural-functional perspectives.

The other, more prevalent sociological orientation views socialization mainly as self-concept formation. The development of self and identity in the context of intimate and reciprocal relations is considered the core of socialization. This view is closely associated with the symbolic interactionist perspective, a synthesis of various strands of pragmatism, behaviorism, and idealism that emerged in the 1920s and 1930s in the writings of a number of scholars at the University of Chicago, especially Mead (1934). In Mead's writings, the self is a reflexive, thoroughly social phenomenon that develops through language or symbolic interaction. Language enables the development of role-taking, by which the individual is able to view himself or herself from the perspective of another person. This becomes the basis for selfhood and the interpenetration of self and society. Mead and other symbolic interactionists have argued that self and society are two sides of the same coin. The basis for their assertion is that the content of self-conceptions (e.g., identities) reflects the aspects of the social process with which the individual is involved through the internalization of role identities, values, and meanings. This internalization in turn reproduces society. From the interactionist perspective, both self and society depend on the same process of social interaction by which "realities" are created and constantly negotiated (Gecas 1982).

For contemporary interactionists as well, socialization is distinguished from other types of learning and other forms of social influence by its relevance for self-conceptions, that is, for people's thoughts and feelings about themselves. As such, socialization is not merely the process of learning rules or norms or behavior patterns; it is a matter of learning these things only to the extent to which they become part of the way people think of themselves. The mark of successful socialization is the transformation of social control into self-control. This is accomplished largely through the development of identities, the various labels and characteristics attributed to the self. Commitment to identities (such as son, mother, professor, honest person) is a source of motivation for individuals to act in accordance with the values and norms implied by those identities (Foote 1951; Stryker

1980; Gecas 1986). The focus on identity also emphasizes the membership component of socialization: To be socialized is to belong to a social group.

Socialization as identity formation occurs through a number of more specific processes associated with self-concept development: reflected appraisals, social comparisons, self-attributions, and identification (Gecas and Burke [1995] and Rosenberg [1979] discuss these processes). Reflected appraisals, based on Cooley's (1902) "looking-glass self" metaphor, refer to people's perceptions of how others see and evaluate them. To some extent people come to see themselves as they think others (particularly significant others) see them. People also develop conceptions of themselves with regard to specific attributes by comparing themselves to others (social comparisons) and making self-inferences from observing their own actions and their consequences (self-attributions). Particularly important to socialization as identity formation is the process of identification. Initially used by Sigmund Freud, this concept refers to the child's emotional attachment to the parent and desire to be like the parent; as a consequence, the child internalizes and adopts the parent's values, beliefs, and other characteristics. Among other things, through identification with the parent, the child becomes more receptive to parental influence.

Identification also is used to refer to the imputation or ascription of identities. Here the focus is on the establishment of identities in social interaction, which is an important aspect of defining situations and constructing realities. This also has important socializing consequences, as much of the literature on labeling, stereotyping, and expectancy effects attests.

CONTENT AND CONTEXTS OF SOCIALIZATION

Much research on socialization has been concerned with identifying the aspects of the socializee's development that are affected by particular agents and contexts of socialization and through particular processes. The focus has been primarily on the family context, in which the initial or *primary* socialization of the individual takes place. Studies of child rearing in "normal" as well as "abnormal" situations (e.g., institutionalized children, "closet children" feral, children") have identified a num-

ber of conditions that must be present for primary socialization to take place, that is, for the child to become a person. These conditions include the use of symbolic interaction (language) in the context of an intimate, nurturant relationship between an adult and a child. These conditions are necessary for the initial sense of self to emerge and for normal cognitive and even physical development to take place. The claim that the family (in some form) is a universal feature of human societies is based in large part on this important socialization function.

Parental support continues to be important in the socialization of offspring through childhood, adolescence, and beyond. It is one of the most robust variables in the literature on child rearing. Parental support has been found to be positively related to a child's cognitive development, moral behavior, conformity to adult standards, self-esteem, academic achievement, and social competence. Conversely, lack of parental support is associated with negative socialization outcomes for children and adolescents: low self-esteem, delinquency, deviance, drug use, and various other problem behaviors (Rollins and Thomas 1979; Peterson and Hann 1999).

Parental control is almost as prominent as support in the socialization literature. "Control" refers to the degree to and the manner in which parents attempt to place constraints on a child's behavior. Other terms used for this dimension of parenting are punishment, discipline, restrictiveness, permissiveness, protectiveness, supervision, strictness, and monitoring. Parental control is a more complicated variable than is parental support. It is necessary to distinguish different types or styles of control because they frequently have opposite socialization consequences. An important distinction is that between "authoritarian" and "authoritative" control (Baumrind 1978) or "coercion" and "induction" (Rollins and Thomas 1979). Authoritarian or coercive control (control based on force, threat, or physical punishment) is associated with negative or unfavorable socialization outcomes, whereas authoritative or inductive control (control based on reason and explanation) has positive outcomes.

The most powerful models of parental influence in the socialization of children are those which combine the dimensions of support and

control. Parents are most effective as agents of socialization when they express a high level of support and exercise inductive control. In these conditions, children are most likely to identify with their parents, internalize parental values and expectations, use parents as their models, and become receptive to attempts at parental influence. Conversely, low parental support and reliance on coercive control are associated with unfavorable socialization outcomes (for reviews of this literature, see Peterson and Rollins 1987; Maccoby and Martin 1983; and Rollins and Thomas 1979).

Parental support and control cover much of the ground in the research on child rearing but not all of it. Other important socialization variables here are extent of parental involvement with the child (e.g., time spent), level of performance expectations, extent to which political or religious beliefs and value systems are taught to the child by the parent, and various characteristics of the parent, such as patience, tolerance, honesty, integrity, competence, and age and sex (of parent and child). Many factors affect the process and outcomes of family socialization.

Much of the socialization that takes place in the family involves learning appropriate role behavior associated with the various family positions. For the child, the most significant of these behaviors involve sex and age roles. Through processes of reinforcement from parents and others, identification with various role models, and parental admonitions and instructions, a child is socialized into the behavioral expectations associated with these roles. Of the two, sex roles have received more of the research attention on role learning in the family (Block [1983] provides a review). This research suggests that sex-role socialization is extensive (usually starting at birth with differential treatment of male and female infants), pervasive (various agents and contexts of socialization), and consequential for a wide range of other individual and social outcomes. A prominent theme in much contemporary research on sex-role socialization is that the differential treatment that emphasizes "masculine" characteristics for boys and "feminine" characteristics for girls is detrimental to the development of both girls and boys and to the relationship between the sexes (Bem [1974] discusses the virtues of androgyny). This research reflects the ethos of equality between the sexes in most modern societies.

Most studies of socialization within the family assume a unidirectional influence from parent to child. Parents typically are viewed as agents of socialization (part of the job description of a parent), and children as objects of socialization. Given the disparities in power, status, and competence between parent and child, it is justifiably assumed that the direction of influence is mainly from parent to child. However, it has become increasingly evident that socialization is a reciprocal process, with children influencing parents as well. Over the past few decades, the thinking with regard to socialization processes has shifted from unidirectional to bidirectional and reciprocal models (Corsaro and Eder 1995; Gecas 1981). For example, in considering the association between parental punishment and a child's deviant behavior, which is one of the most consistent findings in socialization research, it can be argued that the child's behavior is both a consequence and a cause of the parental behavior. That is, a child's aggressive or deviant behavior may *elicit* more punitive parental behavior as well as being affected by the parental behavior. Socialization increasingly is viewed as reciprocal, even though the degree of influence is typically not equal.

Besides parents and other adult kin, siblings serve as agents of socialization within the family context. As family size increases, more of the socialization of the younger children is taken on by their older siblings, either by default or because the parents delegate this responsibility to the older children. Some have argued that this puts younger children in large families at a disadvantage with regard to cognitive development, since they have relatively less contact with the most competent and committed family members, the parents (Zajonc 1976). However, these findings, based mostly on cross-sectional data, have not gone unchallenged (Galbraith 1982; Blake 1989).

An increasingly pervasive agent of socialization in contemporary families is television. Children spend more time watching television than at any other activity except school and sleep (Bronfenbrenner 1970). The purpose of most television programs children watch is typically not to socialize or educate but to entertain and sell products. However, a good deal of unintended socialization is likely to occur, from shaping conceptions of reality (e.g., sex roles and ethnic stereotypes) to styles of behavior and tastes. In general, television

is perceived as having a negative influence on children, with the exception of a few educational programs on public television. Much of the concern has focused on the extensive violence and sexual themes and situations in television programs. Bandura et al.'s (1963) work on modeling has persuasively shown that exposure to aggressive behavior tends to increase aggression in the viewer. Along with its undesirable consequences for child socialization, Bronfenbrenner (1970) observes that television is detrimental to child development with regard to the behavior it prevents, that is, the human interaction that is forgone in the course of being a passive viewer. The role of television as an agent of socialization in families seems to be increasing by default as the amount of contact between parents and their children decreases. Various social forces (such as increasing numbers of working mothers, single-parent families, dual-career families, and the professionalization of child care) have decreased the amount of parent-child interaction and thus parents' role as a socializing agent. This vacuum has been filled increasingly by the child's involvement with television and with peers. For children in American society, television, peer groups, and school are increasingly important agents of socialization.

Like the family, the school is an institution whose mandate is to socialize children. The school's mission, however, is more narrowly defined than is that of the family and is concerned primarily with the formal instruction and the development of children's cognitive skills. In this sense, the school context is less involved in *primary* socialization (i.e., the development of basic values, beliefs, motivations, and conceptions of the self) and more involved in *secondary* socialization (i.e., the development of knowledge and skills). This is not a very precise distinction, however. In the course of the socialization experienced in school, things other than skills and knowledge also are learned, such as norms, values, attitudes, and various aspects of a child's personality and self-concept. Much more is typically learned in school than what is explicitly taught.

Many activities associated with school (specifically in the classroom) have implications for a child's self-concept (Hewitt 1998). For example, one of the most important activities involves evaluation of the student's performance by the teacher:

performance on tests, class reports, presentations, assignments, and the like. Success in these activities, based on one's own efforts, is good for self-esteem and builds confidence in one's abilities. However, failure is not, and *public* failure is even worse. School provides numerous opportunities for public failure as well as public success. One of the consequences of performance evaluations may be the categorization or "labeling" of students, by teachers as well as others, as "smart," "dumb," "slow learner," "underachiever," and so on. Negative as well as positive labels affect the way in which others respond to a person and, through their responses, reinforce and shape that person in the labeled direction. This process is called "expectancy effects" (Jones 1977) or "self-fulfilling prophecy" (Merton 1957). Rosenthal and Jacobson (1968) found that teachers' expectations of students, even when based on erroneous information, had a significant effect on how students developed over the course of the school year: When the teacher was led to believe that a student would be a "slow learner," that student was more likely to do poorly in class. Labeling and expectancy effects occur in most socialization contexts and have important consequences for self-concept development.

However, students, like other socializees, are not passive recipients of the pressures they experience. Covington and Beery (1976) propose that two fundamentally different motivation patterns emerge in schools as a result of these pressures: One is oriented toward striving for success, and the other toward avoiding failure. Failure-avoiding strategies (such as nonparticipation, withdrawal, procrastination, and putting off work assignments until too late) are attempts to disassociate one's performance from one's ability and worth. Failure then can be attributed to lack of effort or to external circumstances (less damaging attributions for the self), not to lack of ability (a more damaging attribution). This is a form of role distancing, the separation of the self from the behavior required of a role occupant; it is also an obstacle to school achievement. As Covington and Beery (1976) point out, failure-avoiding strategies are self-defeating: In their attempts to avoid feelings of failure, these students increase the probability of actual failure. For some students this is one of the unintended and undesirable consequences of classroom socialization. In the process of socializing students toward achievement and mastery (desir-

able outcomes), pressures are generated that may result in undesirable adaptations.

The third most important context for the socialization of children and adolescents is the peer group. In terms of structure and function, the peer group is a very different context from family and school. Unlike those two contexts, it is not the "job" of peers to socialize each other, even though a great deal of childhood socialization occurs in this context, some of it in reaction against the socialization experienced in the family and school.

There are several important features of the peer group as a context of socialization. Most important, it is a *voluntary* association, and for most children it is the first. This permits greater freedom of choice regarding associations in the group. A second important feature is that association is between status equals. Consequently, interaction is more likely to be based on egalitarian norms. Status distinctions emerge, of course, but are more likely to be based on achievement and negotiation. However, the basic relationship within peer groups is not hierarchical; rather, it is the friendship bond, based on equality, mutual tolerance, and concern. Third, the peer group is an arena for the exercise of independence from adult control. As such, it is often the context for the development of values, norms, and behavior in opposition to those of adults (such as the subcultures described by Coleman [1961] and in much of the literature on juvenile delinquency). Fourth, children's peer groups, in contemporary American society at least, typically are segregated by sex and differ in organizational patterns: Girls' peer groups tend to feature closely knit and egalitarian friendships, whereas boys' peer groups tend to be loosely knit, larger groups with clear status hierarchies. An important socialization consequence of intensive association with same-sex peers and involvement in sex-typed activities is that this strongly reinforces identification and belongingness with members of the same sex and contributes to the development of stereotypical attitudes toward members of the opposite sex. Not only sex-role identity but also much of sexual socialization during childhood occur in the context of peer rather than parent-child associations, since parents are much less interested in discussing sexual matters with their children than are the children's peers (Fine 1987; Corsaro and Eder 1990). Peers provide an alternative reference group for children as well as

an alternative source of self-esteem and identity. For these reasons, attachment to peers may be even stronger than attachment to family, especially for adolescents.

The socialization experienced by adults generally falls in the category of secondary socialization, building on the socialization experiences of childhood. Much of this is role-specific (Brim 1968), that is, learning the knowledge and skills required for the performance of specific adult roles, such as occupation, marriage, and parenthood. As individuals become committed to the roles they play, they come to identify themselves and think of themselves in terms of these role-identities (Stryker 1980).

Since work is a dominant activity and setting for most adult men and women, much of adult socialization involves either preparation for an occupation or career (which usually takes place specialized schools or training programs such as law school, medical school, and college) or on-the-job training. The work setting can have a substantial socializing effect on workers, affecting more than just their knowledge and skills. Kohn and Schooler (1983) have shown how certain occupational conditions affect the development of a worker's values and personality. Specifically, they found that work that is routine, closely supervised, and relatively uncomplicated gives rise to values of conformity, whereas work that is complex and encourages self-direction increases the value workers place on independence and autonomy. Kanter (1977) found that the nature of work relations, particularly the structure of opportunity on the job, affects workers' attitudes and behaviors as a consequence of their adaptations to the work situation. Workers' adaptations to their work situations do not necessarily lead to commitment to the job or self-investment in terms of the occupational role. On the contrary, a prevalent theme in much of the sociological literature on work and workers (especially that with a Marxist perspective) deals with the alienating consequences of work in capitalist societies.

Many other contexts have socializing consequences for adults: family, political and religious organizations, recreational settings, and voluntary associations. The socialization that takes place in these contexts can be considered "developmental" (Wheeler 1966) because it builds on previous

socialization and is a continuation and expansion of past socialization experiences. *Resocialization* refers to socialization experiences that represent a more radical change in the person. Resocialization contexts (e.g., mental hospitals, some prisons, reform schools, therapy groups, political indoctrination camps, religious conversion settings) have as their explicit goal the transformation of the individual. An important feature of resocialization is the replacement of one's previous set of beliefs, values, and especially conceptions of the self with a new set grounded in the socializing group's ideology or world view. This has been described as a process of death and rebirth of the self (Lifton 1963). Typically, this is accomplished through intense small group interaction in which the physical and symbolic environments are highly controlled by the agents of socialization. It is an experience that usually involves considerable stress for the socializee.

SOCIALIZATION OVER THE LIFE COURSE

Socialization is a lifelong process of change. Even though the socialization experienced in the family is in some ways the most consequential, individuals typically have important socializing experiences throughout their lives. A central theme in the life-course literature is the degree of continuity and consistency in personality as an individual moves through the life course. Positions on this issue range from the claim that personality is shaped largely during early childhood (most evident in psychoanalytic theories) to the claim that people are thoroughly malleable, changing across situations and throughout their lives (characteristic of constructivist theories). The majority appear to argue for an intermediate position, maintaining that the "core" personality or self-concept develops in early socialization experiences, while various other characteristics are added to self through the acquisition of new roles, identities, and socializing experiences (Brim 1966). For example, Clausen (1993) found that the development of "planful competence" during the childhood and early adolescent years affected the life course of adults many years later, resulting in individual histories of cumulative advantage or disadvantage. The previous discussion suggests how contexts of socialization, which are typically age-graded, can contribute to the development of different aspects of

individuals associated with different ages and stages of life.

Some important socializing experiences and changes are keyed to developmental or maturational considerations: There are differences between the concerns and capabilities of children and those of adolescents, those of young adults and those of people in middle age, and those of the middle-aged and those of older persons. Erikson's (1959) developmental scheme, building on the Freudian theory of psychosexual development but extending it beyond childhood, emphasizes the different developmental tasks associated with different stages of life. The challenges or developmental tasks proposed by Erikson are (1) trust versus mistrust, (2) autonomy versus shame, (3) initiative versus guilt, (4) industry versus inferiority, (5) identity versus identity confusion, (6) intimacy versus isolation, (7) generativity versus self-absorption, and (8) integrity versus despair. Most of the socialization research guided by Erikson's formulations has focused on stage 5, adolescence, and the developmental task highlighting identity concerns. In modern society adolescence has long been considered a time when self-concept concerns increase in prominence. Physiological changes and changes in social circumstances (e.g., high school, dating, career considerations) contribute to an increase in self-awareness and concern about how one is viewed by others. Research by developmental psychologists generally has found that good family relations (those high in parental support, communication, involvement, and inductive control) facilitate the development of ego identity in adolescence (Gecas and Seff [1990] and Steinmetz 1999 provide reviews). By adolescence, however, the influence of parents is substantially less than it was during childhood. Increasingly, other agents and contexts of socialization become important to the adolescent: peers, school, friends, coaches, and so forth. The adolescent's struggles with identity are worked out in a number of competing arenas.

Identity concerns are not limited to adolescence, of course. If one considers socialization a lifelong process of self-concept formation, matters of identity are important at various stages of the individual's development. Identity concerns are most likely to be accentuated during periods of transition, particularly those involving entrance into or exit from social statuses and roles. Some of

these role transitions are institutionalized and highly ritualized. The rites of passage in various cultures marking the transition from childhood to adulthood can be elaborate and dramatic. Sometimes this involves acquiring a new name as well as a new status (as in many of the Plains Indian cultures). In contemporary Western societies, these status passages may be less dramatic but still quite consequential for the person: getting a driver's license, high school graduation, marriage, divorce, the first full-time job, retirement, widowhood. In general, each major transition initiates a new socializing experience or situation that has implications for the individual's self-concept.

Some theorists have focused on transitions in adulthood (Levinson 1978; Levinson and Crumpler 1996) and examined the circumstances that can lead to a "midlife crisis" an acute reexamination of the self. Evidence that such a crisis typically occurs at midlife is sparse. The adult years, especially in the later stages, are still relatively neglected by life-course scholars compared to studies of childhood and adolescence, but this may be changing. As longevity continues to increase in modern society, so will concern with socializing experiences in the later stages of life. We may be expanding some stages (e.g., postretirement and widowhood) as well as creating new ones, such as the "nursing home stage," as the life span increases.

In considering socialization over the life course, it is necessary to take history and culture into account. Not just the content of socialization during various "stages" of life but also the stages themselves vary with the culture and the historical context. For example, adolescence as an identifiable stage of life is a relatively recent historical construct in Western societies, closely associated with the extension of formal education to high school (Gecas and Seff 1990). Even childhood, as Aries (1960) documents, is not universally considered a distinct stage of life. The modern conception of childhood as an identifiably distinct stage emerged during the European Renaissance, partly as a consequence of the emergence of parochial schools. More recently, Elder (1974) has shown a historical consciousness in his life-course analyses by examining how specific historical events (e.g., the Great Depression; World War II) differentially affected two cohorts of children and their families. Whether there are eight stages of life, four stages,

or seven stages (as Shakespeare observed) depends on the society and one's analytic purposes.

CONTEMPORARY ISSUES AND THEMES IN SOCIALIZATION RESEARCH

For much of its history, the concept of socialization has been heavily imbued with the notion of adaptation and conformity of the individual to societal expectations. The past few decades, however, have seen a marked shift to a more active view of the self, with an emphasis on self-socialization. Renewed interest in the self-concept as a source of motivation (Gecas 1986) and an agent in its environment has contributed to this shift, as has the increased interest in adult socialization (Levenson & Crumpler 1996). Even in studies of parent-child interaction, the child (even the infant) is increasingly viewed as an active partner in his or her socialization (Rheingold 1969). In short, the outcomes of socialization (whether conceptualized as values, self-conceptions, behavior patterns, or beliefs) are increasingly viewed as the products of reciprocal and negotiated interactions between agent and socializee.

A concern with social structure and its effects on the process and outcomes of socialization is still the hallmark of the sociological orientation to socialization, from social class influences (Gecas 1979) to the effects of family structure. Changes in family structure over the past few decades have increased interest in the effects of single-parent families, reconstituted families, and day care on child socialization (McLanahan and Sandefur 1994). Some of these changes have negative consequences for child socialization, some are benign, and some are ambiguous. It is evident that family trends and their consequences for child socialization will continue to generate a great deal of passionate debate in public and academic spheres because of their policy and value implications (Popenoe [1993] and Skolnick [1991] present contrasting views on the implications of these trends).

While most of socialization research has involved mainstream American populations, interest in cultural and subcultural variations in socialization experiences has been increasing. Socialization scholars have become sensitive to the criticism that our theories of socialization and self-conception are ethnocentric, reflecting a parochial, Western

perspective. This cultural self-consciousness has generated some interesting comparative studies, especially comparisons of socialization experiences in individualistic cultures (such as most Western societies) with those in collectivistic cultures (such as most Asian and many African cultures). In general, the self in collectivistic cultures is experienced much more in relational terms, that is, as interdependent, socially situated, and lacking definition outside the group context. By contrast, in individualistic cultures the self is more likely to be experienced as autonomous and unique and much less as a part of the social context. The socialization experiences in the former cultures tend to emphasize the primacy of the group (e.g., one's family, clan, or society) over the individual, whereas in the latter the emphasis is on the development of independence, individual uniqueness, the ego, and autonomy (Markus and Kitayama 1991; Neisser and Jopling 1997). Ethnic subcultures within American society, such as Mexican-Americans and Native Americans, also reflect a more collectivist ethos than does mainstream culture, with consequences for socialization patterns. Within American society the cultural influences of ethnic minorities on socialization patterns typically interact with and may be confounded by social class influences. For example, studies of African-American families and peer groups may reflect adaptations to economic deprivation as much as they reflect distinct subcultural elements.

What effect will rapidly evolving computer technology have on the socialization of children and adults? The ubiquity of computers in classrooms, homes, workplaces, and recreation centers is evident in American society. Children are becoming involved with this technology at a very early age; even preschoolers are becoming "computer-literate." Unlike television, computers are an interactive technology that is likely to engage and develop the user's cognitive and motor skills. Thus, there is reason to hope that the influence of computers on children's development will be beneficial or at least benign, as some scholars have suggested (Turkle 1984). Computers and information technologies are rapidly transforming modern societies, affecting most aspects of people's lives. Surely they also are affecting the processes and outcomes of socialization, but the nature of these processes and outcomes remains to be studied by socialization scholars.

In traditional, relatively stable societies (which are increasingly rare), socialization is relatively routine and unproblematic. By contrast, in modern societies characterized by rapid social and cultural change, the socialization of children and adults is increasingly problematic and more likely to be contentious but also more interesting.

SOCIAL-POLICY ANALYSIS

See Public policy analysis.

SOCIETAL STRATIFICATION

Societal stratification phenomena are the relatively enduring, hierarchically ordered relationships of power among the units of which society is composed. The smallest units are adults, gainfully employed men and/or women, nuclear families, or sometimes extended families or households. Such units are ordered from highest to lowest in terms of power: political power, acquisitional power, the power of prestige, and the power of informational standing. Everybody experiences stratification every day, although a person often notices it only in the sense that some people seem better or worse off than he or she is. Social thinkers, powerful people, and revolutionaries have always been especially concerned with stratification.

Secure knowledge of the varying forms stratification structures may take is important because of the effects those structures have on many aspects of human experience, such as people's dreams of a better life, efforts to improve their situations, strivings for success, fear of failure, sympathy for the less fortunate, envy of others' good fortune, and even feelings about revolution.

A complete understanding of stratification requires several kinds of knowledge: first, what stratification structures consist of and how they vary; second, the individual and collective consequences of the different states of those structures; and third, the factors that make stratification structures change. This article reviews current thinking on the first of these elements.

HISTORY: CLASSICAL THEORY

Two different lines of thought inform modern theory on societal stratification. One is *classical* theory; concerned with political power and privilege, it employs historical evidence. The other is the *empirical tradition*, which deals with systematic data on stratification as it exists contemporarily. Present-day theory of the behavior of stratification phenomena can be traced to Karl Marx's challenge to the manufacturing and financial elites of his day. Behind his concerns and those of the working class for which he was Europe's chief spokesman for many years lay the great economic and political upheavals of the eighteenth and nineteenth centuries.

The American and French revolutions and their aftermath culminated in legislation that made adults in many countries equal before the law. The related wave of emancipation of slaves and serfs in Europe and the Americas was also part of the intellectual environment of that day. Of more direct relevance to Marx's thinking was the rise of trade and the factory system, along with the growth of cities and the expansion of wealth. Marx saw urban populations dividing into two opposed classes. The capitalist class employed the workers; owned the workplaces, machines, and tools; and had ready access to large amounts of money for investment. The capitalists were opposed by their employees, the working class, who had nothing to offer but their time and energy. In Marx's view,

these two classes differ in terms of power and privilege: power because capitalists give orders that workers must accept, privilege because capitalists take the surplus (whatever is left after paying the cost of production) for themselves and their investments, leaving for workers only the wages that the market for labor forces capitalists to pay. Actually, Marx was interested in how these classes came into being and the conflicting interests they expressed. He did not write specifically on societal stratification as it is understood today.

Later writers on stratification, attempting to elucidate or contradict Marx, spelled out more complex sets of stratification dimensions. Weber (1946, 1947) saw power as the general factor basic to the enduring inequalities referred to as stratification. Sometimes, like Marx, he used categories whose underlying dimensions had to be elucidated by others. Party, class, and status groups were his key concepts. When these concepts are dimensionalized (reconstituted as variables), "party" is seen to be legitimate political influence, "class" is seen to express a hierarchical order of economic status, and the variable underlying "status groups" is seen to be their hierarchical order according to the degree of social honor. In other writings, Weber saw education as a stratification variable. In still others, he often wrote about authority, or legitimate superordinate and subordinate relations of power. Weber said nothing about how people are distributed in these dimensions or, of course, about how and why such distributions vary.

More thoroughly and precisely than Marx or Weber, Sorokin (1927) crafted the bases of modern theories of societal stratification. He distinguished political stratification, economic stratification, and occupational stratification. The first is a dimension of political power, and the second a dimension of the power of income and wealth. He left the dimensionality of occupational status unclear, sometimes implying that it was authority, sometimes privilege, and sometimes intelligence. Much of Sorokin's theory of societal stratification remains intact. First, he noted that all societies are stratified to some degree, a position widely accepted today. Second, empirical researchers continue to refine and elucidate his concepts of occupational status and occupational mobility. Third, in this connection he asked why occupational stratification exists and concluded that organized com-

munal life requires mechanisms and people to coordinate essential activities and that such coordination demands and rewards unusual ability. This view, now called *the functionalist hypothesis*, has been elaborated and disputed ever since. Fourth, he held that the degree of stratification varies from society to society and over time within given society: Stratification, he said, is in “ceaseless fluctuation.” Sorokin specified several ways in which stratification structures may vary. The whole structure may rise or fall; the top may rise or fall, changing the degree of inequality; and the “profile,” or the shape of the distribution, may vary. Similarly, the rate of individual upward or downward mobility may vary, and whole strata may rise or fall.

Sorokin thus presented a theory that specified (1) the general dimensions by which people are stratified within a society, (2) some ways in which the distributions of people on those dimensions may vary, and (3) why stratification exists. Also, he held such structures to be in ceaseless change.

The latest work in the classical tradition is that of Lenski (1966). His key dimensions are power, privilege, and prestige, in that order of importance. Beyond this, Lenski offers three main ideas. First, both functional theory and conflict theory, its opposite, are partly right. Society’s needs demand coordination, implying the existence of strata based on power or authority and implying a degree of consent on the part of many of those whose activities are organized by others. However, conflict results from that control: Authority is often abused and, even when it is not, may be misunderstood. Second, inequalities are mostly those of power, with inequalities of privilege and prestige following mostly as consequences of them. Third, the degree of inequality, which is seen as a single phenomenon encompassing the rate of mobility and the distance between strata, increased with the growing comprehensiveness and complexity of society until the Industrial Revolution, after which it declined. According to Lenski, the main forces driving change in the degree of inequality are the size of the surplus of production and, undergirding this, the march of technological efficiency.

Lenski is clearly in the classical tradition in his concern with power and privilege and dependence on historical evidence. To some extent, he echoes

Sorokin’s concern with variations in stratification structures through an emphasis on the degree of inequality. He provides a compelling treatment of the issue of conflict versus societal necessity in regard to the existence of stratification. He uses historical evidence effectively and systematically to mark variations of inequality in agrarian and horticultural societies. However, Lenski’s emphasis on two main, all-encompassing aspects of stratification—power (his key criterion variable) and inequality (used to denote the way in which power and its concomitants are apportioned)—forces too many separately varying stratification phenomena into too few molds. This problem becomes critical in industrial societies, where stratification dimensions vary independently of one another.

HISTORY: THE EMPIRICAL TRADITION

As has been noted, this tradition of research on stratification is concerned with the here and now. This line of research has developed excellence in the measurement of the hierarchical positions of small demographic units within larger stratification structures. Although newer than the classical tradition, it has a long history. Several more or less independent status-measurement devices were formulated in the 1920s and 1930s. Most were concerned with either the prestige of the breadwinner’s occupation or the quality of the home. They tended to share certain assumptions: that stratification consists of a single hierarchy, in the early days usually called *social class*; that one or two different scales are sufficient to test hypotheses concerning social class; that social class positions can be distinguished by direct observation and/or interviews with someone who knows the status holders; that routines can be devised that allow one to assign valid and reliable numerical scores to each status holder on each of the scales used to measure social class; that the unit to be scored is the household, which can be one person or several persons living in a single home; and that it is the whole unit that is to be scored, whether with data on the home or data on the head of the household. Many of these devices became obsolete because they had to be recalibrated for each new community or type of community to which they were applied. Those that survived—education and occupational status—did so because they provide

comparable scores across large populations, such as nations.

Of the two main survivors, educational attainment is easy to measure: the exact number of school years successfully completed from none through sixteen, seventeen, eighteen, and so on. Measurement of occupational status is another matter. Two systems are currently in use. Occupational prestige ratings assume that each person in a given occupation shares the prestige most people attribute to that occupation. Occupational prestige scales have been constructed for many countries (Treiman 1977). Occupational socioeconomic status indices (SEI) are scales that use education and income to measure the status level of each occupation and then attribute to an individual the resulting score of her or his occupation. In the United States, Treiman's prestige scale and the SEI provide highly correlated occupational scores (Featherman and Hauser 1978).

Regardless of the original intent of such scales—to measure positions in what once was believed to be the only stratification hierarchy—the two variables educational attainment and occupational status are also appropriate for use with the classical theorists' multidimensional view of stratification.

A SYNTHESIS

The current synthesis was carried out by stratification theorists who were both sensitive to the concerns of classical theorists with power and privilege and steeped in the empirical tradition. Thus, they brought the classical theorists' concern with political power, economic power, and social honor (Weber), including Sorokin's occupational status and Lenski's prestige, together with the empiricists' concern with education and occupational status (overlapping Weber, Sorokin, and Lenski) and with quantitative measurement and analysis.

Svalastoga's *Social Differentiation* (1965) appears to be the first statement of the synthesis. Svalastoga indicates the centrality of four dimensions of status: political, economic, social (mostly occupational), and informational (mostly educational). He calls attention to structural variations through his "parameters": the degree of inequality, the correlation among dimensions, and the degree of permeability (intergenerational circulation mo-

bility or movement up and down the hierarchies). Duncan (1968) both accepted and clarified Svalastoga's synthesis. His list of "scales of reward or status" provides a good outline of the large number of variables that should be measured to achieve a full-scale determination of people's levels on each status dimension. Also, he divides three of Svalastoga's four dimensions into two categories each. He, like Svalastoga, then lists three ways in which the structure of stratification variable may vary. The first is the degree of inequality. The second is called "rigidity of inequality" or "status crystallization," which is the same as Svalastoga's "correlation." The third is "rigidity of stratification," which is Svalastoga's "permeability" turned upside down.

Like Sorokin's and others' positions, Haller's (1970) statement of the synthesis assumes that stratification to one degree or another exists in all societies at all times. Revised slightly in this article, this form of the synthesis holds that there are two classes of dimensions of stratification. The first are "content"—or *power*—dimensions, after Weber: the capability of a given unit to elicit from others behavior promoted by the first unit, with such power having been routinized by coercion or consent. Agreeing conceptually but not always terminologically with the classical writers, this expression of the synthesis posits political power, economic power, and the power of prestige as universal dimensions of power. For civilized societies, it adds the power of years of formal education.

This position thus posits legitimized political influence (including authority) as the dimension underlying Weber's "party," Sorokin's "political stratification," Lenski's "power," and Svalastoga's "political status." It posits Weber's "class," Sorokin's "economic stratification," Lenski's "privilege," and Svalastoga's economic status as referring to the same set of hierarchical phenomena: access to goods and services—the *economic* dimension of a stratification structure. From Weber, it takes the variable of social honor; from Sorokin and modern occupational status researchers, that of occupational stratification; from Svalastoga, that of social status; and from Lenski, that of prestige. From the empirical tradition, it takes the measurement of occupational power ("status"). All these elements are seen as referring to a third homogeneous set of hierarchical phe-

nomena: the power of respect or deference attributed to a unit because of that unit's participation in a social category (such as an occupation) that has a specific level of evaluation by a society—the *prestige* dimension of societal stratification. As has been indicated, from Svalastoga and Duncan, with much support from the empiricists and also some from Weber, it takes informational power as a content dimension of a stratification structure, with education as its main indicator.

At the general level, each power dimension is of course presumed to be applicable in some form to all human societies as far back as human communal life can be traced. It is the exact expression of each dimension and the relationship among the dimension that vary across time and place. For entire contemporary societies, the main expressions of each dimension seem to be the following: for the political power dimension, *political power*, a variable researchers cannot yet measure despite its centrality in classical theory; for the economic dimension, *income* (occasionally wealth), a variable of concern to those in the empirical tradition; for the *prestige dimension*, *occupational status* in either of its two main forms of occupational prestige ratings (Treiman 1977) and occupational socio-economic index scores (Featherman and Hauser 1978); and for the informational power dimension, *educational attainment level* in terms of years of formal schooling successfully completed. Thus, in recent years it has become apparent that for today's societies, the main variables of the empirical tradition have central places among the content dimensions of the classical tradition. Income, occupational status, and education are the theoretically defensible variables most readily available to measure three of the four classical content dimensions.

Like Sorokin's, Svalastoga's, and Duncan's, Haller's formulation of the synthesis specifies several structural dimensions, with each one held to be applicable to every appropriate measure of each content dimension. The three structural dimensions of Svalastoga and Duncan are included: degree of inequality, status crystallization, and degree of status inheritance. Two others from Sorokin are included, although they are modified to fit today's understanding. One is the general level or central tendency, and the other is a division of Sorokin's concept of profile into two con-

cepts: mode structure and skewness. Although calculated from data on small units, each structural dimension applies to the society as a whole. Although logically they are partly dependent on one another, each one makes a unique contribution to an understanding of stratification. Each appears to be amenable to statistical description. Each is applicable to every indicator of the standing of every small unit (say, family) in the society. Valid measures of each content dimension taken at one point in time on a generalizable sample of the population of small units of that society would provide a complete description of the stratification structure of that society at that time. Successive measures would provide a complete description of the evolution of that society's stratification structure over time, thus providing a general idea of the variations in the degree of stratification in that society. Each applies to comparisons over time or among societies.

General Level. As Sorokin realized, the levels of structural dimensions may rise and fall as wholes. That is, the average economic, political, prestige, and informational standing of small units changes over time. These rises and falls may be seen in changes in the central tendency—say, the arithmetic mean or the median value—of the standing of small units. The rises and falls of the central tendency of any one of these dimensions do not necessarily follow the same pattern as those of another. Average economic, prestige, and informational power may increase, for example, while average political influence falls. This could happen in a society where a development-oriented dictatorship reduces citizen political participation while increasing levels of income, raising prestige by upgrading the occupational structure, and increasing access to education. Indeed, the economic, prestige, and educational levels of the populations of the more developed democracies have increased almost consistently since World War II, though this may not always be said for dictatorships. Also, raising the level of the occupational structure is exactly what some researchers mean by *upward structural mobility*, the case in which almost everyone is carried upward by changes in the economy that eliminate low-skill jobs while adding specialized jobs.

Degree of Inequality. The distances among the small units of a society may increase or de-

crease over time. This, so to speak, stretches the positions on the power dimensions apart or squeezes them together. The statistical term for this is the *degree of dispersion*. A number of measures of dispersion exist, such as the standard deviation (or its square, the variance), the range, the semi-interquartile (or quintile, decile, etc.) range, the share distributions, and the Gini, Theil, and Kuznets coefficients. There are two basic types of inequality: absolute and relative. Absolute conceptions assume that the metric on which the degree of inequality is measured is fixed so that as, say, real income per capita grows, the dollar difference between the mean of the top 10 percent and the mean of the bottom 10 percent of the small units may increase while each is rising above its previous level, with the slope of the top rising faster than is the slope of the bottom. For income, a proper description of these phenomena would be “changes in the *size distribution* of income.” Absolute inequality and its changes are sometimes published. Much more often published are the *share distributions* of income. For any society at any time, share distributions take the total amount of, say, income as a constant 100 percent (or 1.00) and determine the degree to which the whole amount, regardless of its absolute size, is evenly or unevenly divided among the population. These distributions include the percentage of all income held by the top X percent and the bottom Y percent of the population. Or, as in the case of the Gini, Theil, and Kuznets coefficients, they use values ranging from 1.0 to zero, in which 1.00 is the maximum degree of inequality and zero is complete equality. Viewed at one point in time in a single society, measures of relative inequality are useful, but for comparison among societies or across time in the same society, they may be misleading. In fact, for many years the share distribution measures of the income of the American people remained essentially unchanged while the size distribution inequality increased dramatically (U.S. Department of Commerce 1980). This was the case because real per capita income was increasing rapidly. The greater the degree of inequality, the greater the degree of stratification.

Crystallization. It has long been recognized that a stratification structure may tend toward or away from monolithicity, in which the different power dimensions merge into a single hierarchy or tend to be in partially separate hierarchies. At one extreme, the position of a small unit on any

one of the dimensions can be found by knowing its position on any other dimension. In other words, if the four content dimensions are perfectly correlated, those in lofty positions on one dimension also will be in lofty positions on all the other dimensions, while those in humble positions on one will be in similarly low positions on any other. At the opposite extreme, a unit’s position on a given content dimension is irrelevant to its position on any other. In the real world, any two or three might be highly interrelated, all might be moderately intercorrelated, and so forth. For obvious reasons, Svalastoga called this structural dimension “correlation.” Others have called it “status crystallization.” Note that crystallization levels and forms may be summarized better by a method called *factor analysis* than by the correlations themselves. Factor analysis can show which sets of content variables tend to vary together in a population and which do not. It also can help determine which are the dominant dimensions and which are of lesser importance in a given stratification structure. For example, it appears that the former Soviet stratification structure was dominated by the political dimension; the American, by the economic dimension. Factor analysis of the correlations of the content dimensions could indicate whether these beliefs are true. The greater the degree of crystallization, the greater the degree of stratification.

Status Inheritance. Status inheritance is the degree to which people’s level on a given content dimension is controlled by that of their parents. It is exactly the obverse of circulation mobility: A high degree of power position inheritance implies a low degree of circulation mobility. The basic statistical summary of this phenomenon is either the correlation coefficient (r) or the coefficient of determination (r^2) of the power dimension positions of offspring and their parents. (The r^2 tells how much one variable is determined by the others.) The greater the degree of status inheritance, the greater the degree of stratification.

Sorokin’s Profile. Every variable has a so-called distribution, a shape that appears when the number of scores (the *frequency*) is plotted against the value of scores. Much statistical theory today assumes that real-world distributions conform to certain mathematical shapes. The bell-shaped “normal” curve is the one most often used. For distri-

bution of income, the “log normal” curve, with which the distribution of the natural logarithm of the individual amounts forms a normal curve, is often employed. Stratification researchers often take it for granted that the distributions of power dimensions are either normal or log normal, but there is no sociological reason to assume this. The shape of the distribution of a content dimension is precisely what Sorokin meant by his term “profile.” Lacking the data and concepts to proceed further, he simply called the real-world shapes of these distributions their profiles. Today we can see that there are two aspects of each profile: mode structure and skewness.

In strikingly underdeveloped societies, almost everyone is concentrated at the very lowest values of economic, political, occupational, and educational power: extremely poor, utterly uninfluential, of low prestige, and illiterate. Above those people, their “betters” are arranged in rank order, with a wide range in which the few people who are above the bottom dwindle up the line to a handful of individuals of lofty standing. Each such distribution would have a very low mode (or distinct cluster of cases) and median (where half of the cases are higher and half are lower) and a higher arithmetic mean, with a sharply skewed tail. In somewhat more developed societies, such distributions, instead of yielding bell-shaped or log normal curves, might show multiple modes, with many people concentrated around a fairly low point, quite a few concentrated around a point a bit higher, a few concentrated toward the top, and after that a sharp skewing up to the very few at the top. The consequences of such forms for the lives of the people involved are no doubt great. For example, if in a certain society almost everyone is destitute, the few who are more or less well to do are highly visible. Even if the wealthy were really not far above the others, everybody would think of that society as being highly stratified. If in another society people are bunched together at several points along a hierarchy, thus forming multiple modes, or discrete classes, those in each mode might come to consider themselves members of a special class in opposition to those concentrated at another mode. Thus, the exact forms of profiles are essential to a description of a society’s stratification structure. Theoretically, these forms have substantial consequences for many stratification-dependent behaviors.

Profile: Mode Structure. Mode structure refers to the number, size, and location of distinct modes on the distribution of each content variable. In polymodal structures, the more pronounced the modes, the greater the degree of stratification.

Profile: Skewness. Several statistical devices exist to mark the degree of skewness. The greater the level of skewness, the greater the degree of stratification.

ILLUSTRATIONS

Data by which to measure and compare stratification structures are exceedingly difficult to obtain. A complete description at a specific point in time requires well-measured, valid indicators of four power dimensions, one or more for each dimension. For each indicator, several measurements must be made: The average level, the degree of absolute and relative inequality, the degree and factor-analytic forms of the crystallization of the whole set of indicators of the power dimension, the degree of power position inheritance, and the distributions of each one must be plotted to indicate its mode structure and measure its skewness. Describing such an overall structure requires the construction of 24 or more different indicators of structural dimensions. These indicators have to be based on representative, societywide samples large enough to permit the recording of small differences, as in the case of the few people at the upper end of a skewed distribution. The study of variations in the structure of stratification demands that comparable measurements be taken on the same variable at different times and in different places. In itself, the requirement of comparability is extremely severe when one is making comparisons among societies with different cultures or over long periods of time within the same society.

Exploratory work of this sort has been conducted on data provided by Brazil. The data were collected on a national probability sample of households in 1973 and are available for all employed men and women in the households sampled. These people are the “small units” of the descriptive analysis presented below. Brazil is a particularly good place in which to conduct such exploratory research for two reasons: It is a large country

whose regions are markedly different from each other in terms of development, and it has only one language and culture. The first factor makes it feasible to test for structural variations of stratification associated with development levels, treating regions as societies; the second eases the problem of comparability.

As was indicated earlier, it is not currently feasible to obtain measures of the political power dimension in Brazil or anywhere else. However, there is widespread agreement that income is a proper measure of the economic status dimension, that occupational status instruments based on the average education and income of each occupation are proper measures of the prestige dimension, and that education is a similarly appropriate measure of the informational status dimension. These data are available for some of the parameters that would have to be assessed to obtain a complete description of the regional-development variations of the Brazilian stratification structure in 1973.

Here one is comparing sharply different development regions. The stratification structures of three of Brazil's socioeconomic development (SED) macroregions in 1970 were delineated by obtaining multiple-item, factor-weighted SED scores on that nation's 360 official continental microregions and plotting their levels on the map of Brazil (Haller 1983). This showed the following five macroregions: the Developed South (median SED = 78 on a scale of zero to 100), the South's Developing Periphery (median SED = 54), the Undeveloped Amazonia (median SED = 32.5), the Unevenly Developed Northeast (median SED = 31), and the Underdeveloped Middle North (median SED = 13).

Obviously, this article cannot reproduce each one of the structural dimensions for each SED macroregion for men and for women. Instead, it provides a few key illustrations for three of the regions: the Developed, the Developing, and the Underdeveloped.

Variables routinely used as indicators were formulated to measure three of the four stratification content dimensions: education in years successfully completed, occupational status scores (composed of canonically weighted scores based on the education and income of each occupation), and annual income in 1973 U.S. dollars.

The illustrations are based on regularly employed men and women 15 to 65 years of age. All such persons who lived in the three regions under comparison and were part of the sample have been included. The numbers of sample members vary sharply by region and by sex. The Developed South is much more populous than the other two regions, and about three times more men than women are employed. The largest of the six gender-by-region subsamples thus consists of men in the South: over 40,000 (see Table 1). The smallest consists of women in the South's Developing Periphery: over 2,500.

Let us begin with the profiles (see Figure 1), graphs that have been sketched to show the shape of the stratification structures for men and for women as they appear in the three regions. There are two reasons for paying close attention to these curves. First, they show power relations among the people. The presence of multiple modes shows the existence of discrete and potentially opposed classes. Both the mode structure and the marked skewing indicate a high degree of stratification for each sample. Second, the fact that these distributions diverge sharply from normal or log normal curves shows that the numbers, that is, the data presented in Tables 1 and 2, are at best approximate because the shapes of the distributions affect their meaning.

The curves show the following:

1. Multiple modes are exhibited by both men and women in 11 of the 12 graphs pertaining to the developed and developing regions. The exception is distribution of women's income in the developing region.
2. For the two most developed regions, comparable curves show just about the same mode structure. In these regions, education tends to be bi- or trimodal and occupational status tends to be at least trimodal. Among men and among women in the developing region, income also exhibits multiple modes. In the underdeveloped region, the shape of the curves is markedly different form that of the others. The curves in this region show a heavy concentration of both men and women at the bottom of each indicator variable,

SOCIETAL STRATIFICATION

**Illustrative Variations of Brazilian Regional Stratification Structures by Development,
Employed Persons Age 15-65, 1973.**

STRATIFICATION CONTENT VARIABLE	REGION					
	Men			Women		
	Developed	Developing	Underdeveloped	Developed	Developing	Underdeveloped
<i>Education</i>						
General level (average)	4.9	4.2	1.7	5.3	5.1	1.6
Absolute inequality (Standard deviation)	3.9	3.8	2.3	4.3	4.5	2.7
<i>Occupational Status</i>						
General level (average)	19.4	16.8	6.7	20.3	21.1	8.6
Absolute inequality (Standard deviation)	18.9	18.0	10.8	19.7	20.4	14.6
Circulation mobility (1-r ²)	0.72	0.79	0.85	0.69	0.75	0.63
<i>Income, Annual</i>						
General level (average)	1,800	1,423	536	891	610	264
Absolute inequality (Standard deviation)	2,670	2,330	903	1,132	864	400
Number of Persons	1,578	7,686	5,841	15,711	2,581	2,777

Table 1

NOTE: *Education* is in estimated years. *Occupational status* is in canonical socioeconomic status units (0-100); *circulation mobility* is intergenerational. *Income* is in U.S. dollars.

- though some of the region's six graphs show the formation of small second and sometimes third modes at high status levels. The apparent conclusion is that the underdeveloped area exhibits a relatively high degree of equality at the very bottom of the Brazilian stratification structure. This is precisely the opposite of the thinking among many observers of Brazil, who believe that inequality is greater in the underdeveloped region (perhaps because of the glaring visibility of the tiny stratum at the top).
3. Each curve shows a high degree of skewness. That is, the highest positions are held by a tiny proportion of the people, and on the whole, as the tail of the distribution lengthens, the higher the level, the tinier the percentage of the people.
 4. In every case, the main modes are the one or two at the bottom, where most people tend to be concentrated.
 5. Almost every graph shows a tendency for one or two smaller modes to appear toward the middle of the distribution. For education, this occurs at around grade 12. For occupational status it is about 50 units, or the level of office clerks, primary school teachers, and the like. For income, it is about \$2,000 to \$3,000 per year, or a monthly wage between \$160 and \$250.
 6. There may be a tiny mode near the top of the educational and occupational status distribution in the more developed regions.
 7. For occupational status and income, women are more concentrated toward the bottom than are men.

Figure 1. Illustrative Variations of Brazilian Regional Stratification Profiles, by Development, Employed Persons Age 15–65, 1973

SOURCE: See Table 1 for definitions and sample sizes.

8. Clearly, the main regional variations in profile are between the two more developed regions and the underdeveloped region.
9. In terms of mode structure, the more developed areas seem more stratified than does the underdeveloped area.
10. In terms of skewness, it appears that the underdeveloped area is more highly stratified.

Data on the general levels and absolute inequality levels of the three content dimensions are presented in Table 1. For occupational status, the degree of circulation mobility also is presented. The general level rises with development for all three variables, except for the occupational levels of women in the developing region, whose status is slightly higher than that of women in the developed region. Again, with two exceptions among women in the developing region, the higher the level of development, the greater the degree of absolute inequality. Echoing what was gleaned from the graphs, the general level and the absolute

inequality levels of the underdeveloped region are markedly lower than those in the other areas. Finally, among men, the higher the level of development, the lower the degree of circulation mobility. Women show no trend in this regard.

Evidence regarding structural crystallization is presented in Table 2. Among men, the higher the level of development, the higher the degree of crystallization. Among women, the same trend may be present in the data, but with one small inconsistency.

CONCLUSION

This article has attempted to describe the contemporary synthesis of classical and empirical traditions of sociological thought concerning societal stratification, with special emphasis on what may be learned about ways to describe variations in stratification structures. It also presents some illustrations showing how indicators of some of the structural dimensions vary across development regions among employed men and women in

Illustrative Variations in Structural Crystallization among Brazilian Development Regions, Employed Persons Age 15-65, 1973 (Correlation Coefficients).

STRATIFICATION CONTENT VARIABLE	REGION

	Developed	Developing	Underdeveloped	Developed	Developing	Underdeveloped
Education by occupational status	0.52	0.51	0.35	0.65	0.67	0.52
Education by income	.27	.18	.16	.23	.20	.20
Occupational status by income	.23	.16	.13	.23	.17	.16

Table 2

Brazil. In general, these indicators show that the more highly developed a region is, the more stratified it is.

Measuring stratification variations among societies is an immense task because of the number of variables that must be studied and because of differences in culture, language, and social organization among peoples. Still, at both the individual and societal levels, the effects of structural differences of stratification are among the most perplexing of this age and perhaps of all ages. For this reason, understanding how and why stratification structures vary and specifying the consequences of such differences are worth the considerable effort required.

ARCHIBALD O. HALLER

SOCIETY AND TECHNOLOGICAL RISKS

If there is an organizing theme in sociology, it is social order: what it looks like, how to think about the various forms it takes, and how to explain it. Conversely, what happens when social order breaks down? What changes are wrought in how people see the world, and most important, what is altered in how they relate to one another when social order goes awry? The study of risk, danger, and catastrophe is a special case of the larger field of social breakdown.

Sociologists have long been interested in phenomena that harm people and what people value. Until recently, most of this work concentrated on harm from natural events such as earthquakes, floods, and tornadoes, but many researchers now write about “technical” or “technological” risks. In some ways the distinction between natural and technological risks or disasters is not helpful: There is no objective difference between a death caused by a fire and a death caused by an airplane crash. Yet in other ways those who have been fascinated by how modern technologies fail people have asked a broader set of questions than they could have if they did *not* see a difference between natural and technological risks. They have asked new questions about the functions of expertise and science in modern society, the roles of power and authority in the creation of danger, and the capacity of people to build systems they cannot control.

In this encyclopedia of sociology, risk and danger are treated mainly as a sociological problem, but this is not necessarily the case. Scholars writing about these issues come from economics, geography, psychology (Mellers et al. 1998), anthropology (Oliver-Smith 1996), and even engineering (Starr 1995) and physics. This is basically a good thing: Too much sociology is self-referential and inbred, and truly interdisciplinary work creates considerable intellectual, if not professional, excitement. No one can write about technological risks in an interesting way without reading and thinking in interdisciplinary terms.

Scholars concerned with technological risks have addressed a wide variety of topics that range from how individuals think about risks to how nation-states develop strategies to mitigate threats from failures of high technology. Some scholars even write about risks that might be faced by societies far in the future. Toxic threats have drawn particularly close scrutiny from scholars, and there are important sociological studies of Love Canal, Three Mile Island, Chernobyl, Bhopal, the *Challenger*, nuclear waste, and nuclear weapons. One reason for this is that toxic risks invert the way natural disasters do damage. Rather than assaulting people from the outside, as do other calamities, toxic hazards assault bodies from within. Toxic injuries also have no definable end, and so their victims can never know when they are safe from further damage. The point here is that the

meaning of toxic threats is fundamentally different from that of natural disasters (Couch and Kroll-Smith 1985; Erikson 1990, 1994). The disruption in social order thus can be largely internal, with psychological and emotional suffering caused by the breakdown of external social systems (Sorokin 1968).

In general, the sociology of risk is concerned with researching and explaining how interactions between technology and modes of social organization create hazards or the potential for hazards (Clarke and Short 1993). A hazard can be an actual threat to people’s lives (toxic chemical contamination, for example) or the *perception* that there is a threat. Indeed, many analysts focus on risk perception: what people think is dangerous and why they think what they do (Freudenburg 1988). The word “technology” refers to the social and mechanical tools people use to accomplish something, such as the design of a nuclear power plant and the vocabularies used by experts when they talk about effectively evacuating an urban area after a major radiation release from a nuclear power plant. “Modes of social organization” refers to both social structure (e.g., hierarchies of power) and culture (e.g., the degree of legitimacy granted to experts). In the twenty-first century society will continue its march toward social and technical complexity. One expression of this complexity is a capacity to create machines and institutional arrangements that are at once grand and terrifying. With these developments, it seems, publics are increasingly aware of the potentially devastating consequences of system failures even as they enjoy the cornucopia engendered by modern social organization and modern technology.

This is an opportune place to identify an area of research that will be increasingly important for both intellectual and policy reasons. A lot of work in psychology and economics, which echoes the concerns of political and economic elites, concerns public perception of risk. Much of that work has shown that the general public does not make decisions in accordance with a hyperrational calculus in which its preferences and values are always consistent and, more to the point, agree with those of trained scientific researchers. Consonant with the concern with public irrationality is the notion that people panic when faced with risks they do not understand. It is easy to find this idea

in media reports of high-level politicians' remarks after a large accident: Politicians worry that people will overreact in very unproductive ways. The image is one of people trampling each other to make for the exits of a burning building or escape from a sniper's random rifle shots. Translated to perception of risk regarding accidents and disasters, the image becomes one of individuals pursuing their self-interest to the exclusion of those of their neighbors and communities: to get out of Love Canal, to run away from Three Mile Island, or to flee a burning airplane that has barely managed to land.

In fact, research indicates that people *rarely* panic even when it might be rational to do so. I have reviewed scores of cases of natural and technological disasters—trains fall over and release toxic chemicals that endanger a town, earthquakes shake a city to its core, fires threaten to level an entire neighborhood—and have found very few instances of uncontrolled flight at the expense of others. After the Chernobyl catastrophe in 1986 there was some panic, though that response might have been highly sensible. The U.S. firebombing of Tokyo in World War II also elicited some cases of panic. With exceptions of that sort, it is hard to find widespread panic after any type of disaster. Even events such as the fire at the Beverly Hills Supper Club and the stampede at the Who concert, which are commonly thought of as examples of panic, were not (Johnson 1987). Rather than panic, the modal reaction is one of terror, followed by stunned reflection or sometimes anomie and ending with a fairly orderly response (e.g., reconstruction or evacuation). Even in the horrors chronicled by the U.S. Strategic Bombing Survey, cities burn, bodies explode, houses fall down, and still people do not panic (Janis 1951; Hersey 1985).

One way to classify research on risk is in terms of micro and macro perspectives. Both micro and macro studies have made important contributions to an understanding of the connections between risk, technology, and society. Micro-level research, generally speaking, is concerned with the personal, political, and social dilemmas posed by technology and activities that threaten the quality of people's lives. Macro-level work on risk does not deny the importance of micro-oriented research but asks different questions and seeks answers to those questions at an institutional level of analysis.

As some of the examples below illustrate, much macro work emphasizes the importance of the institutional context within which decisions about risk are made. Sociologists of risk are keen to distinguish between public and private decisions. Some people make choices that affect mainly themselves, while those in positions of authority make choices that have important implications for others. This is only one among many ways in which the sociology of risk is concerned with issues of power and the distribution of hazards and benefits.

THE MICRO LEVEL

As noted above, a substantial body of work has demonstrated that the public overestimates threats that are dramatic (e.g., from airplane accidents), particularly violent (e.g., from handguns), and potentially catastrophic (e.g., from nuclear power plants). Similarly, people tend to underestimate more prosaic chronic threats such as those from botulism and asthma. Several explanations for this phenomenon have been proposed; the one that is most convincing focuses on the mechanisms through which information about risks is channeled to people (Kahneman et al. 1982). Specifically, the media—especially newspapers and television—are more likely to feature dramatic, violent, or catastrophic calamities than less sensational threats. One reason the media find such risks more interesting is that they are easier to cover and hence more easily fit into tight deadlines. Covering prosaic risks is also more time-consuming than covering short, dramatic accidents. Thus, there are several good structural reasons why the media pay attention to high-drama risks and neglect low-drama risks. Scholars are able to explain why the public has biased estimates of risk by focusing on the structural connections between people and the media, specifically on the constraints that lead the media to be biased about certain types of information.

Another example at the micro level of analysis is found in the work of Heimer (1988, 1992; Heimer and Staffen 1998), who analyzed how information is used and transmitted in intensive care units for infants. Her study is cast at a micro level of analysis in the sense that one of her concerns is how parents think about information regarding terribly sick babies. However, like all

good sociological studies, Heimer's connects what parents think with the social contexts in which they find themselves. For example, one of her findings is that when hospital personnel transmit information to parents about their infants, that process is structured to protect the hospital from lawsuits and only secondarily to apprise parents of the condition of their children. Thus, Heimer describes, much as a psychologist might, how parents think but also demonstrates that how they think is contingent on the organizational needs of hospitals.

THE MACRO LEVEL

Macro-level work on risk includes research on how professionals influence the behavior of regulatory agencies, how organizations blunder and break down (Vaughan 1999), how social movements arise to push issues into the public debate, and how national cultures influence which risks are considered acceptable (Douglas 1985). Many macro theorists are deeply concerned with how the institutional structure of society makes some risks more likely than others to gain political and intellectual attention (Clarke 1988). Consider motor vehicle risks. Nearly 40,000 people are killed on U.S. highways every year, and most people would agree that that is an appalling mortality rate. Although it is a commonplace that half those deaths are alcohol-related, it is not really known how much of the carnage is in fact due to alcohol (Gusfield 1981). Nevertheless, one probably can reasonably assume that a significant proportion is caused by drunk drivers (even 10 percent would be 4,000 people). Most people would agree that 4,000 deaths per year is grounds for concern, yet it also is known that high rates of fatal traffic accidents are associated with speeding, wrong turns, and improper passing. Objectively, there is no difference between a death caused by someone making a wrong turn and one caused by a drunk driver, yet most cultures say the two deaths are very different. In the United States there is even a small social movement galvanized around the issue of drunk drivers, an example of which is the organization called Mothers Against Drunk Driving. Why is there no organization called Mothers Against Improper Passers? A sociological answer is that most cultures frown on using drugs to alter one's degree of self-control and that a person who does so is defined as morally decadent and lacking social

responsibility. Thus the opprobrium unleashed on drunken drivers has less to do with the objective magnitude of the problem than with the apparent danger such drivers represent to the cultural value of self-control.

Another example of macro work on risk, this time concerning organizations and symbols, is the oil spill from the *Exxon-Valdez* tanker in March 1989. At the time, the Exxon spill was the worst ever to occur in U.S. waters, leaking at least eleven million gallons into Prince William Sound and the Gulf of Alaska. The spill caused massive loss of wildlife, and although no people died, it did disrupt social relationships, create a political crisis, and reorient debates about the safety of oil transportation systems in the United States. From a sociological point of view, one of the most interesting things about the spill is how corporations and regulatory agencies plan for large oil spills. Sound research shows that not much can be done about large amounts of spilled oil (Clarke 1990), yet organizations continue to create elaborate plans for what they will do to contain large spills and how they will clean the oil from beaches and shorelines. They do this even though there has never been a case of successful containment or recovery on the open seas. Organizations create plans that will never work because such plans are master metaphors for taming the wild, subjugating uncertainty, and proclaiming expertise. In modern societies, expert knowledge and rational organization are of paramount importance, and there now seems to be an institutionalized incapacity to admit that some things may be beyond people's control (Clarke 1999).

Another example is the 1984 tragedy in Bhopal, India. At least 2,600 people died when a complex accident in a Union Carbide plant released toxic chemicals into the environment. At the time, Bhopal was the worst single industrial accident in history (the nuclear meltdown at Chernobyl in 1986 eventually will lead to more deaths). The Bhopal tragedy was certainly an organizational failure, as studies have documented (Shrivastava 1987). However, what was most interesting about the Bhopal accident was that the risk created by the Union Carbide chemical plant had become institutionalized to the point where very few, if any, of the key players, were worried about a potential catastrophe. The poor people who lived next to the plant

seemed to have accepted official assurances that they were safe and in any case had little choice in the matter. Government officials—the ones assuring those who lived near the plant of their safety—seemed to have accepted the disastrous potential of the plant as part of the price of having a large corporation in their country. For their part, corporate officials and experts seemed to have given insufficient thought to the possibility of killing several thousand Indians. One reason the Bhopal disaster is sociologically interesting is the degree to which groups and organizations come to accept risk as part of their everyday lives. The same observation might be made of automobile driving, nuclear power plants, and lead-contaminated water pipes (even brass pipes contain about 7 percent lead).

Anyone reading about how social organization and technology can break down must wonder whether it must always be so. Some people believe that it must, and although those scholars may be wrong (Clarke 1993), they cannot be ignored. High-reliability organizations (HROs), as they are called, are said to be possible. These organizations are alleged to be so safe that they are error-free. The claim is not that these organizations cannot fail but that they never do so in an important way (Roberts 1993). Somehow these organizations (a U.S. nuclear aircraft carrier is a good example) are able to maintain a strict hierarchy while enabling people low in the hierarchy to intervene in the functioning of the organization to prevent failure (contradicting how most organizations work). Moreover, rather than cover up their mistakes as most organizations do, HROs try hard to learn from theirs. Finally, these organizations have a lot of redundancy built into them, preventing small errors from escalating into complete system failure.

High-reliability theory is animated by a disagreement with what is called normal accident theory (NAT) (Perrow 1984). NAT views the complexity of high-technology systems as problematic. The components in complex systems, say, a nuclear power plant, can fail in ways that no one could have anticipated and that no one understands when a catastrophe unfolds. From this view, rather than safety, redundancies can add technical complexity and lead to the formation of political interest groups, both of which can interfere with safe operations (Sagan 1993). Rather than honest learning, NAT stresses that managers and experts

often engage in *symbolic* representations of safety, trying to convince the public, regulators, and other organizations that they are on top of potential problems (Clarke and Perrow 1996). An important contribution of NAT lies in locating the source of risk in organizations per se. Its structural emphasis draws attention away from easy and familiar explanations such as human error.

The contrast between NAT and HRO theory goes beyond their assessments of the inevitability of organizational failure, for the two schools of thought exemplify the concern with social order and disorder that I mentioned above. High-reliability theory is optimistic about human perfectibility, highlighting society's tendency to create and maintain order; normal accident theory is pessimistic about human perfectibility, fundamentally viewing failure and disorder as inherent in the human condition.

An important work that emphasizes the imperfections of organization is Vaughan's book on the *Challenger* accident (1996). Vaughan argues that what looked like a highly risky decision—to send the *Challenger* up that day—was in fact normal given the routines and expectations that organized the thoughts of the officials and experts involved in that choice. An important reason for this “normalization of danger” was the high production pressures that the decision makers faced. It was not a matter of people deliberately taking chances they knew were unreasonable because of clear, external, imposing pressures. It was a more subtle process by which the very definition of “reasonable” shifted in a way that did not contravene those pressures. Vaughan's view stresses the commonality of error in all organizations. Some organizations make computer chips, some make space flights, but all fail. Vaughan details the mechanisms that produced a certain worldview of danger and safety that prevailed at NASA, and in so doing she connects micro and macro, structure and culture.

Every year the natural environment seems to be more polluted than it was the preceding year. Why? A commonsense explanation might claim that people do not care enough about the environment, perhaps attributing callous attitudes and personal greed to politicians and corporations. Such an explanation would focus on the motives of individual managers and politicians but from a

sociological point of view would miss the all-important institutions in which such decision makers function. Sociologists know that those who occupy top positions in government and corporate organizations are not without intelligence and good sense. These decision makers may be individually quite concerned about environmental degradation, but because of their structural locations, they are subject to pressures that may be at odds with environmental health and welfare. These pressures originate in specific social structures that create institutional interests that may be contrary to individual preferences (Clarke 1988). A corporate executive seeks (and *must* seek) to remain in business, if necessary at the expense of others' well-being or the environment. A similar explanation accounts for why Ford's president, Lee Iacocca, in the 1970s marketed Pintos that had propensity to explode and burn. In other words, market institutions are arranged so that it is sensible for any individual or organization to force negative externalities on society. For its part, one of the key functions of government is to maintain a political and economic environment that is favorable to business. Thus, an explanation that centers on the institutional constraints and incentives that shape decisions about pollution can account for the behavior of organizations, experts, and officials far better than can an explanation that focuses on their personal characteristics.

FUTURE DIRECTIONS

Future developments in the sociology of risk probably will revolve around issues of social conflict: its bases, meaning, and role in spurring social change. Society—and sociology—will be confronted with fundamental dilemmas in the twenty-first century. Society will have to deal with issues of environmental justice and the likelihood that pollution and risk are unequally distributed. Modernity brings both fruits and poisons. In particular, people must come to grips with what may be the primary dilemma of modern times: How can an industrial and democratic system that yields such a high standard of living also be involved in the creation of terrible hazards? Answering this question will require a recognition that many of the most frightening threats—nuclear meltdowns near large cities, toxic leachate in water tables, ozone destruction, explosions of liquefied natural gas from supertankers, failure to contain nuclear waste—almost seem

beyond control. It may be the case that before society can better control political and technological systems, people must admit that some aspects of the technical world are not within human control.

LEE CLARKE

SOCIOBIOLOGY, HUMAN

THE DARWINIAN SETTING

Sociobiology is the term used to describe a relatively recent stage in the continuing development of evolutionary biology. It systematically brings the study of social behavior under the umbrella of the Synthetic Theory (or the Modern Synthesis) that, starting in the 1920s, arose from the marriage of Darwinian theory and Mendelian, or genetic, science (Huxley 1942). The most challenging aspect of the new elaboration concerns a decisive

step into human behavior. Sociologists (and social scientists in general) have not responded with enthusiasm; the old anthropocentrism with its extreme stress on culture and socialization (environmentalism) is still dominant. Resistance, however, is slowly breaking down, and one may speak of a human sociobiology taking the form of "evolutionary anthropology," "evolutionary psychology," "evolutionary sociology", and so forth. It can even be stated that human sociobiology may represent the beginning of the long-desired synthesis of the social sciences. At the same time, the introduction of cultural parameters into evolutionary explanation may further enrich the modern synthesis.

The term "sociobiology" harks back to the mid-1940s, and the evolutionary study of behavior began to develop rapidly only in the 1960s. However, its roots can be traced back to Darwin's ([1859] 1958) theory of evolution by natural selection, still the cornerstone of evolutionary science. From today's perspective, Darwin's theory can be conveniently stated as follows:

1. The rate of reproduction in populations, such as species, tends to be faster than the growth of the resources needed to sustain all their members.
2. As a result, populations experience a real or potential scarcity of resources.
3. This scarcity stimulates the "struggle for existence": competition of various kinds both within and between populations.
4. Some individuals in any given population are more successful than others in the struggle and thus are more likely to survive long enough to reproduce.
5. This differential reproductive success is in the last analysis the result of "variations" between individuals: genetic differences. That is, some variations are better suited (adapted) than others for the competition.
6. The better adapted these variations are, the more likely they are to be inherited by one's descendants.
7. This generational preservation of favorable variations and the concomitant elimination of unfavorable ones are together referred to as "natural selection."

This theory either contains or fosters the basic elements of the theoretical program of sociobiology. Specifically, (1) it establishes natural selection as the basic mechanism in the evolution of behavior, (2) its stress on competition calls attention to the perennial question regarding the role of altruism and selfishness in social life, (3) its focus on heredity suggests that aspects of human behavior, including culture, may be at least partly the result of natural selection and thus of forces long at work in human evolution, (4) perhaps more important, it guides inquiry toward a systematic theory of human nature. The crucial question of this theory is: In the course of human evolutionary time, what *innate* behavioral tendencies (predispositions, psychological adaptations, epigenetic rules, etc.) have been forged by natural selection and environmental pressures acting on genetic matter? These adaptations are likely to be implicated to some degree in socialization processes, thus proposing a more complete explanation in social science.

ELEMENTS OF SOCIOBIOLOGICAL THEORY

The modern synthesis stimulated scientific activity in general and, through such disciplines as entomology, primatology, and ethology, paved the way to the evolutionary study of behavior. Then in 1975 a seminal work proclaimed the advent of a "new synthesis" (Wilson 1975). The master stroke of sociobiology is the revival of "the struggle for existence," that is, the *behavioral* aspect of evolution on which natural selection was clearly based in the work of Darwin. The ultimate consequence of this struggle, or competition for resources, is natural selection: the differential contribution of offspring to future generations. This differential is a rough measure of what Darwin, following the sociologist Herbert Spencer, called "fitness." Accordingly, we are already in a position to state that *in the last analysis* individuals (or simply organisms) may be productively viewed as being in competition with one another for reproductive success, or genetic fitness. (Without the behavioral component, the statement would read, classical Darwinian logic: Organisms are the descendants of the more reproductively successful organisms.)

The Maximization Principle. This Darwinian-Mendelian idea is rendered more formally by what is considered the general law or principle of

sociobiology. Sometimes referred to as the maximization (or fitness) principle, this law states that, while organisms engage in all sorts of behaviors, in the last analysis they tend to behave in ways that maximize their inclusive fitness, or the chance of conveying their genotype (genetic makeup) to future generations. This is a probability statement: That is, some individuals are more successful than others in the reproductive competition. This idea of variability reflects the logic of natural selection and accommodates many facts that may seem strange or contradictory of evolutionary theory. A case in point is the parental abuse of children. Clearly, if organisms differ in the degree to which they behave adaptively one effective way to show this is for them to differ in the way they treat their children. However, this statement is heuristically a bit "lazy": It stimulates research insufficiently. Like many other laws in science, it would be more useful if it took the form of a contingent proposition. A first approximation in this direction is available and the provisos proposed are "creature comforts," "self-deception," and "autonomization of behavior" (the tendency of means, such as wealth, to become ends in themselves), all of which appear to condition negatively the maximization tendency (Lopreato 1989; for incisive analyses of this argument, see Crippen 1994; Maryanski 1998, pp. 11-16; Maryanski and Turner 1998, pp. 128-131).

The use of the adjective "inclusive" is intended to underscore the fact, better understood in the post-Darwinian period (Hamilton 1964), that the fitness of organisms is measured in terms of their relatedness both to their offspring and to other members of their genetic kin, whom they typically favor in many fundamental ways over nonkin. Hence, family life issues are central foci of sociobiology. Also, the maximization principle does not fit neatly into the mold of individual experiences. Human beings are not overtly obsessed with the enhancement of their fitness, and some, as was noted above, actually behave maladaptively. It is necessary to keep in mind, therefore, that the principle does not assume consciousness of the fitness consequences of behavior.

The fitness principle performs various functions. The crucial one is to logically structure established discoveries and thus stimulate cumulative, systematic knowledge. Central in this undertaking is the discovery of the mental rules that may be said to constitute human nature. Are people,

for example, constituted to facilitate the persistent prejudices and ethnic affiliations that periodically flare up in bloody conflicts across the globe? Surely, people grow up with such prejudices and absorb them, but why is this learning universal? Is it possible that it is an effect of evolutionary forces? To learn any given behavior, one must have a capacity for it in the brain. Try as humans might, they never can be socialized to behave like foxes, or like any other animal. Aristotle was correct in his metaphor of the oak acorn: If an acorn becomes anything, it can only become an oak, never, say, a fig tree.

The Law of Altruism. As fitness theory develops, the principle surrounds itself with auxiliary statements of theory that facilitate the quest for a theory of human nature. In what follows, this article touches on a few of these. Let us start by noting that central to sociobiological reasoning is the metaphor of “the selfish gene” (Dawkins 1976), which recalls the so-called Hobbesian question of order: For whose benefit does the individual behave? Selfishness is such a prevalent concept in evolutionary science that according to Wilson (1975, p. 3), the question of its opposite, what the sociologist Auguste Comte termed “altruism,” constitutes “the central theoretical problem of sociobiology.” Acts that benefit others are commonly observed in all behavioral disciplines. How to explain them? The social and moral disciplines have been of little help, largely because of the ambiguity of their concepts. What seems altruistic to scholar X is viewed as selfish by colleague Y.

Sociobiologists have taken a major step toward the solution of this problem. Countless observations coupled with the logic of the fitness principle have led to the position that altruism strictly viewed refers to genetically “self-destructive behavior performed for the benefit of others” (Wilson 1975, p. 578). In short, genuine altruism reduces the benefactor’s fitness; hence, if it arises in a given population, natural selection may be expected to wipe it out fairly quickly. If, for example, Mary is driven by her genes to do good for John at the expense of her own reproductive interest (e.g., cohabit with him and then be abandoned childless at an age when her chances of marriage and/or reproduction are greatly reduced), her altruistic genes will not be represented in the next generation (unless they are conveyed by her blood kin). What is it, then, that people call altru-

ism? Typically, it is either favoritism toward kin (*nepotistic favoritism*) or favoritism accompanied by the expectation of reciprocation (*reciprocal altruism*). Both types benefit the “altruist,” sometimes with interest. Evolutionists’ venture into the topic of altruism has produced rich harvests, particularly the discovery of *kin selection and inclusive fitness* (Hamilton 1964) and the theory of *reciprocal altruism* (Trivers 1971), which together yield the law of altruism.

Kin selection and inclusive fitness are dramatically illustrated by the study of eusocial insects, such as ants. Approximately three-quarters of these animals are female (“workers”), and very few reproduce. It would be a mistake, however, to consider them genuine altruists. Workers are so named because they are very diligent in catering to the needs of the queen (typically their reproductive mother) and her prodigious brood. Furthermore, given their peculiar reproductive system (*haplodiploidy*, whereby females have both parents while males, hatched from unfertilized eggs, have only a mother), workers are more closely related to the future generations than are their counterparts in diploid species such as mammals. As a result, failure to reproduce results in little or no loss in fitness. In short, eusocial insects have evolved according to kin selection and inclusive fitness. Indeed, this strategy is widespread among social animals. In humans, this fact is underscored by last wills and testaments, according to which people rarely bequeath their (fitness-enhancing) resources to anyone except blood kin (Clignet 1992).

Kin Selection and Ethnic Conflict. The familism inherent in kin selection has numerous expressions. One is related to the widespread phenomenon of ethnic identification and the recurrent cases of ethnic violence that often take everyone but the participants by surprise. More than eighty years ago, Pareto applied the logic of kin selection to explain the formation of persistent groups such as ethnic groups. They are “natural formations,” he argued (1916, section 1022), “growing up about a nucleus which is generally the family, with appendages of one sort or another, and the permanence of such groups in time engenders or strengthens certain sentiments that, in their turn, render the groups more compact, more stable, better able to endure.” This evolutionary perspective on ethnicity and ethnocentrism had been foreshadowed by Sumner (1906) and was subsequently approximated

by several sociologists (e.g., Park and Burgess 1921; Gordon 1964). More recently, van den Berghe (1981) produced a thoroughly evolutionary theory of ethnicity and ethnic conflict (see also Lopreato and Crippen 1999, chap. 9).

Sociologists continue to debate the causes of ethnic phenomena, typically focusing on cultural factors, such as differences in language or religion, that are specific to given times and places. Are such factors relevant? Very probably, but ethnic phenomena are persistent and universal; across the globe there are numberless mixtures of peoples who have an awfully hard time living together in peace. Any universal phenomenon requires first and foremost a universal explanation.

In brief, during nearly all of human evolutionary history people lived in small bands of about twenty-five to fifty individuals, often surrounded by neighbors who coveted their resources. Warfare or the threat of it was frequent. Benedict (1934, pp. 7–8) described “primitive man”: “From the beginning he was a provincial who raised the barriers high. Whether it was a question of choosing a wife or taking a head, the first and important distinction was between his own group and those beyond the pale. His own group, and all its ways of behaving, was unique.” Intense internal solidarity was a precondition of survival. To practice it was also to practice kin selection and kin favoritism. Since the modern human brain evolved in such circumstances, it can be concluded that the tendency to identify with one’s own “clan”—to distinguish between “us” and “them”—is alive and well in human society. Ethnicity is an extension of the family. Nepotistic favoritism is wired in the brain, and at the *ultimate* or general level it and the kin selection to which it is inextricably associated are the cause of the persistence of ethnic identification and recurrent ethnic conflict. “Who am I?” “Who are mine?” These are enduring whispers in the human psyche.

Of course, it is difficult to answer such questions in the megasociety, and that is one reason why most of the time people live in a reasonably peaceful relationship with their neighbors. Still, people are attentive to markers of “weness” such as a common name, common historical experiences, distinctive cuisine and artistic expressions, and often a common language, in historical time if not now (van den Berghe 1981).

Reciprocal altruism. Reciprocal altruism refers to the fact that if and when people engage in actions that benefit others, they do so with the expectation, conscious or not, that the others will repay, especially if they are not related. This is the object of a much-tested and growing theory first stated by Trivers (1971). According to the basics of this theory, the evolution of reciprocal altruism was facilitated by three broad conditions: (1) repeated situations in which the value of altruism to beneficiaries was, in terms of fitness, greater than the cost incurred by the benefactors, (2) membership in a small group featuring little or no migration, thus enhancing the chances of reciprocity, (3) fairly equal ability between pairs of individuals to engage in mutual help. Trivers proceeds to argue that a system of reciprocal altruism is subject to “cheating”: Some individuals do not reciprocate the benefits they receive. Indeed, an underlying assumption of Trivers’s theory is that givers are motivated to receive more than they give. Accordingly, as reciprocal altruism was evolving, another set of adaptations, what Trivers terms a “psychological system,” was arising fairly in step with it; their function was to regulate cheating. They include emotions such as friendship, sympathy, trust, suspicion, and moralistic aggression, along with hypocrisy and feelings of guilt.

Combining the logic of kin selection and reciprocal altruism, it is possible to state a *law of altruism* as follows: *In keeping with the fitness principle, social organisms have evolved to favor others (1) in direct proportion to their degree of genetic relatedness to them and (2) to the extent that the benefit they derive from doing good to others is, in terms of fitness, equal to or greater than the cost of their altruism.*

The law is relevant to various human phenomena, and casts light on a number of puzzles. For instance, social scientists have noted that the exchange of gifts is a universal institution in human society (Mauss [1925] 1954). Moreover, a version of this tendency termed “potlatch” is in varying degrees “a universal mode of culture” (Lévi-Strauss [1949] 1969). In an extreme form of potlatch practiced by the “Indians” of Vancouver and Alaska, one gives with a view to crushing another and thus gaining “privileges, titles, rank, authority, and prestige” (Lévi-Strauss [1949] 1969, chap. 5). Specifically, gifts are given to a competitor with the shared understanding that the recipient will reciprocate with interest after a reasonable interval.

When such an obligation cannot be met, the recipient loses status, titles, and so forth. Social theorists have been eager to downplay the individual's selfish undercurrent and the social conflict it engenders. The law of altruism conversely predicts selfishness, competition, and precariousness of status in one's group.

Nevertheless, the extreme stress on selfishness cannot go unchallenged for the human species. The only known attempt of this sort avoids the genetic trap (altruists are by definition "selected out"). Using a biocultural perspective at the core of which is the evolution of *the idea of the soul* and *self-deception*, it concludes that behaviors intended to save the soul mimic fitness-enhancing behaviors (Lopreato 1984, pp. 207-235). Catholic nuns and Buddhist monks, for example, practice celibacy and other forms of ascetic behavior in view of immortal ends. Typically, they contribute little or nothing to the fitness-enhancing resources of their blood relatives. Yet their type manages somehow to "reproduce" itself. Genuine or "ascetic" altruism may be rare in human society, but it is a cultural fact.

The Law of Anisogamy. Human psychological adaptations may be divided into two major types. One is specieswide, referring to innate tendencies that in varying degrees cut across gender. Examples include tendencies toward kin favoritism, ethnic identification, reciprocal altruism, and cheating. The other major class accounts for the fact that throughout human society there have been some remarkable differences, as well as similarities, along sex lines (Trivers 1972; Kimura 1992; Lopreato and Crippen 1999). The differences are suggested by a basic diversity in physioanatomy. *Anisogamy*, the name given to it, refers to the difference in size and structure between male and female sex cells (gametes). Male gametes (sperm) are minuscule and contribute only genes to reproduction. They are produced in huge quantities almost continuously after the onset of sexual maturity. The reproductive potential of males is therefore huge, and some men have fathered thousands of children (Betzig 1986). By contrast, female gametes are much larger, are nutritious, and are produced *in utero* once in a lifetime. Then, beginning at menarche, they are released, typically one at a time, about once a month, so that on average women produce some 300 to 400 mature eggs in a lifetime, only a very small number of which are

likely to result in offspring. Women are constituted to bear the cost of pregnancy, nursing, and much of the protection and guardianship, at least during the offspring's tender years. In short, each child represents a huge reproductive investment for the typical woman.

By contrast, males make a very small investment. They do not get pregnant or suffer nausea; nor do they risk their life at the birth of a child and for months or years afterward. If we consider such other facts as abandonment, divorce, and the refusal or failure to provide child support, the level of paternal investment is on average truly puny. There is no intention here to condemn men or glorify women. It is a matter of trying to grasp certain facts in order to understand certain others. Males and females have evolved under the pressure of significantly different, though partly complementary, reproductive strategies, and much of their behavior is an effect of this fact. It is now time to state what was earlier termed the *law of anisogamy* (Lopreato 1992, p. 1998): *The two sexes are endowed with differing reproductive strategies, and their behaviors reflect that difference in direct proportion to their relevance to it.* The closer one gets to the fundamental activities of life (sexual behavior, family life, and among endless others the conditions that recall the division of labor in the clan, the type of society in which the human species spent 99.5 percent of its history), the more likely one is to observe the effects of anisogamy. The basic implications of anisogamy have been drawn by Trivers (1972) in a seminal paper on "relative parental investment."

Differential Parental Investment and Sexual Selection. The law of anisogamy contains a number of corollaries. The two major ones noted briefly here are very closely related. Differential parental investment (DPI) states in effect that females make both a greater initial parental investment and greater subsequent parental investments than do males, so that their behavior is more finely adjusted to the well-being and reproductive success of the offspring. Supporting facts are legion. They are epitomized by the following widely noted findings, among others: On average females are more cautious than males in their sexual activity, and they tend to prefer as mates men who are in fact, or show promise of becoming, relatively rich in the resources needed to raise healthy and reproductively viable offspring. Mating has always been far riskier for women, and this fact is deeply rooted in the

brain. As a consequence, it tends to express itself even in times and places where mating need not have reproductive consequences. For millions of years, and even today in much of the world, an unwanted pregnancy or a pregnancy with a partner who will contribute little or nothing to the well-being of the offspring may consume a large portion of a woman's reproductive potential. In summary, women go for quality; men, for the allure of quantity.

A study of 10,047 individuals living in various countries on six continents strongly suggests that culture has a notable influence on mate preferences and that the two sexes agree on some of the basic requirements of a good mate, such as honesty and dependability. However, the findings also reveal some marked universal differences that are predictable from the law of anisogamy. For instance, females are significantly more likely than males to emphasize ambition and industriousness. Conversely, males more than females prefer mates who are physically attractive, younger than themselves, and at the peak of their reproductive value even if they are of lower socioeconomic status (Buss 1989).

The sexual selection (SS) corollary may be stated in Trivers's (1972, p. 140) words as follows: "Individuals of the sex investing less will compete among themselves to breed with members of the sex investing more, since an individual of the former can increase its reproductive success by investing successfully in the offspring of several members of the limiting sex."

The idea of sexual selection is a remarkable example of great ideas that emerge out of creative confusion. Darwin understood that in the final analysis the measure of survival is reproductive success. Nevertheless, he tended to focus on survival as *longevity*. As a result, certain observations, both behavioral and physical, confronted him with a special challenge. Why the great horns, the displays, the mimicry, the special weapons, "the instrumental music," or, among other male characteristics, the huge tail of the peacock? Such unusual features tend to attract predators and thus reduce longevity. Darwin (1859, but especially 1871) concluded that if such "secondary sexual characters" enhance the bearers' ability to reproduce, they are likely to be favored by natural selection even if they act negatively on longevity. However, because

such characters were conspicuous in sexual competition, they suggested to him the label "sexual selection." There is some debate over the meaning of this term (see Mayr 1972 for a review), but it is safe to say that it refers not to a type of selection but instead to a major cause of natural selection. "After all," as Dobzhansky et al. (1977, p. 118) noted, "Darwinian fitness is reproductive fitness," whatever the cause. Sexual selection, or *competition for mates*, refers most explicitly to the struggle for genetic survival. It further suggests that much animal behavior and appearance are adapted not so much to the problem of daily survival as to the job of securing adequate mates.

Viewed as competition, sexual selection has become a valuable tool of research, especially in view of certain distinctions suggested by Darwin himself. In current language there are two major types of sexual selection. One, often termed "intrasexual selection," subsumes a female-female competition and a male-male one. The other refers to a form of male-male competition, too (the competition "to charm the females"), but Darwin viewed it as an effect of the females' response to "charm." Accordingly, it has come to be known as *female choice* (or "intersexual selection"). It is evident that differential parental investment and sexual selection are closely linked properties of anisogamy. In fact, one may combine the logic of DPI and SS to state what may be termed the DPI-SS corollary as follows: *Given anisogamy, females have been selected to engage in choosy behavior, while males have been selected to specialize in agonistic behavior.*

Female choosiness in human beings takes many forms. This article has mentioned the tendency to prefer resource-rich mates. As a group, even in a highly developed society like the United States, women pay less attention to looks, have and claim to want fewer sexual partners, are less likely to have their first sexual experience with a stranger, are more likely to expect a commitment before engaging in sex, and among many other differences, are less likely to cheat on their mates, whether husbands, cohabitators, or boyfriends (Laumann et al. 1994).

Competitiveness, too, takes many forms. One is reflected in the ancient and still fairly common practice of polygyny, especially if one considers the greater tendency of divorced men to remarry and have further children (Betzig 1986; Lenski

and Lenski 1987). Another form is expressed in violent behavior. Killing, for example, is throughout the world a largely male behavior and is concentrated among young men during the peak years of their reproductive life. Prominent among the motives for homicide are sexual jealousy and rivalry as well as dominance contests in various contexts (Daly and Wilson 1988). Death by trauma (murder and accidents) accounts for a relatively high percentage of male mortality and part of the lower life expectancy of men (Verbrugge 1989). Of course, there are many other forms of competitiveness, and women are not immune to the tendency to practice them.

Of Sex Roles. Sociological practice is almost entirely environmentalist and often clashes with an evolutionary perspective. For example, according to “feminist” authors, especially so-called *gender feminists*, men and women are born with identical potentials. The idea that, given anisogamy, the brain has been neuroendocrinally gendered (Kimura 1992) is extraneous if not altogether offensive to them. They argue conversely that society is ruled by a system of *patriarchy*, and socialization thus proceeds to produce differences that are detrimental to women. Girls are socialized to be passive and subordinate, while boys are trained to strive for success and dominance (Lerner 1986, p. 29). In short, so-called sex roles are the effect of culturally prescribed discrimination and must be explained in terms of cultural causes only. Some writers go so far as to argue that physiology is irrelevant or that “human physiology is *socially* constructed and gendered” (Lorber 1994, p. 46; emphasis added).

Sociobiologists do not deny that once an arrangement such as patriarchy is in place, the channels of socialization tend to develop in view of its mandates. However, science does not merely assert facts; it seeks to explain them. As Hrdy (1997, pp. 7–8; italics in the original) notes, “an evolutionary perspective pushes the search for patriarchy’s origins back . . . by millions of years by asking an additional question: *Why* should males seek to control females?” That is, why patriarchy in the first place? Accordingly, it less superficially identifies sexual selection “rather than male desire for power as the engine driving the system” of patriarchy.

To understand patriarchal phenomena and have more than a wishful chance of bringing effective cultural forces to bear on them, one must

begin by answering Hrdy’s question. In the process, a very unpleasant irony will be uncovered. The dynamics that produced patriarchy include female complicity with domineering males. Male dominance has been achieved at least in part because of female preference (female choice) for dominant males. Indeed, males dominate females by dominating other males with female help. Thus, the pickle that many people find so distasteful “turns out to have been seasoned with only a sprinkle of culture at best, although once culture arose it made it even more tartish. It is also true that our female ancestors had a hand in the preparation” (Lopreato and Crippen 1999). Moreover, women throughout the world continue to support patriarchy through their persistent tendency to favor dominant males.

CONCLUSION

In order to advance, would-be sciences need to discover the value of a number of time-tested techniques. These techniques include especially the use of remote concepts and logical ways to operationalize them, the nomothetic derivation and testing of hypotheses, and the logical structuring of the hypotheses in a body of systematic, cumulative knowledge that facilitates further research and discovery. The history of science strongly suggests that to accomplish even these minimal feats, it is necessary to either discover one general principle or to borrow it in full or modified form from a cognate and more advanced science. At the start of the third millennium there is still no general principle in sociology, general in the sense that it would contain the logic for a large number of derivative statements linking discovery and explanation across the institutional framework. The fitness principle and the theoretical tools surrounding it constitute an invitation from sociology’s most proximate natural science to embrace the fact that the human brain represents a tenacious link to a past that in part is still present. The potential payoff is likely to be far greater than even the most sanguine evolutionists can imagine. It may suffice to consider that just as Newtonian laws eliminated the old prejudice of geocentrism, thus freeing the mind to behold previously inconceivable wonders of nature, sociobiology offers a human perspective from a distance, thus freeing the mind from the still-oppressive assumptions of

anthropocentrism and *temporecentrism*, benighting corollaries of geocentrism.

According to many critics of sociobiology, since certain behaviors are “natural,” they are not subject to cultural intervention. This is an error that sociobiologists do not commit. Because they are evolutionists, their theorizing is subject to a systemic perspective: “Phenotype” (any feature of anatomy, physiology, or behavior) is a result of the interaction between genotype and environment, including culture. It is essential to have knowledge of both. To change the world, as many scholars are inclined to do, with knowledge (always imperfect) of one to the exclusion of the other is not only obscurantism; it is poor, perhaps dangerous, engineering as well.

SOCIOCULTURAL ANTHROPOLOGY

In the United States, anthropology usually is considered to consist of four subdisciplines, or “subfields”: archaeology (describing and understanding past human behavior by examining material remains), physical or biological anthropology (describing the evolution and modern physical variation of the human species), anthropological linguistics, and sociocultural anthropology. Most university departments of anthropology have faculty in three or four of these subdisciplines. Sociocultural anthropology often is called simply cultural anthropology in the United States, although a few academic programs use the term “social anthropology,” the common designation in Europe. Some anthropologists identify applied anthropology as a fifth subfield, while others consider it part of sociocultural anthropology.

Anthropology is defined as the study of human commonalities and differences and expressly includes the entire temporal and geographic range of humankind in its scope. The database of the discipline is large, including prehistoric populations as well as every variety of contemporary society. In distinguishing itself from other social sciences, anthropology emphasizes the holistic, comparative, culture-centered, and fieldwork-dependent nature of the discipline.

In Europe, social anthropology is more closely allied with economics, history, and political philosophy than it is with physical anthropology and archaeology, which often are taught in separate programs. As social anthropology evolved in Europe, it came to be associated with studies of the economy, ecology, polity, kinship patterns, and social organization of non-Western peoples, particularly in colonial Africa and Asia. The European approach to theory was associated with sociological (especially functionalist) and, more recently, historical approaches. In the United States, where research focused initially on Native Americans and was strongly influenced by the particularistic descriptive approach of Franz Boas’s ethnogra-

phy, anthropology came to be associated with culture, that “complex whole” (in Edward Tylor’s words) encompassing customs, language, material culture, social order, philosophy, arts, and so on. European social anthropologists have not failed to address culture and Americans have not neglected social structure, yet the difference in terminology distinguishes an emphasis on social relations from an emphasis on shared meaning and behavior.

The heart of sociocultural anthropology is ethnography, the written description of a culture group. Ethnography has undergone many changes since it began with field reports by missionaries and colonial officials. The pace of change has increased since the 1960s, as recognition of global links has become standard, other social scientists have adopted ethnographic methods, and postmodernism has imposed stricter self-reflective criteria on writers. The methodological partner of ethnography is ethnology, the comparative study of societies. In its first decades, anthropology established the ideal that a complete ethnographic record of the world’s cultures would allow comparative studies that would lead to generalizations about the evolution and functioning of all societies. Cross-cultural studies continue to be one of the distinctive contributions of anthropology to the social sciences.

HISTORY

Anthropology and sociology share common origins in the nineteenth-century European search for a science of society. Sociocultural anthropology and sociology also share a theoretical history in the ongoing struggle between the desire for a generalizing, rule-seeking science and that for a humanistic reflection of particular lives. Throughout the twentieth century, academic specialization and differences in research topics, geographic focus, and methodological emphasis separated the two disciplines. In the last several decades, globalization has fostered a partial reconvergence of methods and subjects, though not of worldviews, ethos, or academic bureaucracies.

Sociocultural anthropology often is contrasted with sociology: It is said that anthropologists study small-scale societies, assume that those societies are self-sufficient, and are usually outsiders (politically, ethnically, and economically) to the groups they study. These generalizations are partly true.

The methods of sociocultural anthropology have emphasized the usefulness of seeking “the large in the small” by becoming intimately acquainted with a single band, village, tribe, island, or neighborhood, and anthropology’s early link to colonialism and its base of support in Europe, Japan, China, and the United States has privileged wealthy outsiders as observers of peasants, tribal peoples, and marginalized groups. However, anthropology has always kept the larger picture in mind, and for every study of an “isolated” population, there are ethnographies that reveal links at the regional, national, and global levels. The affiliation of sociocultural anthropology with archaeology and paleoanthropology ensures that the long term and the large scale are never far from sight. Ethnographies of industrialized societies, ranging from ethnic minorities to corporate cultures, begin with the microcosm but connect to larger questions. Sociology has been associated from its beginnings with studies of modernization and globalization in Western societies. In the postwar world, anthropologists became of necessity students of these processes in the same small communities that had been their prewar subjects of study. Anthropologists have sought ways to encompass urban life, regional processes, and global economic and political transformations in their work, leading them to develop skills in quantitative social research as well as their traditional qualitative methods.

Developments in method and theory in the twentieth century have led to a widely perceived split between sociocultural anthropologists who seek a “natural science of society” and those who emphasize anthropology’s humanistic role as an interpreter of cultural worlds. These differences are reflected in the distinction between “emic” and “etic” strategies. Based on the linguistic concept of the phoneme, emic work calls for the researcher to understand the “inside” view, focus on meaning and interpretation, and “grasp the native’s point of view . . . to realize *his* vision of *his* world,” in Bronislaw Malinowski’s words. A good ethnography enables readers to understand the motives, meanings, and emotions of a different cultural world. The etic (from “phonetic”) approach seeks generalizations beyond the internal cultural worlds of actors, applying social science concepts to the particulars of a culture and often using cross-cultural comparisons to test hypotheses. A good ethnography presents data that can be

compared with other cases. In recent years, the writing of ethnography has self-consciously struggled to develop a style that can evoke the sensibility of a culture while including descriptive information in a format that allows cross-cultural comparisons.

Sociocultural anthropology begins with description and usually intends that description (ethnography) to be a prelude to cross-cultural comparison that will lead to generalizations about types of societies or even about human universals. At the same time, anthropologists are as likely as other social scientists to be influenced by fashions in theory.

THEORY

The nineteenth-century origins of anthropology, like those of sociology, are rooted in the expanding inquiry into the nature of human society that characterizes the nineteenth and early twentieth centuries, but anthropology’s roots also involve the questions of biological and social evolutionism characteristic of the era, as epitomized in the work of Charles Darwin and Herbert Spencer. Anthropology and sociology share origins in the foundational work of Durkheim, Weber, and Marx. However, cultural anthropology adds to its pantheon of ancestors Tylor, Morgan, and Frazer; it is in the work of these three men that one can see how anthropology was set on a different trajectory. The American Lewis Henry Morgan (*Ancient Society*, 1877) and the British Edward Burnett Tylor (*Primitive Culture*, 1871) and James Frazer (*The Golden Bough*, 1890) are counted among the founders of anthropology because they sought to establish general laws of human society through the comparative study of historical and contemporary peoples. Tylor, Morgan, and Frazer were unilineal evolutionists who believed that universal stages of evolution could be identified in the transition from simple to complex societies and that modern peoples could be ranked in this evolutionary scale. These two strands—the belief that comparison can produce scientific generalizations and the search for evolutionary processes—continue to characterize anthropology, though the racist evolutionism of these early approaches was discarded as anthropology was established as a discipline in the 1920s and 1930s.

While the work of the nineteenth-century social theorists presaged both anthropology and sociology, by the turn of the century, each field was established in separate academic departments and increasingly distinct research programs. In the United States, anthropology as a scholarly project emerged through the work of scholars drawn to the task of reconstructing Native American cultures and languages, especially under the auspices of the Bureau of American Ethnology and the formative political, administrative, and scientific work of Franz Boas. Boas responded to the prevailing ideas of unilineal evolutionism with a theory that came to be called historical particularism, rejecting broad generalizations about stages of evolution in favor of detailed studies of the environmental context and historical development of particular societies. Boas also trained the first generation of professional anthropologists in the United States, and his students, such as Alfred L. Kroeber, Robert Lowie, and Edward Sapir, pioneered new theories that could replace unilineal evolutionism. Sapir's and Benjamin Whorf's work on links between language and culture, Margaret Mead's on enculturation and psychological anthropology, Ruth Benedict's on ethos, Zora Neale Hurston's on folklore, and Kroeber's on the superorganic all fostered decades of theoretical development that pushed American anthropology in distinctive directions. Field studies with Native Americans and other North American minorities honed the skills of the first generations of American anthropologists in linguistic work, informant interviews, life histories, and historical reconstruction and established the holistic style of American anthropology, integrating archaeology, linguistics, and physical anthropology with the study of society and culture.

While Boas's students filled library shelves with detailed and impressive ethnographies, a new theoretical orientation developed in Great Britain that would have a great impact on the culture-centered world of American anthropology. This was functionalism, and its key proponents in anthropology were Bronislaw Malinowski (psychological functionalism) and A. R. Radcliffe-Brown (structural functionalism). The period of interest in the ways in which cultural institutions maintain social order—which affected the United States when Radcliffe-Brown and Malinowski spent time at American departments of anthropology in the

1930s—marks the point at which most texts officially distinguish British social anthropology from American cultural anthropology. Radcliffe-Brown countered Boasian particularism with an emphasis on the search for general laws of society and stimulated a generation of European and American students to do the same. British social anthropologists turned their analytic focus on the study of persons and relations in persisting social structures and pushed themselves and their students to develop the close observation, incisive analysis, and careful record keeping that marked the coming of age of long-term participant observation as a research method. Functionalist studies took place in the context of colonialism, with the limitations and power imbalance that that implies, yet remain impressive for the quality of detail and their capacity to integrate descriptions of political, economic, and kinship relations. Many ethnographic classics were produced by British social anthropologists of that era (e.g., Malinowski's *Argonauts of the Western Pacific* in 1922 and Evans-Pritchard's *Witchcraft, Oracles and Magic among the Azande* in 1937 and *The Nuer*, 1940) and their students, including Raymond Firth, Meyer Fortes, Audrey Richards, Lucy Mair, Edmund Leach, Max Gluckman, and Fred Eggan.

While American anthropologists added the study of social structure and function to their repertoire, they did not abandon their interest in historical developments, language, personality, and ethos and retained a “four-fields” orientation in the training of graduate students. While some social anthropologists found the idea of culture impossibly vague, American anthropologists reveled in the complexity of the concept, with Kroeber and Kluckhohn assembling a compendium of more than 150 definitions of “culture.” Stimulated by the challenge of British social anthropology, the work of Kroeber, Mead, Benedict, and Sapir from the 1920s through the 1950s explored culture as a distinct level of analysis and a way to grasp the distinctive ethos and worldview of each culture, along with the active role of the individual's acts and words in shaping a culture.

In the 1940s and 1950s, the influence of materialist approaches in the social sciences, while limited by the anticommunism in American public life (explicitly Marxist approaches did not appear until the 1970s), was manifested in a new set of evolutionary and generalizing approaches in Ameri-

can anthropology. The work of Julian Steward and Leslie White laid the groundwork for a new approach to studies of adaptation and cultural change. White argued for an evolutionary scheme in which culture (the uniquely human capacity to manipulate symbols), as the superorganic human adaptive mechanism, develops through evolutionary stages marked by the increasing ability of human groups to capture energy through technological systems. Steward worked on a smaller scale, arguing for the analysis of structural similarities among cultures at a regional level, which can be understood by recognizing the hierarchical relations among three “levels of sociocultural integration”: techno-economics (infrastructure), sociopolitical organization, and ideology (superstructure). Steward’s scheme allowed anthropologists to catalogue cultures as structural types and encouraged the study of change over time in a “multilineal evolutionary” process that he contrasted with White’s more abstract global stages.

Materialist studies continued to develop and to shape archaeology as well as cultural anthropology. Marshall Sahlins and Elman R. Service merged White’s and Steward’s approaches in a neoevolutionist theory that encouraged both archaeologists and materialist-oriented sociocultural anthropologists to consider the regional and large-scale classification and development of societies. Marvin Harris, Eleanor Burke Leacock, and Morton Fried attempted to explain cultural diversity and change in the context of the causal primacy of production and reproduction. In the 1960s and 1970s, the new field of cultural ecology developed a “neofunctionalist” approach that allowed scientists to include cultural and social aspects of human behavior in natural science research. Roy Rappaport’s 1967 *Pigs for the Ancestors* began with an effort to measure the energy intake and outflow of a highland New Guinea population; the 1984 edition included a lengthy discussion of criticisms of neofunctionalist theory and the applicability of adaptive and evolutionary concepts to human groups.

In France, Claude Lévi-Strauss was developing ideas that would transform the world of social science through structuralism, which emerged in the 1960s and 1970s as a totalizing theory aiming at uncovering the common structures of the human mind. Structuralism, which was influenced by the linguistics theories of Saussure and Jakobson, treated the products of culture as symbolic sys-

tems and examined the formal patterns of those systems in order to envision discern universal structures and cognitive patterns of the human mind. Structuralism was applied to myths, kinship, relations to art, and every other aspect of culture. The work of Lévi-Strauss, Edmund Leach, and other structuralists drew sharp rebuttals from theorists who sought explanations of human diversity in material and social conditions rather than in mental templates. Although the abstractness of structuralism eventually limited its interest to students of culture, it continues to be a useful technique, particularly in the analysis of the symbolic products of culture.

Ethnoscience, which emerged in the 1950s, also examined the mental categories underlying cultural products. Drawing heavily on linguistic theory and methodology, ethnoscience tried to develop fieldwork methods sufficiently rigorous to delineate the mental models that generate words and behavior and, in its emphasis on the emic approach, insisted on the necessity of fully accessing the native understanding of cultural domains. As ethnoscience faded in importance in the 1970s, it was succeeded by cognitive anthropology, the cross-cultural study of cognition.

Structuralism, ethnoscience, and responses to materialist neoevolutionist theory stimulated the emergence of symbolic anthropology and cultural analysis in the 1960s and 1970s, and this in turn led to the “interpretive turn” that has continued in cultural anthropology through the rest of the century. Again, linguistics proved influential, as David Schneider, Clifford Geertz, and Victor Turner explored new ways to study the cultural construction of meaning and the public representation of meaning in cultural elements. Most symbolic anthropologists focus on the description and interpretation of particular cultural cases, emphasizing the ethnographer’s role in explicating cultural events or products, though a few symbolic anthropologists, such as Mary Douglas, have sought general models of symbol systems. Symbolic anthropology shifted in the 1980s toward interpretive anthropology, which in turn generated a decade of reflection on the writing of ethnography, seeking modes of representation that would represent the worldview, internal logic, and emotional sensibility of a culture. Emerging from interpretive approaches have been experiments in ethnography, renewed interest in life histories, and extensive

critiques of an etic-oriented ethnography that relies on the authoritative voice of an “outside” observer and author. The 1980s also saw a new interest in history, spurred in part by the work of French scholars such as Braudel, Bourdieu, and Foucault and also playing a part in drawing some sociocultural anthropologists toward humanistic approaches.

American cultural anthropology has always taken an interest in evolutionary questions, and in the 1970s, the biologist E. O. Wilson used sociobiology to challenge social scientists to study the role of natural selection in human behavior. Anthropologists’ immediate response was to criticize sociobiology as sociologically naive, culture-bound, and potentially racist and sexist. In the longer term, however, this challenge renewed anthropologists’ interest in the holistic approach to culture, stimulating new approaches to the flexible and complex linkage of genetic inheritance and cultural malleability. Archaeologists, physical anthropologists, and cultural anthropologists share an interest in these long-term questions, which now are studied as “human behavioral ecology.”

ORGANIZATION

While anthropological theory has participated in many of the trends in the social sciences in this century, anthropologists most often speak of themselves in terms of the topics they study and the geographic areas in which they are expert. A cultural anthropologist might say that she studies “gender issues in the Middle East,” “political hierarchy in Polynesia,” or “hunter-gatherer ecology in the Arctic,” with the implication that her theoretical school is a less useful category or that one might include several different theoretical or methodological approaches to one’s topic.

A review of textbooks in anthropology and courses offered in larger departments provides an indication of the overlap and the difference in range between sociological and anthropological topics. Traditional topics in anthropology include the categories of sociopolitical life (political anthropology, the anthropology of religion, social organization, patterns of subsistence, economic anthropology), cross-cultural approaches to all social science topics (ethnicity and identity, psychological anthropology, urban anthropology, ethnohistory, gender), theoretical approaches (sym-

bolic anthropology, cultural ecology), applied topics (legal anthropology, developmental anthropology, culture change, medical anthropology, education and culture), and topics reflecting the persistent holism of the anthropological enterprise (language and culture, genetics and behavior).

Anthropologists’ regional focus traditionally has been small-scale non-Western societies, but this has changed dramatically in the last fifty years. While sociologists and other social scientists have become more active in non-Western contexts (particularly economic development and modernization), anthropologists have become more active in studying Western societies, using their traditional skills of small-community ethnography, cultural models, and comparison in these situations. However, as part of their postgraduate training, most American and European anthropologists do a lengthy period of participant observation research in a small-scale society, usually a foraging band or a tribal or peasant society.

One stimulus to anthropologists’ willingness to become wholeheartedly involved in the study of Western, industrialized, and mass societies has been the growth in applied work. While sociology was committed to researching public policy issues from its beginning, anthropology has only intermittently taken on research directed at social problems and policy issues. Beginning with government work during World War II and the postwar Fox and Vicos projects in applied anthropology and as a result of globalization and limited academic job opportunities for anthropologists, there has been an increase in putting anthropological concepts and methods to the service of immediate outcomes rather than academic research. The greatest demand for applied anthropology is in economic and social development, medical anthropology, the anthropology of education, and international business.

METHODS

Anthropology was born in the theories of “armchair anthropologists” who based their theories about the evolution of human beliefs and societies on the reports of colonial officials, missionaries, and merchants. Since that time, the commitment of researchers such as Boas, Mead, and Malinowski to detailed, long-term field studies has generated

the impulse that has sustained generations of anthropologists in an effort to produce detailed, fine-grained, firsthand descriptions of the world's cultures. Cultural anthropology has long held that long-term participant observation, including mastery of local languages, is the best way to produce valid ethnographic description. Participant observation is the source of anthropology's ethnographic database and the foundation on which controlled cross-cultural comparison is built.

The work of field research and the writing of ethnography have received much attention in recent decades. Participant observation is now an umbrella term for a research project that, while it extends over the long term (usually at least a year) and relies on the use of the local language, key informants, and living "close to the ground" with the people being studied, is likely to include a range of additional research techniques. Sociocultural anthropologists also are trained in kinship analysis, unstructured and structured interviews, questionnaires, scales, taxonomies, and direct and unobtrusive observation. In the past decade, there has been a growing expectation that researchers will combine qualitative and quantitative research methods, increasing both the validity and the reliability of ethnographic work. Applied anthropology has generated its own methods, some of them shaped by the time and cash restraints of nonacademic research, such as rapid rural assessment, participatory appraisal, and decision-tree modeling.

Cross-cultural comparison has been a goal of anthropology from the start. The first armchair anthropologists used sometimes unreliable secondhand information to generate categories and stages of social evolution, but researchers soon employed more scientific methods. Archaeologists' work on regional and chronological linkages encouraged ethnologists to trace the development, distribution, and diffusion of culture traits (especially in the United States, with Boas's encouragement). British social anthropologists and the neoevolutionists urged the use of regional and global comparisons to generate models of structural stability and change. George P. Murdock greatly facilitated large-scale comparison when he created the Human Relations Area Files, the physical form of the great database of human cultures anthropology had long sought. Cross-cultural studies in anthropology have allowed anthropologists to generate and test midlevel hypotheses about

cultural patterns and allowed social scientists to test the broader validity of hypotheses generated in Western contexts.

CURRENT ISSUES

In surveying the history of anthropological theory, one often notices the persistent tension between materialist and idealist ways of studying culture. In the current environment, after a decade of postmodern critiques, this tension has actually split a few academic departments, severing archaeology and biological anthropology from cultural anthropology, or "scientific" from "humanistic" approaches. Research specialization and job-market pressures also interfere with the holistic four-fields approach that American anthropologists have long considered their hallmark. In addition, sociocultural anthropology has been pressed by the inroads of literary criticism, cultural studies, ethnic studies, and other related fields into its traditional preserve. Like other social sciences, anthropology feels that it is living through a "crisis" that represents both a point in a repeated cycle of theoretical change and a response to national and global contexts.

However, the end of the twentieth century has seen a wider range of research and applied work than had ever been done previously (see recent issues of *American Anthropologist*, *American Ethnologist*, *Current Anthropology*, and *Human Organization*). Current work in anthropology includes traditional detailed ethnographies that aim to increase the descriptive database of the world's cultures, problem-focused fieldwork aimed at elucidating theoretical puzzles, reflexive ethnography that attempts to find a moral and artistic center from which to write, analyses of organizations and evaluations of programs intended to guide policy decisions, and hypothesis-testing data crunching. The long-standing distinction between materialist and idealist approaches continues as interpretive, postmodern anthropology seeks new ways to do the job it has been critiquing for a decade and as ecological, evolutionist, and materialist approaches argue with renewed vigor for a scientific discipline.

Sociocultural anthropology and sociology share modern interests in agency; power; the relative role of social structures and individual action in culture change; the intersections of ethnicity, class,

and gender; and the historical shaping of modern institutions and cultural representations. In all its interests, ongoing input from archaeology, biological anthropology, and linguistics has given sociocultural anthropology a uniquely broad and deep perspective on the human condition, and its stream of theory is fed from these other sources of knowledge about the human condition. In describing the commonalities that unite cultural anthropology, Rob Borofsky speaks of anthropologists' shared ethics: a desire to publicize "human commonalities" (especially in countering racism), the valuing of cultural diversity, and the use of cultural differences "as a form of cultural critique" of the anthropologist's home culture and in general of industrial mass society. Despite an explosion of variation in what sociocultural anthropologists do, anthropologists' holistic and comparative worldview remains distinctive.

LIN POYER

SOCIOLINGUISTICS

When Brown and Gilman published their classic work on pronouns of power and solidarity (1960; see also 1989), no one characterized that paper as a major contribution to "sociolinguistics." When Gumperz and Hymes published their updated *Directions in Sociolinguistics* in 1986 (the 1972 edition was based on a 1966 publication of the American Anthropological Association), they were providing a paradigmatic definition of recognizable enterprise; that book included contributions by many of the founders. A two-part survey of sociolinguistics written in 1973 (Grimshaw 1973b, 1974a) noted that more had been published on sociolinguistic topics in the early 1970s than in all previous years. That review commented on about fifty new titles; only a few sociologists (particularly Basil Bernstein and Joshua Fishman, each with several volumes) were represented. In the three decades since that time, interest in language *in use* (micro sociolinguistics) has continued to grow exponentially; while that interest still is not seen as part of mainstream sociology, it is moving in that direction (Lemert 1979). Interest in more macro dimensions of the sociology of language—for instance, language conflict, language maintenance, and language spread and decline—also has grown, though much more slowly.

SOME ACTIVITIES AND SOME LABELS

At least a dozen specialties investigate some aspect of language: its origins, structure, invariant and variant features, acquisition, use in social contexts, change, spread, and death, and so on. Among those specialties, there are at least five whose practitioners do not consider themselves sociolinguists or sociologists of language and whose research seldom is incorporated directly into sociolinguistics/sociology of language (SL/SOL) investigations:

1. Formal linguistics that focuses on languages as autonomous systems and investigates how those systems work independently of human and/or social agency. This activity often is referred to as "autonomous linguistics" and occasionally as "nonhyphenated linguistics."
2. Anthropological linguistics devoted to a "description" (writing of grammars and

dictionaries and audio and phonemic recording of phonological systems) of languages in specific, usually nonmodern societies.

3. Psycholinguistics, which covers a wide range of topics, including the acoustics of perception, cognitive constraints on the complexity of clausal embedding, theories of innateness and learning in language acquisition, and the physical location of language functions in the brain.
4. Social psychology of language (from psychological social psychology), wide-ranging specialty that includes research on message characteristics and influence, self-disclosure, relationships between personality and speech, and relationships among body movements, speech, and "meaning."
5. Conversation analysis/ethnomethodology (CA), an approach that views talk in much the same way formal linguists view language: as a system that is syntactically organized and has structure that can be discerned independently of the social attributes of participants in particular talk.

CA has identified devices such as "preinvitations" and "preclosings" as well as ways of constructing accusations without accusing anyone explicitly (Atkinson and Drew 1979); workers in the field are interested in how these devices are used in the course of the immediate talk, not in how they might be directed to more complex goals of conversational participants. Whalen (1991) notes that CA "examines talk as an object in its own right, as a fundamental type of social action, rather than primarily as a resource for documenting other social processes." None of the five activities listed above deals with language primarily as social resource.

In contrast, another handful of specialties focuses on the social dimensions of language/talk as interactional resource, a component of individual and group identity, and a social object. The ethnography of speaking and ethnolinguistics, like the anthropological practices from which they take their names, focus on the diversity of available linguistic resources and the uses to which those resources are put in individual speech communities and in human society at large, respectively.

There is a strong comparative dimension to these arenas of investigation.

Sociolinguistics manifests a different kind of comparative orientation. The micro variety usually focuses on interactional accomplishment through the medium of language in use in social contexts: (1) comparisons of means and ends, including attention both to how individual ends can be accomplished by different means (ways of talking) and to how different outcomes may simultaneously result (intentionally or otherwise) from the production of same or very similar bits of talk, and (2) comparisons of the different resources available to different participants in talk. The sociology of language, as the macro variety of sociolinguistics often is called (Grimshaw 1987a), tends to focus on distributional studies, such as the distribution of language varieties across individual repertoires and the distribution of repertoires across social aggregates, categories, and groups (nations or classes, genders or age groups, and families or friendship networks, respectively). At the most macro level, this implies studies of language maintenance, supersession and change, conflict, and so on.

The sociological social psychology of language is oriented to group effects on individual behaviors, including the acquisition of social-cultural competence through the medium of talk, the role of talk in the acquisition and organization of evaluative orientations, and uses of talk/written language in social control. At some point, the last activity shades off into symbolic interactionism; this boundary is not explored here. Finally, specialized studies of proxemics (social and interpersonal spacing) and kinesics (body movement, the organization of facial features, gesture, posture) have been done from both sociological and psychological perspectives (Hall 1966, 1974; Kendon, [1977] 1990).

SOME QUESTIONS OF ORIENTATION

Since later sections of this article illustrate how sociological theory can be enriched by empirical SL/SOL research in specific substantive areas, the comments here are limited to four questions of general orientation in theoretical work in SL/SOL: (1) What are causal and other relations between language/speech and other social behavior(s)? (2) Are grammars of social interaction pos-

sible, and is there a universal grammar? (3) What is the relevance of a micro–macro distinction for understanding the importance of language/speech in social life, and now are the two levels articulated in social behavior? (4) Is theoretical advance and/or understanding best sought by focusing on social processes or on specific substantive arenas of social behavior?

Causal Directionality/Covariation/Cotemporality/Mutuality. As in other varieties of social behavior, SL/SOL theory and research must deal with complex problems of cause and effect. There are four principal perspectives on the causal relationship between social structure and language (see Grimshaw 1974b; Hymes 1966):

1. That which sees language as fundamental (or as source, cause, independent variable, or set of independent variables), a position consonant both with an extreme Whorfian position (language *determines* how people think) and the commonsense observation that people sometimes do not know what is going on until they hear other people talking
2. That which sees social structure as a determinant or an independent variable or set of such variables, position consonant with people’s awareness that they talk differently in different situations, with different interlocutors, and depending on the nature of their interactional goals
3. That which sees neither as prior to the other, with both being seen as co-occurring and codetermining
4. That which sees both as being determined by a third factor, whether innate features of the human mind—the view of Cartesian linguistics (Chomsky 1966, 1968)—*Weltanschauung*, or the intrinsic demands of an ordered universe

Most SL/SOL correlational studies focus on how the location of individuals or groups in the social structure is *reflected* in speech and/or other language behavior, as in the case of regional or class dialects, or *determines* it, as in the case of the section of a language variety in different situations and with different conversational partners (Blom and Gumperz 1972) or of pronominal forms or

other names (for a review of some of this literature, see Grimshaw 1980a). A smaller but substantial number of correlational studies attempt to discover how language use (spoken and written) is associated with interactional outcomes as varied as providing or not providing a requested favor, succeeding or not succeeding in school, and deciding whether to go to war (for a review, see Grimshaw 1981; for illustrations of claims about language use and the risks of war, see Chilton 1985; Wertsch and Mehan 1988). Although closer scrutiny often reveals that *ways of talking* are themselves resources that are differentially available to interactants with different social origins, some language resources appear to be available throughout social structures. Ways of talking in turn have been shown to have effects independent of structural relations.

Figure 1 is a simplified schematic representation of a mutual-embeddedness perspective. It is also a schematic showing how the processes of cultural reproduction would operate in a world without change. Bernstein (1975), Bourdieu (Bourdieu and Passeron 1977), Cicourel (1980a, 1980b, 1981), Collins (1981a, 1981b), and Habermas (1984–1987) all address the question of cultural reproduction and questions of change. All take essentially mutuality perspectives. All accord central importance to language in the reproduction process. Collins explicates ways in which language is simultaneously a resource in interaction and a source of change. Only Bernstein and Cicourel actually collect data on language in use, and only Cicourel directly investigates talk. None of these scholars would strongly disagree with this characterization; each would wish to “complete” the chart by incorporating neglected features (see Bernstein’s diagram of the process [1975, p. 24], with its foregrounding of different transmission agencies, such as family and education; modes of social control; specific speech varieties; and context-dependent and -independent meanings).

In the mid-1960s, Fischer (1965, 1966) published perhaps the strongest version of the mutual-embeddedness position and, from the disciplinary perspective of sociology, perhaps the most esoterically documented. (The papers are reviewed extensively in Grimshaw 1974b.) Fischer argued nothing less than phonological and syntactic differences between two related but mutually unintelligible languages (Trukese and Ponapean, separated for

Figure 1. Sketch of a mutual-embeddedness perspective (cultural reproduction without change)

about eight centuries) are isomorphic to differences in the social structures of the two societies:

As societies become more complex and social roles become more differentiated, the realized meaning of words in particular contexts becomes less important than the common or basic meaning. Speakers are forced to assume a greater cognitive gap between themselves and their listeners. At the same time, the basic meaning of the items of the lexicon tends to become more abstract and attenuated, since speakers have less need for words which can express much meaning in compact form to listeners who are conceived as being much like the self; they have more need, instead, for words which can be used in many different contexts with many different listeners who are conceived of as being very different from the self and from each other. (Fischer 1966, p. 178)

The mutuality perspective is a richly suggestive one.

Grammars of Social Interaction/A Grammar of Social Interaction. Linguists write grammars; that is, they describe and write “rules” for phonological and syntactic systems for individual languages. They are also committed to the goal of writing a grammar of language, that is, identifying in grammars of individual languages features and/or rules that hold for all languages: a universal grammar. They distinguish between absolute and quantitative universals (i.e., between features

of all languages that can be explained on theoretical grounds as required constituents and features that occur in all or most languages, such as terms for female derived from that for male [this kind of feature is known as marking], but for which no theoretically principled basis can be identified) and between weaker and stronger claims of universality (i.e., between a claim that all languages contain certain elements [nouns, verbs, prepositions] and a claim that those elements appear in the same order in utterances in every language).

An interest in the intrinsic ordering of the universe and a concern to avoid repeating old errors and rediscovering the already known are central in linguists’ interest in both the regularities in individual languages and universal rules. Sociologists have similar concerns in seeking to discover the rules of interactional grammars for specific societies or groups and in seeking social interactional universals and the role of language in use in both grammars and the grammar. Although there are greetings in most, if not all, societies (this is more a quantitative than an absolute universal, and there are societies in which greeting is the marked case and nongreeting the unmarked), how they are done, to whom, and to what purpose may vary considerably (Firth 1972; Goffman 1971; Ibrahim et al. 1976; Kendon and Ferber 1973).

Similarly, there must be a need for information everywhere, but questions are not the appropriate manner for obtaining information in every

society (see Goody 1978; sources cited in Grimshaw 1969). Again, it seems likely that interpersonal relations of power and affect and considerations of valence and cost are everywhere involved in requesting behavior (Brown and Levinson 1987; Grimshaw 1989); their relative importance and the consequent variety of modes of requesting behaviors vary considerably.

Ways of talking are everywhere critical resources in interaction; very little is known, however, about what features of *language in use in social contexts* may be universal or, for that matter, about which rules *within* speech communities (or social groups) are variant and which are invariant (Labov 1968; Grimshaw 1973a). Indeed, some sociologists find the notion of rule misleading on grounds that expectations and behaviors are always under negotiation (Berger and Luckmann 1966). Notions of rules and exceptions vary across disciplines (Edgerton 1985; Labov 1968; Grimshaw 1973a, 1981).

Micro-Macro, Conversation, and Interaction/ Official Languages and Language Policies, SL/ SOL. These distinctions, along with the familiar polarities of social psychology and social organization—or qualitative and quantitative methods—often appear in discussions of sociological interest in language and language in use. Three sorts of questions can be asked in this arena:

1. What are sociology's interests in what goes on in conversation/interaction, and what does a specific focus on talk teach sociologists that other modes of study do not?
2. What are sociology's interests in looking at language as an individual social attribute that, aggregated, has supra-individual importance in ways similar to ethnic group, class, religion, and other categorical attributes? What are sociology's interests in questions about how language is linked to life chances, why and how it becomes a focus of positive and negative attitudes, and how languages spread, change, contract, and die?
3. How do the things that go on in individual conversations on the micro level get articulated with, and aggregated into, processes of change in languages themselves, in their prestige, in policies re-

garding their use, and so on, on the macro level?

As was suggested above, the micro-macro question is closely related both to those about mutual embeddedness and to those about cultural reproduction. The dimension added by asking the articulation question is that of social change: If socializing/cultural transmission agencies operate to *reproduce* values, attitudes, behaviors, and so on, in new generations, how does change occur? A perspective offered by Collins (1981a, 1981b) is that participants bring to *everyday* conversations interactional resources that are enhanced or reduced in the course of interaction and that modest changes in interactional resources ultimately eventuate in changes in institutions and cultural systems—and languages. Related formulations are cited in Grimshaw (1987b). The macro-micro questions constrain one to think deeply both about processes of change and about how people try to get co-conversationalists to agree with them or to do what they want those them to do.

Substance or Process: “Top-Down” or “Bottom-Up.” Two additional questions about the construction and use of theory have methodological as well as theory-building implications. The first question is whether when sociologists study the uses of language in specific contexts such as educational, military, or medical institutions, they are interested primarily in understanding (1) the institutions themselves, (2) social processes such as negotiation or socialization or, more broadly, conflict or cooperation, (3) a specific kind of situated interaction, such as an interview, as a representative of a species of situation, or (4) how talk works in interaction. There are, of course, no pure cases. The second question has been put by Cicourel (1980a) as a distinction between “top-down” and “bottom-up” theorizing. By “top-down,” Cicourel means approaching corpora of talk with sets of conceptual notions ranging from the generality of “cultural reproduction” or “role” and/or “conflict” to the specificity of “role conflict” or different “footings” in talk (Goffman 1981). By “bottom-up,” he refers to researchers immersing themselves in their data and identifying regularities, then validating that identification, then discovering regularities in relations between previously observed regularities, and so on. All the investigators whose work is mentioned in this

article—indeed, all sociologists—would like to believe that they let their data guide them to theory construction, and all are to some extent guided in their work by prior theoretical constructions.

DATA, DATA, EVERYWHERE

While sociologists sometimes are intimidated by the complex structure of formal linguistic theory, they may be equally envious of the easy access of linguists to their data, either in their own intuitions about the languages they speak or in the bath of talk and writing in which all people live (compare the ways of studying phonology in, for example, Chomsky and Halle 1968; W. Labov 1980). Students of SL/SOL share the advantage that many of the data in which they are interested are fairly accessible and, with modern technology, fairly easy to collect (denial of access and questions of ethics aside). They share the disadvantage that many of the sociological questions they want to study—matters as varied as (1) attitudes about different speech varieties, (2) the impact of stratification on the acquisition of those attitudes, and (3) the ways in which phonological variation *affects* stratification—can be considerably more difficult to identify, conceptualize, and measure. Just as there are fundamental questions about theoretical orientation in SL/SOL, there are fundamental questions about methods.

This brief discussion can comment on only a few of these methodological questions: (1) What constitutes optimal data for SL and SOL, or micro and macro, research? (2) How can the optimal data best be collected? (3) What need is there for modes of work, such as comprehensive discourse analysis (CDA), that differ from more familiar modes of sociological investigation? (4) What are the roles of collaborative and comparative studies in SL/SOL research?

What Constitutes Optimal Types of Data for SL/SOL? Labov (1972a) remarked that linguists work variously in library, bush, closet, laboratory, and street, where they collect and/or produce data that can be labeled texts, elicitations, intuitions, experimental results, and observations, respectively. Among the many sorts of data that can be useful in the investigation of SL/SOL issues, those associated with the following four “how” questions are central:

1. *How* do people actually talk/write? This has two dimensions: (a) What varieties of language (spoken and written are assumed in the following discussion) do individual members of speech communities control? (b) How do individuals employ their language resources in social interaction? The optimal data for such studies are extended texts.
2. *How* are language varieties and patterns of use distributed across categories of age, class, gender, occupation, nationality, religious affiliation, and residence? The optimal data here are a combination of sampled texts and observations.
3. *How* do members of social groups learn about language and its appropriate use, and how do they learn second (and higher-order) languages? The optimal data here are experimental results and observations and, to a lesser extent, texts.
4. *How* do people feel about language; that is, what are the attitudes of individuals and groups toward language varieties, repertoires, language change, and literacy? Data that have been employed in addressing these questions have included all five of the varieties listed by Labov (1972a), and each has proved useful.

What Are the Criteria for Optimal Data?

There is no such thing as a “verbatim” record without electronic recording, and optimal records of conversation include both high-fidelity audio recording and possibly multiple sound-image recordings (for discussions of sound-image recording, including some of the controversies about such data collection, see Feld and Williams 1975; Grimshaw 1982, 1989). When one is working with written texts, optimal data include photographic copies of handwritten originals as well as printed versions. Whatever texts and observations are collected and used as data, however, those materials are valuable only to the extent that contexts of both “situation” and “text” (i.e., embedding talk and written material) are provided (the distinction is Halliday’s following Malinowski). Two excellent articulations of the importance of context that suggest different boundaries for what must be taken into account are those of Corsaro (1981, 1985) and Cicourel (esp. 1994).

People are often skeptical of claims about what talk is actually like until they see it transcribed; they then are skeptical that the transcription is accurate until they hear electronically recorded audio while reading a transcript. Investigators who work with texts, elicitation, and observations must always take into account the effects of monitoring in most varieties of SL/SOL data; Labov (1972a) has referred to the Observer's Paradox; that is, "we want to observe how people talk when they are not being observed." One also should keep in mind, however, Sol Worth's observation that all behavior, however carefully monitored, is "natural" (personal communication). Labov has developed elicitation techniques that have the advantage of generating different levels of self-consciousness of, and thus monitoring of, talk (see, e.g., 1972b).

Other concerns with data in SL/SOL research are, like those just reviewed, quite similar to those in sociological research in general. Self-report data on language varieties employed by oneself or one's family or of uses of literacy are notoriously unreliable, and definitions and measurements of individual attributes such as literacy and bilingual fluency are often inconsistent.

The Need for Methods Specific to SL/SOL. Many of the data employed in SL/SOL research are the same as or very similar to those employed in other arenas of sociology, as are the methods employed in analysis. This similarity may be least evident in the case of the activities labeled "conversation analysis" (see Whalen 1991) and "comprehensive discourse analysis" (Labov and Fanshel 1977). Labov and Fanshel realize that the goal of comprehensiveness is chimerical: their pioneering study demonstrated the importance of such aspects of talk as prosodic and paralinguistic features. Lexical, syntactic, and even phonological selection are deeply involved in what is "actually said" (i.e., interactionally intended) in talk (for a discussion of the process of "disambiguation" of text, see Grimshaw 1987c). Sociologists have employed CDA and adaptations of it to ask more specifically sociological questions. Other students have developed similarly fine-grained approaches to written texts (Silverman and Torode 1980). Perhaps sociologists are now aware that questions about language as language have sociological significance and that talk and writing are no longer just media that contain answers to other questions.

Collaborative, Comparative, and Corroborative Research on SL/SOL. While SL and SOL research and publications have increased tremendously in the last few decades, their literatures continue to be diffuse. There have been few replications. Most research has been on English, and much of the material on other languages is published in English. While much of the early activity in SL was interdisciplinary, there have been few truly interdisciplinary studies (for a discussion of problems with such projects, see Grimshaw, Feld et al. 1994) or parallel studies of shared data (see, however, Chafe 1980; Dorval 1990; Grimshaw, Burke, et al. 1994). There have been few explicitly comparative studies in which the same or collaborating investigators have simultaneously studied the "same" phenomenon in different speech communities (see, however, Watson-Gegeo and White 1990) or in different institutional contexts in same societies (see, however, Grimshaw 1990). There is reason to believe that all three of these important kinds of research are on the increase. Scholars all over the world are trying out SL formulations largely generated in the United States and Europe in their own societies, more and more work is being done on related SL phenomena in societies and speech communities where earlier work followed more traditional courses in linguistics and anthropological linguistics, and researchers from an increasingly wide range of disciplinary backgrounds are finding in SL/SOL data and theory materials to use in addressing their own questions.

An Additional, Residual, Neglected Question. Claims about the relative validity, reliability, and general worth of quantitative and qualitative research appear in SL/SOL, as they do in most areas of sociological work. While the modes of work are loosely associated with the micro-macro distinction, there are representations of both modes in both arenas.

SL/SOL AS A RESOURCE IN SOCIOLOGICAL THEORY BUILDING

A diminishing number of sociologists remain unfamiliar with SL/SOL and therefore unaware of both substantive findings and theoretical developments that could be helpful in their work. It is possible here to mention only a few contributions to the understanding of (1) substantive areas, (2) social processes, and (3) relations among language,

literature, identity, and so on. Let us begin with two instances of sociologically relevant contributions by the linguist best known to sociologists (possibly excepting Chomsky), William Labov, and then turn to research by sociologists and other nonlinguists that focuses from the outset on identifiably sociological concerns.

Suggestive Empirical Findings. Studies of classrooms, courtrooms, and clinics have generated findings that sometimes have resulted in changes in pedagogic, legal, and medical practice as well as contributed to our theoretical understanding of SL/SOL. Studies of a multitude of other settings, ranging from street, to dinner table, to backyard party, to workplace, also have produced important theoretical insights. Two of these findings come from Labov's quantitative studies of language use in urban areas of the eastern United States (New York City and Philadelphia); the first has important implications for understanding social stratification, the second for understanding ethnic (and possibly class) relations, and both for understanding processes of social change.

In studies of dialects associated with class, Labov and others have shown that linguistically insecure informants, more often than not women with aspirations for upward social mobility (or concerns about slipping), often hypercorrect their phonological production in the direction of what they perceive as prestige variants, thus producing the prestige variant with higher frequencies than do those at social levels above them—and sometimes produce it inappropriately (Labov gives as an example, “Hi, say, that’s hawfully good of you”). Awareness of this phenomenon should alert sociologists to look for analogues in other behavioral arenas (there is a family relationship to anticipatory socialization; the roots of the labeled behaviors may differ quite considerably); Labov (1972b, 1986) has pointed out important implications of this research for studies of linguistic (and, one may add, social) change.

Labov's second finding is that the speech of urban blacks who have contact with whites continues to be modified in the direction of the grammar of the dominant group, while blacks in the increasingly segregated inner cities speak ever more divergent language varieties. This divergence co-occurs with concomitant differentiation in incomes and educational achievement, heightening

social distance and probably enhancing intergroup hostility (see Williams et al. 1964). Labov comments, “The linguistic situation correlates with the formation of what has been called a ‘permanent underclass’” (1986, p. 278).

Some Little Concepts and Some Central Processes. Studies of actual talk that occurs in the course of everyday interaction have generated both (1) concepts that allow one to taxonomically identify previously unspecified regularities in that interaction (in a manner similar to Goffman's labeling of, among other things, front and back regions, side involvements, and the more specifically talk-related “footing”) and (2) new understandings of the working of what might be called “master social processes,” such as conflict and socialization. Instances of the former (all from Grimshaw 1989) are the identification of hyperinvolvement (a phenomenon in which interactants are so deeply involved in the ongoing that they miss the things they intend to monitor), defects of nerve (a situation in which interactants know how to do something but are reluctant to do it because they are concerned that it may generate injury to self or another party), and phenomena such as topic avoidance, topic exploitation, and topic truncation (the last occurring when it becomes obvious to an interactant that interactional goals are not going to be accomplished).

An instance of this is Corsaro's (1985) demonstration of the processes involved in children's learning how to recognize and construct the cultures and social structures in which they find themselves. Another is Grimshaw's (1990) distillation of the reported findings of a number of individual studies of conflict talk into propositions about the conflict process (see below).

Discourse in organizations: What can be learned from a language-oriented approach to social structure and social behavior depends on researchers' choices of an “entering wedge” (the term is John Useem's), that is, the selection of units of analysis, particulars of language in use to be attended, and questions to be asked. The paragraphs below will address things that have been learned from studies of language in use in (1) public bureaucracies in Sweden, focusing on *narratives* in the public domain, (2) organizations (primarily in the United States), employing a *conversation analytic* method, (3) a specific event within a university (a disserta-

tion defense) examined by an interdisciplinary group employing a range of approaches and asking a number of different questions, and (4) a sampling of more narrowly focused studies of language in use.

Focus on narrative: Czarniawska is a student of management and organization who disclaims linguistic or sociolinguistic competences language in use is nonetheless central to her analyses of public administration in Sweden. In *Narrating the Organization* (1997), Czarniawska demonstrates for the study of organizations, a central descriptive and analytic role of stories/narratives and a dramaturgical perspective. Czarniawska asserts that stories rule people's lives and constitute the basis for the construction of society (p. 5); she seems to believe that the centrality of narrative as the main source of knowledge "in the practice of organizing . . . is not likely to generate much opposition" (pp. 5–6). I find this surprising if true. Her project is to apply the narrative perspective (for which she credits Jean-Francois Lyotard) to elucidate continuities and change in Swedish public institutions and/or organizations at various governmental levels. The argument is dense, and the examples unfamiliar; the demonstration is persuasive both for the organizations studied and for the application of this perspective to other arenas of social life.

Czarniawska conceptualizes organizational life as stories, and organizational theories as ways of reading stories (pp. 26–29). She invokes Burke and Goffman in identifying drama and autobiography as special kinds of narratives (p. 32), noting (following Merelman) how drama, for example, can simultaneously or alternatively generate catharsis, personification, identification, and suspense (p. 36). She observes that stories not only can be vehicles for identity claiming by their tellers but also can be contested by other stories, unsuccessfully performed, and turned into serials (and sagas); importantly, all descriptions favor the theories of their tellers (p. 71).

In her exposition of how she studied Swedish public organizations, Czarniawska reviews a number of methodological conundrums related to the logic of inquiry of interpretive studies, including (1) *interruption* of texts (p. 92, per Silverman and Torode 1980), (2) the advantages of "outsiderness" (p. 62), (3) issues of case studies versus "window" studies (pp. 64 ff), (4) the identification of action

"nets" in organizational "fields" (p. 66), and (5) the place of notions of institutionalization and norms in studies focusing on narratives (pp. 68 ff.).

Focusing on two specialized fields—municipal administration and social insurance—she shows how *stories*, *themes*, and *serials* can be employed to elucidate the role of "good" and "bad" friction in social change, how new and old ways of acting have been integrated, and how new processes of "companyization" and "computerization" change the workplaces of individuals as well as the larger bureaucratic landscape. Narratives are central to people's lives, and Czarniawska has shown the necessity of attending to them.

Conversation(al) analysis as a sociological method: CA is treated elsewhere in this encyclopedia; conversational analysis (CAs) do not consider themselves sociolinguists or sociologists of language. For many years, the author has told CAs that their work is highly original, exciting, and of great potential value to sociology and that that potential will be achieved only when they integrate CA methods and concepts into more traditional sociology, simultaneously showing how traditional sociological concepts and perspectives ranging from status and role, to social structure, to socioeconomic status (SES), to self-esteem could help in interpreting CA findings.

Increasing numbers of researchers across the social sciences and humanities have come to value CA as an approach to everyday talk; until recently, CA-trained sociologists did not undertake to *demonstrate* the value of talk as data for studying fundamental sociological questions such as how social organization is constituted, reproduced, and modified—and how members contribute to that constitution, reproduction, and modification through talk—in what may appear to be mundane and unremarkable interactions. (CA methods are increasingly being employed in sociological analyses. Atkinson and Drew [1979] on Court proceedings, Maynard [1984] on plea bargaining, and Goodwin [1990] on black children's play groups are impressive examples. These studies do not as directly as the work discussed here foreground the epistemological issues implied by the CA posture described above [see, for example, Boden pp. 214–215].)

Boden (1994) provides a demonstration that many readers will find convincing. Using audio-recorded talk from telephone calls and meetings

of varying levels of formality collected in organizations ranging from a travel agency and a local television station to hospitals and a university administrative department to the Oval Office, Boden shares her understanding of the sometimes extraordinarily delicate but analytically identifiable ways in which talk is employed to “inform, amuse, update, gossip, review, reassess, reason, instruct, revise, argue, debate, contest, and actually *constitute* the moments, myths and, through time, the very *structuring* of [the] organization” (p. 8). The argument is often dense, and for readers unfamiliar with CA, it may be difficult to follow. The way in which an accountant comes to see that physicians in different departments may differently view policy change that could improve a hospital’s overall revenue position but reduce “their” money (p. 58 ff) is a case in point.

Boden’s goal is to use her collected talk to undertake two quite different but complementary projects:

(1) to examine a range of more specific aspects of the organization of talk in the work settings that make up the business day; and (2) to discover through those materials how an apparently fragmentary process of information gathering, transmission, and very local assimilation is transformed into the goals, agendas, and decisions of organizations (p. 107).

In the course of pursuing her projects, Boden shows how members of organizations can at the same time account for their behaviors in terms of a “rational actor” model and be unaware of how actual decision making is accomplished incrementally in fragments of unremembered and individually unremarkable chat rather than through a focused weighing of “rational” considerations. Boden simultaneously shows how concurrent and articulated employ of the previously segregated conceptual apparatuses of general sociology and CA (e.g., adjacency organization, agenda, bracketing, placement, sequence [centrally and critically], turn and so on) is mutually enhancing.

Boden argues that stages of (1) collection of actual talk, (2) identification of sequentiality in that talk, and (3) discovery in the talk and its sequentiality of the fundamental stuff and fundamentals of organization, (4) allow and/or contribute to sociological theory at levels of considerable abstractness (p. 206 ff). One may find in Boden’s

study a convincing *demonstration* of Collins’s “microfoundations of macrosociology” perspective.

Boden goes a step further and anticipates the result in offices of the future of today’s incremental changes (p. 209 ff); they will be places with more talk (and reduced opportunities for reflection), sped-up expectations of productivity, increased scope of action for all personnel, a flattened hierarchy, and real downsizing. Careful study of Boden’s book allows one to see how (1) she came to make such a projection and (2) one can evaluate a novel and productive application of CA to central sociological issues.

Collaborative work across disciplines: As early as the 1970s, concern was expressed about the increasingly disparate and noncumulative character of work on language in use in social contexts (Grimshaw 1973b, 1974a). In response to this concern, the Committee on Sociolinguistics of the Social Science Research Council initiated in the 1970s the Multiple Analysis Project (MAP), in which representatives of different disciplines and different theoretical and methodological approaches agreed to undertake analyses of a shared corpus of data, in this case a ten-minute fragment of a doctoral dissertation defense (Grimshaw 1989; Grimshaw, Burke, et al. 1994). The author has (Grimshaw 1994a) attempted to assess the success of this project in achieving its goals of theoretical cumulation, testing the comparative strengths and weaknesses of analytic approaches and methods, and an illumination of a shared corpus of data beyond that available from one or two studies by individual researchers. While it is not possible to conclude that one or another of the analytic modes employed is more comprehensive, a reading of the studies together conveys a sense of the complexity of language use in talk in its several contexts beyond the richness of most studies done from single analytic perspectives (but not all; see Labov and Fanshel [1977], who synthesized a variety of perspectives in their pioneering study of Rhoda and her therapist).

The anthropologists, linguists, and sociologists who investigated the dissertation segment variously focused on laminations of context (Cicourel 1994), formulaic talk (Wong Fillmore 1994), clause structure (Halliday 1994), humor (Fillmore 1994), [Who didn’t find funny that which sociologists in the defense thought was.], speech acts, cohesive

devices (Burke 1994; Hasan 1994), prosodic features and contextualization cues (Cook-Gumperz and Gumperz 1994), proforms (Grimshaw 1994b), and many other elements of the talk to study an equally wide range of behavioral outcomes. The outcomes included the reproduction and/or reshaping of social structure; control of the course of talk (and, by extension, interaction); creation of social relations; social and sociolinguistic constraints on discourse and interaction; negotiation of meaning; the notion of fluency, humor, laughter, and short-term social reorganization; membership-affiliation-identification processes and the structuring of group boundaries; and “face work” and political maneuvering. Each of these varieties of behavioral outcome is autonomously a sociological matter. In more macro directions, they are also deeply implicated in the search for answers to the following five interrelated questions; the answers to which require attending to particularities of language in use:

1. How is social structure generated, sustained, reproduced, and changed?
2. What is the role of social interaction/talk in the creation, realization, maintenance, and so on, of social structure?
3. How does interaction *work*? What permits it to continue and even flourish in social environments of competitiveness and aggressiveness?
4. What is the role of “meaning” in driving interaction and shaping social relations? How is “meaning” socially constrained and sociolinguistically/linguistically signaled?
5. What resources—social, sociolinguistic, and linguistic—are available to interactants for signaling meaning, sustaining interaction, and creating social relations?

What is going on, in short, when someone orders another person rather than asking or cajoling, or when someone says, “Don’t include *me* in that you!” or when an interactant says, “Along those lines . . .” and then challenges something said by an interlocutor/conversational partner?

Other convergences: Ochs, Schegloff, et al. (1996), another volume of studies of language in use, provides additional evidence of the convergence of CA (and linguistic) concerns with those of

both sociolinguists and more traditional sociologists. The book is innovative in that the collaboration it reports is among pioneers in articulating work in formal syntax, CA, paralinguistics (e.g., voice quality, intonation, and tempo), kinesics (e.g., facial expression, gesture, and “body language”), and proxemics (interpersonal distancing and arrangements of “things” in space) in investigating interactional accomplishment. It illustrates some of the range of autonomously syntactic (e.g., clausal organization and reorganization, employ of inflection and particles, movement of nouns or verbs), prosodic and paralinguistic, pragmatic, and other devices available in different languages and cultures (English, Finnish, Japanese, Kaluli) for the management of turns (including shifts of rights to the floor, acceptance or rejection of interruptions, and simultaneous speech), making credible claims, and making cautious characterizations of those not present or accomplishing a joint response to disruption. Fox et al. (1996) claim that English clause beginnings are richer than Japanese with information about “how clause is likely to continue,” thus providing potential interrupters with valuable information. They also observe that repair (by the speaker or another person) extends the possibilities for how an utterance can be completed *in any language* (p. 220). They are talking about *syntactic resources for interaction*. Some of these resources and/or devices are both familiar and fun in a Goffmanesque manner, as when the reader is introduced to and immediately resonates to notions such as “trailoffs” and “rush-throughs” (Schegloff) and “outlastings” (Lerner 1996).

The book is informative because in addition to demonstrating the interinfluence of syntax and interaction, it provides windows to sociological understandings revealed when seldom exploited perspectives are applied to concerns at the core of sociology, including issues of symbolic interaction, the socialization of neophytes, and social change. Beyond this, it allows similarly (and seminal) novel views of specialties such as the sociology of science and that of occupations. Particularly instructive, for example, are Ochs, et al. (1996), on how scientists construct indeterminate referential identities—sometimes in the process blurring the distinction between themselves and the physical world under their scrutiny—and how meaning is built through routine interpretive activity involving talk, gesture, and graphic representation. Also

engrossing is Goodwin's (1996) rich integration of different channels of behavior (syntactic production, intonation, body movement, display of awareness of a world beyond the immediate and ongoing) in a dynamic reconceptualization of Goffman's notion of participation framework as it operates in situations of disruption (of initially unknown magnitude) of routines—in an airport control tower.

Sociologists can profit from this book because of sociologically relevant questions posed, answers given, and because of passing observations. Lerner's (1996) thoughtful and suggestive work on how and why interlocutors complete utterances of speakers without being asked initially suggests as functions of such completion (1) agreement, (2) preemption of disagreement, (3) collaboration, and (4) heckling (p. 244). Lerner later argues that an early opportunistic completion may be intended to initiate or sustain a special alignment with a speaker such as affiliation (pp. 263–264). Sorjonen (1996) suggests that repeats and the Finnish particles *niin* and *joo* variously function as (1) interrogatives, (2) exclamations, (3) requests for confirmation (p. 279 ff.), (4) challenges, and (5) expressions of ritualized disbelief. There are obvious parallels to English. She also has some observations on sweetening recommendations of others when the recommender suspects that an unwanted invitation or request may be forthcoming. Schieffelin (1996, p. 442 ff.) shows how the invention and introduction of an evidential construction to refer to printed religious material, translatable as “known from this source/not known before,” not only has granted authority to written text when there is no basis in fact for doing so but also has been associated with the introduction of higher status for a new role of interpreter of Christianity in a society where prior stratification rested on different bases (and, not incidentally, also to a lowering of the status of women in a previously more egalitarian society).

Social conflict as process: conflict talk as language in use in social context: Early studies of intragroup conflict were largely experimental (often involving researcher-instigated disputes in dyads), usually nonattentive to particulars of subjects' talk, and, in part because of these two features, likely to overestimate the proportion of disputes that are in some way “resolved” (Corsaro and Rizzo 1990; Goodwin 1996). These writers and others have suggested that many pioneer stu-

dents of conflict talk (and social conflict more generally; for an early modern commentary, see Bernard 1950) were concerned with the disruptive consequences of disputation and thus tended to underestimate more positively valued outcomes, such as the creation of social organization and socialization of conflict participants (long ago identified by Simmel and others). In recent years researchers have, with great profit, turned increasingly to texts of actual disputes.

Students of processes of social conflict have more frequently than most other social scientists sought to formalize the regularities they have discovered in this phenomenon in propositions (see Coser 1956; Mack and Snyder 1957; Williams 1947; Williams et al. 1964). Taking into account the interaction of the sociological variables (affect, power, valence) and considerations of continua such as intensity, hostility, and violence and matters of external threat and internal cohesion as manifested in a range of studies of conflict talk, the author has formulated preliminary propositions. Space limitations constrain discussion of various sorts of propositions or of how sets of propositions permit the forecasting of patterns of conflict talk. Consider, however, the following:

Many disputes include instances of assignment of blame or responsibility (see Fillmore 1971). A discourse rule for this behavior might look like the following:

1. *Rule for assigning blame (responsibility).* If A asserts that B should and could have performed a behavior X_1 but willfully did not or that B should and could have avoided performing a behavior X_2 but nonetheless wilfully performed it, A is heard as blaming B for the nonoccurrence or occurrence of X_1 or X_2 , respectively (Grimshaw, 1992 p. 312).

The influence of power on the availability of aggressive, uncompromising, and sometimes hostile modes of talk in conflict is similar to its influence and constraint on other selection of ways of talking:

2. *Ceteris paribus*, selection of more “confrontational” modes of conflict talk (e.g., threats or insults and increased amplitude or physiological rage displays, threatening kinesic posture, or gestures)

is directly related to increasing relative power (Grimshaw 1992, p. 315).

It is interesting to note that in talk where the parties are proxy military representatives of superpowers discussing matters of very high valence, confrontational modes generally are avoided (Grimshaw 1992). A growing literature on conflict talk demonstrates that the behavior of interest is simultaneously immensely complicated and has a rich potential for new understandings both of social conflict itself and of discourse more generally. This is true even though records of critically important conflict-talk events on the group and international levels have not been available for study (Grimshaw 1992).

Language, Writing, Literacy, and Literature.

Recent events have demonstrated the continuing importance of what Geertz (1963) labeled “primordial sentiments” and shown that feelings about language are central among those sentiments. The range of sociological and sociologically relevant ways in which both language in general and writing and literacy in particular permeate and/or pervade human cultural and social structures and relations, as well as conceptions of identity and of self on the individual level, defies easy summary or description. People go to court in defense of their mother tongue; people have also fought in the streets and burned themselves alive over language issues. Becoming literate in any language can be primarily an instrumental acquisition; in some instances, it can have profound effects on both individual personalities and social organization (see, particularly, J. Goody 1987). The “invention” and development of national languages can have reverberating effects through previously atomized collectivities (Anderson 1990); when printed material becomes available, it can have critical impacts both on change in general (Eisenstein 1979) and on the development of national communities and identities (Anderson 1983).

Sociologists of literature have shown how national literatures can reveal cultural and social values (e.g., Moore 1971); sociologists who study both contemporary life and that in past times are becoming increasingly aware of the rich data in personal documents from journals to correspondence. It is even possible to hear the question, “Who wants citizens to be literate, and to what

ends?” (the implication is that social control may be as much a goal as is the enrichment of individual lives [see Kress and Hodge 1979]). Related interests have drawn a number of investigators to study of *how* written materials affect their readers, a question that has been addressed both by methods that project the “interruption” or “interrogation” of written and/or spoken texts (Silverman and Torode 1980) and by those of psycholinguistics or cognitive science.

Language and personal and social identity:

This introduction to matters of language in use in social contexts should not be closed without mention of a dimension of social life increasingly recognized by sociological social psychologists as well as sociolinguists. This section includes brief reviews of two studies that focus on this *use* of language in identity matters and closes with a listing of suggestive but previously unexamined questions.

Constitution of morally relevant categories of people: T. Labov (1980) has been concerned with specifying how ascriptions of morality are made in conversational discourse and about whom (i.e., which persons and collections of persons) they are made. She has concluded that a task prior to the location of evaluation and obligation in talk is the specification of how people are located in talk and how morally relevant categories of people are constituted.

According to Labov (1980), all types of “collections of people” (a term “used to designate any plurality of people which can be referred to in talk or systematically inferred from the talk”) are potentially relevant in moral matters; since there is a potentially infinite number of such collections, it is imperative to develop procedures for reducing the number to be examined in any given investigation, that is, to discover principled bases for classifying collections. She does this by first developing discovery procedures for locating collections and then gathering the collections into sets bounded by common identifying dimensions.

Labov (1980) observes that references in talk to collections of people often occur in the form of common nouns, proper names, and pronouns. What people are often unaware of, she argues, are collections of “hidden people,” that is, “those collections of people not immediately evident in

the surface talk, but systematically retrievable.” Collections are hidden in five ways:

1. In references to social organization(s), incidents, and specific categories (e.g., in the case of academic settings, belonging-to-department-people, participating-in-defense-people, and faculty people).
2. Social characterizations, that is, collections defined by verbs of activity or specific attributes (e.g., candidate-attacking-people or candidate-defending-people or identification by gender, academic rank, features of personal appearance, voice quality, etc.) She (p. 135) notes that some activities, such as guessing, telling, and thinking, since they are features of all people, are nondiscriminating and thus analytically without value.
3. Ellipsed individuals or collections (i.e., where there is shared knowledge of past characterizations).
4. Collections concealed in references to time or place.
5. Plurals hidden in singulars.

Collections can conveniently be labeled as “feature plus people,” for instance, “doing research on language and identity people” or “reading encyclopedia articles people,” to make “*explicit in a standardized way what features of the people are being considered*” (emphasis added). It is precisely such explicitness that is needed for the specification of identities and their boundaries.

Labov realizes that the identification of collections used by individual speakers is not sufficient to permit an understanding of how discussion of moral matters is accomplished in talk, and she continues by raising several critical questions. The general question is, “How do analysts (and interlocutors) know that coconversationalists are talking about a ‘same’ collection?” There is no easy answer to this question; collections to which reference is being made change in the course of a single speaker’s utterance, overlap across utterances, shift across utterances because the original speaker’s identification was unclear or because a hearer-become-speaker misheard or deliberately misunderstood (Grimshaw 1980b) the original identification, are layered, subsumed, expanded (Labov’s

notion of layering is loosely akin to both the linguistic and Goffman’s [1981] more specialized uses of the term “embedding”), and so on. Resolution of these complexities is a requirement for coherent and cohesive discourse. Labov proposes the “notion of ‘category consensus’ for a situation where the relevance of a given collection of people is shown interactional support” and “which occurs as co-interactants ratify the use of specific collections of people.” Category consensus is not always achieved; like other varieties of consensus, it is often the subject of challenge, negotiation, and metadiscussion. This is, of course, what the study of identity(ies) is about.

Exploitation of referential ambiguity in pronominal usage: A complication is introduced by the use of definite or indefinite articles such as “reading-the-Borgatta-encyclopedia people” versus “reading-an-encyclopedia people.” This introduces the possibility of the use of referential ambiguity in language as an interactional resource. The question of how collectivities (both categories and groups) are constituted and bounded and how that boundedness may be explicitly or implicitly signaled in spoken or written discourse provides a venue for additional demonstration of the value for sociology of examination of language in use. Personal and other pronouns are a useful resource in boundary work; their referential ambiguity also provides a resource exploitable for including and excluding both those present and those absent from relevant social collectivities (Grimshaw 1994a).

The fact that there are times when hearers or readers don’t know to what person or set of persons reference is being made can be weighted with social implication when it is not clear, for example, *who* is being scolded or praised, positively or negatively or neutrally characterized, or invited or rejected. Uncertainty can persist even in the presence of apparently disambiguating specifications such as “you all,” “all of you,” “the *n* of us” (when the collection address includes *n*-plus persons), and “the four of them.” Hearer-readers ordinarily are able to make inferences that are correct or close enough that they can sustain conversation (or reading) without continuously finding it necessary to stop to resolve ambiguities. It is also true, of course, that ambiguities may go unrecognized, be recognized but not resolved, or even be intentionally exploited. Unresolved ambiguities can be in-

consequential, but they may occasionally have delayed consequences of considerable importance (e.g., when “uninvited” guests turn up or unintended “insults” are repaid with interest).

Most readers will be far more familiar with the language–identity connection in which people participate whenever they talk with others. Except under extreme circumstances (ongoing or pending disaster) or service situations in which interactants are treated more as part of the scene than as other humans, the first thing people do when a partner in interaction speaks (in person, on the telephone, or in writing) is to “place” that person in terms of background (in which one usually includes age, education, ethnicity and national origin, gender, occupation, regional provenance, social class, and, depending on situation, other achieved and ascribed attributes). This sensitivity to the link between how people speak and who they are is further demonstrated by the ways in which the speech of others is imitated in “poshing up” (Goffman 1979) and in the production, with varying degrees of friendliness, condescension, and hostility, of “mock” Spanish or black English or other real or imagined languages (Hill).

Note, for example, the insertion of foreign words and phrases (insertion of not-currently-in-use-code speech: (1) foreign words and phrases, e.g., *āp kē bād*, *buenos dias*, *je ne sais pas*, *obrigado*, *paz*, *СПАСІБО*, *was gibts*) (2) technical terms and phrases, such as “deep structure,” “diglossia,” “dope,” “gigabyte,” “identity,” “S and M,” “sole-noid,” and (3) phonological variants and regional dialect lexical items or, more comprehensively, code *switches* in which a different language, dialect, or register is employed for an extensive stretch of talk. How are such insertions and switches to be interpreted? Readers will be able to construct scenarios in which the following are or are intended to be conveyed: “I am one of you,” “I am not one of you, but I am attuned and sympathetic to you,” “I and those of my auditors who understand what I have just said are different (superior to?) from those who did not understand,” “I and those who understand my metaphorical use of a variant are different from (superior to) those who processes it nonmetaphorically” (e.g., “humorous” employ of socially disvalued variants).

Questions of language in use and matters of identity (and thus of stratification, life chances,

social conflict, and so on) are inextricably interrelated and intertwined; neither can be fully comprehended without attention to the other.

APPLIED SOCIOLINGUISTICS, SOCIAL AMELIORATION, AND THEORY BUILDING

The increased interest in SL/SOL has been accompanied by and contributed to by growing public exposure to and interest in language as a social problem. Consider in the last decade of the twentieth century in the United States alone issues of free speech (“hate crime” versus political correctness, arrests for public “cursing”) in both public discourse and on private computers, the “English as official language” movement and accompanying disputes about “rights” to non-English ballots or other government documents, and the public hue and cry about “Ebonics.” Public concern about propriety in language use is not a new phenomenon (see Kamensky 1997).

Work on “real” problems in a variety of institutional areas has benefited from a growing body of theory, to which it has in turn contributed. Again a distinction can be made between micro and macro concerns. Micro sociolinguistic research has been done on how communication fails in classrooms, courtrooms, and clinics; macro studies have examined how the speaking of socially disvalued language varieties is associated with educational failure, differential treatment in the judicial system, and unsuccessful interaction with medical services delivery systems. Ameliorative programs have ranged from bilingualism in education to the English as official language movement, from the provision of interpreters in the courtroom to attempts to simplify legal language, and from attempts to teach prospective doctors to become better interviewers and listeners to trying to get doctors to use less technical language. Bitter controversies have raged over how the ways children talk are related to educational success and failure; the Ebonics dispute is one instance among many (see Labov 1982). Some investigators have argued that some language varieties are not suited for abstract, critical, logical, and propositional thought; others, that the success and failure of persons who speak in different ways are determined by the political preferences about language varieties of gatekeepers such as teachers and employers.

Recent years have seen the development of the role of the “language scientist” as an expert witness (e.g., Rieber and Stewart 1990); SL considerations are sometimes deeply involved in such testimony. Many of these programs and much of this work initially grew out of concerns with language varieties associated with ethnicity (in the United States, different varieties of Spanish and, particularly, Black Vernacular English (BVE)). There has also been more explicit attention paid to problems of communication across classes, age groups, and, particularly, gender; Tannen’s (1990) book on gender differences in talk spent many months on best-seller lists.

On a more explicitly macro level, language planning and language policy have become more visible arenas of government activity in both rich countries, which must deal with visiting or immigrant workers who speak unfamiliar languages, and poor countries, which must make decisions about which competing languages are going to receive official status and support or about which orthography to employ for previously unwritten languages. (The latter is a decision that is likely to have political as well as economic implications.) They must in some cases decide whether high literacy (often seen as an index of modernism) will ultimately contribute to their economies (or other values) as much as or more than would other investments (on outcomes of increases in literacy in industrial [izing] and less developed countries, respectively, see Graff 1979; Goody 1987). Both rich and poor countries must deal with native multilingualism; they have done it with varying success in Belgium, Canada, Finland, India, Indonesia, the former Soviet Union, Spain, Switzerland, and a number of countries in Africa (see McRae 1983, 1986, 1997, for excellent studies on Switzerland, Belgium, and Finland, respectively).

SOCIOLOGY AMONG THE SOCIAL SCIENCES

The relationship between sociology and the other social sciences is in reality a relationship between sectors of different disciplines, not between whole disciplines. Sociology is one of the most open disciplines toward other disciplines. This openness is manifested in the citation patterns in academic publications, which allows one to measure the degree of coherence of a discipline, the relationship between specialties within a discipline, and the interactions among disciplines. If specialists in a subdiscipline tend to cite mostly or exclusively specialists in the same subdiscipline and if relatively few authors cite outside their subdiscipline, as a whole the discipline has a low degree of internal coherence. In this case, the real loci of research are the specialties. If, by contrast, a significant proportion of authors cross the borders of their specialties, the discipline as a whole can be considered an integrated territory.

As can be seen in the analytic and alphabetical indices of most compendiums and textbooks, sociology has a weak core. The fragmentation of the discipline into isolated specialties can be seen in most sociological treatises: "We divide up the discipline into a number of topics, each the subject of a chapter. These chapters are minimally integrated" (Calhoun 1992, p. 185). Theoretical sociology is presented as a subfield disconnected from substantive domains: "General sociology has been relegated primarily to introductory textbooks and to a lesser extent to a sort of social theory that most practicing sociologists use but little in their work" (Calhoun 1992, p. 185). For instance, in Smelser (1988), the twenty-two chapters represent autonomous specialties that are only weakly related to each other. Few of the 3,200 authors cited in that work are mentioned in more than one specialty (Dogan 1997). This lack of a consensus among sociologists has been emphasized in a symposium devoted to that book (Calhoun and Land 1989).

In most general works of sociology published in the last two decades, the most frequently cited authors are ancestors, not contemporary sociologists. With exceptions such as Parsons, Merton, Lazarsfeld, and Mills, few mentors belong to the immediately previous generation. Nowadays, sociologists, in their pattern of references, are like children elevated by their grandparents. This cult

of the ancestors is surprising, because "following advances in the division of labor and specialization, the works of the classics ceased to be directly useful to an average sociologist. To do correct research in a specialized branch of sociology one does not in fact have to read the works—bulky, often abstruse, and semi-philosophical in nature—written by Marx and Spencer, Simmel and Weber, Mead and Znaniecki. To do such research it suffices to master, on the basis of a possibly recent handbook, the standard techniques and the current theories of the middle range" (Szacki 1982, p. 360).

The fragmentation of sociology can be explained in part by the absence of consensus on a dominant, integrative theory or widely accepted paradigm. If a consensus could be reached among sociologists, it would be that sociology has a small, soft, and old core, that sociology is not a centripetal discipline, and that it expands in all directions.

There is very little communication between the fifty specialized domains recognized by the International Sociological Association (ISA) and between the thirty sectors of the American Sociological Association. If cooperation among the specialized fields is weak or absent, a vivid traffic can be observed between each specialized sociological domain and across disciplinary borders: the specialized group of scholars belonging formally to other disciplines, particularly specialties rooted in social psychology, social demography, social anthropology, social history, social geography, social ecology, some branches of political science, political economy, and sociolinguistics. A double phenomenon appears in the sociological literature of the last two decades: a division of the discipline into noncommunicating specialties and an opening of the disciplinary frontiers to specialties from different disciplines.

Bridges are built over the disciplinary borders. The circulation on these bridges is almost as important as the circulation along the internal arteries of formal sociology. The importance of this "foreign" trade can be measured. In a study covering four decades from 1936 to 1975, it was found that sociologists cited articles in sociology journals 58 percent of the time; political scientists cited scholars from their own discipline only 41 percent of the time; anthropologists referred 51 percent of the time to their colleagues; psychologists referred

73 percent of the time to their own kin, and 79 percent of the economists did the same (Rigney and Barnes 1980, p. 117). These figures indicate that in each social science a significant proportion of theoretical, methodological, and substantive communication has been with other disciplines, with the most open discipline being sociology and the most autonomous being economics.

In an analysis of journals identified as belonging to sociology and economics, there was a significant shift from sociology to “interdisciplinary sociology” and from economics to “interdisciplinary economics” between 1972 and 1987. The criterion for interdisciplinarity was the proportion of cited references in the journals of the respective disciplines (Crane and Small 1992, p. 204–205). An analysis by those authors in terms of clusters of references shows a clear increase in interdisciplinary relationships.

In addition to this the crossing of disciplinary borders, another important trend in the last fifteen years has been the multiplication of new hybrid journals that cross disciplines and specialties. More than 300 hybrid journals in English that concern sociology directly or indirectly have been established in this period, along with many others in French and German. Most of these new journals have a limited circulation and are addressed to readers in highly specialized subfields.

FROM SPECIALIZATION TO FRAGMENTATION TO HYBRIDIZATION

The fragmentation of disciplines is generated by an inevitable and growing process of specialization. All the sciences experience such specialization. As a discipline grows, its practitioners generally become increasingly specialized and inevitably neglect other areas of the discipline. The division of physics into physics and astronomy and the division of chemistry into organic chemistry and physical chemistry are examples in the natural sciences. In the social sciences, what was originally the study of law divided into law and political science; anthropology split into physical anthropology and cultural anthropology; and psychology broke up into psychology, social psychology, psychotherapy, and psychiatry.

Each formal discipline gradually becomes too large and unmanageable for empirical research.

No theory or conceptual framework can encompass the entire territory of sociology. Talcott Parsons was the last one to attempt such a unification, but his ambition was unrealistic (Johnston 1997). Contemporary theories are influential only within their subdisciplines. The process of fragmentation and specialization eventually is followed by a process of recombination of the specialties into new hybrid domains. These recombinations correspond to the logic of multiple and concatenated causality in the social sciences.

The more renowned new hybrid domains hoist their own flags, for instance, political sociology, which is a fusion of sectors from both of its parent disciplines; social psychology, which is already autonomous; political economy, which detaches large sectors from economics and political science and smaller sectors from sociology; and historical sociology, which has revived on both sides of the Atlantic. None of these four subfields were mentioned three decades ago by Smelser (1967). This absence shows the changes that have occurred since then.

It is pointless to lament the fragmentation of sociology or any other social science, because the interaction between specialties in different disciplines is beneficial. All social sciences, sociology in particular, have grown in depth and breadth through exchanges with cognate specialties in other disciplines. What some scholars perceive as dispersion is in reality an expansion of knowledge and an inevitable trend.

In the history of social sciences, the progression from fragmentation to specialization to hybridization has taken one of the following six forms:

1. Division in two parts, or bifurcation. The history of the sciences is a long chain of divisions. One of the oldest, going back to Aristotle, is the separation of philosophy and political theory. One of the most recent is the divorce of cognitive science from traditional psychology.
2. Changing the boundaries of formal disciplines. The growth of specialties at the interstices between disciplines has as a consequence the shrinking of the borders of the parent disciplines. When social psychology became independent, psychol-

ogy lost an enormous territory. One of the borders of economics retracted when political economy was emancipated. Anthropology has seen its frontiers retract as a result of modernization, industrialization, and urbanization; consequently, urban studies expanded. The margins of political science are in perpetual change.

3. Migration of individual scholars from one formal discipline to another or to a new territory. The founders of sociology have moved away from philosophy, such as Durkheim; from history, such as Weber; or from economics, such as Pareto (see Dogan and Pahre 1990).
4. The convergence of two domains in a new hybrid field. One of the most recent examples in medical sciences is the intermingling of fragments of cardiology with fragments of pneumonology. The nomenclature of social sciences is full of such hybrid fields.
5. Outgrowth from the mother discipline for pragmatic reasons, to the point of joining another formal discipline. For instance, sociology of medicine, the most populated sociological subdiscipline, is today located more often in hospitals than in departments of sociology; it has become a problem-solving subdiscipline.
6. Borrowing from neighboring disciplines and exchanging concepts, theories, methods, practices, tools, and substance. This borrowing and lending process is an important route of hybridization. All the social sciences share concepts, theories, and methods. The contribution of sociology to this shared repository is impressive. Sociology has devised and exported many more concepts to neighboring disciplines than have borrowed from it (Dogan 1996). Most theories formulated in a discipline sooner or later spread to other disciplines. The diffusion of theories across disciplinary borders is one of the arguments that could be invoked by those who advocate more interdisciplinary strategies in the social sciences. The borrowing and lending of methods among disciplines have itineraries different from those for the

spread of concepts and theories. As contributions of methodology in social sciences, the most productive in strategies and techniques of research were until recently psychology, econometrics, social psychology, and statistics. For concepts and theories, the most creative disciplines are sociology, political science, economics, anthropology, and philosophy.

A distinction must be made between interdisciplinary amalgamation and hybridization through recombination of specialties belonging to different disciplines. A “unified sociology” existed only in the early phase of sociological development. Hybridization of specialties came later, after the maturation of the process of the internal fragmentation of disciplines. The word “interdisciplinary” is misleading when used to describe contemporary trends, because today only specialties overlap, not entire disciplines. The word “hybridization” may seem to be imported from biology, but it has been used by social scientists such as Piaget and Lazarsfeld.

Sociometric studies show that many specialists are more in touch with colleagues in other disciplines than with colleagues in their own disciplines. The “invisible college” described by Robert Merton, Diana Crane, and other sociologists of science is an eminent multispeciality institution because it ensures communication not only from one university to another and across all national borders but also between specialists attached administratively to different disciplines. The networks of cross-disciplinary influence are obliterating the old classification of the social sciences.

RECOMBINATION OF SOCIOLOGICAL SPECIALTIES WITH SPECIALTIES IN OTHER SOCIAL SCIENCES

Sociology has exchanged concepts, theories, methods, practices, and substance most intensively with three other disciplines: political science, history, and economics. The analysis here will focus first on these three disciplines. The well-known dominion of social psychology can be surveyed briefly. The relationships between sociology and social geography have long been difficult and poor. What happens in the absence of intermingling? Other specialties intervene in the empty space, as in case of ecological geography. I have to forgo the

overlapping areas between sociology and social anthropology, social demography, ethnology and sociolinguistics, but the comments on the process of fragmentation of disciplines, on multiplication of specialties, and recombination of the specialties in new hybrid fields are also applicable to them.

Relations with Political Science. A double phenomenon can be observed in the relationship between sociology and political science. First, there is weak communication within each of these two disciplines among the multiple specialized fields, an impermeability between the specialized research subfields that belong formally to the same discipline. The disciplines appear like watertight compartments in large ships (Dogan 1997). Typically, there is relatively little scholarly exchange between a student of the American Congress and a specialist in Middle Eastern politics, between a political philosopher and an expert in statistical analysis, and between an Africanist and an expert on welfare states. However most of these scholars are likely to have relationships with cognate specialties in neighboring disciplines. The diversity of methodological schools contributes to the fragmentation of each discipline.

Second, across disciplinary frontiers there is a vivid traffic between special fields or subfields belonging to one discipline and similar or cognate fields in the other discipline. A convincing way to show the importance of these cross-disciplinary bridges is to rank on two columns the fifty research committees of the ISA and the forty committees of the International Political Science Association (IPSA). For each area of research in one discipline there is a homologue in the other discipline: religion, ethnicity, generations, gender, mass communication, elites, socialization, crime, social inequality and so on. To these interminglings should be added theoretical and methodological pairs: All major schools and sects are represented in both disciplines from rationalists to Marxists and from qualitative methods to proponents of quantification.

The relationships between sociology and political science can be observed by counting the proportion of authors belonging to a discipline who cite articles from other disciplines. Such an analysis of footnotes in major journals shows the trade across disciplinary frontiers and the changes in trade routes over time. In terms of import-export balance, political science has borrowed

from economics, sociology, and social psychology, and has exported mostly to sociology.

There has been a change in the cross-fertilization of political science. In the 1950s and 1960s, sociology was the major lender to political science, making important contributions such as group theory, political socialization, social cleavages, and systems theory. In the 1970s and 1980s, economics was the major cross-fertilizer of political science, especially with theories of public goods and collective action, game theory, social choice, and international trade theory. Psychology has been a constant exporter to political science and sociology, but at a lower level. In the 1960s, its major contributions came from personality theory and the study of values.

One domain of sociology—political sociology—and one domain of political science—comparative politics—have privileged relations, in some cases achieving a real fusion. In the history of comparative research, there was a privileged moment of cooperation and convergence between political sociology and comparative politics in the 1960s. Between 1958 and 1972, three dozen important books and articles were published that shared three characteristics: comparison by quantification, hybridization, and cumulative knowledge. That combination had never previously been achieved in the history of sociology and political science (Dogan 1994, p. 39). This privileged moment also marks a break with European classical comparisons in the sociological style of Tocqueville, Mill, Marx, Weber, and Pareto.

The alarm over the parochial state of comparative politics after the subjugation of all social sciences during the period of totalitarianism in Europe (Scheuch 1992) and before their renaissance in the United States was raised by Roy Macridis in 1955. At the same time (1954), the Statistical Bureau of the United Nations started to publish “social statistics” on demographic variables, income, standards of living, social mobility, sanitary conditions, nutrition, housing, education, work, and criminality. These sources facilitated the encounter between political sociology and comparative politics.

In 1957, *Reports on the World Social Situation* began to be published by the Department of Economic and Social Affairs of the United Nations. The chapters in these publications in 1961 and

1963 on “the interrelations of social and economic development and the problem of balance” and on “social-economic patterns” are contributions that can be read profitably today by sociologists interested on developmental theories. Lipset’s *Political Man* (1959) borrowed from all the social sciences. A year later, Deutsch produced his “manifesto” (Deutsch 1960), followed by a seminal article (Deutsch 1962). Both articles dealt with comparative indicators. The following year an important article by Cutright (1963) was published that appears in retrospect to have been prophetic. In the same year, Arthur Banks and Robert Textor published *A Cross-Polity Survey*, in which the majority of the fifty-seven variables are of direct interest to sociologists. Shortly afterward, the *World Handbook of Political and Social Indicators* by B. Russett et al. discussed seventy-five variables, the majority with sociological significance. In *Comparative Politics* by G. Almond and G. Bingham Powell (1966), several social sciences, particularly sociology and social anthropology, are seen in the background. From that moment on, the field of international comparisons became bifurcated, with both trends being related to political sociology. One road continues with quantitative research, in which contributors constantly use nonpolitical factors in their analyses of the correlates of democracy and transition to democracy. An important contribution comes again from the Development Program of the United Nations, the *Human Development Report* (1990 and after). In this publication, gross national product (GNP) per capita is replaced by a new indicator: purchasing power parity (PPP).

The other road gave priority to sectoral comparisons, for instance, the eight volumes on development published by the Princeton University Press, where politics is most of the time a dependent variable explained by social economic and cultural factors. About a thousand books and articles appear in a selected bibliography of sectoral comparisons published during the last three decades. About half of their authors belong administratively to political science, a quarter belong to sociology, and a quarter are hybrids scholars.

Comparative political sociology does not consist only in cross national analysis. It is also a cross-disciplinary endeavor, because in comparative research one is crossing units (nations) and variables (numerical or nominal). The variables are usually more numerous than the units. The relations be-

tween variables are often more important for theoretical explanations than are discoveries of analogies and differences between nations. In comparative political sociology, there is not a single major book that attempts to explain politics strictly by reference to political variables. Of course, the amount of hybridization varies with the subject and the ability of the author to omit what should be implicitly admitted.

More than 200 contemporary European and American scholars have held a joint appointment in the departments of sociology and political science or have moved from one to the other. Some comparativists cannot be locked in only one of these two disciplines.

Historical Sociology and Social History. History is the most heterogeneous discipline in the social sciences, dispersed in time and space. It is divided into a nomothetic part and an ideographic part. The dispute over the role and borders of history, which in France goes back to Durkheim, Simiand (1903), and Seignobos, does not seem to have ended. Three generations later, history has been excluded from the social sciences under the authority of an international institution: It is not numbered among the nomothetic sciences covered in UNESCO’s *Main Trends in the Social and Human Sciences*. Historians do not appear to have reacted vigorously to this affront. Indeed some have come to terms with it: “The progress of history in the last fifty years is the result of a series of marriages: with economics, then with demography, even with geography . . . with ethnology, sociology and psychoanalysis. When all is said and done, the new history sees itself as something like an auxiliary science of the other social sciences” (Chaunu 1979, p. 5). This is clearly not the opinion of the other French historians (*Annales* 1989, p. 1323), who are resolutely committed to interdisciplinarity: “History will progress only in the context of interdisciplinarity.”

As long as the focus is on the long time span and the comparative approach, there is agreement between Durkheim and Braudel. At a distance of sixty years, using different words, they say much the same thing: “History can be a science only in so far as it compares, and there can be no explanation without comparison . . . Once it starts comparing, history becomes indistinct from sociology” (Durkheim in the first issue of *L’Année Sociologique*

1898). Braudel is just as accommodating: "Where the long time span is concerned, the point is not simply that history and sociology tie in with each other and support each other but rather that they merge into one" (Braudel 1962, p. 93). However, this refers only to the part of history that compares while considering the long time span; other fields of history have very little to do with sociology. Similarly, many sociologists do not need to have recourse to history to resolve the problems with which they are concerned. Durkheim and Braudel would have been more explicit if instead of considering their disciplines as a whole, they had referred clearly to their common territory, which is now called comparative social history or historical sociology. Once it is accepted that history and sociology overlap only in certain areas, the long territorial dispute between history and sociology will become a thing of the past. However, this is only one sector of history brought face to face with a sector of another discipline. Exchanges with economics have thus generated economic history, which is of interest only to enough historians and economists, to provide material for several major journals. Each human activity has its historian, who, in order to perform his or her task, has to hunt in other people's lands.

On the other side of the Atlantic, as soon as their disciplines had begun to fragment, innovative historians and sociologists reached out to one another. Frederick Jackson Turner's study of the American frontier was a marriage of sociology and history with the benediction of geography. Later, sociologists such as Bellah (*Tokugawa Religion*, 1959) and Lipset (*The First New Nation*, 1963) were joined by a new generation of historians, represented by Charles Tilly's *The Vendee* (1964), Barrington Moore's *Social Origins of Dictatorship and Democracy* (1966). This interweaving of sociology and history continues to the present day.

"Most sociologists and historians have no clear understanding of what historical sociology really is" (Aronson 1969, p. 294). Unlike in economics, political science, or linguistics, the distinction is not based on subject matter. Many have attempted to clarify the differences between the two disciplines, leaving no two authors in agreement (see Boudon 1979; Lipset and Hofstadter 1968; Tilly 1981). The reason for the lack of consensus is clear: The remarkable diversity of the historical sociologies, to say nothing that of their parent

disciplines, makes any unidimensional characterization of the issue unsatisfactory.

The comparative method is a very useful way to unify general statements of causality of historical events. One of the first to take this path was the French school in the journal *Annales*, which developed an approach to social history that was both sociological and comparative. Marc Bloch was one of the most influential figures in the development of this school both in his programmatic statement *Pour une histoire comparée des sociétés européennes* (1928) and in *La société féodale* (1939–1940). For some historians it is impossible to assess the validity of any causal interpretation on the basis of a single case, making a comparative approach absolutely necessary for useful explanation (Cahnman and Boskoff 1964, p. 7). Comparative history overcomes the fragmentation of specialized (and especially national) history. Examining similar causal processes in two or more specific contexts can illuminate the nature of the causal forces at work and improve one's understanding of the events being studied.

The dialogue between the specific and the general is an important issue explored by many who discuss historical sociology. Along these lines, Burke (1980) isolates two different aspects of the contributions history can make to sociology, one negative and one positive. The negative contribution entails picking away at the edifice constructed by others by showing how a theory does not fit one's society. This entails tests that are hazardous for any theory, but the theories that survive are proved to be of greater value. The positive contribution involves working out from the general to the particular in order to construct a revised general theory. This task is especially valuable because a sociologist's generalizations often appear vacuous to a historian. Historians have invalidated many of the theories of sociologists and political scientists.

When posed in this fashion, the social sciences' insistence on generalization can be helpful for historians. In the words of a sociologist turned historian, "Whatever else they do, the social sciences serve as a giant warehouse of causal theories and concepts involving causal analogies; the problem is to pick one's way through the junk to the solid merchandise" (Tilly 1981, p. 12). When one

finds solid ground, a simple application of sociological theory to historical problems can be innovative.

Knapp (1984) suggests that historians can help overcome the inattention to context of most social theory. He argues that one of the major problems in sociological theory is the implicit or explicit *ceteris paribus* (all else being equal) clause. Since all other factors are never the same in the real world, such theories are repeatedly disconfirmed and often appear vacuous: "When sociologists (or political scientists, economists, or anthropologists) decide that concern with theory absolves them from concern with history, their product will not only be irrelevant historically, it will not even be adequate as theory" (Knapp 1984, p. 34). When theories are opened up to allow variation in the *ceteris paribus* clause, they can be applied to specific historical contexts. Historians who are most familiar with the peculiarities of "their" period or country have much to add to social theory in this type of research.

Contrary to what is generally believed, historical sociology sometimes is not based on quantified research. Nonetheless, quantification is so ubiquitous in most social sciences that it is easy for historians to misunderstand the nature of the field. As Tilly points out, "In field after field, the leading edge of the change was some form of quantification. Because of that uniformity, many nonquantitative historians mistook the prow for the whole ship" (Tilly 1981, p. 34). Quantified data are for most sociologists what primary sources are for historians: Some historians cannot resist quoting diaries, and some sociologists cannot resist quantifying. Both kinds of evidence have advantages and disadvantages, and each discipline can gain from making greater use of the kind of evidence most useful to the other.

In addition to a difference in method, history and sociology often are distinguished by their conceptual inventories. There are a number of sociological concepts historians can use to their advantage, such as structure, function, social role, kinship, socialization, deviance, social class and stratification, social mobility, modernization, patrons and clients, and factions. The breadth of this list makes it clear that there is much room for hybridization of subfields across the disciplinary boundaries. For instance the concept of "development" is central in several social sciences (Riggs 1984).

Relations with Eclectic Economics. To discuss the relationship between sociology and economics, it is necessary to distinguish several varieties of economists: econometricians, monodisciplinary monetarist theorists, landless theorists, and eclectic transgressors of borders (a fifth variety, economic historians, has been expelled from the field). The first two varieties have well-known physiognomies. Landless theorists (Rose 1991) are economists who believe that they do not have to deal with nation-states and tend to reduce all countries to a single model. They travel at the level of landless economies. One may assume that the first three varieties are outstanding contributors to scientific knowledge, since so many of them have been awarded Nobel prizes, but here only the last variety has good relations with the other social sciences.

Eclectic economists denounce the reductionism advocated by other economists. Four decades ago, Hayek wrote that "nobody can be a great economist—and I am even tempted to add that the economist who is only an economist is likely to become a nuisance if not a positive danger" (Hayek 1956, p. 463). For the Nobel prize laureate Buchanan, "it becomes increasingly clear that the channels of effective communication do not extend throughout the discipline that we variously call 'economics' and that some 'economists' are able to communicate far more effectively with some scholars in the noneconomic disciplines than with those presumably within their own professional category" (Buchanan 1966, p. 181). Another Nobel prize laureate asked: "Why should economics be interdisciplinary? The answer is, presumably, because otherwise it will make mistakes; the neglect of all but the narrowly economic interactions will lead to false conclusions that could be avoided" (Solow 1970, p. 101). Many economists state that "it is necessary to reduce the use of the clause *ceteris paribus*, to adopt an interdisciplinary approach, that is to say to open economics to multidimensionality" (Bartoli 1991, p. 490).

Economics is also divided, but to a lesser degree than the other social sciences. It has maintained some coherence but has had to pay a high price for this by considerably reducing its field. At one time, economics reached a fork in the path: It could have chosen intellectual expansion and the penetration of other disciplines at the cost of heterogeneity and diversification and at the risk of

dispersal (a risk taken by sociology and by political science); it chose instead to remain true to itself, thereby forfeiting vast territories. Many economists consider that the choice of purity, methodological rigor, and hermetic terminology was the right choice.

It is thus clear that self-sufficiency eventually leads to a shrinking of borders, but this does not mean general impoverishment, since the lands abandoned by economists were soon cultivated by others. Those lands now have their own departments, research centers, and professional schools (management, political economy, development science). The position of economics in the constellation of the social sciences today might have been more dominant if so many economists had not withdrawn into monodisciplinary.

This situation is surprising in that “few classical sociologists have failed to assign a central place in their theories to the relationship between economy and society: from Marx and Weber to Schumpeter, Polanyi, Parsons and Smelser” (Martinelli and Smelser 1990).

If many economists have locked themselves in an ivory tower and allowed whole areas to escape from their scrutiny, other economists have advocated an “imperialistic expansion of economics into the traditional domains of sociology, political science, anthropology, law and social biology” (Hirschleifer 1985, p. 53; Radnitzky and Bernholz 1986). Several of these economists are famous scholars, including several Nobel laureates. A kind of manifesto has been published in *The American Economic Review*:

It is ultimately impossible to carve off a distinct territory for economics, bordering upon but separated from other social disciplines. Economics interpenetrates them all, and is reciprocally penetrated by them. There is only one social science. What gives economics its imperialist invasive power is that our analytical categories are truly universal in applicability. Thus economics really does constitute the universal grammar of social science. But there is a flip side to this. While scientific work in anthropology and sociology and political science and the like will become increasingly indistinguishable from economics, economists will reciprocally have to become aware of their functions. Ultimately, good economics will also

have to be good anthropology and sociology and political science and psychology. (Hirschleifer 1985, p. 53)

This view is anachronistic, but many outstanding economists have succeeded not only in exporting their knowledge to other disciplines but also in invading them with their methods and theories and achieving innovative research. Arrow's *Social Choice and Individual Values* (1951) led mathematically trained economists to apply game theory to a variety of social conflict situations. Several works made such applications, including Anthony Down's *An Economic Theory of Democracy* (1957), Duncan Black's *The Theory of Committees and Elections* (1958), Buchanan and Tullock's *The Calculus of Consent* (1962), Riker's *The Theory of Political Coalitions* (1962), and Olson's *The Logic of Collective Action* (1965). Since then, many social scientists have borrowed ideas and techniques from economists and applied them to the analysis of various processes and situations. The economists were the first in the field because they had a longer tradition of mathematical training and used more abstract and thus more widely applicable concepts. The other social sciences had learned statistics in order to handle the interpretation of their empirical data but were much slower to learn advanced mathematics. In a number of important graduate schools, economists hold joint appointments with other social science departments.

Some economists continue to spread the application of their analytic techniques to outside fields. Becker wrote a book on discrimination and prejudice and in *Treatise on the Family* (1981), applied economic analysis to topics such as the incidence of marriage, divorce, and childbearing. He was awarded the Nobel Prize in Economic Sciences in 1992 for his work applying economics to different areas of human behavior, particularly the family, a traditional stronghold of demography. Gordon Tullock's *The Economics of Non-Human Societies* deals with ants, termites, bees, mole rats, sponges, and slime molds. Many similar examples could be given (Szenberg 1992): “The fields to which the economic approach or perspective has been applied over the last thirty or forty years include politics, sociology, ethnology, law, biology, psychology” (Radnitzky and Bernholz 1986). An examination of recent issues of journals of economic literature shows that some economists explore a wide range of issues. Among these

eclectic economists a few who work in another discipline and then return immediately to the home discipline. Intriligator (1991) has presented in a schematic way the patterns of cross-fertilization among the behavioral sciences by identifying concepts and theories developed in economics and adopted by others. He traces in terms of input-output the itinerary of social choice theory, structural models, decision theory, organization theory, bounded rationality, utility theory, game theory, the concept of balance of power, and anomie.

The interactions between economics and political science are deeper than those between economics and sociology. Many economists are better known in political science than in economics, particularly in the domain of political economy. In *A New Handbook of Political Science* (Goodin and Klingemann 1996), the new economic sociology receives great attention, but it is not clear how it is different from the older political economy. This work should be confronted with *Handbook of Economic Sociology* (Smelser and Swedberg 1994). For instance, Offe describes the "asymmetry" between the two disciplines: "Political economists do have an economic theory of institutions and tend to disregard this demarcation line separating spheres. Sociologists have perhaps only the rudiments of a sociological theory of what is going on in markets and firms, while the most ambitious argument that sociologists do have to offer effectively demonstrates that non-economic spheres of society are not only constituted in different ways than the economy, but that the economy itself depends on non-economic spheres" (Offe 1992, p. 687).

Social Psychology. Most sociologists are not involved in the kind of research that interests most psychologists, and vice versa. For the majority of sociologists and the majority of psychologists, their respective territories are clearly separated. Nevertheless, between the two disciplines there is a condominium, social psychology, inhabited by hybrid scholars, some of whom have begun their scientific activity in one of the two disciplines while others started as "hybrids." In addition, for many sociologists who are not social psychologists, psychology is the nearest and most important disciplinary neighbor. What Inkeles wrote three decades ago is still valid: "It would not be at all difficult to assemble a set of fifty or one hundred recent articles in social psychology, chosen half from the psychological and half from the sociological jour-

nals, which would be so much alike that no one, judging without knowledge of source or author, could with any precision discriminate those written by professional sociologists from those written by psychologists. Several considerations follow from this simple fact. Clearly, the two disciplines cannot be defined in terms of what psychologists and sociologists respectively do, since they so often do the same thing" (Inkeles 1970, p. 404).

The growth of social psychology during the last two generations makes Durkheim's arguments in favor of the supremacy of sociology over psychology irrelevant, along with the old debate about the individual-society dichotomy: "The claim to a principled distinction of sociology from psychology based on the distinction of individual from society is challenged by the substantial attention that at least some sociologists pay to individuals, by difficulties in describing psychology as the study of individuals, and by difficulties in the very conceptual distinction of individual from society" (Calhoun 1992, p. 175). At the early stages of the discipline's postwar history, psychology had been the most cited cognate discipline by sociologists, but during the last two decades, it was partly overtaken by political science and economics. Meanwhile social psychology has become an autonomous discipline.

Relations with Ecological Geography. As a reaction against the exaggerations of the sociologist Huntington (1924), who was criticized by Pitirim Sorokin in 1928, an entire generation of American sociologists was dissuaded from taking geographic factors into consideration. Even today, most sociologists and geographers ignore each other.

Until recently, sociologists neglected environmental and climatic factors, but many prominent hybrid scholars did not remain silent. Lewis noted that: "it is important to identify the reasons why tropical countries have lagged during the last two hundred years in the process of modern economic growth" (Lewis 1955, p. 53). Galbraith wrote: "If one marks off a belt a couple of thousand miles in width encircling the earth at the equator one finds within it no developed countries . . . Everywhere the standard of living is low and the span of human life is short" (Galbraith 1957, p. 39-41). The book published by Kamarck, director of the Economic Development Institute of the World Bank, challenges the common perception of tropical areas.

Trypanosomiasis, carried by the tsetse fly, prevented much of Africa from progressing beyond the subsistence level: "For centuries, by killing transport animals, it abetted the isolation of Tropical Africa from the rest of the world and the isolation of the various African peoples from one another" (Kamarck 1976, p. 38). An area of Africa larger than the United States thus had been denied to cattle (Kamarck 1976, p. 39). Agricultural production in the humid tropics is limited by the condition of the soil, which has become laterite (Kamarck 1976, p. 25). Surveys by the World Health Organization and the World Food Organization estimated that parasitic worms infected over one billion people throughout the tropics and subtropics. Hookworm disease, characterized by anemia, weakness, and fever, infected 500 million in those areas (Kamarck 1976, p. 75).

These ecological factors are confirmed by a considerable amount of research in tropical areas during the last several decades by geologists, geographers, biologists, zoologists, botanists, agronomists, epidemiologists, parasitologists, climatologists, experts of the World Bank and several agencies of the United Nations, and hybrid scientists well versed in tropical agriculture, the exploitation of minerals, and the sanitary conditions in those countries. The situation has improved, according to dozens of reports prepared by international organizations. To explain the economic underdevelopment of tropical Africa and other tropical areas, natural sciences and demography are brought into the picture. Dependency theory may be of some help for Latin America and eastern Europe, though much less so for tropical Africa.

The literature on the ecological parameters of the tropics can be contrasted with the literature on the transfer of flora and fauna from one temperate zone to another. For instance, Crosby's *Ecological Imperialism: The Biological Expansion of Europe 900-1900* (1986), casts new light on the building of American power.

This is an example of what can happen when a discipline neglects an important topic. The vacuum left by the absence of sociological studies of this geographic-ecological-economic issue has been filled by eclectic economists and hybrid ecologists.

Sociologists and geographers have met not in vast "interdisciplinary" work but in a series of individual fields such as urban studies. In the

history of this hybrid in the United States, important work came from sociologists in the subfields of "human ecology," geographers influenced by sociologists, and scholars in both disciplines working on spatial statistics. Once a hybrid, urban studies is now a department at many large universities in Europe and the United States.

Urban studies as a quasi-discipline includes subfields that overlap specialties in sociology, geography, and anthropology. It also encompasses architecture, which covers engineering (building design and methods), the natural sciences (climatology, energy conservation), the social sciences (social-physical research), the humanities (history of architecture), and some hybrids of its own (urban planning). Some architects today are well versed in engineering, the natural sciences, the social sciences, and the humanities, as well as urban planning.

Urban studies also has been influenced by economics and economic geography. This hybrid has made its major contribution in the area of location theories for agricultural, industrial, and commercial activities. Communication seems to be much better with geographers and even sociologists than it is with economists, partly because the inductive nature of much of this work makes it difficult to integrate into deductive economic theory.

Other sociologists have drawn from sectors of geography in conjunction with history and economy. Rokkan (1995) has suggested a conceptual framework for comparative political analysis. He weaves together Parsonian pattern variables, the sequence of various kinds of "crises," and the typically Scandinavian notion of center-periphery relations into a geographic schema built around the main Hansa-Rhine-Italy trade routes, the notion of a country's distance from Rome, and whether a state faces seaward or is landbound. This schema is very suggestive not only because it can clarify the different political outcomes in the states of modern Europe but also because it can help one understand why many once-powerful states have disappeared, such as Scotland, Wales, Brittany, Bohemia, Bavaria, and Aragon.

Today, geography's breadth can be seen in the multiplication of hybrid subfields. The discipline now encompasses the subfields of human geography, cultural geography, biogeography, geomorphology, climatology, medical geography, economic

geography, political geography, urban geography, environmental science, regional geography, and cartography. Each subfield relates directly to specialties outside the discipline. Different interests have favored closer contacts sometimes with one field and sometimes with another. These outside fields have made some of geography's most important advances.

As a result of all these trends, there is an incredible fragmentation that has made geography span large areas in both the natural and social sciences, with a general tendency to drift from the former to the latter. From studying habitats, geographers have turned to studying societies. Many traditional geographers have become social scientists.

As in other disciplines, interaction has kept geography on the move. Many geographers have developed their method and have penetrated other disciplines to such a degree that they have become specialists in another discipline (geology, hydrology or ethnology) or one sector of another discipline. Such emigration leaves the old core of the discipline empty. At a symposium on the social sciences in Paris in 1982, a geographer asked, "With the progress of the other social sciences, what remains proper to geography? A residual part, or a boring nomenclature? . . . Does geography still have its own domain, or is it a relic . . . of an old division of labor? Has geography an identity and, if so, of what is it made?" (Brunet 1982, pp. 383, 402). As is true for the other social sciences, its identity can be found in hybrid specialties, not in disciplinary unity.

CONCLUSION

The contemporary social sciences have experienced three major trends: rapid expansion, fragmentation of formal disciplines by increasing specialization, and recombination of specialties in new hybrid domains. The social sciences have expanded enormously over the last four decades. During the years 1956-1960, the number of citations in the Social Science Citation Index (SSCI) for all social sciences amounted to 2,400,000. Thirty years later, in the years 1986-1990 the number of articles cited in this thesaurus rose to about 18,000,000, increasing by a factor of 7.5 (SSCI 1994, pp. 61-63).

It is difficult to evaluate the number of articles rooted in sociology or relevant for sociologists even if one can locate the origin of the articles and adopt criteria for what is relevant and what is not. The main difficulty comes from the ambiguity and arbitrariness of the borders of these disciplines. Between one-quarter and one-third of the articles cited by sociologists in the last few decades were written by economists, political scientists, psychologists, historians, geographers, and other social scientists.

In 1994, the SSCI contained almost two million citations involving 400,000 authors from fifteen disciplines and from many countries, an average of five citations per author. Among those citations, between 5 and 8 percent referred to articles written by sociologists. Obviously, no one can master the entire spectrum of sociology. There are no paradigms in the discipline, only partial and contested theories and moving borders. One can succeed in finding one's way in the bibliographical labyrinth because the scientific patrimony is structured in sectors, subdisciplines, areas, fields, subfields, specialties, topics, and niches in spite of the fact that the borders are blurred. This increasing specialization within sociology is the main route of scientific advancement. Some scholars recommend an interdisciplinary approach. Just as some seem to believe that the social sciences can be neatly categorized, many others persist in pursuing interdisciplinarity. That recommendation is not realistic because it overlooks an essential phenomenon in the history of science: specialization through a process of fragmentation.

To understand scientific creativity, another phenomenon is even more important than the expansion of the scientific literature and the increase in specialization: the recombination of specialties into new hybrid domains, a phenomenon called the hybridization of scientific knowledge.

A hybrid scholar is a specialist who crosses the borders of her or his home discipline by integrating into her or his research factors, variables, theories, concepts, methods, and substance generated in other disciplines. Different disciplines may proceed from different foci to examine the same phenomenon. This multidisciplinary implies a division of territories between disciplines. In contrast, hybridization implies an overlapping of segments of disciplines, a recombination of knowl-

edge in new and specialized fields. Innovation in each discipline depends largely on exchanges with other fields belonging to other disciplines. At the highest levels, most researchers belong to a hybrid subdiscipline. Alternatively, they may belong to a hybrid field or subfield.

An innovative recombination is a blending of fragments of sciences. When old fields grow, they accumulate such masses of material that they split up. Each fragment of the discipline then confronts the fragments of other fields across disciplinary boundaries, losing contact with its siblings in the old discipline. A specialist in urbanization has less in common with a sociologist studying elite recruitment than he or she does with a geographer doing research on the distribution of cities, who in turn has more in common with a colleague in economics analyzing urban income inequality.

Most hybrid specialties and domains recognize their genealogical roots: political economy, social psychology, social geography, historical sociology, genetic demography, psycholinguistics, political anthropology, social ecology, biogeography, and many others. The hybrid specialties branch out in turn, giving rise, to an even larger member of hybrids (Dogan and Pahre 1990, pp. 63–76).

Among the ISA research committees and study groups, about half focus on hybrid specialties. The number of sociologists who work across disciplinary borders is so high that there is more communication between various fields of sociology and their cognates outside the discipline than there is between fields within sociology.

One can find in the literature of each social science, with the possible exception of linguistics and econometrics, complaints about the “lack of core”: “The substantive core of the discipline may have dissolved” (Halliday and Janowitz 1992, p. 3). Dozens of similar testimonies could be collected. If so many scholars formulate the same diagnosis, that means that most disciplines are facing a problem of self-identity. However, if one considers that the real world cannot be cut into disciplinary pieces, this issue of disciplinary identity may appear fallacious.

It is difficult or impossible to inquire into the large social phenomena within a strictly monodisciplinary framework. Only by taking a position at the crossroads of many branches of

knowledge can one explain the impact of technological advancement on structural unemployment in western Europe, the proliferation of giant cities in the third world, the economic decline of the United Kingdom and the economic growth of Japan, or how a child learns to speak. Whenever a question of such magnitude is raised, one finds oneself at the intersection of numerous disciplines and specialties. All major issues cross the formal borders of disciplines: war and peace, generational change, the freedom–equality nexus, individualism in advanced societies, and fundamentalism in traditional societies. Most specialists are not located in the so-called core of a discipline. They are in the outer rings, in contact with specialists from other disciplines. They borrow and lend at the frontiers; they are hybrid scholars. The notion of hybridization does not mean “two whole disciplines in a single skull” but a recombination of two or several domains of knowledge originating from different disciplines.

Most classical sociologists were interdisciplinary generalists, but in recent times, cross-disciplinary advancements have been achieved not by generalists but by hybrid specialists. The hybrid specialist today may be in reality a “marginal” scholar in each of the disciplines from which he or she borrows, including his or her original discipline, but such a specialist becomes central to the intersection of two or several disciplines (Dogan 1999).

Today most social scientists admit that the best alternative to the difficulty of experimentation in their disciplines is the comparative method, which is one of the few ways to validate or falsify generalizations in the “soft” sciences. The comparative method is the key to circulation among sciences.

Comparative sociologists and comparative political scientists have developed methods to a greater extent than have workers in other social sciences. One of them wrote: “There is no noncomparative sociological theory. All scientific analyses are a subset of the general set entitled comparative analysis . . . any generalized statement involving variables implies a comparison” (Levy 1970, p. 100).

Major social phenomena cannot be explained in a strictly monodisciplinary framework or in the absence of a comparative perspective. It is only by taking up a position at the crossroad of various branches of knowledge and simultaneously adopt-

ing comparative perspective that social scientists can advance knowledge. The intersections of hybrid specialties and comparative approaches are privileged sites in the social sciences.

MATTEI DOGAN

SOCIOLOGY OF EDUCATION

In the broadest perspective, education refers to all efforts to impart knowledge and shape values; hence, it has essentially the same meaning as socialization. However, when sociologists speak of education, they generally use a more specific meaning: the deliberate process, outside the family, by which societies transmit knowledge, values, and norms to prepare young people for adult roles (and, to a lesser extent, prepare adults for new roles). This process acquires institutional status when these activities make instruction the central defining purpose, are differentiated from other social realms, and involve defined roles of teacher and learner (Clark 1968). Schools exemplify this type of institutionalization.

The central insight of the sociology of education is that schools are socially embedded institutions that are crucially shaped by their social environment and crucially shape it. The field encompasses both micro- and macro-sociological concerns in diverse subfields such as stratification, economic development, socialization and the family, organi-

zations, culture, and the sociology of knowledge. To understand modern society, it is essential to understand the role of education. Not only is education a primary agent of socialization and allocation, modern societies have developed formidable ideologies that suggest that education *should* have this defining impact (Meyer 1977).

Durkheim (1977) was the intellectual pioneer in this field, tracing the historical connections between the form and content of schools and larger social forces such as the rise of the bourgeoisie and the trend toward individualism. Largely because the field focuses so intensively on stratification-related issues (e.g., the impact of family background on educational attainment), the larger issues raised by Marx and Weber are readily evident in current scholarship. However, as Dreeben's (1994) historical account indicates, the direct contribution of the discipline's founders to the development of the sociology of education in the United States was minimal; indeed, even the foremost early American sociologists in the field did not decisively shape its development.

In *The Sociology of Teaching*, Waller (1932) examined teaching as an occupational role and school organization as a mechanism of social control. He emphasized the role of the school in the conflict-ridden socialization of the young as well as the interpersonal and organizational mechanisms that furthered students' acceptance of the normative order. Although now recognized as a classic, Waller's analysis stimulated little work for several decades.

Although less focused on education per se, Sorokin (1927) portrayed schools as a key channel of mobility with their own distinctive form of social testing. He argued that increasing opportunities for schooling would stratify the society, not level it. However, Blau and Duncan's (1967) paradigm-setting study of status attainment (see below) did not refer to Sorokin's analysis of education despite their appreciation of his larger concern for the significance of social mobility. Warner's and Hollingshead's community studies considered education integral to community social organization, especially through its connection to the stratification system, but their influence, like that of Waller and Sorokin, was more a matter of suggesting general ideas than of establishing a cumulative research tradition.

As a subfield within the sociological discipline, the sociology of education has been propelled largely by a host of practical, policy-related issues that emerged with the development of the mass educational system. Essentially, research has focused on whether education has delivered on its promise of creating more rational, culturally adapted, and productive individuals and, by extension, a "better" society. The field was particularly energized by the egalitarian concerns of the 1960s: How "fair" is the distribution of opportunity in schools and in the larger society, and how can disparities be reduced? These questions continue to animate the field.

THEORETICAL DEBATES

Much research, even the most policy-oriented, has been grounded, often implicitly, in more general analytic perspectives on the role of education in modern society. The two main orientations are functionalism and conflict theory, though other, less encompassing perspectives also have shaped the field significantly.

Functionalism. In the functionalist view, schools serve the presumed needs of a social order committed to rationality, meritocracy, and democracy. They provide individuals with the necessary cognitive skills and cultural outlook to be successful workers and citizens (Parsons 1959; Dreeben 1968) and provide society with an efficient, fair way of sorting and selecting "talents" so that the most capable can assume the most responsible positions (Clark 1962). Complementing this sociological work is human capital theory in economics, which contends that investment in education enhances individual productivity and aggregate economic growth (Schultz 1961). The criticism in the 1980s that poor schooling had contributed significantly to America's decline in the international economy reflects a popular version of this theoretical orientation.

However, in the 1970s, both the increasing prominence of critical political forces and the accumulated weight of research spurred a theoretical challenge. Important parts of the empirical base of functionalism were questioned: that schools taught productive skills, that mass education had ushered in a meritocratic social order, and that education had furthered social equality. A number of conflict-oriented approaches emerged.

Neo-Marxist Theory. Neo-Marxist scholars have provided the most thorough challenge to the functionalist position. For all the diversity within this conflict theory, the main point is that the organization of schools largely reflects the dictates of the corporate-capitalist economy. In the most noted formulation, Bowles and Gintis (1976) argue that education must fulfill the needs of capitalism: efficiently allocating differently socialized individuals to appropriate slots in the corporate hierarchy, transferring privilege from generation to generation, and accomplishing both while maintaining a semblance of legitimacy. Thus, the changing demands of capitalist production and the power of capitalist elites determine the nature of the educational system.

More recent neo-Marxist scholarship (Willis 1981) emphasized that schools are not only agents of social reproduction but also important sites of resistance to the capitalist order. Many neo-Marxists also have emphasized the “relative autonomy” of the state from economic forces and, correspondingly, the partial responsiveness of schools to demands from subordinate groups (Carnoy and Levin 1985). Other scholars in this general critical tradition have turned in “post-Marxist” directions, emphasizing inequities related to gender and race along with class, but the common, defining point remains that educational inequities reflect and perpetuate the inequities of capitalist society and that oppressed groups have an objective interest in fundamental social transformation (Aronowitz and Giroux 1985). This newer critical approach has developed with relatively little connection to mainstream approaches (i.e., positivistic, often reform-oriented research) despite some similarities in concerns (e.g., student disruptions and challenges to authority in schools) (Davies 1995).

Obviously, neo-Marxists do not share the essentially benign vision of the social order in functionalist thought, but both perspectives view the organization of schooling as “intimately connected with the changing character of work and the larger process of industrialization in modern society” (Hurn 1993, p. 86). These competing perspectives are rooted in similar logical forms of causal argument: To explain educational organization and change, functionalists invoke the “needs” of the society, while neo-Marxists invoke the “needs” of the capitalist order for the same purpose. Critics contend that both perspectives posit

an overly tight, rational link between schools and the economy and concomitantly downplay the institutional autonomy as schools as well as the complexity of political struggles over education (Kingston 1986).

Status Conflict. Arising out of the Weberian tradition, the status conflict approach emphasizes the attempts of various groups—primarily defined by ethnicity, race, and class—to use education as a mechanism to win or maintain privilege (Collins 1979). The evolving structure of the educational system reflects the outcomes of these struggles as groups attempt to control the system for their own benefit. With varying success, status groups use education both to build group cohesion and to restrict entry to desired positions to those certified by “their” schools. However, as lower-status groups seek social mobility by acquiring more educational credentials, enrollments may expand beyond what is technically necessary. In this view, then, the educational system is not necessarily functional to capitalist interests or other imputed system needs.

Consistent with this view, a primary effect of schools, especially at the elite level, is to provide *cultural capital*, of which educational credentials are the main markers (Bourdieu and Passeron 1977). This form of capital refers to the personal style, social outlooks and values, and aesthetic tastes that make a person suitable for socially valued positions. (The point of comparison is *human capital*, an individual’s productive, technical skills.) In this perspective, education is rewarded because occupational gatekeepers value particular forms of cultural capital, and thus education is a key mechanism of class and status reproduction.

The Interpretative Tradition. Sociologists in the interpretative tradition view schools as places where meaning is socially constructed through everyday interactions. This tradition incorporates the general orientations of phenomenology, symbolic interactionism, and ethnomethodology. Accordingly, micro-level concerns predominate—for example, what do teachers expect their students to learn, and how do those expectations condition their conduct in class?—and research tends to rely on qualitative techniques. This tradition is unified by a general sense of what kinds of questions to ask (and how to ask them) rather than a set of related

theoretical propositions or a body of accumulated findings.

EMPIRICAL STUDIES

The highly selective review of empirical studies that follows focuses on the two key questions in contemporary American sociology of education: (1) How is education involved in the distribution of life chances? (2) How are family status and school characteristics connected to educational attainment and/or academic achievement? With few exceptions, analyses of education in other countries are not considered. The field is dominated by American research, and American sociologists have engaged in relatively little comparative research. Baker (1994) speculates that this lack of a comparative research tradition in the United States reflects both a belief in American "exceptionalism" (for instance, an extreme emphasis on mass access) and a strong focus on micro-level issues that do not necessarily call for comparative research designs.

Schooling and Life Chances. Throughout the twentieth century in all industrial countries, there has been a dramatic upgrading in the occupational structure *and* a dramatic expansion in educational systems. Ever more jobs have come to require academic qualifications, a process that usually is interpreted as being driven by the rationalism and universalism of modernization. In this functionalist perspective, academic skills are presumed to be technically required and meritocratically rewarded, transforming the stratification system so that individual achievements rather than ascriptive characteristics determine life chances.

This interpretation has been subject to empirical test at two levels: (1) the *individual level*—to what extent, absolutely and relatively, does education affect economic attainment? and (2) the *macro level*—to what extent have educational expansion and the increasing significance of schools for occupational attainment increased overall equality of opportunity?

At the first level, as part of the general analysis of *status attainment*, researchers have concentrated on measuring the connection between individuals' schooling and their economic position. Building on Blau and Duncan's (1967) work, researchers have repeatedly documented in multivariate mod-

els that education (measured in years of schooling and degree completion) has by far the largest independent impact on adult attainment (Featherman and Hauser 1978; Jencks et al. 1979). By comparison, the net direct effects of family status (usually measured in terms of parental education and occupation) are modest. Indeed, among the college-educated in recent years, higher family status confers no extra advantage at all (Hout 1988).

Earlier in life, however, family status is substantially related to educational attainment. The total effect (direct and indirect) of family status on occupational attainment is therefore substantial, though its impact is mediated very largely through educational attainment. In effect, then, education plays a double-sided role in the stratification process. Education is the great equalizer: It confers largely similar benefits to all regardless of family origins. However, it is also the great reproducer: Higher-status families transmit their position across generations largely through the educational attainment of their children.

The strong connection between schooling and occupational attainment is open to diverse interpretations. Most prominently, human capital theory suggests that education enhances productivity, and because people are paid in accordance with their marginal productivity, the well educated enjoy greater prospects. In favor of this interpretation is the fact that schooling is demonstrably linked to the enhancement of academic competencies (Fischer et al. 1996) and that basic academic skills are substantially correlated with job performance in a wide variety of settings (Hunter 1986).

By contrast, credentials theory portrays the educational institution as a sorting device in which individuals are slotted to particular positions in the occupational hierarchy on the basis of academic credentials, often with little regard for their individual productive capacities. The fact that possessing specific credentials (especially a college degree) has positive career effects, net of both years of schooling and measured academic ability, provides indirect support for this view. That is, there appears to be a "sheepskin effect," so that employers value the degree per se, although people with degrees may have unmeasured productive capacities or dispositions that account for their success (Jencks et al. 1979). Moreover, the credentialist argument is strengthened by the fact

that in some elite segments of the labor market, employers primarily recruit graduates of certain prestigious programs and make little effort to discern differences in the academic-based skills of those included in the restricted applicant pool (Kingston and Clawson 1990).

Both views seem to have some merit; indeed, they may be partially complementary. Employers may generally use educational attainment as a low-cost, rough proxy for productive skill, and for certain positions they may favor holders of particular degrees because of their presumed cultural dispositions and the prestige that their presence lends the organization. The relative explanatory power of the human capital and credentialist perspectives may vary across segments of the labor market.

At the macro level, it might be expected that the great expansion of access to education has reduced the impact of family origins on educational attainment, increasing equality of opportunity, but that has proved to be more the exception than the rule. A rigorous thirteen-country comparative study identified two patterns: greater equalization among socioeconomic strata in the Netherlands and Sweden and virtual stability in the rest, including the United States (Shavit and Blossfeld 1993), where the strata have largely maintained their relative positions as average attainment has increased. Thus, the impact of educational policies designed to promote equality appears minimal; even in Sweden and the Netherlands, the trend toward equalization emerged before reforms were introduced.

Socioeconomic Status and Achievement. Given the centrality of educational attainment in the general attainment process, researchers have focused on the substantial relationship between socioeconomic status and educational attainment. (This relationship appears to be stronger in highly developed societies than in developing societies.) The best predictor of educational attainment is academic achievement (i.e., higher grades and test scores); the school system consistently rewards academic performance and in that sense is meritocratic. Regardless of academic performance, children from socially advantaged families have somewhat disproportionate success in moving through the educational system, but the main

reason higher-status students have this success is that they achieve better in schools.

The question here is, Why do higher-status students achieve better in schools? Clearly, there is no simple answer. Research has pointed to the following family-related factors, among others:

1. *Material resources.* Richer families can purchase the materials (e.g., books) and experiences that foster intellectual development.
2. *Parental expectations and/or encouragement.* Well-educated parents more actively stress the importance of academic achievement, and their own success through schooling encourages their children to accept that value.
3. *Direct parental involvement in home learning activities.* Higher-status parents are more willing and able to teach academic lessons at home and help with homework.
4. *Verbal and analytic stimulation.* In higher-status families, interactions between parents and children are more likely to promote verbal sophistication and reasoning.
5. *Family structure and parenting style.* The presence of two parents and parenting styles involving warm interactions favor academic achievement, and both factors are related to socioeconomic status (SES).
6. *Parental involvement in schools.* Higher-status parents are better able to interact effectively with teachers and administrators to secure favorable treatment and understand expectations.
7. *Cultural "fit" with schools.* The cultural styles of higher-status students are more compatible with the prevailing norms and values in schools.
8. *Social capital.* Initially Coleman's (1988) idea, this refers to the extent and nature of the connections between parents and children as well as the connections with other family and community members. By providing informational, emotional, and other resources, these connections facilitate adaptations to the demands of schools.

9. *Social context.* Higher-status families are likely to live in communities where other families promote achievement and their children's peers are committed to academic achievement.
10. *Genetic advantage.* Early IQ is related to SES, and intelligence is related to academic performance.

Individually, none of these factors seems to account for a large part of the overall relationship between SES and academic achievement, nor is the relative significance of these factors clear, yet the very length of the list suggests the complexity of the issue. Higher-status students are not all similarly advantaged by each of these factors, and lower-status students are not all similarly disadvantaged by each one. The substantial aggregate relationship between SES and achievement undoubtedly reflects complex interactions among the many home-related contributing causes. As is more thoroughly discussed below, the mediating impact of school resources and practices is much less consequential.

The Racial Gap. The black-white disparity in academic performance remains large despite some notable reductions in recent years, and it is economically significant. A number of researchers have shown that for younger cohorts, the racial disparity in earnings is accounted for very largely by differences in basic academic skills as measured by scores on tests such as Armed Forces Qualifications Test (Farkas 1996).

Why this gap persists is unclear, partly because until recently, sociologists and other social scientists were wary of addressing such a politically explosive issue. Most relevant for the discussion here is the fact this gap cannot be explained by blacks' lesser school resources (see "School Effects," below). Largely drawing on the work of scholars in related fields, the sociological consensus appears to be that the racial disparity does not reflect a *group*-based difference in genetic potential (Jencks and Phillips 1998). (At the individual level, there is undoubtedly some genetic component to IQ among people of all races.) Moreover, this gap cannot be attributed largely to racial differences in economic advantage: Socioeconomic status explains only about a third of it. However, a broader index of family environment, including parental practices, may account for up to two-

thirds of the gap (Phillips et al. 1998). A complete explanation probably will involve many of the factors previously noted in the discussion of the relation between SES and achievement but also include the distinctive cultural barriers that "involuntary minorities" face in many societies (Ogbu 1978) as well as subtle interactional processes within schools.

Racial disparities in educational attainment have declined dramatically. High school graduation rates are now virtually the same, and the remaining disparity in college attendance reflects blacks' lower economic resources, not a distinctive racial barrier.

School Effects. The governmental report *Equality of Educational Opportunity* (Coleman et al. 1966) strongly challenged conventional wisdom about the connections among economic status, schools, and achievement. In doing so, it fundamentally shaped the agenda for further research in this area.

Attempting to identify the characteristics of schools that improve learning, the so-called Coleman Report documented two key points. First, there is a weak relationship between social status and school quality as measured by indicators such as expenditure per pupil, teachers' experience, and class size despite considerable racial segregation. Second, these measures of school quality have very little *overall* effect on school achievement (scores on standardized tests) independent of students' family background. The Coleman Report also showed, however, that school effects were notably larger for black and Hispanic students than they were for whites and Asians. Among the school effects, the racial composition of schools was the most critical: Blacks did somewhat better in integrated schools.

Later research largely validated the main conclusions of the Coleman Report, but also modified them, often by considering more subtle aspects of school quality. For instance, some school resources, including expenditures, seem to enhance achievement, but the predominance of home factors on achievement remains undisputed. In regard to another between-schools effect, Coleman argued for the educational superiority of Catholic schools, an advantage he attributed to their communal caring spirit and high academic expectations for all students. The Coleman Report did not consider such cultural matters or specific educational prac-

tices. Much of the post-Coleman Report research focused on within-school effects because gross between-school effects appeared to be relatively minor.

Ability grouping in elementary schools and tracking in high schools have attracted attention, largely as a source of inequalities of academic performance. The premise of these practices is that students differ substantially in academic ability and will learn more if taught with students of similar ability. Although many different practices are grouped under the term "tracking," students in the "top" groups generally receive a more demanding education, with higher expectations, more sophisticated content, and a quicker pace, and are disproportionately from advantaged families. The obvious but not fully settled issue is whether schools "discriminate" in favor of the socially advantaged in making placements. At the high school level, controlling for measures of prior achievement (themselves affected by family factors), higher SES seems to enhance one's chances modestly, though achievement factors are predominant in placement. Blacks are somewhat favored in the process if one controls for prior achievement. At the elementary school level, research is less consistent, though one study indicates that neither test scores nor family background predicts early reading group placement (Pallas et al. 1994).

Another important but not fully settled issue is whether students in certain ability groups or tracks learn more because of their placement. Gamoran (1992) shows that the effects of tracking are conditioned substantially by the characteristics of the tracking system (for example, how much mobility between tracks is allowed) and subject matter. However, by way of gross summary, higher track placement per se generally seems to have a modestly beneficial impact on achievement and also seems to increase students' educational aspirations and self-esteem. However, to exemplify the important exceptions to this generalization, it appears that within-class grouping for elementary school mathematics may help both low and high groups.

Teacher Expectations. It is commonly supposed that differences in teachers' expectations explain at least some of the racial and socioeconomic disparities in academic achievement. The

claim is that a self-fulfilling prophecy is at work: Teachers expect less from socially disadvantaged students and treat them accordingly, and therefore these students perform less well in school. Rosenthal and Jacobson's (1968) small-scale experimental study provided the initial impetus for this argument, but follow-up studies in real classrooms suggest that teachers' expectations have little or no effects on later performance.

If the standard for fairness is race neutrality in light of past academic performance, there is little evidence of racial bias in teachers' expectations, but some limited evidence suggests that teachers' beliefs are more consequential for blacks than for whites (Ferguson 1998). More generally, research has not established that socially discriminatory practices in schools significantly explain the link between family and/or racial status and achievement.

Contextual Effects. Not only do students come to school with different backgrounds that affect learning, schools provide students with different social environments that are importantly shaped by the economic and racial composition of the student body. Because peers are so influential in children's and adolescents' lives, the obvious question is whether the social composition of a school affects individual learning beyond the effects attributable to an individual's status characteristics. This issue has had practical significance in light of ongoing public debates about the impact of racial desegregation initiatives.

Evidence about the impact of social context on learning is mixed, but in any case the impact is not large. To the extent that the SES of a student body is consequential, this appears to result from the connection between SES and a positive academic climate in a school. Greater racial integration generally seems to promote black student achievement slightly, but the benefits are more pronounced for black students when they actually have classroom contact with white students rather than just attending a formerly integrated school.

More recent research suggests an important cautionary note about whether integration "works." Entwistle and Alexander (1992), for example, show that on a yearlong basis, in the early grades black students in integrated schools had better reading comprehension than did black students in segregated schools. However, the apparent advantage of integrated schools totally reflects the fact that

black students at integrated schools improved more during the summer than did black students at segregated schools. During the school year black students did slightly better in segregated schools. This analysis exemplifies the increasing recognition that a simple conclusion about integration—works versus does not work—is inadequate.

Learning through the Year. As should be evident, a major issue in the sociology of education is separating the effects of the home from the effects of the school. The perplexing finding is that racial and class disparities in achievement in the early grades become substantially greater as students progress through school. Critics have seized on this finding to indict schools for discriminatory practices that exacerbate social inequality.

However, so-called summer learning research suggests a different interpretation (Alexander and Entwistle 1995; Gamoran 1995). Examining the same students' test scores at the beginning and ending of each of several school years, researchers have shown that (1) despite initial disparities, advantaged and disadvantaged groups have roughly similar gains in achievement during the school year but that (2) advantaged students continue to improve during the summer while disadvantaged students stagnate or decline. As the effects of this process accumulate over the years, initial disparities become ever larger. The important implication is that schools neither reduce nor add to the inequalities that are rooted in homes. Schools in effect passively reproduce existing inequalities.

Enhancing Performance. Although crude measures of school resources (e.g., teacher certification levels) appear at most to be weakly related to school achievement, a burgeoning and increasingly sophisticated line of research finds that effective schools can be identified. These schools are marked by strong leadership committed to academically focused goals and order, high academic demands, and frequent practice of academic skills. This research also directs attention to the benefits of an overall communal culture and classroom interactions that stress cooperative efforts between students and teachers (Lee and Croninger 1994). What appears critical is how resources are organizationally applied.

Macro-Level Effects. This article has focused on the experiences of individuals: how education affects life chances and how personal character-

istics and school experiences affect learning. The unit of analysis, in other words, is the individual. Research in the field much less commonly takes the society as the unit of analysis: How do societal features shape the nature of the educational system? How do the features of this system affect other societal arrangements? An important example of macroanalysis is the generally limited impact of increasing educational access on equality of opportunity (see "Schooling and Life Chances," above). Perhaps the most studied macro-level topic is the relationship between educational expansion and economic growth.

If the individual economic benefits of education are clear, the impact of educational expansion on economic growth is less certain. The orthodox view in economics is that educational expansion promotes growth. This view follows from human capital theory: People with more schooling get higher pay *because* they are more productive, and if more people get more schooling, they will produce more and get paid more, with the aggregate effect being economic growth. Many sociologists are at least partially skeptical of this idea. Undoubtedly, more educated workers get paid more, but the positive (private) rate of return they enjoy reflects greater productivity only if it is assumed that the labor market is perfectly competitive and in equilibrium. This assumption is at least partly problematic given socially discriminatory employment practices, internal labor markets with seniority rules and restricted job mobility, professional and union restrictions of labor supply, and public sector employment with politically determined pay structures.

Allocation theory—which also is called the credentialing perspective—offers an alternative explanation of the link between education and economic rewards. In brief, employers assume that the more educated, as a group, are *relatively* desirable people to hire (for reasons that may or may not reflect their individual productive capacities); and in turn, how people are ranked in the educational hierarchy becomes linked to how they are ranked in the hierarchy of the *existing* job structure. Educational expansion, then, does not necessarily promote economic growth; it only affects who gets which of the already existing jobs. To the extent that credentialing processes are operative, it is impossible to infer aggregate effects on growth from individual-level data on income.

Given the ambiguous implications of individual income data, the best way to examine the issue is through aggregate, *national*-level studies of how education affects economic growth. The accumulated weight of this research undercuts claims about the large *universal* benefits of more education of all types. Benavot (1992), for example, establishes the following for a large sample of developed and poor countries in the period 1913–1985: Throughout the period, the expansion of primary education promoted growth; the expansion of secondary education had more modest impact, and only during times of worldwide prosperity; and tertiary education tended to *retard* growth at all times. In the United States, moreover, tertiary enrollments have never stimulated growth (Walters and Rubinson, 1983).

However, even if more education is not a universal economic “fix,” in certain circumstances particular types of education may stimulate growth in specific sectors. Reviewing single-country times series studies that use an aggregate production function model, Rubinson and Fuller (1992) conclude that education had the greatest beneficial impact when it created the kinds of skills that were suited to an economy’s sectoral mix and technological demands. However, a good fit between the educational system and the economy is by no means certain because educational expansion and the actual educational content of schools are so often driven by political processes, not technological demands.

Even if the actual economic impact of education is often less than is commonly supposed, the widespread belief in the general modernizing benefits of education is central to an ideology that permeates the entire world. Indeed, in Meyer’s institutionalist perspective (Meyer and Hannan 1979; Meyer 1977), the quest to appear modern has induced later-developing societies to mimic the educational practices of the early modernizers so that many school structures, rituals, and formal curricular contents are remarkably similar throughout the world. In turn, this institutionalized similarity means that on a global basis, certain types of knowledge become defined as relatively significant, the elite and mass positions become defined and legitimated by educational certification, and assumptions about a national culture rest on the existence of mass education. Nevertheless, if education is associated at the individual level with

certain democratic values, educational expansion per se does not appear to contribute to the emergence of democratic regimes or state power.

THE REFORMIST PROJECT

Policy debates about education have often been contentious, fueled by larger ideological and political struggles. In conservative times, schools have been pressed to emphasize discipline and social and/or intellectual sorting; conversely, in more liberal times, issues of equality and inclusion have come to the fore. The apparent result is cyclical, pendulum-like swings in policy between, say, an emphasis on common core requirements and highly differentiated curricula.

While differences at the rhetorical level have sometimes been sharp, actual changes in practice in much of the twentieth century have been relatively minor. This reflects the institutionalization of the school, meaning that there is a widespread collective sense of what a “real” school is like (Tyack and Cuban 1995). This institutionalization rests on popular legitimization and the recurrent practices of school administrators and teachers. Concrete practices such as the division of knowledge into particular subject areas, the spatial organization of classrooms, and the separation of students into age-based grades are all part of the “real” school. Educational practices that depart from this pattern have had limited acceptance, for example, open classrooms in the 1970s. The lesson for current reformers is that policies that modify institutionalized practices, not fundamentally challenge them, are more likely to be successful and that the political support of in-the-school educators is critical for success.

Indeed, much policy-oriented research has had a mildly reformist bent, primarily concerned with making existing schools “work better.” That has largely — and narrowly—meant producing students with higher scores on standardized tests in the basic academic subject areas. Critics have questioned both the validity of these tests and the desirability of evaluating school “success” in these limited terms alone. Proponents contend that scores on these tests have considerable predictive validity for later school and occupational performance and that their standardized results permit rigorous comparisons across groups and school settings.

The welter of policy-related studies is impossible to summarize here (and the distinction between sociological research and educational research is hardly sharp), but two general types of contributions from sociologists stand out. The first is essentially a debunking contribution: Sociologists have shown what does *not* work despite fervent beliefs to the contrary. The previously discussed Coleman Report is the most prominent example, undercutting the liberal faith of the 1960s that differences in school resources substantially account for racial and socioeconomic differences in academic achievement.

The second contribution is essentially methodological, alerting policymakers to the fact that many apparent school effects may largely or even totally reflect selection biases. That is, if groups of students are subject to different educational practices, are any differences in their performance attributable to the educational practices per se, or are different sorts of students subject to different practices, thus accounting for the association between practice and performance? In recent years, controversies about the efficacy of private and Catholic schools, related to larger debates about school choice plans, have centrally involved the issue of selection bias. In the most sophisticated study, Bryk et al. (1993) demonstrate net positive effects of Catholic schools on academic achievement and show that the gap in achievement between white and minority students is reduced in Catholic schools.

Even with the most sophisticated multilevel, multivariate statistical models, however, sociologists cannot make firm *causal* claims by analyzing survey data. However, by ruling out many potential sources of spuriousness, these analyses can suggest interventions that are likely to have a positive effect. True experiments, which involve the actual manipulation of the treatment and/or practice, are rare. In a state-sponsored experiment in Tennessee, starting in kindergarten, students were randomly assigned to varying sized classes (with and without a teacher's aide). The results showed that students, especially minority students, benefited academically from small classes (thirteen to seventeen students) and that the benefits persisted even when the students later moved to larger classes (Finn and Achilles 1990). Prior nonexperimental analyses had shown, across the

range of class size in existing schools, that class size had very little or no effect.

Now that it is accepted that schools can make a difference in learning despite the great significance of family-based factors, the research agenda probably will focus on specifying the conditions in which particular school practices are most effective. This will involve analyzing inside-school practices as well as the links between families and schools and between schools and the workplace.

PAUL W. KINGSTON

SOCIOLOGY OF ISLAM

Like Christianity and Judaism, Islam is an Abrahamic religion based on prophecy, prophethood, and the revealed text. It began in sixth-century Arabia and spread rapidly to regions outside the Arabian peninsula. A hundred years after Mohammed had declared it a prophetic religion, Islam had spread to almost all the regions of the known civilized world. This early political success and the idea that the divine message for the proper ordering of society is complete and final account for the social pervasiveness of this religion. The first factor inhibits the handing over of spheres of life to nonreligious authority, and the second makes it difficult to offer rival versions of the blueprint. This social pervasiveness makes Islam especially interesting in the sociology of religion (Gellner 1983, p.2).

Islam is the second largest religion, with an estimated 1.2 billion adherents, constituting about 20 percent of the world population in 1998. Approximately 900 million Muslims live in forty-five Muslim-majority countries. Table 1 provides a sociodemographic profile of Muslim countries included in the *World Development Report* published annually by the World Bank. In terms of size, the Islamic world constitutes a significant part of humanity and therefore warrants a sociologically informed understanding and analysis of its religious, social, and political trends. The following topics will be covered in this article: social, ideological, and economic factors in the origins of Islam; Islam and the rise of the modern West; Islam, Muslim society, and social theory; Islam and fundamentalism; the Islamic state; gender issues

in Muslim societies; and, Muslim minorities in the West.

SOCIAL FACTORS IN THE ORIGINS OF ISLAM

Social science scholarship in the twentieth century has been influenced by three dominant intellectual traditions: Marxism, Weberian, and functionalism. Their influence has shaped the analytic approach to historical events, resulting in an increasing focus on the relationship between social and economic factors and historical events. The study of Islam and Muslim societies often reflects these influences.

One strand of scholarship has focused on the analysis of various factors in the origins and early development of Islam. A discussion of the economic and social aspects of the origins of Islam provides a test case for a closer investigation of the wider issues raised by the dominant paradigms in sociology. A number of historical studies have dealt with this issue primarily in terms of the diffusion of Jewish and Christian teaching in pre-Islamic Arabia that laid the foundation for the rise of Islam (Torrey 1933; Bell 1926; Kroeber 1948). The aim of these and similar studies has been to identify and understand how certain ideas and cultural elements utilized by Islam derived from preexisting religions or to point to the existence of elements analogous to Islam in other religious traditions in the same general area.

Another scholarly tradition has approached the analysis of the early development of Islam in terms of sociological and anthropological concepts and traces the origins of Islam primarily to the change in social organization in pre-Islamic Meccan society caused by the spread of trade. Wolf (1951) provides an overview of these studies and shows that the tendencies Mohammed brought to fruition were prominent in pre-Islamic Arabia. The spread of commerce and rapid urban development had caused the emergence of classlike groupings from the preceding network of kin relations. This also contributed to the emergence of a divine being specifically linked to the regulation of nonkin relations as the chief deity. These changes created a disjunction between the ideological basis of social organization and the functional social reality and thus spawned disruption and conflict. Islam arose as a moderating religious-

Sociodemographic Profile of Selected Muslim Countries

ethical social movement under these social conditions. According to Wolf:

The religious revolution associated with the name of Mohammed permitted the establishment of an incipient state structure. It replaced allegiance to the kinship unit with allegiance to a state structure, an allegiance phrased in religious terms. It limited the disruptive exercise of kin-based mechanisms of blood feud. It put an end to the extension of ritual kin ties to serve as links between tribes. It based itself instead on the armed force of the faithful as the core of a social order which included both believers and unbelievers. It evolved a rudimentary judicial authority, patterned after the role of the pre-Islamic soothsayer, but possessed of new significance. The limitation of the blood feud permitted war to emerge as a special prerogative of the state power. The state taxed both Muslims and non-Muslims, in ways patterned after pre-Islamic models but to new ends. Finally, it located the center of the state in urban settlements, surrounding the town with a set of religious symbols that served functionally to increase its prestige and role. (1951, pp. 352–353)

In his historical studies of early Islam, Watt (1954, 1955, 1962a, 1962b) also analyzed the economic, social, and ideological aspects of the origins of Islam. His analysis of the economic situation in pre-Islamic Arabia shows that the economic transition from a nomadic to a mercantile economy had resulted in social upheaval and general malaise. He also found a close affinity between the ideology of Islam and the situation that prevailed in early seventh-century Mecca. However, his analysis led him to question the nature and direction of the relationship between Islamic doctrines and the social and economic conditions of pre-Islamic Meccan society. Are doctrines causally dependent on the social order in such a way that they can be deduced from it? Or is the ideology of Islam a creative factor that made a contribution to the course of events? Watt argues that there was nothing inevitable about the development of a world religion from the economic and social circumstances of early seventh-century Mecca. The malaise of the times might have been alleviated without achieving anything of more than transient and local importance. He argues that the formulation of Islamic ideology was a creative response to the

situation, not an automatic result of interacting factors.

According to Watt, the creative response of Islamic ideology is reflected in key foundational Koranic ideas such as *Ummah* and *Rasul*. Like other Koranic ideas, these ideas can be connected to earlier Jewish and Christian conceptions as well as to pre-Islamic Arabian ideas, but the Koranic conceptions had a unique new and creative dimension that made them especially relevant to the contemporary Arabian situation. Mere repetitions of current ideas in the Koran would have rendered those ideas devoid of creative novelty, whereas sheer novelty would have made them unintelligible. What the Koran does is take the familiar conceptions and transmute them into something new and original (Watt 1954, p. 172). In this synthesis, the old images are to some extent transformed but retain their power to release the energy of the human psyche. From this perspective, the Koranic conceptions and images of *Ummah* and *Rasul* took on new meanings that were a combination of the old conceptions and additional meanings conferred by the Koran, which was thus able to release the energies of the older images and inaugurate a vigorous new religion. This energy was directed, among other things, toward the establishment of the Islamic state and the unification of Arabia (Watt 1954, pp. 173–4).

Debate about the social factors in the origins of Islam continues (Engineer 1990; Crone 1996). However, it is evident that under the influence of dominant theoretical paradigms in sociology, this debate has provided new insights into the role of social, economic, and cultural factors in shaping the ideology of Islam and the early development of Islamic social formations.

THE “SOCIAL PROJECT” OF ISLAM

Another recent development has been a revival of interest in the “social project” of Islam. The most significant contributions have come from the work of Rahman (1982, 1989), who claims, “A central aim of the Koran is to establish a viable social order on earth that will be just and ethically based” (1989, p. 37). This aim was declared against the backdrop of an Arabian society characterized by polytheism, exploitation of the poor, general neglect of social responsibility, degradation of morals,

injustice toward women and the less powerful, and tribalism. The Koran and the genesis of the Muslim community occurred in the light of history and against the social historical background. The Koranic response to specific conditions is the product of a "coherent philosophy" and "attitude toward life" that Rahman calls "the intellectual tradition" of Islam. This tradition was subverted and undermined by an emphasis on literalist interpretations of the Koran by Ulema Islamic scholars. The Islamic scholarship molded by Ulema came to emphasize "minimal Islam", focusing on the "five pillars," and negative and punitive Islam. Islamic scholarship thus became rigid, fossilized, and largely removed from the intellectual tradition of the Koran. Rahman argues that the intellectual tradition of the Koran requires that Koranic thought be dependent on a factual and proper study of social conditions in order to develop Islamic social norms for reforming society (Rahman 1982).

ISLAM AND THE RISE OF THE MODERN WEST

An important strand of historical scholarship has focused on the relationship between Islam and the rise of the modern West. This question was the focus of *Mohammed and Charlemagne* (Pirenne 1939). According to Pirenne, for centuries after the political collapse of the Roman Empire, the economic and social life of western Europe continued to move exclusively to the rhythm of the ancient world. The civilization of Romania had long outlived the Roman Empire in the West. It survived because the economic life based on the Mediterranean had continued to thrive. It was only after the Arab-Muslim conquests of the eastern and southern Mediterranean in the seventh century A.D. that this Mediterranean-wide economy was disrupted by the Islamic conquest. The Arab-Muslim war fleets closed the Mediterranean to shipping in the later seventh century.

Deprived of its Mediterranean-wide horizons, civilized western Europe closed in on itself, and the under-Romanized world of northern Gaul and Germany gained prominence. The Mediterranean Roman Empire in the West was replaced by a western Europe dominated by a northern Frankish aristocracy that gave rise to a society in which wealth was restricted to land. Its rulers, deprived of the wealth generated by trade, had to reward

their followers with grants of land, and thus feudalism was born. The empire of Charlemagne, a northern Germanic empire inconceivable in any previous century, marked the beginning of the Middle Ages. Pirenne shows that by breaking the unity of the Mediterranean, the conquest made by the Arab-Muslim war fleets ruptured Romano-Byzantine economic and cultural domination over western Europe, which was forced to rely on its own material and cultural resources. From this analysis Pirenne draws his famous observation: "It is therefore strictly correct to say that without Mohammed Charlemagne would have been inconceivable" (Pirenne 1939, p. 234).

The Pirenne thesis linked great historical events that have occupied the attention of historians for a long time: the demise of the classical world centered on the Mediterranean and the rise of the empire of Charlemagne. Pirenne demonstrated that these two events, which are central to the rise of the modern West, are linked to the rise of Islam and its expansion to the Mediterranean. Pirenne's well-documented generalizations have attracted praise as well as criticism from historians who are often wary of broad generalizations (see Hodges and Whitehouse 1983).

While Pirenne's thesis attempts to link the rise and development of Islam to the rise of the modern West, paradoxically, equally influential hypothesis postulates instead a "clash of civilizations." This hypothesis, advanced by Samuel Huntington (1993), holds that whereas in the pre-Cold War era military and political conflicts occurred within the Western civilizations, after the end of the Cold War the conflict moved out of its Western phase and its centerpiece became the interaction between the West and non-Western civilizations and among non-Western civilizations. According to Huntington, future conflicts will occur along the fault lines that separate those civilizations. Globalization tends to heighten civilizational identity, and as a result, civilizational differences are difficult to reconcile and override political and economic factors.

Huntington (1993) postulates that the greatest threat of conflict for the West comes from religious fundamentalism, especially Islamic fundamentalism. He sees Islamic fundamentalism as arising from the failures of Muslim countries to achieve political and economic development of

their masses. This failure is exacerbated by the demographic structure of the Muslim world, especially the large bulge in the middle of the age pyramid (the youth). Huntington suggests that Muslim countries have a historical propensity toward violence. The domination and hegemony of the West, he claims, will force an alliance between the Confucianist and Islamic civilizations, and that alliance will challenge Western interests, values, and power, resulting in a civilizational clash. Huntington postulates that civilizational conflict will replace ideological and other forms of conflicts in the future. The outcome of this change is that civilizational conflicts will become more intense, violent, and sustained. This thesis was criticized as a new form of Orientalism. Other criticisms have centered on Huntington's assumption of civilizational unity as well as his assumptions about the basis of alliances between Confucianist and Islamic civilizations (Ajami 1993; Ahluwalia and Mayer 1994).

ISLAM, MUSLIM SOCIETY, AND SOCIAL THEORY

Ibn Khaldun and the political sociology of Muslim society. The sociology of Islam primarily refers to the empirical study of Muslim societies. In this respect, it has occupied an important place in the theoretical discourse of a number of theorists from Ibn Khaldun and Weber to Gellner. It is beyond the scope of this article to provide an exhaustive overview of how Muslim society and Islam have been treated in social theory (for studies of the Islamic revolution in Iran, see Shariati 1979; Fischer 1980; Arjonaud 1988). This section will provide a general overview of the subject in the works of four social theorists: Ibn Khaldun, Weber, Gellner, and Geertz.

Ibn Khaldun, an Arab historian and sociologist (1332–1406), is perhaps the most notable theorist of Muslim society. In the prolegomena (introduction) to his monumental work on universal history, he conceived and formulated the most comprehensive synthesis in the human sciences ever achieved by a Muslim thinker. In the prolegomena, among other topics, he probably provided the first modern outline of sociological principles. He defined sociology as “the study of human society in its different forms, the nature and characteristics of each of these forms, and the

laws governing its development” (Khaldun 1992, p. 7). The basic sociological principles he enunciates are as follows:

1. Social phenomena seem to obey laws that while not as absolute as those governing natural phenomena, are sufficiently constant to cause social events to follow regular, well-defined patterns and sequences.
2. These laws operate on masses and cannot be influenced significantly by isolated individuals.
3. Sociological laws can be discovered only by gathering many facts and observing circumstances and sequences through historical records and the observation of present events.
4. Societies are not static. Social forms change and evolve as a result of contact and interaction between different people and classes, population changes, and economic inequality.
5. Sociological laws are not a reflection only of biological impulses or physical factors but also of social forces.

He then applied these principles to the analysis of Muslim societies (Khaldun 1992, p. 8–9).

The core of Ibn Khaldun's sociology is his concept of *Asabiyya* (social solidarity). For Khaldun, society is natural and necessary, since isolated individuals can neither defend themselves against powerful enemies nor satisfy their economic wants. However, individual aggressiveness would make social life impossible unless it was curbed by some sanction. This sanction may be provided by a powerful individual imposing his will on the rest or by social solidarity. The need for a common authority generates the state, which is to society as form is to matter and is inseparable from it. Ibn Khaldun traces the origin of social solidarity to blood and kinship ties. Nevertheless, social solidarity is shaped by the nature and character of social organization. In this lies the genius of his theory of Muslim social formations and circulation of the elite.

The nature of tribal life generates the strongest form of social solidarity and social cohesion, producing social, political, and civic virtues that

characterize tribespeople. For Khaldun, leadership exists only through superiority, and superiority only through group feeling. Domination and authority are the rewards for social cohesion. Only those with superior social cohesion succeed in becoming rulers, but a civilization (state-society) consists of tribes and cities. The division of labor is the essence of urban life. It is the key to cities' capacity to supply economic and cultural services that tribespeople are unable to provide for themselves because the tribal ethos spurns specialization. Civilization needs cities to provide economic wealth, which is achieved through specialization and a complex division of labor. Specialization, however, is inherently incompatible with social cohesion and the martial spirit. There emerges a need to provide a new basis for social bonds, and religion becomes the most powerful force in holding together a sedentary people. Scripturalistic and puritanical religion has as a natural affinity with urban life. The combination of religious and tribal solidarity is formidable, and to it Ibn Khaldun attributes the rapid and sweeping conquests of the Muslim Arabs in the seventh century.

The dialectic between the tribe and the city forms the basis of the model of circulation of the elite in society. The Khaldunian model rests on the distinction and contrast between the tribe and the city. Zubiada (1995) has provided a succinct summary of this model:

Dynasties which have conquered the city and its wealth do so with the militant vigor of their nomadic stock, and the solidarity (asabiyya) of their kinship bonds. In time, the rulers become settled and accustomed to the comforts and luxuries of the city, the branches of their kin develop factional interests and competition over wealth and power which saps solidarity. The cost of their expanding retinue and luxury spending leads to an intensification of the taxation burden on the urban populations and their growing discontent. The growing weakness of the rulers encourages aspiring tribal dynasties, lusting for the city, to organize military campaigns which ultimately topple the rulers and replace them, only to repeat the cycle. (1995, p. 154; see also Turner 1999)

Ibn Khaldun's sociological generalizations about the Muslim social formations of his time can be summarized in the following statements:

1. Nomadic tribes conquer sedentary societies because of their greater cohesiveness.
2. The combination of tribal solidarity and a puritanical scripturalistic urban religion is overwhelming.
3. Conquest tends to be followed by luxury and softening, which lead to decay and annihilation of the ruling dynasty.

These three statements describe the rise and fall of many historical Muslim social formations in the Middle East and North Africa.

Weber, Islam, and Capitalism. Weber's theoretical interest in and interpretation of Islam is related to his exploration of the affinity of faith and modern socioeconomic organizations. Through a comparative study of world religions, Weber formulated *The Protestant Ethic and Spirit of Capitalism* (Weber 1958). In his analysis, Weber demonstrated an elective affinity between certain types of religious ideas and particular types of economic activity. He hypothesized a nexus between Protestant religious beliefs and the development of modern capitalism and used his study of comparative religion to show why modern capitalism could not have emerged in other societies, including Islamic society. Weber saw Islam as a prophetic, this-worldly, salvationist religion with strong connections with other Abrahamic religions and regarded it as a useful test case of his thesis.

Weber argued that rational formal law, autonomous cities, an independent bourgeois class, and political stability were totally absent in Islamic society because of prebendal feudalism and the domination of patrimonial bureaucracy. He also argued that a hedonistic spirit and an accommodating Koranic ethic could not produce salvation anxiety and that asceticism was blocked by two important social groups: the warrior group that was the social carrier of Islam and the Sufi brotherhoods that developed mystical religiosity.

Weber's characterization of Islam has been criticized as "factually wrong" (Turner 1974b, p. 238). Gellner (1983) describes Weber's notion about the affinity between the bourgeoisie style of life and religious sobriety and asceticism as "a piece of Judaeo-Protestant ethnocentrism" (Gellner 1983, p. 78). Gellner also challenges Weber's contention that the institutional preconditions of modern capitalism were not restricted to the West but

that it was the ideological element (i.e., the Protestant ethic) that provides the crucial differentia, the extra spark that, in conjunction with the required structural preconditions, explains the miracle. According to Gellner, "the differentiae of Islam seem institutional rather than ideological. Ideological parallels to Christianity can be found, but they operate in a contrasted institutional milieu" (1983, p. 6).

Gellner's Theory of Muslim Society. Gellner made some of the most significant contributions to the sociology of Islam over the past three decades. Building on David Hume, Ibn Khaldun, Marshal Hodgson, and others, he provides a model of Muslim society that aspires to a general interpretation of all past and present Muslim societies. In *Muslim Society* (1983) and other writings (Gellner 1969, 1992, 1994), Gellner identifies unvarying features of Muslim societies that make them susceptible to sociological analysis. Building on the work of Ibn Khaldun, he postulates a dialectic between city and tribe, each with its own form of religion. The central and perhaps most important feature of Islam, according to Gellner, is that it was internally divided into the high Islam of scholars and the folk (low) Islam of the people. High Islam is primarily urban, and folk Islam is primarily tribal and rural. Although the boundaries between the two were not sharp but gradual and ambiguous, they nevertheless projected a distinctive tradition.

High Islam is carried by urban scholars recruited largely from the trading bourgeois classes and reflecting the natural tastes and values of urban middle classes. Those values include order, rule observance, sobriety, and learning, along with an aversion to superstition, hysteria, and emotional excess. High Islam stresses the severely monotheistic and nomocratic nature of Islam, is mindful of the prohibition of claims of mediation between God and the individual, and generally is oriented toward puritanism and scripturalism. Folk Islam is superstitious and mediationist. It stresses magic more than learning and ecstasy more than rule observance. Rustics encounter writing mainly in the form of amulets and manipulative magic. Far from avoiding mediation, folk Islam is centered on it. Its most characteristic institution is the saint cult, in which the saint is more often living rather than dead. This form of faith generally is known in the literature as religious brotherhoods

or Sufi orders. Urban religion is Weberian (textual and puritanical), and rural and tribal religion is Durkheimian.

Each religious tradition has a place in the social structure. Saint cults are prominent in the tribal or rural countryside and provide invaluable services in rural conditions: mediating between groups, facilitating trade and exchanges, and providing symbolism that allows illiterate rustics believers to identify enthusiastically with a scriptural religion. The folk Islamic tradition, through its ecstatic rituals, provides the poor with an escape from their miserable conditions. High Islam provides the urban population, and to some extent the whole society, with its charter and constitution entrenched by the sacred texts, which can mobilize resistance against an unjust state. The two systems often coexisted in an amiable symbiosis, but a tension remained that would surface from time to time in the form of a puritan revivalist movement to transform folk Islam in the image of high Islam. Gellner argues that in the traditional order Islam may be described as a permanent or recurrent, but ever-reversed, Reformation. In each cycle, the revivalist puritan impulse would in the end yield to the contrary social requirements (Gellner 1994).

Under modern conditions, the pattern of interaction between the two religious traditions has been transformed. The centralization of political power and the ability of the state to rule effectively with modern technology and control over the military and the economy have undermined the social basis of folk Islam. Puritanism and scripturalism have become symbols of urban sophistication and modernity. According to Gellner, this constitutes the basic mechanism of the massive transfer of loyalty from folk Islam to a scripturalist, fundamentalist variant of Islam: "This is the essence of the cultural history of Islam of the last hundred years. What had once been a minority accomplishment or privilege, a form of the faith practised by a cultural elite, has come to define society as a whole" (Gellner 1994, p. 22).

In short, conditions of modernity (mass literacy, urbanization, modern education, and technology) have reinforced the power of scripturalist, puritanical urban Islam and its challenge to secular power; this explains the current rise of Islamic revivalist and fundamentalist movements. The validity of Gellner's model of Muslim society has

been challenged in the historical and the modern contexts. It has been criticized for ignoring the different meanings and roles of concepts and entities such as Ulema in different historical contexts and in different societies and instead treating them as sociological or political constants. Modern Islamism, critics argue, is a political ideology and is distinct from anything in Muslim history, which in recent years has become a dominant idiom for the expression of various and sometimes contradictory interests, aspirations, and frustrations (Zubiada 1995). However, even his critics agree that Gellner's model of Muslim society is the most ambitious attempt in modern sociology to identify the internal religious dynamics that play a significant and in certain conditions, critical role in determining the political character and socioreligious trajectories of Muslim societies.

Geertz and the Islamization process. Like Gellner, Geertz has made significant contributions to the sociology of Islam through his anthropological studies, in this case of religious life in Indonesia and Morocco. His work illustrates the modes of incorporation of Islam into already existing and well-developed cultures and shows how those incorporations manifest themselves in the different Islamic traditions that over time come to characterize them. Geertz shows that in the socio-cultural and ecological setting of Morocco, the "cultural center" of Islam was developed not in the great cities but in the mobile, aggressive, fluid, and fragmented world of tribes on the periphery. It was out of the tribes that the forming impulses of Islamic civilization in Morocco came and stamped their mentality on future developments. "Islam in Barbary was—and, to a fair extent still is, basically the Islam of saint worship and moral severity, magical power and aggressive piety, and this for all practical purposes is as true in the alleys of Fez and Marrakech as in the expanses of the Atlas or the Sahara" (Geertz 1968, p. 9).

In the tropical heartland of Indonesia, with its productive peasant society and Indic cultural heritage, once Islam was incorporated, it found a distinctive cultural and religious expression. In Indonesia, Islam did not construct a civilization but appropriated it. The Javanese social structure was shaped by a centralized state and a productive and industrious peasantry. The social structure was highly differentiated and developed, and when Islam came, its expression was influenced pro-

foundly by the context. The Indonesian Islamic tradition was malleable, tentative, syncretic, and multivocal. In Morocco and other Middle Eastern societies, Islam was a powerful force for cultural homogeneity, moral consensus and standardization of fundamental beliefs and values. In Indonesia, Islam was a powerful force for cultural diversification and sharply variant and even incompatible worldviews and values.

The gentry, which was acculturated to Indic ritualism and pantheism, developed a subjectivist and illuminationist approach to Islam. The peasantry absorbed Islamic concepts and practices into its folk religion and developed a distinctive contemplative tradition. The trading classes were exposed to Arabian Islam and, because of their greater exposure to the Meccan pilgrimage, cultivated a doctrinal religious tradition. Islam in Indonesia therefore developed as a syncretic and multivocal religious tradition whose expression differed from one sector of the society to another (Geertz 1960, 1968).

Geertz's work, like Gellner's, provides a framework for explaining the diversity of religious traditions in Muslim societies and indeed the existence of religious diversity in all religions. As Geertz observes, "Religious faith, even when it is fed from a common source, is as much a particularising force as a generalizing one, and indeed whatever universality a given religious tradition manages to attain arises from its ability to engage a widening set of individual, even idiosyncratic, conceptions of life and yet somehow sustain and elaborate them all" (Geertz 1968, p. 14). The purpose of this account is to illustrate that Islam occupies an important place in theoretical discourse on modern sociology. As empirical and comparative study of Muslim societies develops, it will provide more opportunities to test and refine some of the existing theoretical propositions as well as develop new ones (see Arjomand 1988; Fischer 1980; Beyer 1994; Irfani 1983).

Islam and Fundamentalism. Fundamentalism emerged in all the major world religions in the last quarter of the twentieth century and gained prominence and influence in the 1990s (Marty and Appleby 1991, 1992, 1993). It is defined as "a distinctive tendency—a habit of mind and a pattern of behaviour—found within modern religious communities and embodied in certain rep-

representative individuals and movements. Fundamentalism is, in other words, a religious way of being that manifests itself as a strategy by which beleaguered believers attempt to preserve their distinctive identity as a people or group" (Martin and Appleby 1992, p. 34). Feeling that this identity is at risk, fundamentalists try to fortify it by means of a selective retrieval of doctrines, beliefs, and practices from a sacred past as well as modern times. This renewed religious identity becomes the exclusive and absolute basis for a re-created political and social order. While there are differences between fundamentalist movements in general, their endeavor to establish a "new" political and social order always relies on charismatic and authoritarian leadership. These movements also feature a disciplined inner core of elites and organizations as well as a large population of sympathizers who may be called on in times of need. Fundamentalists often follow a rigorous sociomoral code and have clear strategies to achieve their goals.

Religious fundamentalism is a growing and important part of social change in Muslim countries. Its main goal is to establish the Sharia (Islamic law) as the explicit, comprehensive, and exclusive legal basis of society (Marty and Appleby 1991, 1992; Beinin and Stork 1997; Esposito 1983). Hardly a day passes without a reference to Islamic fundamentalism in the international media. All Muslim societies are affected by it, although there are large differences among them in terms of its presence and power. Is Islamic fundamentalism the inevitable destiny of all Muslim countries, or is it only a part of larger process of social change? Are there certain social, economic, historical, and other preconditions that predispose some Muslim countries more than others to Islamic fundamentalism? Are there different types of Islamic fundamentalism? These and related questions have been posed and explored by several contributors to the Fundamentalism Project of the American Academy of Arts and Sciences (Marty and Appleby 1991). There are three competing theories of Islamic fundamentalism: Watt's (1988) "crisis of self-image," Gellner's (1983) "pattern of distribution of dominant religious traditions," and the "modernization and religious purification" theory advanced by a number of social scientists (Tamney 1980; Hassan 1985; Yap 1980; Rahman 1982).

Crisis of Self-Image. Distilling insights from his works on the history and sociology of Islam,

Watt (1988) has proposed that the principal root of Islamic fundamentalism is the domination of the traditional "Islamic world view" and the corresponding "self-image of Islam" in the thinking of Islamic intellectuals and great masses of ordinary Muslims. According to Watt,

the important distinction is between those Muslims who fully accept the traditional world view and want to maintain it intact and those who see that it needs to be corrected in some respects. The former group are fundamentalists . . . while the latter group will be referred to as Liberals. (1988, p. 2)

Among both groups, many different political movements and attitudes can be found. The Ulema (religious scholars), who are the primary bearers and transmitters of the traditional worldview, are mostly reactionary in the sense that they tend to oppose reforms. Other Islamic intellectuals subscribe to a variety of reformist elements and sometimes are very critical of the Ulema, but the reforms they are interested in are mostly social and political and leave the traditional worldview of Islam unchanged. Watt then identifies important aspects of the traditional worldview: (1) the unchanging static world that is predicated on the complete absence of the idea of development, (2) the finality of Islam, (3) the self-sufficiency of Islam (Watt sees this reflected in the Muslim's conception of knowledge; when a Muslim thinks of knowledge, it is primarily "knowledge for living," whereas when a Westerner thinks of knowledge, it is mainly "knowledge for power"), (4) Islam in history (the widespread belief that Islam will ultimately be triumphant in changing the whole world into *dar-al-Islam* (the sphere of Islam), and (5) the idealization of Muhammed and early Islam, which renders critical and historically objective scholarship highly problematic in the Muslim consciousness and deviation from (1988) idealized and romanticized notions as a heresy and "unthinkable." According to Watt "These features of the Islamic worldview and the corresponding self-image are the basis of Islamic fundamentalism. The support for fundamentalism is embedded in the consciousness, which fully accepts the traditional worldview and wants to maintain it intact."

Patterns of Distribution of Dominant Religious Tradition. Building on the sociological and historical analyses of Muslim society of Ibn Khaldun

(1958), Weber (1964), Hume (1976), Hodgson (1975), and others, Gellner has advanced a theory of Muslim social formation that is based on his conceptualization of "two strands of Islam." One strand is characterized by "scripturalist puritanism" and represented by the Ulema. This is the Islam of the "fundamentalists." The other strand is characterized by a "hierarchical ecstatic mediationist style and is represented by the 'Saints.'" These two strands have evolved historically as representing two major social structural features of Muslim society: the city and the countryside. Gellner combines these strands of Islam with the political orientation of the elites and proposes a model of Muslim social formations. If one contrasts fundamentalism with laxity along one dimension and social radicalism with traditionalism along another, according to Gellner, one gets four types of Muslim societies or social formations.

The old-style puritanism prevails in areas where a traditional elite survives but is still fairly close to its origin in an Ibn-Khaldunian swing of the pendulum that brought it to power in a fusion of religious enthusiasm and tribal aggression. The new-style puritanism with its elective affinity for social radicalism prevails in areas where colonialism destroyed old elites and a new one elite came from below rather than from the outer wilderness (Gellner 1983, p. 89). An elaboration of Gellner's typology of Islamic social formations is shown in Figure 1.

Modernization and Religious Purification.

This theory holds that religious fundamentalism is one of the consequences of the modernization process. Building on studies by Mol (1972) and Folliet (1955), Tamney (1980) proposed that one way in which modern people are different from traditional people is that they practice purer religious styles. The relationship between modernization and religious purity can take two forms. In its general sense, purification is the opposite of syncretism: It is the elimination of religious elements originating in a traditional religion. Purification means the differentiation of religious traditions at the personality level, so that the individual's religious lifestyle reflects one style of tradition. If being modern means that people are more conscious about the history and the internal structures of various religions, modern people can realize the inconsistencies in a syncretic lifestyle, feel uneasy or even insincere, and seek to purify their lives by

deliberately eliminating elements from religious traditions other than their own. Using this conceptualization, Tamney hypothesizes that modernization is associated with religious purification. His empirical examination of this hypothesis in Indonesia tends to support his theory. Studies by Hassan (1984, 1985a, 1985b) and Irfani (1983) provide some support for this theory.

Islamic Militancy: A New Paradigm? Using the current religious, social, and political conditions of Muslim countries as a kind of "natural experiment," the author is conducting a multicountry study to examine the three competing theories of Islamic fundamentalism outlined in the preceding section. Over 4,400 mostly highly educated Muslim respondents have been surveyed. The empirical evidence shows that the heartlands of the Islamic world, from Indonesia to Egypt, are undergoing a religious renaissance. A large majority of the respondents were devoutly religious. If the term "fundamentalism" is defined to mean a high degree of devotional religiosity, these heartlands are becoming fundamentalist (Hassan 1999d). What are the implications of this for Islamic radicalism? Does this mean increasing support for the militant Islamic movements that are agitating to establish their versions of the Islamic state? Would this increase militancy against the groups or countries they regard as enemies of Islam?

Religious devotion appears to be associated with a decline in the support for militant Islamic movements. A large majority of Muslims do not belong to radical Islamic group. In fact, most of the respondents approved of moderate political leaders who are leading political and social movements for democratic and tolerant societies and political cultures. The declining support for radical and militant movements is paradoxically further radicalizing these movements and transforming them into more violent and secretive organizations. The nature and ruthlessness of violence reflect their desire to gain public attention and are symptomatic of their desperation.

The new form of violence is different from the earlier form that was carried out by organizations often with tacit support from political structures. The new militancy appears to be fueled by a sense of desperation and humiliation caused by globalization and the increasing economic, cultural, technological, and military hegemony of the West.

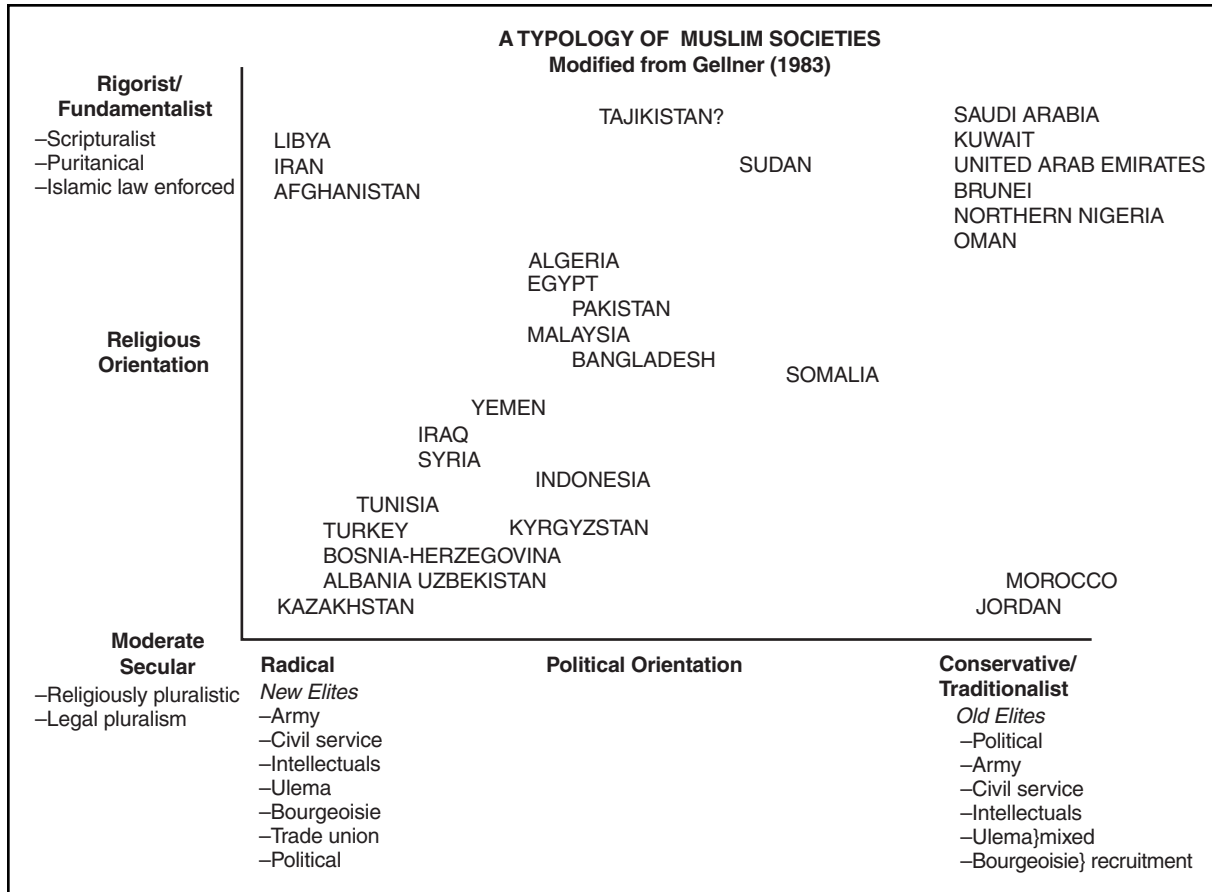

Figure 1

This pattern represents a kind of paradigm shift in the nature, causes, and targets of terrorism carried out by the new militant groups. The old form of militancy attempted to establish the legitimacy of political goals; the new form is guided by religious fanaticism, destruction, and revenge. The old form of militancy identified enemies. The new enemies are ephemeral global conspiracies.

A majority of the respondents regard major Western countries as anti-Islamic. The primary reason for this attitude is not religion, but the perceived indifference and inaction of Western countries toward protecting the Muslim populations of Bosnia-Herzegovina, Palestine, and Chechnya destruction. These views are widely held among the elites. The study provides new insights into the dynamics of the new Islamic militancy. It shows that contrary to the general belief, increasing religiosity in Muslim countries is associated with

political liberalization and diminishing support for militant Islamic groups. The impact of these developments is making the militant movements highly secretive and more violent.

The globalization process is creating a social and cultural hiatus that is affecting the nature and organization of Islamic militancy. The new militancy is not motivated by attitudes toward colonialism and struggles to win the hearts and minds of Muslim populations. Instead, it is fueled by a sense of powerlessness, revenge, and religious fanaticism. The enemy is ephemeral global conspiracies. How Muslim countries and the international community respond to these new developments will have a profound impact on the nature and activities of the new militancy. The solution would require more open and stronger political structures in Muslim countries to legally and politically pursue solutions to the problems posed by the new

militancy. It also will require a change in the attitude that increasing religiosity increases support for militancy, when it actually diminishes support for it.

THE ISLAMIC STATE

The relationship between politics and religion in Muslim societies has been a focus of debate among scholars of Islam for most of this century. A commonly stated view of many Western and Muslim scholars is that Islam is not only a religion but also a blueprint for social order and therefore encompasses all domains of life, including law and the state (Maududi 1960, Lewis 1993; Huntington 1993; Rahman 1982; Watt 1988; Pipes 1981; Esposito 1995; Weber 1978; Turner 1974a; Gellner 1983). This view is reinforced by the fact that Islam does not have a church institution, although it does have the institutions of the Ulema, who act as the guardians of the interpretations of the sacred texts, and the Iman Masjid (leaders of the mosques), who lead the mandatory daily prayers in mosques. It is further argued that this characterization sets Islamic societies apart from Western societies built on the separation of state and religious institutions.

After reviewing the evidence on the separation of state and religion in Islamic history, Lapidus (1996) concludes that the history of the Muslim world reveals two main institutional configurations. The undifferentiated state-religion configuration characterized a small number of Middle Eastern societies. This configuration was characteristic of lineage or tribal societies. The historical norm for agrourban Islamic societies was an institutional configuration that recognized the division between the state and religious spheres:

Despite the common statement (and the Muslim ideal) that the institutions of state and religion are unified, and that Islam is a total way of life which defines political as well as social and family matters, most Muslim societies did not conform to this ideal, but were built around separate institutions of state and religion. (Lapidus 1996, p. 24)

Keddie (1994, p. 463) has described the supposed near identity of religion and the state in Islam more as a "pious myth than reality for most of Islamic history." Similar views of Islamic history

have been advanced by others (Zubiada 1989; Sadowski 1997; Ayubi 1991; Sivan 1985).

Historical scholarship indicates that the institutional configurations of Islamic societies can be classified into two types: (1) "differentiated social formations" (societies in which religion and the state occupy different spaces) and (2) "undifferentiated social formations" (societies in which religion and the state are integrated). While a majority of Islamic societies have been and are differentiated social formations, a small but significant number have been and are societies that can be classified as undifferentiated social formations. A common label used in contemporary discourse to refer to undifferentiated Muslim social formations is "the Islamic state."

The empirical evidence shows that religious institutions and religious elites tend to enjoy greater public trust and legitimacy in differentiated compared to undifferentiated Muslim societies. The underlying dynamics that appear to produce this pattern are related to the functional and performance roles of religious institutions (Luhmann 1982; Beyer 1994) and the ability of religious institutions to mobilize public resistance against an authoritarian state that has a deficit of legitimacy in the public mind (Hassan 1999a and 1999b).

GENDER ISSUES IN MUSLIM SOCIETIES

For many Islamic and Western scholars of Islam, the status, role and position of women are important distinguishing features of Muslim societies that, set them apart from their Western counterparts. Many people in the West regard the status of women in Muslim society as symptomatic of their oppression in Islam (Esposito, 1995, p. 5). It is further argued that gender relations in Islam have been shaped primarily by their Arabian origins. While Islam has borne the marks of its Arabian origin throughout its history, in regard to the position held by women in his community, Mohammed was able to introduce profound changes (Levy 1972; Rahman 1966; Ali 1970).

Islam was instrumental in introducing wide-ranging legal-religious enactments to improve the status and position of women in Arabian society and protect them from male excesses. There are numerous Koranic injunctions to give effect to these changes (Ali 1970, pp. 55-59). These injunc-

tions brought about significant improvements in the status of women in a wide range of public and private spheres, but most important, they gave women a full-fledged personality (Rahman 1966).

However, selective literal, noncontextual, and ahistorical interpretations of sacred texts by Islamic scholars over time have shaped the average Muslim's conservative views and attitudes toward women. One of the major dilemmas faced by the nationalist leaders who spearheaded independence movements from Indonesia to Pakistan and Egypt was "woman issue." Their problem was how to respond to the questions raised by women about their role, status, and function in the new independent states. This generated highly emotional and divisive debates between the Islamic scholars and the nationalist leaders that centered on the issues of marriage and family law and the role and status of women in a modern independent Muslim state (see Esposito 1982; Haddad and Esposito 1998).

Notwithstanding strong resistance from Islamicists in several countries, the new nationalist leaders were able to overcome centuries of resistance and introduce modest changes in family and marriage laws. Those changes were introduced within an Islamic framework that did not expressly violate the appropriate Koranic injunctions and Sunnah (Anderson 1976). Those reforms have been criticized and opposed by a majority of Islamic Ulema and their followers, who regard them as violations of Islamic law and commandments as codified in classical Islamic legal texts as well as thinly veiled attempts to find an Islamic justification for an essentially Western approach to issues of interpersonal relations (Haeri 1993; Esposito 1982). This debate between nationalists and Islamicists continues and according to some evidence is becoming an important part of the political agenda of Islamic fundamentalists (Hardacre 1993; Haeri 1993).

Attitudes toward Veiling and Patriarchy: Veiling and seclusion of women and patriarchy have been important features of Islamic societies. In recent years they have attracted much criticism from Muslim and Western feminist scholars. The tradition and custom of veiling in Islam can be attributed to Islamic history, Islamic texts, and the privileged position of males and their control and dominance of positions of power and authority in Muslim society. Veiling and seclusion of women

and their role and function in society also are intertwined with the management of sexuality in Islam (Levy 1972).

Islam recognizes sexual desire as a natural endowment of the human body and enjoins its followers to satisfy and even enjoy sexual needs, providing a framework for doing so enunciated in the sacred texts. Unlike Christianity, Islam does not sanction or idealize celibacy. Over the centuries, the interpretations of sacred texts by the Ulema have led to the development of an institutional framework for the management and satisfaction of human sexuality through the imposition of control over women. As women are seen not only as sexual beings but also as the embodiment of sex, the social framework that has evolved has come to view the woman's body as pudendal. This conceptualization has led to the development and observance of strict dress codes for women, including veiling and seclusion, to prevent them from displaying their bodily charm and beauty (Haeri 1993; Hardacre 1993; Levy 1972).

Other features of the institutional framework arose out of the fact that women were made the principal actors responsible for preserving the sanctity of the family and reproduction. This led to strict injunctions on the types of roles they could play in the public sphere. Strong social and cultural traditions evolved that placed serious obstacles in the way of women seeking to succeed in public roles. Men, in contrast, were assigned all the public roles as providers, protectors, and arbiters, and this reinforced their power in the domestic domain as well. Patriarchal family structures thus became more functionally suitable to the perpetuation of the institutional framework for the satisfaction and management of the family.

That institutional framework and its accompanying normative requirements as they apply to gender roles, dress codes, veiling and seclusion, and patriarchy are by and large universally accepted in Muslim societies, although their observance varies with economic conditions. For most ordinary Muslims, this practice is in keeping with the supremacy of the male over female postulated by the Koran. However, the vagueness of these edicts has given the Ulema greater authority to interpret them as local custom demands. Some Ulema even appear to have invented tradition to bolster their interpretations which may in fact

conflict with Koranic statements (Levy 1972; Rahman 1982; Mernissi 1989; Rugh 1984).

As a result of internal and external pressures, the governments of most Islamic countries have initiated reforms to improve the quality of citizenship accorded to Muslim women. These reforms have sought to remove some of the obstacles that have prevented gender equality. While varying in scope and intensity from country to country, these reforms have been initiated in most Muslim countries. Some of the reforms have been successful, and, in some countries, such as Iran and Pakistan, the pendulum has swung to more traditionalist views that have gained favor with the current ruling elites. In general, the reforms are having a positive effect, although obstacles still exist. Those obstacles will continue until the rigid attitudes of the Ulema change or lose significance for the general body of Muslims as a result of the decline of their religious authority.

The empirical evidence about attitudes toward veiling, seclusion, and patriarchy indicates that those attitudes are an outcome of complex processes, including the prevalent social, economic, and political conditions in the country that mediate between the traditional Islamic norms and their practice in the local milieu. The material conditions of the country influence the shaping of attitudes toward these issues more strongly than does traditional Islamic ideology. The empirical evidence also indicates that in Muslim societies where men have experienced greater status loss relative to women as a result of public policies aimed at improving the quality of female citizenship, they appear to have compensated for that loss by developing more conservative attitudes toward women, including veiling, seclusion of women, and patriarchy. The evidence also suggests that paradoxically, Muslim societies, that are more successful in providing women with institutional equality may be more successful in generating more positive attitudes toward traditional Islamic values of patriarchy, veiling, and segregation among women (Hassan 1999c).

MUSLIM MINORITIES

The London-based Institute of Muslim Minority Affairs estimates that about three hundred million Muslims live in one hundred forty-nine non-Muslim states. The institute publishes a biannual jour-

nal devoted to studies of Muslim minorities in different countries. With over 100 million Muslims, India is the home of the largest Muslim minority. Over the past fifty years, international labor migration and political upheavals have resulted in increasing Muslim settlement in Europe, Australia, and North America. It is estimated that about 20 million Muslims now reside in Europe. Most of them arrived as immigrants to meet the labor needs of booming west European economies, and their numbers are likely to increase in the future. (Nielsen 1995; Castles 1989).

The Muslim presence in west European countries has raised challenges to both Muslim and European traditions. The evidence shows that on the whole, Muslim communities in European countries are making cultural, social, and religious adjustments to secure their position in society. The host societies are responding by promoting cultural pluralism and containing racism and xenophobic attitudes among some segments of their populations. The cultural interactions between European and Muslim communities is shaping a distinctive European Muslim identity among second-generation Muslims (Nielsen 1995; Gerholm and Lithman 1988).

The Muslim presence in North America, especially in the United States, has been increasing gradually. While there are no reliable statistics on the exact size of the Muslim population in the United States, it is estimated to range from 2 million to 6 million. The American Muslim Council estimates the figure to be around 5.2 million (Duran 1997). Whatever the size, it is a well-established fact that Islam is an important feature of the American religious milieu. Its adherents include American Muslims, who are predominantly of African origin, and more recent immigrants from all over the Muslim world. The most widely known American Muslim group is the Nation of Islam (Gardell 1994). Most of the immigrant Muslims come from south Asian and Middle Eastern countries. They have arrived as skilled and unskilled laborers, students, and refugees from political developments in Muslim countries. The largest concentrations of Muslims are in the metropolitan areas of Los Angeles, New York, and Chicago. Recent sociological studies have focused on acculturation and the tensions Muslim communities experience in adjusting to life in America and how those communities are responding to the compet-

ing demands of belonging to a universal Islamic community (*Ummah*) and maintaining their ethnic or national identity. The evidence shows that the majority of American Muslims are not active participants in the organized religious life of mosque or Islamic center, but continue to identify themselves as Muslims in a social setting characterized by prejudice and misunderstanding (Haddad and Smith 1994; Haddad and Lummis 1987). Similar findings have been reported in studies of Muslim communities in Australia (Hassan 1991; Bouma 1994).

The social pervasiveness of Islam in the modern world and the sociopolitical and religious trajectories of contemporary Muslim societies raise important sociological questions. This article has identified some of the questions and issues that make the sociology of Islam a challenging field of social inquiry. Empirical studies of Muslim societies can be a rich source for evaluating the validity of some of the major propositions of social theory that have been formulated in the context of increasingly secular social settings of modern European and North American countries. Through systematic and comparative studies of Muslim societies, modern sociological scholarship can lay the foundations for a more informed understanding of the social reality of the Muslim world.

RIAZ HASSAN

THE SOCIOLOGY OF KNOWLEDGE

The sociology of knowledge as a subdiscipline in sociology deals with the social and group origins of ideas. In its brief history as a field of study, it has included the entire ideational realm (knowledge, ideas, theories, and mentalities), in an attempt to comprehend how that realm is related to particular social and political forces and how the mental life of a group of people arises within the context of the groups and institutions in which those people live and act. More recently, its subject matter has included not only a society's authoritative ideas and formal knowledges but also those which operate in the realm of everyday life: informal knowledges.

The term "sociology of knowledge" (*Wissenssoziologie*) was first used in 1924 and 1925 by Scheler (1874–1928) (Scheler [1924] 1980, 1992) and Mannheim (1893–1947) (Mannheim [1924] 1952). From its inception, it described a field of inquiry closely linked to problems of European philosophy and historicism. In several important respects, this is an accurate description, for the sociology of knowledge reflected the nineteenth-century German philosophical interest in problems surrounding relativism that were linked to the legacies of Karl Marx, Friedrich Nietzsche, and the historicists, whose cultural philosophy of worldviews (*Weltanschauungsphilosophie*) was influential in German social science from the 1890s to the 1930s. Each of these developments was concerned in different ways with the determinate relationship between thought and society, between knowledge and social structure. For Scheler and Mannheim, *Wissenssoziologie* would serve as an empirical and historical method for resolving the intense conflicts of ideologies in Weimar Germany that followed political and social revolutions of the nineteenth and early twentieth centuries and produced warring groups whose battles were manifestly ideational and grounded in conflicting worldviews. Sociology of knowledge would provide a method, outlined in early statements by Scheler and Mannheim, for unmasking the assumptions of political ideologies and indicating their truth content. However much Scheler and Mannheim differed about the nature of truth within relativism, both agreed that truths do not exist apart from historical and social processes. As mem-

bers of a postwar generation of European intellectuals, they also shared a sense that they were witnessing the gradual disappearance of epistemology and its replacement by the sociology of knowledge as a foundational discipline for all philosophy. As participants in this historical process, they also believed, as did their contemporaries, that intellectuals play a vital role in thought and politics.

The excitement and urgency with which the framers of *Wissenssoziologie* approached the study of the social origins of ideas has been replaced by a widespread acceptance of their premises concerning the social origins of ideas, ideologies, and worldviews. To borrow Weber's term, the sociology of knowledge was "routinized" into the established structures and practices of modern social science. Many of the positions advanced by Scheler, Mannheim, and other early writers in this field (e.g., in the United States by Florian Znaniecki, C. Wright Mills, and Edward Shils) operate today as working propositions for a range of social scientists as well as for specialists in other disciplines, including the subfields of the history of ideas, social psychology, social studies of science, feminist theory, and cultural studies. Even the urgency, expressed by Mannheim, surrounding the problem of relativism as a "contemporary predicament" has been transformed into a commonplace fact. Today, this is certainly the case in the academic world, whereas in the past, the sociology of knowledge provided the occasion for intense controversies about the postulate of the essential "sociality of mind" (Child 1941).

THE SOCIOLOGY OF KNOWLEDGE: TWO APPROACHES

Partly because of the diffusion of the idea of the social nature of knowledge, the sociology of knowledge has been described as an approach or subdiscipline that has no unified field, but only a series of theoretical works and research agendas. Despite this characterization, the subdiscipline of the sociology of knowledge is a recognized field of endeavor that continues to draw new generations of sociologists. Therefore, one may speak of two ways of introducing the sociology of knowledge: The *broad approach* identifies a range of works in sociology and social theory that examine the social nature of mind and knowledge; the *particular ap-*

proach includes the works of specialists the field identified as the sociology of knowledge. Several leading contributors to the sociology of knowledge have provided similar schemes for delineating its subject matter, pointing out that the sociology of knowledge includes both a broad field and a narrow field of studies and that both fields contribute to the sociology of mental and cognitive structures (Remmling 1973; Curtis and Petras 1970; Berger and Luckmann 1966).

The broad approach incorporates a number of works that deal with the relationship of mental life (cognition, consciousness, collective ideas, etc.) and social life (groups, institutions, communities, entire societies). The broad approach treats the sociology of knowledge as a "frame of reference," not a "definite body of theory in its own right" (Curtis and Petras 1970, p.1). Accordingly, the sociology of knowledge is a broad tradition of inquiry, a handing down of key texts and theories, such as theories of the "social determination" of ideas, theories of ideology, the relationship of "real" and "ideal" factors, and the notion of *Weltanschauung*, that are closely linked to the history of sociology. The social theories of Karl Marx, Emile Durkheim, Max Weber, Georg Simmel, and others are studied as classic statements on the relationship of mind, knowledge, and society. This broad approach to the sociology of knowledge has provided not only the basic materials from which particular treatises in the sociology of knowledge have been written (e.g., Stark [1958] 1991; Berger and Luckmann 1966; Gurvitch 1971) but also the materials that have been incorporated into commentaries and edited collections on the sociology of knowledge (Remmling 1973; Curtis and Petras 1970).

In this general sense, the sociology of knowledge is understood as a field that systematizes the leading propositions of the modern social sciences about the social nature of mind. Furthermore, like sociology, the sociology of knowledge constitutes a tradition of inquiry that reflects and shapes the development of modernity. That is, sociology offers a theory of the human mind that is compatible with "our time": The sociology of knowledge "appears as a revision of our way of . . . looking at ourselves and the world. . . . It 'defines' a new 'situation'" (Wolff 1953, p. 618; Wolff cf.1959). Linked as it is to the modernization of conscious-

ness, the sociology of knowledge, broadly conceived, has several distinct national traditions, each focusing on themes characteristic of its own modern intellectual legacies. Therefore, one can speak of French, German, and American traditions of the sociology of knowledge whose roots are based in a Durkheimian “structuralist” legacy, a Marxist or Mannheimian theory of ideology, and a pragmatist theory of mind such as that offered by John Dewey and George Herbert Mead. Each of these national intellectual traditions reflects its particular national and cultural legacies in nineteenth- and twentieth-century modernity; each legacy also can be seen as complementing the sociologies of knowledge of other modern nations, cultures, and civilizations.

A second way of defining the sociology of knowledge considers the field as a particular body of work and examines its origins, development, and future prospects. This approach begins with the original statements of Scheler and Mannheim and proceeds to the later principal works and arguments. The approach also examines major substantive statements made by sociologists identified with its precise subject matter. One of the merits of this approach is that it allows for a critical view of the substantive work in the sociology of knowledge over time and, in keeping with the field’s presuppositions about the existential determination of thought (*Seinsgebundenheit*), opens the question of how social theories of knowledge are themselves subject to change and revision over time. In this sense, the sociology of knowledge offers a metatheory through which sociology can examine how its leading concepts and theories arise in response to particular social and political situations. For example, Marx’s theory of ideology is closely implicated in particular historical conditions of the industrial capitalist order, and its validity is dependent on particular conditions of social and economic organization, such as the separation and autonomy of economic forces in the social order.

Integral to the sociology of knowledge is a *relative theory of knowledge* from which its own concepts and theories are not excepted. Its methods are critical in the classical sense of the word, for it offers a continuous criticism of what it studies, including its own forms of knowledge and criteria of judgment. With this view in mind, a brief history of its statements and theories offers

more than a recounting of its nature and scope. It also draws attention to the reflexive features of all sociological inquiries, particularly the fact that sociology is part of the social reality it studies in that its changing concepts and insights develop out of and address particular social worlds. Sociological theories are neither external nor formal. The brief history of the subfield of the sociology of knowledge that follows is intended to be both a recounting of the leading ideas in this field and a reflexive statement about the social foundations of its theories and presuppositions. The implications that can be drawn from this inquiry are taken up in the conclusion.

A BRIEF SUBSTANTIVE HISTORY

Since its inception in the writings of Scheler and Mannheim, the sociology of knowledge has identified a number of precise ways in which knowledge is socially determined. Scheler’s original essays ([1924] 1980) identifying the field of study provoked commentary and debate. His concept of a society’s “relatively natural *Weltanschauung*” is still central to cultural sociology, as are his propositions concerning the origins of the modern worldview and its scientific ethos. However, Scheler’s importance would be felt decades later (Bershady 1992). It was Mannheim’s formulation of the discipline in *Ideology and Utopia* (German edition 1929, English edition 1936) that originally defined the subject matter of the field and continued to do so for years to come. Those who proposed different sociologies of knowledge after its publication defined their positions relative to Mannheim’s arguments concerning ideology, utopia, and relationism.

Mannheim’s treatise begins with a review and critique of the prevailing and authoritative Marxist theories of ideology (the “particular theory of ideology”) and proceeds toward a theory of ideology in the broader sense: the mental structure in its totality as it appears in different currents of thought and across different social groups. This total conception of ideology examines thought on the structural level, allowing the same object to take on different (group) aspects. This understanding of ideology refers to a person’s, group’s, or society’s entire way of conceiving things as it is provided by particular historical and social settings. The “total conception of ideology” defines

the subject matter of the sociology of knowledge. Like ideologies, “utopias” arise out of particular social and political conditions, but they are distinguished by their opposition to the prevailing order. Utopias are the embodiment of “wish-images” in collective actions that shatter and transform social worlds partially or entirely. Both concepts form part of Mannheim’s theoretical apparatus for a critical but nonevaluative treatment of “ideology” that supersedes the sociohistorical determinism and relativism of Marxism while moving toward a “relationist” notion of truth. The enterprise of the sociology of knowledge examines how collective actions and ideas (ideologies and utopias) emerge out of and are “determined” by the multiple social contexts and positions of their proponents. From an analysis of the various and competing social positions of ideologists and utopians, a kind of “truth” emerges that is grounded in the conditions of intellectual objectivity and detachment from the social conditions that more directly determine ideas. *Ideology and Utopia* established the criteria for a valid knowledge, albeit a *relational* knowledge, of sociohistorical processes. More important, it raised the problems surrounding the historicity of thought and did this within the newly emerging academic discourse of sociology. In the process, this work gave legitimacy to a new set of methodological problems involving the problems of objectivity and truth for the sciences and the humanities.

Despite the many criticisms of *Ideology and Utopia* (particularly Mannheim’s attempt to avoid the pitfalls of historical relativism), the work received wide attention and appreciation inside and outside the social sciences, where the problems posed by relativism continued to attract the attention of workers in both the sciences and the humanities. While reviews of the work focused on its failure to overcome relativism and Mannheim’s excessive reliance on the Marxist conception of ideology, Mannheim’s book provoked discussion and commentary for years (Hughes 1958, p. 420).

In the decades after its publication, *Ideology and Utopia* engaged the leading American social theorists of the period: Merton and Parsons. Merton’s two chapters on the sociology of knowledge in his major work (1957) attempt to integrate the social theory of knowledge with his own “structural-functional” theory and demonstrate how other

theorists (Marx, Weber, Freud, Durkheim) belong to the broader tradition of the social determination of ideas. In essays by Parsons (1959, 1961), Mannheim’s work is criticized and integrated into the approach with which Parsons is identified: the “general theory of action.” The contributions of Merton and Parsons were significant, principally with respect to the prevailing functionalist theories of “action,” not with respect to advancing the sociology of knowledge. In fact, it could be said that the projects outlined by Scheler and Mannheim, particularly their historical and cultural emphasis, did not conform to the program of formal or “general theory” outlined by Parsons for the functional study of all societies or to Merton’s proposal for theories of the “middle range.”

This was not the case for their contemporary Stark ([1958] 1991), whose sociology of knowledge attempted to clarify the principal themes in the study of the social determination of ideas and advance its arguments beyond the Marx–Mannheim tradition and its theory of ideology. An émigré for more than half his life and a scholar educated at the universities of Hamburg, Prague, London, and Geneva, Stark was accustomed to move within many mental, linguistic, and moral frameworks. When it is confronted by an almost dizzying array of viewpoints, social existence loses its taken-for-granted quality. As Remmling (1973) has observed, the relationship between social existence and knowledge, which has been the preoccupation of the sociology of knowledge, has always been that of marginal figures and outsiders. This and other traits Stark shared with Scheler and Mannheim. Stark regarded *Wissenssoziologie* as an indispensable method for understanding both the truth of ideas and the history of ideas; truths do not exist apart from the historical and social process. The traditions of German cultural sociology and *Wissenssoziologie* contain the ideals and conventions in which Stark’s sociology of knowledge becomes most intelligible. He brought to it judgments concerning the “real” and the “ideal” from Weber’s and Simmel’s sociology. From Scheler’s works in particular, he would find ways of returning to the problem of how to find truths or “ideal values” in the realm of relative social realities or “existential facts.”

Stark wrote *The Sociology of Knowledge* to clarify the principal themes of writers, especially sociolo-

gists, who had addressed the problem of the social element in thinking. He also intended it to serve as an introduction to the field that would prepare the way for a detailed and comprehensive history of the sociology of knowledge and its most significant ideas, including the theories of ideology of Marx and Mannheim, the philosophical speculations of the neo-Kantians Heinrich Rickert and Max Weber, and the views of the German phenomenological school of the 1920s, especially Scheler. Each of these ideas was vitally important for his project, but Stark's strongest affinity was with Scheler's struggle to reconcile the antithetical claims of idealism and materialism and his view of the sociology of knowledge as the foundation for a knowledge of eternal values.

Stark's sociology of knowledge is directed primarily toward the study of the precise ways in which human experience, through the mediation of knowledges, takes on a conscious and communicable shape. Eventually, Stark intends to direct this inquiry to the problem of truth, a synthesis of the different styles of thought and their limited truths. For either one of these intentions to be realized, he insists that the theory of ideology can have no place within the bounds of the sociology of knowledge. The idea that social influences enter mental life in the form of lies, self-deceptions, and distortions in thinking and are due to class positions and interests has dominated the Marx-Mannheim tradition and its theory of ideology. Stark's contention, shared by many contemporary writers, is that the sociology of knowledge is concerned with the "social determination of knowledge" (a term with a precise meaning of its own), not with the problem of ideology. In fact, this distinction is an indispensable precondition of the sociology of knowledge. It is intended to direct attention to the study of the extent to which all mental life is grounded in conditions that are ineluctably social and historical; it grants to "social determination" a depth that the theory of ideology does not permit, since that theory deals only with errors and misperceptions (Stark [1958] 1991, pp. 50-55). Even more important, in Stark's view, the theory of social determination is entirely compatible with the theory of truth, whereas the theory of ideology is concerned principally with the social conditions of error or false consciousness. While the theory of ideology will always play a vital role in sociology and the history of ideas, it must

be relegated to a status outside the principal concerns of the sociology of knowledge.

Stark's project involves building bridges between opposing positions (Mannheim's theory of ideology and Scheler's theory of social determination), what in scholastic philosophy was called a *concordantia discordantium canonum*, a reconciliation of opposing positions of thought. Whether these two traditions are indeed contradictory is not of consequence in grasping Stark's argument in *The Sociology of Knowledge*. Stark's willingness to explore with frankness and according to his own convictions the kind of epistemology that he thought consistent with cultural sociology brought him to a social theory of knowledge that was compatible with both *Verstehen* (lit., understanding) sociology and social phenomenology. This theory also dismissed the relevance of either a simple historical materialist theory or a positivist one. The outcome is a theory of social determination that has moved away from Marx and Mannheim and in the direction of a cultural sociology, one that is consistent with contemporary sociology's interest in the broad range of cultural studies.

Less than a decade after Stark's work appeared, Berger and Luckmann's *The Social Construction of Reality* (1966) advanced a sociology of knowledge that was compatible with the view of sociology as a humanistic discipline and the notion that "human reality" is a "socially constructed reality" (p. 189). These authors broadened the field to include all types of knowledge, including the knowledge of everyday life: "[T]he sociology of knowledge must concern itself with whatever passes for 'knowledge' in a society, regardless of the ultimate validity or invalidity (by whatever criteria) of such 'knowledge'" (p. 3). More important, their treatise asked that the sociology of knowledge address how, in the domain of the quotidian, knowledge constitutes social reality, redirecting the traditional theory of social determination of ideas by social realities. What Berger and Luckmann proposed was that knowledge and reality (by which they always mean social reality) exist in a reciprocal or dialectical relationship of mutual constitution. As many have argued, this work placed the sociology of knowledge on an entirely new footing whose focus is the broad range of signifying systems that form and communicate the realm of social realities. Since its publication, the idea of a "con-

structed reality” has summarized a number of concerns of contemporary writers in the sciences and humanities that may be best described as the problem of meaning and the use of philosophical, literary, and historical approaches to study the social construction of meaning.

The methodological implications of this change in sociology and the sociology of knowledge are noteworthy, since interest in the problem of meaning is linked to a methodological framework that is neither causal nor explanatory (the attitudes expressed by Mannheim’s theory of “social determination”) but *semiotic*. The semiotic study of culture is directed toward the study of the symbolic and signifying systems through which a social order is communicated and reproduced. These signifying systems and social practices make up a culture and its structures of meaning. According to Geertz (1973, p. 5), one of the principal semiotic theorists, the analysis of knowledge and culture is “not an experimental science in search of law but an interpretive one in search of meaning.”

In addition to being a proponent of an interpretive method in the social sciences in the 1960s, Geertz, in his essay “Ideology as a Cultural System” (1964), explicitly criticized the sociology of knowledge (Mannheim and Stark explicitly), arguing that the entire enterprise identified with the twin problems of “ideology” and “truth” should be reformulated as the “sociology of meaning.” For Geertz, the sociology of knowledge remained lodged in an older set of presuppositions (principally its use of “ideology”) that prevented it from moving toward a nonevaluative understanding of “culture.” This and other criticisms at the time effectively redirected sociology in the period of the late 1960s toward what has been described as its “postpositivist” phase (Rabinow and Sullivan 1979, 1987). Ironically, this most recent period of sociology, with its rejection of the classical concerns of the sociology of knowledge, has been described by Robertson (1992) as a “*general* sociology-of-knowledge turn” characterized by a focus on the ideational features of the social world or a resurgence of interest in cultural forms more generally. Put simply, contemporary sociology’s turn away from the classical problems and perspectives of the sociology of knowledge occurred precisely at the time when “culture,” “knowledge,” and “language” became central to sociology.

What has been called “the new sociology of knowledge” (Swidler and Arditì 1994; McCarthy 1996) can be seen as part of this larger movement in the social sciences generally, distinguished by a turn away from materialist theories or theories of social structure and in the direction of semiotic theories that focus on the ways in which a society’s multifarious meanings are communicated and reproduced. Hall (1980) has described the theoretical significance of this cultural turn in social science: Its problematic has become closely identified with the problem of the autonomy of cultural practices. The paradigm for studying the range of cultural practices has come largely from structuralist theories (Althusser, Levi-Strauss, Barthes). Language is the theoretical and empirical model, one that is neither positivist nor reductionist but interpretive rather than causal.

THE NEW SOCIOLOGY OF KNOWLEDGE

These arguments and others have been made by recent commentators in what has been called the “new sociology of knowledge.” In the case of Swidler and Arditì (1994), the new approach examines how specific kinds of social organizations (e.g., the media through which knowledge is preserved, organized, and transmitted) order knowledges rather than examining social locations and group interests. These scholars also examine, in light of new theories of social power and practice (Michel Foucault and Pierre Bourdieu), how knowledges maintain social hierarchies and how techniques of power are simultaneously and historically linked to discursive forms (knowledges). They also argue that newer theories of power, gender, and knowledge depart from the economic, class, and institutional focus of the classical sociology of knowledge.

McCarthy’s (1996) theoretical treatise traces changes in three broad national traditions in the sociology of knowledge (German, French, American), delineating the precise ways in which the classical traditions identified with these three national intellectual legacies have moved to models that are linguistically based. McCarthy also points to feminist theories as important contributions to the sociology of knowledge, particularly works in the sociology of science by feminists such as Smith (1987, 1990). These and other changes in sociology are examined against changes in the social location of knowledge and culture today, particu-

larly the predominant role played by systems of mass communication and information technologies. These changes in turn have produced a contemporary culture that is more globally aware, reflexive, and attuned to the operations of culture itself.

CONCLUSION

The brief history of the sociology of knowledge from Mannheim to contemporary sociology lends itself to the type of interpretive scheme that originated with the classical sociology of knowledge, for its principal argument has worked against any formal understanding of either theory or science. Changes in the structures and organizations of social worlds have been functionally related to collective “standpoints” and “perspectives.” Sociologists have witnessed the shift, since midcentury, from “social structure” to “culture” as authoritative schemes for describing and interpreting how social knowledges are “socially determined.” Clearly, this intellectual shift registers changes in the social landscape of late modernity, where the configurations known to sociology as “economy,” “culture,” and “social structure” have undergone changes.

Proponents of the new sociology of knowledge and others have documented changes in the industrial societies of the last half century that correspond to the newer “cultural” theories. Neither Swidler and Arditoni nor McCarthy claims that the sociology of knowledge as a subfield of sociology has been superseded by newer work in sociology and cultural studies. However, they note that the new sociology of knowledge is not yet a unified field, and their proposals for what constitutes this diffuse field constitute an argument reminiscent of those of the proponents of a broad or diffuse sociology of knowledge discussed above. It would seem that the more “cultural” sociology becomes, the more likely it is that the sociology of knowledge will be seen as a broadly inclusive set of studies rather than a subfield with a distinct subject matter. The subject matter of the sociology of knowledge has undergone significant change: What began as the study of competing and conflicting collective ideas and ideologies has become something more cultural and diffuse. Its subject matter today is both more differentiated and more diffuse and includes the study of “informal knowl-

edge,” the knowledge of everyday life. What began as the study of conflicting ideologies has become the study of the unspoken understandings of everyday life, what L. Wirth described in his preface to *Ideology and Utopia* as “the most elemental and important facts about a society . . . those that are seldom debated and generally regarded as settled” (1936, p. xxiii). Today these understandings have become the subject matter of sociology and are no longer generally regarded as “settled.”

E. DOYLE MCCARTHY

SOCIOLOGY OF LAW

In 1963, the U.S. Supreme Court ruled that in all felony trials the accused must be provided with

legal counsel. The case of *Gideon v. Wainwright* (372 U.S. 355, 1963) was widely celebrated as a David and Goliath story of the triumph of the rule of law: An indigent defendant’s handwritten petition had persuaded all nine justices of the Supreme Court to provide a nationwide right to counsel (Lewis 1964). Shortly after Gideon’s victory, Blumberg (1967) published an empirical case study describing the actual work of criminal defense attorneys. That study suggested that Gideon’s case had little relevance to the 90 percent of felony convictions that the prosecution wins not in a courtroom trial but through informal plea bargaining. Moreover, the attorneys to whom the poor were now constitutionally entitled, Blumberg contended, had over the years mutated from trial advocates into bureaucratic cogs whose primary function was to assist the state in processing legal files efficiently.

Blumberg’s deconstruction of the legal myth of the centrality of criminal trials and adversarial counsel exemplifies two central features of the sociology of law. First, that field challenges *legal formalism*, the philosophy that the law stands above social life, develops according to its own internal logic, and autonomously constrains or facilitates social interaction. A sociology of law becomes essential once the law’s dependence on its social organizational context is recognized (for a defense of legal formalism as a research agenda, see Watson 1985). Blumberg tried to show that the right to legal representation is contingent on the economics of legal services and the networks of dependency that link judges, prosecutors, and defense attorneys in ways that undermine the abstract legal model of the adversarial contest. Second, Blumberg’s case rests on observations of legal practice rather than interpretation of the texts of cases and legislation, the stock-in-trade of conventional legal scholarship. As empirical evidence continued to accumulate, Blumberg’s (1967) conclusions about the origins, causes, and consequences of plea bargaining were qualified or supplanted; later research suggests that plea bargains may be even more adversarial than trials ever were (Feeley 1997), that the relationship between caseload pressure and plea bargaining is complex (Holmes et al. 1992), and that the real role of the courtroom trial may be independent of its frequency of occurrence because out-of-court negotiations are conducted “in the shadow of the law” (Mnookin and Kornhauser

1979). Blumberg's study and the later work it inspired illustrate how the sociology of law examines empirical evidence to understand how law is created, enforced, and manipulated in the context of social organization.

SOCIOLOGICAL VERSUS JURISPRUDENTIAL PERSPECTIVES ON LAW

The discipline of sociology does not hold a monopoly on efforts to unveil the connections between law and society. In the twentieth century, Roscoe Pound, Jerome Frank, and other legal scholars abandoned legal formalism and created new ways to understand the differences between the "law in the books" and the "law in practice" (for a concise overview of both developments, see Hunt 1978). Since the late 1970s, the critical legal studies movement and its variants have emerged as a major competitor to legal formalism in legal research and education (Kelman 1987). For example, Freeman (1978) examines how major Supreme Court decisions on civil rights have shifted the bases for legally defining discrimination from the consequences for the victims to the intentions of the perpetrators. Freeman shows how the law's emphasis on the actor's intention constrains the principle of equal protection and perpetuates inequality. While his conclusions are radical, his method is identical to the legal formalists' practice of textual interpretation (Trubek 1984). Critical legal studies' *doctrinal analysis*—its reliance on interpretation of constitutions, statutes, and judgments—has more affinity with literary criticism than with sociological methodologies based on the observation of events. For an example of this distinction, compare Klare (1978) with Wallace et al. (1988). Sociology of law is distinguished more by its methods than by its theories or subject matter.

SOCIAL ORIGINS OF LAWS

A substantial number of historical case studies (e.g., Hall 1952) have traced the social origins of substantive and procedural law. Sociology enters these investigations with a broader comparative agenda, formulating and assessing general theories of the origin of law. Chambliss's (1964) analysis of six centuries of vagrancy laws as a ruling-class

manipulation of criminal law to control labor was a pioneer of contemporary efforts to pursue this line of investigation. Hagan (1980) provides a representative overview of the subsequent sociological analyses of the origins of alcohol and drug prohibition, sexual psychopathology and prostitution laws, and probation. Humphries and Greenberg (1981) produced one of the few sociological efforts showing the relationships among disparate legal changes and linking those changes to their social bases. They explain the diffusion of juvenile courts, probation, parole, and indeterminate sentences in terms of the shift in the political domination of corporate versus competitive capital during the Progressive era. An alternative approach to the study of the creation and diffusion of legal innovation looks to cultural transmission and organizational linkages rather than to underlying economic or social transformations. Grattet et al. (1998) show, for example, how the diffusion of hate crime legislation appears to be influenced by interstate processes of diffusion rather than by local conditions of the economy and society. Soule and Zylan (1997) similarly explore structural and diffusion factors in the reform of Aid to Families with Dependent Children (AFDC) eligibility rules. In terms of both theory and method, the sociology of law offers a rich body of work that reveals the social foundations of change in the law.

SOCIAL STRATIFICATION OF LAW

The most prominent aspect of social structure in sociological investigations of law is stratification. In his early essay *On the Jewish Question*, Marx examined how a legal system that made all litigants equal before the law left them unequal in economic resources and social relationships. Much current research has been devoted to finding new evidence showing how formal legal equality reproduces social hierarchies. Galanter (1974) points out how the organizational properties of the legal system reinforce and in some instances generate inequality. Apart from the extralegal resources they bring to the dispute, repeat players (corporations and career criminals), for example, gain knowledge, skills that are not available, and networks denied to one-shot players. Feeley (1979) found that in a misdemeanor court "the process is the punishment": For the poor, the costs of conviction were minor compared to the costs imposed by

the pretrial stages of the process. Shapiro (1990) developed similar insights into the way in which the rules of evidence and organizational priorities of law enforcement bureaucracies create class differences in the punishment of white-collar crime. These studies go beyond the populist notion that the law is like a cobweb that catches the small flies but lets the large bugs go free. Individual resources matter, but sociological research shown how organizational and institutional contexts shape the manner in which equality *before* the law results in inequality *after* the law.

The largest body of research in the field has been devoted to the examination of discrimination in sentencing in criminal courts. Disparities in the type and duration of sanctions vary markedly by class, race, and/or ethnicity, and gender. For example, with 5 percent of the general population, young African-American males account for nearly half the admissions to state prisons. The initial research problem was to determine the extent to which such disparities represent differential involvement in the kinds of crime that lead to more severe sentences or reflect biases in discretionary decision making in the legal system (for a succinct overview of this research, see Walker et al. 1996). The sociologically relevant discoveries of this research include covariation in the extent of discriminatory decision making with social location (see Myers and Talarico 1987).

SOCIAL IMPACT OF LEGAL CHANGE

Brown v. Board of Education (1954) is perhaps the most celebrated Supreme Court decision of the century. It marked the end of over half a century of the Court's acceptance of legalized racial segregation as being consistent with the constitutional requirement for equal protection under the law. It is usually the case one associates with the conviction that law—Supreme Court decisions, in particular—powerfully shapes social change. Less widely recognized is the fact that in the decade after *Brown*, racial segregation in public schools remained virtually unchanged. The sharpest challenge to conventional conceptions of the social impact of law is Rosenberg's (1991) study of the effect of Supreme Court decisions on school desegregation, abortion, reapportionment, and criminal procedure.

While current controversy centers on Rosenberg's thesis, several other research programs address the conditions under which legal reforms engineer social change. Burstein (1985), for example, specifies the contingencies that influenced the impact of civil rights legislation on the economic position of minorities. Horney and Spohn (1991) examine the impact of rape reform laws in six jurisdictions on several indicators of prosecution. The measurable impact of legal reform proved to be limited, because of the response of local court organizations to externally imposed change. Heimer (1995) illustrates that similar complications appear when legal changes are imposed on hospital work groups. Organizational responses occasionally facilitate rather than inhibit change. Edelman et al. (1992), for example, found that personnel departments tend to exaggerate the legal risks of noncompliance in equal-opportunity cases as a way to enhance their power within the corporation.

ORGANIZATIONAL CONTEXTS OF LEGAL PROCEDURES

A public defender explained to Sudnow (1965) that to work in such an office, one has to know the law—and the ropes. Learning about the organizational ropes of courts, police departments, and law offices has been the objective of a large body of contemporary research in the sociology of law.

Albonetti (1987) utilizes organizational theories to explain variation in the decisions of prosecutors to drop cases or reduce charges; apart from the legal evidence, prosecutors' decisions are shaped by extralegal factors that govern their uncertainty about winning a case at trial. Ofshe and Leo (1997) investigate the coercive persuasion that continues to occur in post-Miranda police interrogations. Police investigators generally follow the letter of the Miranda rules while continuing to practice forms of coercive persuasion that induce most suspects to waive their rights and confess.

Many discoveries about procedure turn on the emergence of informal organizational rules and relationships. Sudnow (1965) found that plea bargains were forged in a common currency of offense seriousness that existed apart from the penal code's definitions of crimes and punishments.

Emerson (1969) showed how the legally relevant aspects of a juvenile's offense and career are organizationally transformed into judgments of character, which then become the real bases for determining verdicts and imposing sentences. This work suggests that due process is a variable whose appearance and effects are shaped by organizational contexts (see Dobbin et al. 1988).

THE ROLE OF GENERAL THEORY IN THE SOCIOLOGY OF LAW

The sociology of law can be distinguished from economics, psychology, and other social science enterprises that have law as their subject matter principally in terms of its integration of its investigations with general theories of social structure. The role of general theory becomes apparent, for example, in comparisons of Japanese and U.S. legal systems that "explain away Japan by attributing every finding to 'Japanese uniqueness' [rather than] treat Japan as a point on a universal continuum" (Miyazawa 1987, p. 239). The case for engaging in the search for such universal continua is made by Black (1976, 1997).

Much current research, however, continues to be guided by one or a combination of the four general theories that initially defined the field. Bentham's utilitarian philosophy underlies rational choice theories of the behavior of law. Studies of deterrence at both individual and organizational levels of analysis continue to pursue this line of theorizing (see Vaughn 1998 for a summary and critique of organizational analysis). Alternatively, the sociological theories of Marx, Durkheim, and Weber articulate properties of social organization that shape and constrain the choices of persons and firms (for an overview, see Garland 1990). Work in the sociology of law thus not only illuminates the institution of law in unique ways but contributes more fundamentally to basic knowledge about human social organization.

JAMES M. INVERARITY

SOCIOLOGY OF RELIGION

An important intellectual shift has taken place in the social scientific study of religion as many of its longest held theoretical positions, passed down from the founders of the field, have been overturned. These changes have been so dramatic and far-reaching that Warner (1993, p. 1044) identified them "as a paradigm shift in progress," an assessment that since that time "has been spectacularly fulfilled" (Greeley 1996, p. 1).

Typically, the emergence of a new paradigm rests on both an empirical basis and a theoretical basis. Over the past thirty years, there has been an explosion of research on religious topics and a substantial number of new facts have accumulated. The bulk of these discoveries have turned out to be inconsistent with the old paradigm. In response to the growing incompatibility between fact and traditional theory, new theories have been constructed to interpret the empirical literature.

There are five major points of dispute between the old and new paradigms. In this article, each one is described, followed by a brief summary of the pertinent evidence. Finally, additional recent trends in the field are noted.

RELIGION IS HARMFUL

For nearly three centuries, social scientists condemned religion as harmful to the individual because it impedes rational thought and harmful to society because it sanctifies tyrants (Stark 1999b). The premise that religion is irrational and psychologically harmful has taken many forms, all of them notable for the open contempt and an-

tagonism they express toward faith. Thus, as Freud explained on one page of his psychoanalytic exposé of faith, *The Future of an Illusion* (1961 [1927], p. 88), religion is an “illusion,” a “sweet—or bitter-sweet—poison,” a “neurosis,” an “intoxicant,” and “childishness to be overcome.” More recently, Carroll (1987, p. 491) claimed that praying the Rosary is “a disguised gratification of repressed anal-erotic desires,” a substitute for playing “with one’s feces.” In a similar fashion, Ostow (1990, p. 113) asserted that evangelical Protestantism is a matter of regression “to the state of mind of the child who resists differentiation from its mother. The messiah and the group itself represent the returning mother.”

In rejecting assertions that religion is rooted in irrationality, proponents of the new paradigm cite a growing literature that finds religion to be a reliable source of better mental and even physical health (Ellison 1991, 1993; Idler and Kasl 1997; Levin 1996; Pargament and Park 1995). Two literature reviews published in 1987, pointed to the positive health effects of religious involvement regardless of the age, sex, race, ethnicity, or nationality of the population being studied (Jarvis and Northcutt 1987; Levin and Schiller 1987). In a more recent review, Levin (1996, p. 850) found that that relationship still holds and suggests that these results point to a “protective epidemiologic effect of religiosity.”

In the field of gerontology, of research on religion and aging has grown so rapidly that a new journal (*Journal of Religious Gerontology*) has emerged and older journals have devoted special issues or sections to discussions of the topic. Krause (1997, p. S291) summarized the literature: “[A]n impressive body of research indicates that elderly people who are involved in religion tend to enjoy better physical and mental health than older adults who are not as religious.”

Not only is religion associated with better mental and physical health, all the current theorizing about religion accepts the rational choice principle as its first axiom (Gill 1998; Greeley 1995; Iannaccone 1990, 1995a, 1995b; Miller 1995; Sherkat 1997; Stark 1996a, 1996b, 1999a; Stark and Bainbridge 1980 [1987], 1996; Stark and Finke 2000; Stark and Iannaccone 1993, 1994). Most of these scholars do not employ the “thin” version of

rational choice currently used in economics (Iannaccone 1995b) but the “thick” version (Ferejohn 1991), similar to what Weber ([1922] 1993, p. 1) had in mind when he wrote that

religiously or magically motivated behavior is relatively rational behavior . . . It follows rules of experience. . . . Thus, religious and magical behavior or thinking must not be set apart from the range of everyday purposive conduct . . .

What about the harmful *social* effects of religion as it sustains the powerful and dispenses false consciousness to the exploited and debased? Engels (Marx and Engels 64 195, p. 316) claimed that early Christianity “first appeared as a religion of slaves and emancipated slaves, of poor people deprived of all rights, of peoples subjugated and dispersed by Rome.” Does it not follow that *religion appeals most strongly to the lower classes?*

While the old paradigm identified religion as the opiate of the people, the new paradigm notes that religion also often is the “amphetamines” of the people in that religion animated many medieval peasant and artisan rebellions (Cohn 1961), generated repeated uprisings among the native peoples of Africa and North America against European encroachment (Wilson 1975), and recently served as a major center of mobilization against tyranny in eastern Europe (Echikson 1990). The notion that religion primarily serves to compensate the deprived and dispossessed has become untenable. The consensus among scholars rejects as “imaginary history” Engels’s notion that the early Christian movement was rooted in proletarian suffering. The facts force the conclusion that Christianity’s greatest early appeal was to the privileged classes (Stark 1996a). In similar fashion, since the early 1940s many researchers have attempted to connect religiousness to social class, but their findings have been weak and inconsistent (Stark and Finke 2000). Consequently, the need for new theorizing on the role of religion in the political affairs of nations has been recognized (Gill 1998).

RELIGION IS DOOMED IN MODERN TIMES

As the social sciences emerged in the wake of the Enlightenment, the leading figures eagerly pro-

claimed the demise of religion. Toqueville wrote in his famous early nineteenth-century study, *Democracy in America* ([1840] 1956, vol. II, p. 319):

The philosophers of the eighteenth century explained in a very simple manner the gradual decay of religious faith. Religious zeal, said they, must necessarily fail the more generally liberty is established and knowledge diffused.

This came to be known as the *secularization thesis*: In response to modernization, “religious institutions, actions, and consciousness, [will] lose their social significance” (Wilson 1982, p. 149). Toqueville was virtually alone in rejecting the secularization thesis; perhaps no other social scientific prediction enjoyed such nearly universal acceptance for so long. Thus, the anthropologist Wallace (1966, p. 265) wrote in an undergraduate textbook:

The evolutionary future of religion is extinction. Belief in supernatural beings and supernatural forces that affect nature without obeying nature’s laws will erode and become only an interesting historical memory . . . Belief in supernatural powers is doomed to die out, all over the world, as the result of the increasing adequacy and diffusion of scientific knowledge.

In the late 1990s, the secularization thesis has been buried under a mountain of contrary facts (Bossy 1985; Duffy 1992; Greeley 1989, 1995, 1996; Murray 1972; Stark 1999c). The primary empirical basis for claims of ongoing secularization has been the very low rates of religious participation in contemporary European nations, where weekly rates of church attendance often are below 5 percent. However, the overwhelming weight of historical research shows that these low rates do not represent a decline. Church attendance always was extremely low in those nations, and it is not clear that they ever were effectively Christianized (Greeley 1995; Stark 1999c). Furthermore, in those nations the overwhelming majority express firm belief in the supernatural, pray, and describe themselves as religious. It is perverse to describe a nation as highly secularized (as those committed to the old paradigm still do) when two-thirds or more of its residents say they are “religious persons” and fewer than 5 percent say they are atheists. The interesting question thus does not con-

cern secularization but is, “[W]hy are these societies of believing non-belongers?” as Davie (1994) has expressed it. What is it about the churches in those nations that prevents them from mobilizing participation?

Looking to the world as a whole, there is no consistent relationship between religious participation and modernization. Indeed, the very few significant, long-term declines in religious participation that have been seen in the world are greatly outnumbered by remarkable increases (Stark and Finke 2000). What needs to be explained, therefore, is not religious decline but *variation*. Finally, the spread of science cannot cause secularization, because science and religion are unrelated. Scientists are as religious as anyone else, and the more scientific their fields, the more religious are American academics (Stark et al. 1996).

ONE LAST SPASM

The twin propositions that religious behavior is rooted in irrationality and that religion must soon yield to secularization have been dealt a blow by the finding that the more liberal (or secularized) a religious body becomes, the more rapidly it loses members, while denominations that sustain more vigorous and traditional theologies have prospered (Finke and Stark 1992; Iannaccone 1994; Kelley 1972; Stark and Finke 2000). How can it be that the “fundamentalists” grow while the liberals lose out? Proponents of the old paradigm have invoked the notion that this is but one final, dying spasm of piety. They claim that the expansion of evangelical Protestant churches in the United States (and presumably in Latin America, where they are experiencing explosive growth) is a frantic “flight from modernity,” that people who feel threatened by the erosion of traditional morality are flocking to religious havens (Berger 1967; Hunter 1987, 1983). Berger (1967, p. 11) described American evangelical Protestant churches as follows: “They are like besieged fortresses, and their mood tends toward a militancy that only superficially covers an underlying sense of panic.” Nearly thirty years later Thurow (1996, p. 232) explained, “Those who lose out economically or who cannot stand the economic uncertainty of not knowing what it takes to succeed in the new era ahead retreat into religious fundamentalism.”

A fatal problem with this explanation is that, as was noted above, the relationship between social class and religiousness is weak and inconsistent. Conservative churches actually include a fair share of highly educated, successful, and sophisticated people who display no apparent fears of modernity (Smith 1998, 2000; Stark and Finke 2000; Woodberry and Smith 1998).

The new paradigm has no difficulty explaining the growth of evangelical churches because it does not confuse price with value. As Iannaccone (1994, 1992) has demonstrated, “strict” churches—those which require more from their members—are a better value because they offer far more in the way of rewards, both worldly and otherworldly. In this sense, to opt for a more traditional religious affiliation is to make the more rational choice, in that it yields a greater ratio of rewards over costs.

IDEALISTIC HUMBUG

Generations of social scientists have embraced the notion that religion is a dependent variable and that whatever appears to be a religious effect is ultimately merely a mask for something more basic, something “material.”

Although social scientists in most other areas of study have long acknowledged the truism that if people define something as real, it can have real consequences, this concession usually has been denied in the area of religion. Instead, there has been a general willingness to agree with Marx that any attempt to explain “reality” by reference to an unreality such as religion is “idealistic humbug.” Rather, one must explain religion by reference to “realities” such as “the mode of production.” That is, one “does not explain practice from the idea but explains the formation of ideas from material practice” (Marx [1845] 1998, p. 61). As Marx’s collaborator Engels explained, “All religion . . . is nothing but the fantastic reflection in men’s minds of those external forces which control their daily life . . . the economic conditions . . . the means of production” (Marx and Engels 1964, pp. 147–148).

These views did not originate with Marx; they have been nearly universal among social scientists for close to three centuries (Stark 1999b). Even Weber, having attributed the rise of capitalism to

the “Protestant ethic,” traced the source of that ethic to material conditions (including the rise of the bourgeoisie, population growth, and colonialism), thus limiting Calvinist doctrines to being at most a *proximate* rather than a *fundamental* cause of capitalism. Even so, Weber has been bitterly criticized for affording religion *any* causal role. Emile Durkheim and his functionalist heirs dismissed religious belief as an insignificant epiphenomenon, regarding ritual as the only active religious ingredient and as being only a proxy for a more basic factor, social solidarity (Stark and Bainbridge 1997).

The new paradigm is committed to the proposition that people often act from religious motives and that in many cases no more fundamental or material cause can be found. Four historical examples reveal the conflict between paradigms on this central issue.

Crusading for Land and Loot. For centuries, historians believed that the Crusades to the Holy Land were motivated by faith, that tens of thousands of European nobles and knights marched to the Holy Land to rescue it from Muslim “desecration.” However, by the end of the nineteenth century social scientists had penetrated those appearances to discover that the crusaders really went in pursuit of land and loot. Having summarized the many economic problems facing Europe in the eleventh century, including the population pressures and land shortages that were said to beset the knightly class, Mayer (1972, pp. 22–25) stressed the “lust for booty” and the “hunger for loot” that motivated the crusaders: “Obviously the crusade acted as a kind of safety valve for a knightly class which was constantly growing in numbers.” He went on to emphasize the need to recognize “the social and economic situation of a class which looked upon the crusade as a way of solving its material problems.”

Although there is extensive evidence that the crusaders truly believed they were going for purely religious reasons, this material can be ignored because there exists a definitive refutation of the materialist position. In 1063, thirty-two years before Urban II called for the First Crusade to the Holy Land, Pope Alexander II, backed by the evangelical efforts of the monks of Cluny, attempted to organize a Crusade to reclaim Moorish Spain.

Here, very close at hand, lay great wealth and an abundance of fertile land, and the Pope had declared that all who fought for the Cross in Spain were entitled not only to absolution for their sins but to all the wealth and “lands they conquered from the infidel” (Runciman 1951, vol. 1, p. 91). However, hardly anyone responded, and little or nothing was achieved. The materialist interpretation of the Crusades fails when faced with the fact that crusaders were not lured to nearby Spain in pursuit of rich and relatively easy pickings, while soon afterward tens of thousands set off for the dry wastes of faraway Palestine and did so again and again. Why did they do that rather than go to Spain? Because Spain was not the Holy Land. Jesus had not walked the streets of Toledo or been crucified in Seville.

Heresy and Class Struggle. Beginning in the eleventh century and lasting through the sixteenth, Europe was swept by mass heretical movements—Waldensians, Cathars (called Albigensians in southern France), Hussites, and many others—culminating in the Reformation. Tens of thousands died on behalf of their religious beliefs, but maybe not.

Many historians possessed of an excessive sociological imagination have claimed that these great heretical movements were not primarily about doctrines and morals, if indeed religious factors were of any significance at all. Instead, they argue, the religious aspect of these movements masked their real basis, which was of course class struggle. Engels (Marx and Engels 1964, pp. 97–123) identified some of these movements, including the Albigensians, as urban heresies in that they represented the class interests of the town bourgeoisie against those of the feudal elites of church and state. But most of the heretical movements were, according to Engels, based on the proletariat, which demanded restoration of the equality and communalism of early Christianity (Engels and many other Marxists have claimed that the early Christians briefly achieved true communism). Engels granted that these class struggles were characterized by religious and mystical rhetoric but dismissed this as false consciousness. Following Engels, many Marxist historians have “exposed” the materialism behind the claims of religious dissent. Thus, in 1936 the Italian historian Antonino de Stefano claimed, “At bottom, the economic argument must have constituted, more than any

dogmatic or religious discussions, the principle motive of the preaching of heresy” (quoted in Russell 1965, p. 231). Even many historians not committed to orthodox Marxism have detected materialism behind medieval dissent. For example, the non-Marxist historian Cohn (1961, p. xiii) reduced medieval heresies to “the desire of the poor to improve the material conditions of their lives,” which “became transfused with phantasies of a new Paradise.”

It is not necessary for proponents of the new paradigm to deny that class conflicts existed in medieval times or to suppose that people participating in heresy never paid any heed to their material interests to reaffirm that religion lay at the heart of these conflicts. If their primary concerns had been worldly, surely most heretics would have recanted when that was the only way out. It was, after all, only their religious notions they had to give up, not their material longings. However, large numbers of them chose death instead. Moreover, these movements drew participants from all levels of the class system. The Albigensians, for example, enlisted not only the bourgeoisie but, in contradiction to Engels, most of the nobility as well as the clergy of southern France and indeed the “masses” (Costen 1997; Lambert 1992; Mundy 1985). Finally, the claim that the majority of the participants in any given heresy consisted of peasants and the poor is lacking in force, even in the instances in which it might be true. Almost everyone in medieval Europe was poor and a peasant. Gauged against this standard, it seems likely that the “proletarian masses” were quite underrepresented in most of these movements (Lambert 1992).

Medieval Jewish Messianic Movements. For Jews the messiah has yet to come, but again and again over the centuries, groups of Jews have hailed his arrival. An early episode resulted, of course, in Christianity, but it would not be an exaggeration to say that hundreds of other messianic movements have occurred in Jewish communities over the past two millennia, and such movements were especially common in the European diaspora during medieval times (Cohen 1967; Lenowitz 1998; Sharot 1982).

In a sophisticated analysis of these religious movements, Sharot (1982, p. 18) noted the huge literature that stresses that messianic movements are

responses to the disruption of social and cultural patterns . . . [produced by] a disaster such as an epidemic, famine, war, or massacre. Following a disaster, persons feel vulnerable, confused, full of anxiety, and they turn to millennial beliefs in order to account for otherwise meaningless events. They interpret the disaster as a prelude to the millennium; thus their deepest despair gives way to the greatest hope.

Although some messianic Jewish movements did erupt after a disaster, as he worked his way through all the better-known cases, Sharot (1982, pp. 65–66) was forced to agree with Cohen's (1967) earlier study that many movements seemed to come out of nowhere in the sense that they arose during periods of relative quiet and therefore that "disaster was not a necessary condition of a messianic outburst."

Sharot made this concession very reluctantly, and often seems to forget it. Nevertheless, his scrupulous accounts of specific incidents frequently show that a movement was the direct result of religious rather than secular influences. In many cases, an episode began with an individual or small group poring over the *Kabbalah* (a collection of Jewish mystical writings) out of purely personal motives and then "discovering" that the millennium was at hand. Thereafter, they shared this knowledge with others, who in turn assisted in arousing a mass following. In other instances, someone became convinced that he was the messiah and was able to convince his family and friends (Stark 1999d).

One can of course argue that Jews in medieval Europe were always victims and hence always ripe for millenarian solutions. However, constants cannot explain variations, and in as many cases as not, nothing special was going on to cause a movement to arise then rather than at some other time except for direct religious influences in the form of people advocating a new religious message or circumstance.

Of course, people often do turn to religion in times of trouble and crisis, but the new paradigm rejects the claim that crises are a necessary condition for religious innovations and recognizes that religious phenomena can be caused by other religious phenomena.

The Mystical 1960s. A huge literature attributes the "explosive growth" of new religious movements in the United States in the late 1960s and early 1970s to profound social causes. Particular attention has been given to uncovering the secular causes of the special appeal of Eastern faiths for Americans in that period. Cox (1983, p. 42) blamed "the most deteriorated, decadent phase of consumer capitalism," charging that converts to Eastern faiths had "been maddened by consumer culture" (p. 40). Serious journals published equally hysterical explanations. As Robbins summarized (1988, p. 60), each of these analyses identified one or more "acute and distinctively modern dislocation which is said to be producing some mode of alienation, anomie or deprivation to which Americans are responding." With a fine grasp of the essentials, Barker (1986, p. 338) commented that "those who have read some of the sociological literature could well be at a loss to understand why *all* young adults are not members [of new religious movements], so all-encompassing are some of the explanations."

In fact, there was no growth, explosive or otherwise, of new religious movements in this era (Melton 1988; Finke and Stark 1992); the rate of new movement formation was constant from 1950 through 1990. As for the brief increase in the proportion of Eastern faiths among new American movements, capitalism had nothing to do with it. Rather, in 1965 the elimination of exclusionary rules against Asian immigration made it possible for the first time for authentic Eastern and Indian religious leaders to seek American followers directly. Consequently, there was an increase in the number of Eastern religious organizations, but the number of actual converts was minuscule. Even so, these movements were the result of *religious* efforts, of face-to-face recruitment activities motivated by the religious convictions of missionizing gurus.

THE EVILS OF PLURALISM

More than three centuries ago, early scholars of comparative religion assumed that by publicizing the beliefs of the world's many faiths, they could advance the cause of atheism, that by virtue of their competing claims, each religion would refute the others (Preus 1987). This view has led to the

claim that faith is a very fragile thing that cannot survive challenge; hence, *pluralism*—the existence of several competing religious bodies in a society—is said to be incompatible with strong religiosity. Durkheim ([1897] 1951, p. 159) asserted that when multiple religious groups compete, religion becomes open to question, dispute, and doubt and thus “the less it dominates lives.” Eventually these views were formulated into elegant sociology by Berger (1967, 1979), who repeatedly argued that pluralism inevitably destroys the plausibility of all religions and only where one faith prevails can there exist a “sacred canopy” that is able to inspire universal confidence and assent.

These notions are mistaken, having been taken over uncritically from the justifications given by European state churches for their monopolies. It is indicative of the undue respect given European social science that American sociologists accepted this view, since religious competition is an obvious basis for the extraordinary levels of religious participation in the United States, in contrast to the religious apathy prevalent in societies with a monopoly church. Indeed, the positive role of competition is obvious in American history. In 1776, when most American colonies were dominated by a state-supported church, about one person in five belonged to any church. After the Revolution, the onset of vigorous religious competition eventually resulted in about two-thirds of Americans belonging to a church (Finke and Stark 1992)

To fully appreciate the power of pluralism, it was necessary to cease treating religion as primarily a psychological phenomenon and take a more sociological view, an approach that also has been characteristic of the new paradigm. The concept of a *religious economy* (Stark 1985) made it possible to adopt an overall perspective on the religious activities in a society and examine the interplay among religious groups. This analysis quickly revealed that the main impact of religious competition on individuals is not confusion or the corrosion of faiths but to present the individual with vigorously offered choices. As Adam Smith pointed out more than two centuries ago, monopoly religions are as subject to laziness and inefficiency as are monopoly business firms. Thus, it is axiomatic in the new paradigm that religious competition strengthens religion because as firms vie for supporters, they tend to specialize their ap-

peals, with the overall result that a higher proportion of the population will be enrolled. As of 1999 there had been more than twenty-five published studies based on many different societies and different eras, offering overwhelming support for this view (Finke and Stark 1998; Stark and Finke 2000).

A FOCUS ON RELIGION

Despite emphasizing that religion does have effects, the new paradigm is not limited to that perspective. Rather, in addition to a sociology of religious effects, the new paradigm has promulgated a sociology of religion *per se*.

For a long time sociologists interested in religion attempted to justify their topic by demonstrating its importance to those who specialized in one of the more of the “secular” areas of the field. Thus, some sociologists devoted studies to demonstrating religious effects on political behavior such as voting and opinions on current issues. Others sought to convince demographers that religion was crucial to fertility studies. This trend has been enshrined in textbooks on the sociology of religion, all of which have consisted almost entirely of chapters on “religion and family,” “religion and economics,” “religion and prejudice,” and so on.

However, having become part of a relatively large and well-established specialty, sociologists in this area have become sufficiently confident to make religion the real center of study rather than trying to draw legitimacy from its connections to other topics. Consequently, there has been renewed attention to what religion is as well as what it does (Boyer 1994; Greeley 1995; Guthrie 1996; Stark 1999a). There also is much new work on religious and mystical experiences (Hood 1997; Howell 1997; Neitz and Spickard 1990; Stark 1999d). Other scholars have focused not on the causes or consequences of prayer but on its nature and practice (Poloma and Gallup 1991; Swatos 1987). Also, increasing attention is being paid to images of God (Barrett 1998; Greeley 1995; Stark forthcoming).

In addition, there is an impressive new literature on religious socialization (Ellison and Sherkat 1993a, 1993b; Granqvist 1998; Kirkpatrick and Shaver 1990; Smith 1998), on denominational switching (Musick and Wilson 1995; Perrin et al.

1997; Sherkat and Wilson 1995), and on conversion (Hall 1998; Rambo 1993; Stark and Finke 2000). Amid all this activity, the case study literature is blooming as never before (Davidman 1991; Goldman 1999; Heelas 1996; Lang and Ragvald 1993; Lawson 1995, 1996, 1998; Neitz 1987; Poloma 1989; Washington 1995).

SOUTHEAST ASIA STUDIES

Southeast Asia consists of the ten countries that lie between the Indian subcontinent and China. On the mainland of Southeast Asia are Myanmar (Burma), Thailand, Laos, Cambodia, and Vietnam. Insular Southeast Asia includes Indonesia, the Philippines, Brunei, Malaysia, and Singapore. While most of Malaysia (Peninsular Malaysia) is on the mainland, that country usually is considered part of insular Southeast Asia because the Malay population (the majority ethnic population) shares a common language and religion with much of the Indonesian population. The city-state of Singapore (on an island connected by a mile-long causeway to Peninsular Malaysia) was historically part of Malaysia, but because of its unique ethnic composition (three-quarters of the population is of Chinese origin), it is more similar to East Asia than to Southeast Asia.

While there are some common geographic and cultural features, diversity is the hallmark of the region. Incredible indigenous cultural variation has been overlaid by centuries of contact, trade, migration, and cultural exchange from within the region, from other parts of Asia, and for the past five hundred years from Europe (for general overviews of the region, see Osborne 1985; Wertheim 1968). The common characteristic of mainland Southeast Asia is Buddhism, although there are very significant variations across and within countries: Islam is the majority religion in Indonesia, Brunei, and Malaysia, while Christianity is the major religion in the Philippines. The lowlands of both mainland and insular Southeast Asia tend to be densely settled, and wet (irrigated) rice agriculture is the predominant feature of the countryside. Rural areas are knitted together with small- and medium-sized market towns. The major metropolitan areas of the region (Jakarta, Bangkok, Singapore, Manila, Rangoon, Kuala Lumpur, Ho Chi Minh City) are typically port cities or are located along major rivers. Many of these towns and cities have significant Chinese minorities (often intermarried with the local population) that play an important role in commerce. Every country has remote highland and mountainous regions that often are populated by ethnic minorities.

In terms of land area, population size, and cultural and linguistic diversity, Southeast Asia is comparable to Europe (excluding the former Soviet Union). By the year 2000, the population of

Southeast Asia will exceed 500 million, about 8 percent of the world's total. Indonesia is the fifth most populous country in the world, while the oil-rich sultanate of Brunei (on the island of Borneo) is one of the smallest. The other large countries of the region—Thailand, Vietnam, and the Philippines—are more populous than all European countries except for the former Soviet Union and Germany. The sea (South China Sea and Indian and Pacific Oceans) surrounds much of the region, especially the immense Indonesian and Filipino archipelagoes. While the sea can be a barrier, the ocean and the rivers of the region are avenues that have fostered local and long-distance trade throughout history. Moreover, the ease of movement throughout the region seems to have shaped cultures that easily absorbed new ideas and immigrants and have been tolerant of diversity.

HISTORY

The contemporary political divisions of the region are largely a product of European imperialism, especially of the nineteenth century. Before European intervention, there were great regional civilizations, both agrarian states and maritime empires that waxed and waned over the millennium. The remains of the temple complexes of Angkor (Cambodia) and Pagan (Burma) rival the architectural achievements of any premodern world civilization. Early Western observers of the city of Melaka (a fifteenth-century maritime empire centered on the west coast of the Malayan peninsula) described it as more magnificent than any contemporary European city. These early polities were founded on intensive rice cultivation with complex irrigation systems, the dominance of regional and long-distance trade, or both. The region also has been deeply influenced by contacts with the great civilizations of India and China. The cultural influences from outside have invariably been transformed into distinctive local forms in different Southeast Asian contexts. Because relatively few written records have survived the tropical environment of Southeast Asia, historical research relies heavily on archeological investigations, epigraphs, and records from other world regions, especially Chinese sources.

European influence began in the sixteenth century with the appearance of Portuguese and Spanish naval forces, followed by the arrival of the

Dutch in the seventeenth century and then by that of the British and French. In the early centuries of contact, European powers were able to dominate the seas and thus limit the expansion of Southeast Asian polities, but they rarely penetrated very far inland from their coastal trading cities. All Southeast Asia was transformed, however, in the nineteenth century as the Industrial Revolution in the West stimulated demand for mineral and agricultural products around the globe. New economic organizations of plantations, mines, and markets led to large-scale migration of people and capital to frontier areas and to the cities of Southeast Asia. There was an accompanying flurry of imperialist wars to grab land, people, and potential resources. In a series of expansions, the British conquered the area of present-day Myanmar (Burma) and Malaysia, the Dutch completed their conquest of the East Indies (now Indonesia), and the French took the areas that formed their Indochina empire (present-day Vietnam, Cambodia, and Laos). At the turn of the twentieth century, the United States defeated nationalist forces to take control of the Philippines just as the Spanish Empire was crumbling. Siam (Thailand) was the only indigenous Southeast Asian state to escape the grip of colonialism.

The political history of the region has not been stable. As Western countries moved toward more democratic social and political institutions over the first decades of the twentieth century, the colonists (British, Dutch, American, and French) constructed authoritarian dependencies in the tropics that were based on export economies and racial ideologies. Although there were stirrings of nationalist sentiment in the first half of the twentieth century, it was only after World War II that the nationalist forces were strong enough and the international environment favorable enough to bring political independence to the region. The critical turning point was the Japanese conquest and occupation of Southeast Asia from 1942 to 1945, which permanently shattered the myth of European superiority. The colonial powers returned after World War II, but they encountered popular nationalist movements that demanded the end of colonialism.

Independence was negotiated peacefully by the Americans in the Philippines and the British in Burma and Malaya, but nationalist forces had to wage wars of independence against the Dutch in

Indonesia (1945–1950) and the French in Vietnam (1945–1954). The interplay of nationalist struggles, class conflicts, and East-West cold war rivalry had a marked influence on political developments in the region. In almost every country there were radical and communist movements that held the allegiance of significant sectors of the population. In several cases, communist parties were part of the nationalist movement but left (or were driven out of) the political arena as domestic and international tensions escalated. Vietnam was unique in that the nationalist movement was led by Communists. After the French were defeated in 1954 and agreed to grant independence to Vietnam, the United States intervened to set up a non-Communist Vietnamese state in the southern region of the country. After another twenty years of war and a million casualties, Vietnam was finally united as an independent state in 1975. Since 1975, however, political tension between the socialist states of Vietnam, Cambodia, and Laos and the other countries in the region has been the dominant feature of international relations there.

Domestic political developments within individual countries in the region have been no less dramatic. Governments have oscillated between authoritarian and democratic forms, with no linear trend. Behind the headlines of military coups, regional wars for autonomy, and “managed” elections have been complex political struggles among various contending groups defined by class, region, ethnicity, and kinship. These struggles have ranged from civil war to fairly open elections. Large-scale violence is not the norm, but massacres in Indonesia, Cambodia, and East Timor have been among the worst of such episodes in modern times. Popular civil protests against ruling elites in the Philippines and Burma had significant domestic and international reverberations. Neither academic scholarship nor political reporting has offered generalizations about or convincing interpretations of the postwar political change in Southeast Asia.

Many of the countries in Southeast Asia have experienced remarkable socioeconomic modernization in the postindependence era. This is most evident for the ASEAN (Association of Southeast Asian Nations) countries of Thailand, Malaysia, Singapore, Indonesia, the Philippines, and Brunei. All indicators of socioeconomic development (gross national product, educational levels, occupational

structure, infant mortality) suggest that Southeast Asia has successfully narrowed the gap with the first world, while other regions of the third world have fallen farther behind. The reasons for the success of some countries and the economic stagnation in other countries are a matter of dispute. The East Asian model of state-sponsored export industrialization is widely discussed in policy and academic circles, but the parallels between East Asian and Southeast Asian economic development strategies are still a matter of considerable uncertainty. Few scholarly studies have examined the causes and consequences of the economic modernization of Southeast Asia.

THE STATUS OF WOMEN

Several theoretical concepts and empirical generalizations have arisen from studies of Southeast Asian societies that have relevance far beyond the region. Empirically, the most common cultural characteristic across the region is the relatively high status of women in Southeast Asian societies, especially compared with East Asia and South Asia. While women still face many social and cultural obstacles in Southeast Asia, the situation appears much different from that in the patriarchal societies of other Asian societies and the traditional female domesticity of many Western societies. While there are a few matrilineal societies in the region, Southeast Asian kinship systems are typically bilateral, with equal importance attached to the husband's and wife's families. The patrilocal custom of an obligatory residence of a newly married couple with or near the groom's family is largely absent in Southeast Asia. The residence of young couples after marriage seems to be largely a matter of choice or is dependent on relative economic opportunities. There is no strong sex preference for children in Southeast Asia, with both girl and boy children seen as desirable.

The relatively positive status of women was evident in earlier times. Reid (1988, pp. 146-172) reports that early European observers were struck by the active role of women in economic and political affairs in Southeast Asia. Traditional folklore also suggests that women play an active role in courtship and that female sexual expectations were as important as men's. Perhaps most unusual was the custom (reported in the fifteenth and sixteenth centuries) of inserting spurs or balls in male

genitals to enhance the sexual pleasure of women (Reid 1988, pp. 148-151).

At present, women seem to be well represented in schools, universities, and employment in all modern sectors of the economy in almost every country in Southeast Asia. There is only a modest scholarly literature on the higher status of women in Southeast Asia (Van Esterik 1982), and few efforts have been made to explain the links between the traditional roles of women as productive workers in the rural rice economy and their relative ease of entry into the modern sector. Demographic research has revealed very rapid declines in fertility in several Southeast Asian countries, particularly Singapore, Thailand, Malaysia, and Indonesia. If the current pace of decline continues, replacement-level fertility (two children per woman) should be reached in the near future (Hirschman and Guest 1990).

AGRICULTURAL INVOLUTION

Scholarship on Southeast Asia often has reached beyond the boundaries of the region to influence debates over social science concepts, theory, and models. Perhaps most influential have been the books and articles on Indonesia by the anthropologist Geertz. His evocative concepts of the "theatre state," "thick description," and "agricultural involution" have stimulated debate and research in several social science disciplines, including sociology. His model of agricultural involution (Geertz 1968) has been one of the most provocative developments in scholarship on Indonesia over the last generation.

A strikingly bold thesis, agricultural involution is an attempt to explain how Java became one of the most densely settled populations in the world within a traditional agricultural economy. To address this question, Geertz presents an ecological interpretation of the evolution (involution) of Javanese social structure in the face of rapid population growth and Dutch colonialism within the constraints (and possibilities) of a wet rice economy. The colonial system prevented industrialization and the development of an indigenous entrepreneurial class. The traditional rice economy, however, could absorb a larger population because additional labor inputs in the maintenance of irrigation facilities, water control, weeding, and harvesting yielded marginal increments in

rice production. Over the decades, this refinement of traditional production technology (involution) led to an increasing rigidification of traditional Javanese culture, thus discouraging innovation and any efforts at social change and reinforcing the structural limits of the colonial system. Even after independence, when structural limits were lifted, the legacy of the past, as reflected in Javanese culture, remained.

Geertz's thesis remains highly controversial, and many of its components have been confronted with negative evidence (for a review of the debate, see White 1983; and Geertz 1984). For example, Geertz deemphasized social class divisions with his interpretation of "shared poverty" as the traditional social strategy. Most research has shown significant inequality of landholding and other socioeconomic dimensions in Javanese villages, although it is not clear if inequality is permanently perpetuated between families across generations. Even accepting many of the criticisms, agricultural involution is a seminal sociological model that should generate empirical research on the historical development of Asian societies.

THE MORAL ECONOMY

A classic question in social science involves the causes of revolution or rebellion. Neither Marxian theory, which emphasizes exploitation, nor relative deprivation theory seems to be a satisfactory model to explain the occurrence of revolutions or rebellions. The most sophisticated sociological theory of peasant rebellion is based on historical materials from Burma and Vietnam by the political scientist J Scott (1976) in *The Moral Economy of the Peasant: Subsistence and Rebellion in Southeast Asia*. Scott argues that peasants rebel only when their normative expectations of a minimum subsistence level are not met. These conditions are more likely to occur when capitalist market relations and colonial states erode traditional societies and the reciprocal obligations of peasants and their patrons.

Scott's thesis has been criticized and hotly debated (Popkin 1979; Keyes 1983). One criticism is that Scott believes that peasants prefer traditional societies and are not responsive to economic opportunity. Scott acknowledges that peasants can be quite innovative and individualistic as long as their minimum subsistence is not at risk.

This debate, however, does not really address the central theoretical contribution of Scott's thesis about the specification of the causes of peasant rebellion.

In a more recent study based on fieldwork in a rural Malaysian village, Scott (1985) examines how class antagonisms are displayed in everyday life. Given that rebellion is a very rare event in most societies, Scott calls attention to political, social, and linguistic behaviors that reveal the depth of descensus and potential social conflict but do not risk violent reaction from the state and powerful elites. In these two books and related publications, Scott has provided original interpretations of peasant political behavior in Southeast Asia and set a research agenda for scholars of other world regions and, more generally, the development of social theory.

CONCLUSION

Scholarship on Southeast Asia, whether in sociology or in other disciplines, has tended to focus on individual countries rather than on the region. Different languages (colonial and indigenous) as well as variations in religious traditions and political and economic systems have reinforced the image of a heterogeneous collection of countries that is labeled a region largely by default. There is tremendous political, economic, and sociocultural diversity in the region; many of these differences, however, are a product of the colonial era and its legacy. The similarity of family systems and the status of women throughout Southeast Asia suggest some common historical and cultural roots for the region. There may well be other social and cultural parallels across Southeast Asia that will be revealed as more comparative research is undertaken (Wolters 1982).

Many indicators of development in Southeast Asia, including very low levels of mortality and almost universal secondary schooling, are approaching the prevailing standards of developed countries. Assuming that current socioeconomic trends continue, several countries in the region probably will follow Japan, Korea, and Taiwan along the path of development in the early decades of the twenty-first century. The study of these processes of modernization and the accompanying changes in politics, family structure, ethnic relations, and

other social spheres should make Southeast Asia an extraordinarily interesting sociological laboratory.

Evolutionary—and sometimes revolutionary—social change continued throughout much of Southeast Asia in the 1990s. After the collapse of the Soviet Union, the socialist countries in the region, including Vietnam, Cambodia, and Laos, moved rapidly toward more market-driven economies. Several political regimes that appeared to be stable for long periods have been transformed. The “people power” popular protests that ended the Marcos regime in the Philippines in the 1980s was echoed by the peaceful transition of power from a military regime in Thailand in the early 1990s and by the ending of the Suharto regime in Indonesia in 1998.

For much of the 1990s, most of Southeast Asia experienced rapid economic growth and the major question was the emerging role of the new middle class (McVey 1992; Girling 1996). This trend was halted in late 1997 by the “Asian economic crisis” that hit the region and affected Thailand, Malaysia, and Indonesia in particular. Both the causes of this crisis and its consequences are currently the subject of much debate. The change of regime in Indonesia and political protests in Malaysia may be the most visible long-term impact may be more profound.

Scholarship inevitably lags behind current events. Several important publications, including the second volume of Reid’s (1990, 1995) *Southeast Asia in the Age of Commerce 1450–1680* and a much expanded version of Wolters’s classic *History, Culture, and Region in Southeast Asian Perspectives 1999*, offer a new understanding of the history of the premodern era. Although the definition of Southeast Asia as a region sometimes has been considered arbitrary, historical studies show common cultural, political, and social forms in many places throughout the region.

One of the defining features of the region has been the relatively easy absorption of peoples, ideas, and cultural practices from elsewhere. In the twentieth century, assimilation into Southeast Asian societies became more difficult with the creation of political and social barriers. These issues are illuminated with considerable insight in Chirot and Reid’s (1997) edited collection that compares the experience of the Chinese in Southeast Asia with that of the Jews in central Europe.

Research on Southeast Asia over the last decade also has been influenced by Anderson’s (1991) *Imagined Communities*, a book originally published in the 1980s. Although Anderson is a specialist on Southeast Asia, his book on the development of nationalism provides comparisons from across the world.

CHARLES HIRSCHMAN

SOVIET AND POST-SOVIET SOCIOLOGY

In prerevolutionary Russia, sociology occupied a marginal position. The state universities offered no instruction in the field, but there was a solid intellectual tradition of historical and theoretical sociology (Maxim Kovalevsky, Nikolai Mikhailovsky, Evgeny de Roberty), the sociology of law (Leon Petraizky, Pitirim Sorokin), and the sociology of social problems (living conditions of industrial workers and peasants, public health, crime and prostitution in the cities). Beginning in the 1860s, the provincial intelligentsia initiated a kind of social movement, *Zemskaja statistika* (Statistics for Local Administration). Since official governmental statistics were unreliable, local statisticians made systematic surveys of households, daily life and public health conditions, and the reading preferences of the population (N. A. Rubakin). A modern system of sampling was elaborated by the statistician A. A. Chuprov for those surveys; K. M. Takhtarev introduced the concept of statistical sociological methods in social research.

In 1916, the Russian Sociological Society was founded, along with the "Sociological Institute," where M. M. Kovalevsky, K. M. Takhtarev, N. I. Kareev, and P. A. Sorokin gave lectures. Western sociological classics by Auguste Comte, Herbert Spencer, Emile Durkheim, Gabriel Tarde, Gustave Le Bon, Georg Simmel, Lester Ward, and others

were available in Russian translations. Most important European sociological papers were immediately translated in the series *New Ideas in Sociology*. There was also a well-developed ethnography and a literary genre of sociological journalism.

The Bolshevik Revolution provided strong stimulus to sociological reflection and empirical social research. In the Soviet government decree "About the Socialist Academy of the Social Sciences," drafted in May 1918, Lenin (1962, p. 372) stressed the need "to organize a series of social researches" and called it "one of the most urgent tasks of the day." However, the Bolsheviks tolerated research only from Marxist and procommunist positions. In the early postrevolutionary years, censorship was relatively weak or inefficient. For example, Sorokin not only established the first sociological laboratory in Petrograd University but also succeeded in publishing (illegally) his two-volume *System of Sociology* (Sorokin 1920), for which he was awarded a doctorate in April 1922. He also conducted important empirical investigations on mass starvation in the districts of Samara and Saratov and examined its influence on various aspects of social life and human behavior.

However, this liberalism or negligence on the part of the authorities was short-lived. In autumn 1922, a group of leading Russian intellectuals, including Sorokin and other prominent social philosophers, was expelled from the country, ending non-Marxist sociology in Soviet Russia.

The tightening ideological control proved detrimental to socialist and Marxist social research as well. Nevertheless, the 1920s was a fruitful period both in empirical research and in theoretical-methodological work. The most important theoretical contributions were in the field of economic sociology (A. V. Chajanov, N. D. Kondratjev). There were also interesting studies on the social organization of labor, the budgeting of time in work and leisure activities (S. G. Strumilin), population dynamics, rural and urban ways of life (A. I. Todorsky, V. E. Kabo), marriage and sexual behavior, social psychology (V. M. Bekhterev), social medicine, and other topics. All this research was finished by the early 1930s.

The Stalinist totalitarian system was incompatible with any kind of social criticism, problem-oriented thinking, or empirical research. Most creative original thinkers were liquidated, and their

books were prohibited. Sociology was declared “bourgeois pseudo-science.” Official social statistics were kept secret or falsified. Empirical research that relied on questionnaires, participant observation, and similar methods was forbidden. All social theory was reduced to the official dogmatic version of historical materialism, which had very little in common with genuine Marxist dialectics. Practically no firsthand information about Western sociology was available.

The revival of sociology in the Soviet Union began during the Khrushchev’s era in the late 1950s. It was initiated by a group of young philosophers and economists with a liberal political orientation. This intellectual initiative received support from reformist and technocratically oriented people in the party and state leadership. The first organizational step in this direction was the establishment in 1958 of the Soviet Sociological Association (SSA). The primary aim of this move was to facilitate participation in international sociological congresses by Soviet ideological bureaucrats in administrative academic positions. Gradually, thanks to personal efforts of Gennady Ossipov, among others, the SSA became a sort of organizational center for the emerging discipline.

To avoid conflicts with the dominant ideology, it was unanimously agreed that the only acceptable “scientific” general sociological theory was Marxist historical materialism but that it should be supplemented by “concrete social research” and eventually some middle-range theories. In 1960 Ossipov organized in the Institute of Philosophy of the USSR Academy of Sciences in Moscow a small unit for research on the new forms of work and daily life. This unit later was transformed into the Department of Concrete Social Research. At about the same time, Vladimir Iadov organized, within the philosophical faculty of Leningrad State University, the Laboratory of Concrete Social Research, which was dedicated to the study of job orientation and workers’ personalities. At the Novosibirsk Institute of Industrial Economics and Organization, Vladimir Shubkin developed a unit for studies of youth issues, including high school children’s professional orientations and social mobility, and Tatiana Zaslavskaiia initiated the fields of economic and rural sociology. Sociology research units appeared under various names at the universities of Sverdlovsk and Tartu (Estonia). In 1968, the independent Institute of Concrete So-

cial Research of the USSR Academy of Sciences was established in Moscow, headed by the eminent economist and vice-president of the USSR Academy of Sciences A. M. Rumiantsev.

According to Shlapentokh (1987), 1965–1972 were the golden years of Soviet sociology. Important original research was done on workers’ attitudes toward their jobs and on the interrelationship of work and personality (Iadov et al. 1970), professional orientations of youth, rural sociology and population migrations (Zaslavskaiia 1970; Zaslavskaiia and Ryvkina 1980; Arutiunian 1971), public opinion and mass media (Grushin 1967; Shlapentokh 1970), industrial sociology (Shkaratan 1978), marriage and the family (Kharchev 1964), personality (Kon 1967), leisure (Gordon and Klopov 1972), political institutions (F. M. Burlatsky, A. A. Galkin), and other topics. At the same time, research on the history of sociology had begun, and a dialogue with Western theoretical ideas instead of a blunt ideological denunciation of everything “non-Marxist” was initiated (Andreeva 1965; Kon Zamoshkin 1966). In theoretical terms, structural functionalism, symbolic interactionism, and C. Wright Mills’s “new sociology” were of particular interest to Soviet sociologists. The American Sociological Association aided these developments by arranging to send professional books and journals to the Soviet Union. In the 1960s, a few Western sociological books and textbooks, beginning with *Modern Sociological Theory in Continuity and Change* edited by H. Becker and A. Boskoff, were translated and published in Russian.

The social and intellectual situation of Soviet sociology was very uncertain. It was completely dependent on the official ideology and the goodwill of party authorities. Even a hint of social criticism was deemed dangerous, and such work could be published only if it was formulated in the ESOPs language. The Institute of Concrete Social Research was under constant attack. Especially devastating and venomous was an attack on Levada’s *Lectures on Sociology* (1969); soon after the attack, Levada was dismissed from Moscow University and deprived of a professorial title. In 1972, the liberal head of the Institute, A. M. Rumiantsev, was replaced by the reactionary Mikhail Rutkevich, who had initiated an ideological campaign against “Western influences.” As a result of his policies, the most prominent and qualified scholars were forced to leave the institute.

Until 1986, Soviet sociology was in bad shape, but the process of its institutionalization continued. It was a period of extensive growth of sociological units. Many new laboratories and departments of applied social research in the universities and sociological and social psychological laboratories in the big industrial plants had been established. Industrial sociologists (the most numerous and active group in the SSA) studied motivation to work, trends in the workforce, the efficiency of different forms of labor organization, in-group relations between workers and employers, and systems of management. The managers, who pretended to be "progressive," elaborated and reported to the party authorities "the plans of social developments" based on sociological studies (later, some of these industrial sociologists were able to consult the new post-soviet businessmen).

In 1972, the Institute of Concrete Social Research was renamed the Institute for Sociological Research. In 1974, the first professional journal, *Sotsiologicheskie Issledovania (Sociological Research)*, was inaugurated (the first editor in chief was Anatoly Kharchev). SSA membership grew continuously. In the late 1980s, the SSA had about 8,500 individual and 300 collective members and twenty-one regional branches. The technical and statistical level of sociological research in the 1970s and 1980s improved considerably. Some new sociological subdisciplines emerged. At its apogee, before the collapse of the Soviet Union, the SSA had thirty-eight specialized sections, including twelve research committees, directly connected with the respective International Sociological Association (ISA) committees. The geography of sociological research centers has also expanded.

The general intellectual and theoretical level of Soviet sociology was, with few exceptions, inadequate. Relatively free theoretical reflection was limited to the marginal fields of social psychology, anthropology, and history. Most sociological research was done on the micro level and involved separate industrial plants, without any attempt at broad theoretical generalization. Publications of a more general character were mostly apologies for the so-called real socialism. Sociological theories were divided between historical materialism and dogmatic ideological scholasticism, "the theory of scientific communism." Attempts to narrow the gap between sociological statements and social realities were ruthlessly punished by the authori-

ties. The Leningrad sociological school, perhaps the best in the country, was decimated by the local party leadership in the mid-1980s. Zaslavskaja was in serious trouble when her report, which was highly critical of the prospects for economic reforms without parallel political changes, was published in the West. The public image of sociology had changed dramatically: In the 1960s, the new discipline was associated in the public's mind with social criticism and progressive economic reforms, and in the late 1970s, industrial sociologists sometimes were represented in the mass media as sly manipulators helping plant managers play down workers' discontent.

Perestroika and glasnost drastically changed the place of sociology in Soviet society. Mikhail Gorbachev and his team claimed that they needed an objective social science for information and advice, and the majority of Soviet sociologists were, from the beginning, strong supporters of reforms. In 1986, Zaslavskaja was elected president of the SSA. In 1987, a special resolution of the Communist Party Central Committee acknowledged that sociology was an important scientific discipline. In 1988, the Institute of Sociological Research was transformed into the Institute of Sociology, and V. Iadov was appointed its director. Sociologists (for example, Galina Starovoitova) took an active part in political life not only as advisers to the government but as deputies of central and local soviets and, after 1991, the post-Soviet parliaments of independent states. There were no longer official restrictions on the topics suitable for sociological research, and the publication of results became much easier. Some newspapers introduced regular sociological columns.

However, the relationship between sociology and political power is always problematic. On the one hand, neither Gorbachev nor Boris Yeltsin really needed or followed sociological advice. Very often, they did the opposite of what they have been advised to do. For example, Gorbachev's catastrophic antialcohol campaign, which was the first irreparable blow to the state budget and created the first wave of organized crime, was initiated despite strong and unanimous objections from social scientists. While making his fatal decisions about the Chechen war, Yeltsin completely ignored professional opinions. These experiences made sociologists more critical of the regime.

On the other hand, sociologists have been neither intellectually nor morally ready for new social responsibilities. The lack of a sociological imagination and their predominantly functionalist or empiricist mentality made them more comfortable with post hoc explanations of events than with responsible and reliable predictions. Social scientists are always more sure about what should not be done than about what to do, and Soviet sociology had never had a unified professional body.

By 1991 but especially after 1993, there was a deep political and intellectual schism in the former Soviet sociology. The majority of its founders remained faithful to liberal, democratic, and pro-Western ideas. However, liberal politicians, they often did not know how to apply those general principles to particular Russian, Ukrainian, or other situations. On the contrary, the former "scientific communists," who declared themselves sociologists or politologists after 1991 and who hold now many if not most university chairs, proclaim their fidelity to Marxism-Leninism, often with a strong flavor of Russian nationalism, traditionalism, and religious orthodoxy. The gap between these two wings is irreconcilable, and that gap has many organizational, ideological, and educational implications.

In the 1990s, there were essential changes in the institutional structure of sociological communities in all the post-Soviet states as well as in areas of research. To replace the SSA, several national, republican sociological associations have been formed. Sometimes there are more than one sociological association in the same country. Alongside the national Sociological Association of Russia (Russian Sociological Society), which is a collective member of the ISA, Ossipov organized an alternative Association of Sociologists and Demographers; he also initiated the split in the Institute of Sociology (IS) of RAS and created in the framework of RAS a new Institute of Social and Political Problems (ISPP), that became one of the main intellectual centers of communist and nationalist opposition to reforms. The coexistence of the two centers is by no means peaceful.

The main research projects of the IS include the theory and history of the discipline, quantitative and qualitative methodology, social stratification, sociocultural processes in Russia in the context of global social and economic changes, changes

in personality, social identities and new forms of solidarities, economic and political elites, environmental studies, family and gender, social organizations, and social conflicts. The IS has an affiliation in St. Petersburg (director Serguei Golod). The IS is also combining research with teaching undergraduates and postgraduate students. The European University in St. Petersburg (rector Boris Firsov), has departments of history, political sciences, and sociology.

Fundamental sociological research is also being done in other academic institutions and universities, such as those in Novosibirsk (rural and regional sociology), Samara (sociology of labor), and Nizni Novgorod (stratification and regional studies). Research on interethnic relationships and conflicts is concentrated in the Institute of Ethnology and Anthropology of the RAS; population and gender studies are conducted in the Institute for Social-Economic Studies of Population, and so on. Many sociological groups and centers are moving from one academic institute to another or becoming fully independent, especially if they can make money by doing applied research.

Public opinion and market surveys centers became independent enterprises, some of which were united in the Russian Guild of Pollsters and Marketing Researchers. The All-Russian Public Opinion Research Center (directed by Yuri Levada) is a leading national center for public opinion polls; among many others, the Independent Public Opinion Research Service *Vox Populi* (VP), founded by Boris Grushin, and *Obshechestvennoe mnenie* (the Foundation of Public Opinion polls) are the most visible. Many sociologists are working as political image makers, speechwriters, economic consultants, and so on.

Sociology is now an institutionalized discipline in Baltic states, Armenia, Georgia, Kazakhstan, Uzbekistan, Belarus, and Ukraine. Especially visible progress in research and teaching sociology has occurred in Estonia and Ukraine. In the Soviet Union, Estonia was one of the few places where Western traditions of sociology were known and maintained. Since 1991, the main focus of sociological research in Estonia has been the empirical description and theoretical interpretation of the rapid social changes taking place in all spheres of society. The main traditional branches of Estonian sociology were social structure and stratification

(M. Titma, E. Saar); family and living conditions (Narusk 1995); the environment (M. Heidmets, Y. Kruusvall); urban sociology (M. Pavelson, K. Paadam), the mass media; youth; and education (P. Kenkmann). New situations have stimulated theoretical analyses of transitional processes (Lauristin and Vihalemm 1997) and explorations of new areas of research, such as the integration of the Russophone minority in Estonian society, poverty and social deprivation, political sociology, and public opinion research. In the second half of the 1990s, the dominant theoretical paradigm of social research in Estonia shifted from traditional structural functionalism to social constructivism. The main centers of sociological research in Estonia are the University of Tartu, the Pedagogical University of Tallinn, and the Institute for International and Social Studies in Tallinn.

In 1991, the Institute of Sociology of the Academy of Sciences of Ukraine and the first independent research center, the Kiev International Institute of Sociology, were founded. Together with the universities of Kiev, Kharkiv, Lviv, and Odessa, these Institutes have become centers of the development of sociological science in Ukraine. The basic topics of studies are social transformations and change (E. Golorakha, V. Khmelko, O. Kutsenko, E. Yakuba), economic and political sociology (I. Bekestina, N. Panina), ethnosociology, (N. Chernysh, M. Shulga, and B. Yertukh) sociology of mass consciousness (N. Kostenko, V. Ossorskiy, I. Popora), social psychology, relationships between social structures and personality under conditions of radical social change, the sociology of the Chernobyl catastrophe, and gender studies. In 1992, the Sociological Association of Ukraine was reorganized as an independent national association. Since 1993, the preparation of sociologists, using the programs and textbooks of Western universities, began at the oldest university in eastern Europe, Kiev-Mohyla Academy (founded in 1632). The academic journal *Sociology: Theory, Methods, Marketing* began to be issued in Ukrainian (1998) and Russian (1999).

The main problem confronting Russian sociology is the shortage of money and professional personnel. Until 1989 in the Soviet Union, there was practically no undergraduate sociological education; only a few courses in applied (mainly industrial) sociology were offered. Now sociological departments and schools have established in Mos-

cow, Saint Petersburg, Novosibirsk, Ekaterinburg, and some other state universities, and there are about two hundred departments of sociology and political science in other colleges. The Russian Ministry of Higher Education issued the "State Standard" in sociology, which prescribed teaching the discipline as a multitheoretical one, not merely Marxist-oriented. Up-to-date methods of teaching sociology are provided by new educational centers: the Moscow School of Social and Economic Sciences, the European University in Saint Petersburg, the Faculty of Sociology of the Academic Institute of Sociology, and the High School of Economics in Moscow. According to the official statistics, in 1998 more than 6,600 university students studied sociology as their main subject. The discipline is taught also in many high schools and lyceums. With the financial support of different foundations (George Soros is the leading donor), sociological classics, world-recognized modern authors (P. Bourdieu, Z. Bauman, A. Giddens, Y. Habermas, and many others) and teaching materials (handbooks and readers) have been published. New professional journals, including *The Russian Public Opinion Monitor* (edited by T. Zaslavskaja and Y. Levada), *Sociological Journal* (edited by G. Batygin), *Sociology-4M: Methodology, Methods, Mathematical Models* (edited by V. Iadov); *The World of Russia* (edited by O. Shkaratan), have been published. In Russia, the Baltic states, and Ukraine, there are summer schools and advanced courses in theory and subdisciplines of sociology for young teachers and postgraduates where internationally renowned scholars lecture. The exchange of graduate students in sociology between post-Soviet, U.S., and west European universities is growing rapidly. Prominent Western sociologists are invited regularly to give lectures and seminars at Russian and other independent state universities and vice versa.

Post-Soviet sociology is now ideologically and organizationally open and interested in international contacts and exchanges on all levels. There are many joint research projects with American, Canadian, German, French, Finnish, Japanese, and other scholars. Most of these projects are related to current political attitudes and value orientations, ethnic relations and regional studies, stratification, personality studies, social minorities, organizational culture, and modernization. The annual international symposia "Where Is Russia going?" are organized by the Independent Mos-

cow School of Economics and Political Sciences (T. Shanin and T. Zaslavskaja).

High-level studies are being conducted on the problems of the economic and political elites (Kryshtanovskaja 1997), environmental sociology (Yanitsky 1993), gender and life stories (Semenova and Foteeva 1996), political sociology (Zdravomyslova 1998), and the sociology of culture (Ionin 1996). Some of these projects are the result of academic international cooperation, while others are financed by charity funds the State foundation for humanities (John D. and Catherine T. MacArthur Foundation, Open Society Institute, Ford Foundation, and others), and voluntary associations.

The prospects for the development of post-Soviet sociology depend on the fate of economic and democratic transformations. The gigantic social experiment unfolding in the post-Soviet region needs creative support from the social sciences. It is a powerful stimulus for sociological imagination and theory construction. Today sociologists in these countries are overburdened by the need to search for immediate practical solutions to urgent political and economic issues and have no time for quiet theoretical reflection. The most important sociological contributions to reforms are still the public opinion polls and information about current social processes. The next step seems to be the emergence of a sociology of social problems interpreted not only in the specific national contexts but in the context of the global problems of civilization as well. This, may lead to the revival of historical and comparative macrosociology and produce new theoretical insights. All this will be feasible, however, only as the result of intensive international and interdisciplinary intellectual cooperation.

SPORT

People in all cultures have always engaged in playful physical activities and used human movement as part of their everyday routines and collective rituals (Huizinga 1955). The first examples of organized games in societies worldwide probably emerged in the form of various combinations of physical activities and religious rituals (Guttman 1978). Those games were connected closely with the social structures, social relations, and belief systems in their societies. Although they often recreated and reaffirmed existing systems of power relations and dominant ideologies, they sometimes served as sites for resistant or oppositional behaviors (Guttman 1994; Sage 1998). Variations in the forms and dynamics of physical activities and games indicate that they are cultural practices that serve different social purposes and take on different meanings from time to time and place to place. Research on these variations has provided valuable insights into social processes, structures, and ideologies (Gruneau 1999; Sage 1998).

The physical activities that most sociologists identify as "modern sports" emerged in connection with a combination of rationalization, industrialization, democratization, and urbanization processes in the eighteenth and nineteenth centuries. As various forms of physical activities and play were constructed as institutionalized, competitive, rule-governed challenges and games, they became associated with a range of processes and structures in societies. To varying degrees in different settings, "organized sports" were implicated in processes of social development and the structure of family life, socialization and education, identity

formation and government policy, commodification and the economy, and globalization and the media. Today, sports constitute a significant part of the social, cultural, political, and economic fabric of most societies.

As cultural practices, organized sports constitute an increasingly important part of people's lives and collective life in groups, organizations, communities, and societies. In addition to capturing individual and collective attention, they are implicated in power relations and ideological formation associated with social class, gender, race and ethnicity, sexuality, and physical ability. Because sports are social constructions, they may develop around particular ideas about the body and human nature, how people should relate to one another, expression and competence, human abilities and potential, manhood and womanhood, and what is important and unimportant in life. These ideas usually support and reproduce the dominant ideology in a society, but this is not always the case. Ideology is complex; therefore, the relationship between sports and ideological formation and transformation is sometimes inconsistent or even contradictory. Furthermore, sports come in many forms, and those forms can have many different associated social meanings.

Although sports continue to exist for the enjoyment of the participants, commercialized forms are planned, promoted, and presented for the entertainment of vast numbers of spectators. Sport events such as the Olympic Games, soccer's World Cup (men's and women's), the Tour de France, the tennis championships at Wimbledon, American football's Super Bowl, and championship boxing bouts capture the interest of billions of people when they are televised by satellite in over 200 countries around the world. These and other formally organized sports events are national and global industries. They are implicated in processes of state formation and capitalist expansion and are organized and presented as consumer activities for both participants and spectators. Although sport programs, events, and organizations may be subsidized directly or indirectly by local or national governments, support increasingly comes from corporations eager to associate their products and images with cultural activities and events that are a primary source of pleasure for people all over the world. Corporate executives have come to realize, as did Gramsci (1971) when he discussed

hegemony and consensus-generating processes, that sponsoring people's pleasures can be crucial in creating a consensus to support corporate expansion. At the same time, most sport organizations have sought corporate support.

People of all ages connect with sports through the media. Newspapers in many cities devote entire sections of their daily editions to sports, especially in North America, where the space devoted to sports frequently surpasses that given to the economy, politics, or any other single topic of interest (Lever and Wheeler 1993). Major magazines and dozens of specialty magazines cater to a wide range of interests among participants and fans. Radio coverage of sporting events and sports talk shows capture the attention of millions of listeners every day in some countries. Television coverage of sports, together with commentary about sports, is the most prevalent category of video programming in many countries. First the transistor radio and more recently satellites and Internet technology have enabled millions of people around the world to share their interest in sports. As Internet technology expands, these media-facilitated connections that revolve around sports will take new forms with unpredictable social implications.

Worldwide, many people recognize high-profile teams and athletes, and this recognition fuels everything from product consumption to tourism. Sports images are a pervasive part of life in many cultures, and the attention given to certain athletes today has turned them into celebrities, if not cultural heroes. In cultures in which there have been assumed connections between participation in sports and character formation, there has been a tendency to expect highly visible and popular athletes to become role models of dominant values and lifestyles, especially for impressionable young people. This has created a paradoxical situation in which athletes often are held to a higher degree of moral accountability than are other celebrities while at the same time being permitted or led to assume permission to act in ways that go beyond traditional normative boundaries.

People around the world increasingly talk about sports. Relationships often revolve around sports, especially among men but also among a growing number of women. Some people identify with teams and athletes so closely that what happens in

sports influences their moods and overall sense of well-being. In fact, people's identities as athletes and fans may be more important to them than their identities related to education, religion, work, and family.

Overall, sports and sports images have become a pervasive part of people's everyday lives, especially among those who live in countries where resources are relatively plentiful and the media are widespread. For this reason, sports are logical topics for the attention of sociologists and others concerned with social life.

USING SOCIOLOGY TO STUDY SPORTS

Although play and games received attention from various European and North American behavioral and social scientists between the 1880s and the middle of the 20th century, sports received scarce attention in that period (Loy and Kenyon 1969). Of course, there were notable exceptions. Thorstein Veblen wrote about college sports in the United States in 1899 in *Theory of the Leisure Class*. Max Weber mentioned English Puritan opposition to sports in the 1904 and 1905 volumes of *The Protestant Ethic and the Spirit of Capitalism*, and William Graham Sumner discussed "popular sports" in his 1906 *Folkways*. Willard Waller devoted attention to the "integrative functions" of sports in U.S. high schools in *The Sociology of Teaching* in 1932.

The first analyst to refer to a "sociology of sport" was Theodor Adorno's student Heinz Risse, who published *Sociologie des Sports* in 1921. Sports received little or no further analytic attention from social scientists until after World War II. Then, in the mid-1950s, there was a slow but steady accumulation of analyses of sports done by scholars in Europe and North America (Loy and Kenyon 1969; Dunning 1971).

The origins of the sociology of sport can be traced to both sociology and physical education (Ingham and Donnelly 1997; Sage 1997). The field initially was institutionalized in academic terms through the formation of the International Committee for Sport Sociology (ICSS) and the publication of the *International Review for Sport Sociology* (IRSS) in the mid-1960s. The ICSS was a subcommittee of the International Council of Sport Science and Physical Education and the International Sociological Association, and it sponsored the publi-

cation of the IRSS. Other publications in the 1960s and 1970s provided examples of the research and conceptual issues discussed by scholars who claimed an affiliation with the sociology of sport (Kenyon 1969; Krotee 1979; Lüschen 1970). In addition to meeting at the annual conferences of the ICSS beginning in the mid-1960s, many scholars in the sociology of sport also met at the annual conferences of the North American Society for the Sociology of Sport (NASSS). This organization was founded in 1978. It has sponsored conferences every year since then, and its membership has been as high as 326 in 1998. In 1984, the *Sociology of Sport Journal* was published under the sponsorship of the NASSS.

Although the sociology of sport involves scholars from many countries and has its foundations in traditional academic disciplines, its early growth was fueled partly by the radical and reform-oriented work of social activists trained in a variety of social sciences. That work attracted the attention of a number of young scholars in both sociology and physical education. For example, in U.S. universities, many courses devoted to the analysis of sport in society in the 1970s highlighted sport as a social institution, but many also used sports as a focal point for critical analyses of U.S. society as a whole. Objections to the war in Vietnam inspired analyses of autocratic and militaristic forms of social organization in sports and other spheres of social life. Critiques of capitalism were tied to research on the role of competition in social life and the rise of highly competitive youth and interscholastic sports. Concern with high rates of aggression and violence in society was tied to an analysis of contact sports that emphasize the physical domination of opponents. Analyses of racial and civil rights issues were tied to discussions of racism in sports and to issues that precipitated the boycott of the 1968 Mexico City Olympic Games by some black American athletes (Edwards 1969). Analyses of gender relations were inspired by the widespread failure of U.S. high schools and universities to comply with Title IX legislation that, among other things, mandated gender equity in all sport programs sponsored by schools that received federal funds.

Today, those who are dedicated to studying sports as social and cultural phenomena constitute a small but active, diverse, and steadily expanding collection of scholars from sociology, physical edu-

cation and kinesiology, sport studies, and cultural studies departments. This has made the field unique because many of these scholars have realized that to maintain the field they must engage each other despite differences in the research questions they ask and the theoretical perspectives and methodologies they use.

Mainstream sociology has been slow at the institutional level to acknowledge the growing social and cultural significance of sports and sports participation. The tendency among sociologists to give priority to studies of work over studies of play, sports, or leisure accounts for much of this disciplinary inertia. Furthermore, sports have been seen by many sociologists as nonserious, nonproductive dimensions of society and culture that do not merit scholarly attention. Consequently, the sociology of sport has continued to exist on the fringes of sociology, and studying sports generally does not forward to a scholar's career in sociology departments. For example, in 1998–1999, only 149 (1.3 percent) of the 11,247 members of the American Sociological Association (ASA) declared "Leisure/Sport/Recreation" as one of their three major areas of interest, and over half those scholars focused primarily on leisure rather than sports. Only thirty-seven ASA members identified "Leisure/Sports Recreation" as their primary research and/or teaching topic (0.3 percent of ASA members), and only two Canadian and two U.S. sociology departments offer a graduate program in the sociology of sport, according to the 1998 Guide to Graduate Departments of Sociology. At the 1998 annual ASA meeting, there were approximately 3,800 presenters and copresenters, and only 20 dealt with sport-related topics in their presentations; only 2 of the 525 sessions were devoted to the sociology of sport. Patterns are similar in Canada, Great Britain, and Australia (Rowe et al. 1997).

In physical education and kinesiology, the primary focus of most scholars has been on motor learning, exercise physiology, biomechanics, and physical performance rather than the social dimensions of sports (see Sage 1997). Social and cultural issues have not been given a high priority in the discipline except when research has had practical implications for those who teach physical education, coach athletes, or administer sport programs. As the legitimacy and role of physical education departments have been questioned in many

universities, the scholars in those departments have been slow to embrace the frequently critical analyses of sports done by those who use sociological theories and perspectives. Therefore, studying sports as social phenomena has not earned many scholars high status among their peers in physical education and kinesiology departments. However, the majority of sociology of sport scholars with doctorates have earned their degrees and now have options in departments of physical education or kinesiology and departments of sport studies and human movement studies.

There have been noteworthy indications of change. For example, there are a number of journals devoted to social analyses of sports (*Sociology of Sport Journal*, *International Review for the Sociology of Sport*, *Journal of Sport & Social Issues*, *Culture, Sport, Society*). Many mainstream journals in sociology and physical education now accept and publish research that uses sociological perspectives to study sports. National and regional professional associations in sociology and physical education in many countries sponsor regular sessions in the sociology of sport at their annual conferences. Annual conferences also are held by a number of national and regional sociology of sport associations around the world, including those in Japan, Korea, and Brazil as well as the countries of North America and Europe. The International Sociology of Sport Association (ISSA, formerly the ICSS) holds annual conferences and meets regularly with the International Sociological Association. Attendance at many of these conferences has been consistent, and the quality of the programs has been impressive. The existence of such organizational endorsement and support, along with continued growth in the pervasiveness and visibility of sports in society, suggests that the discipline will continue to grow.

Among other indications of growth, articles in the *Sociology of Sport Journal* are cited regularly in social science literature. Scholars in the field are recognized as “public intellectuals” by journalists and reporters associated with the mass media. Quotes and references to sociology of sport research appear increasingly in the popular print and electronic media. Amazon.com, the world’s major Internet bookseller, listed over 260 books in its “Sociology of Sport” reference category in March 1999. Most important, major publishers such as McGraw-Hill estimate that every year nearly

30,000 university students take courses in the “sport in society” category.

Complicating the issue of future growth is the fact that scholars in this field regularly disagree about how to “do” the sociology of sport. Some prefer to see themselves as scientific experts who do research on questions of organization and efficiency, while others prefer to see themselves as facilitators or even agents of cultural transformation whose research gives a voice to and empowers people who lack resources or have been pushed to the margins of society. This and other disagreements raise important questions about the production and use of scientific knowledge, and many scholars in the sociology of sport are debating those questions. As in sociology as a whole, the sociology of sport is now a site for theoretical and paradigmatic debates that some scholars fear will fragment the field and subvert the maintenance of an institutionalized professional community (Ingham and Donnelly 1997). Of course, this is a challenge faced in many disciplines and their associated professional organizations.

CONCEPTUAL AND THEORETICAL ISSUES

Through the mid-1980s, most research in the sociology of sport was based on two assumptions. First, sport was assumed to be a social institution similar to other major social institutions (Lüschen and Sage 1981). Second, sports were assumed to be institutionalized competitive activities that involve physical exertion and the use of physical skills by individuals motivated by a combination of personal enjoyment and external rewards (Coakley 1990). These conceptual assumptions identified the focus of the sociology of sport and placed theory and research on sports within the traditional parameters of sociological theory and research.

Theory and research based on these assumptions were informative. However, many scholars in the field came to realize that when analytic attention is focused on institutionalized and competitive activities, there is a tendency to overlook the lives of people who have neither the resources to formally organize their physical activities nor the desire to make them competitive. Scholars became sensitive to the possibility that this tendency can reinforce the ideologies and forms of social organization that have disadvantaged certain categories and collections of people in contemporary

societies (Coakley 1998). This encouraged some scholars to ask critical questions about sports as contested activities in societies. Consequently, their research has come to focus more on the connections between sports and systems of power and privilege and the changes needed to involve more people in the determination of what sports can and should be in society.

These scholars used an alternative approach to defining sports that revolved around two questions: What gets to count as a sport in a group or society? and Whose sports count the most? These questions forced them to focus more directly on the social and cultural contexts in which ideas are formed about physical activities and the social processes that privilege some forms of physical activities. Those who have used this approach also note numerous cultural differences in how people identify sports and include them in their lives. In cultures that emphasize cooperative relationships, the idea that people should compete for rewards may be defined as disruptive, if not immoral, and for people in cultures that emphasize competition, physical activities and games that have no winners may seem pointless. These cultural differences are important because there is no universal agreement about the meaning, purpose, and organization of sports. Similarly, there is no general agreement about who will participate in sports, the circumstances in which participation will occur, or who will sponsor sports or the reasons for sponsorship. It is now assumed widely by scholars who study sports that these factors have varied over time from group to group and society to society and that sociological research should focus on the struggle over whose ideas about sports become dominant at any particular time in particular groups or societies. This in turn has highlighted issues of culture and power relations in theory and research in the sociology of sport.

Before the mid-1980s, most research and conceptual discussions in the sociology of sport were inspired or informed by structural functionalist theories and conflict theories (Lüschen and Sage 1981; Coakley 1990), and in parts of western Europe, figurational sociology was used by some scholars who studied sports (see Dunning 1992). Those with structural functionalist perspectives often focused on questions about sports and issues of socialization and character development, social integration, achievement motivation, and struc-

tural adaptations to change in society. The connections between sports and other major social institutions and between sports and the satisfaction of social system needs were the major topics of concern.

Those who used conflict theories viewed sports as an expression of class conflict and market forces and a structure linked to societal and state institutions. Their work was inspired by various interpretations of Marxist theory and research focused generally on connections between capitalist forms of production and consumption and social behaviors in sports and on the ways in which sports promote an ideological consciousness that is consistent with the needs and interests of capital. Specifically, they studied the role of sports in processes of alienation, capitalist expansion, nationalism and militarism, and racism and sexism (Brohm 1978; Hoch 1972).

Figurational, or “process,” sociology was and continues to be inspired by the work of Elias (Elias 1978; Elias and Dunning 1986; Jarvie and Maguire 1994). Figurational sociologists have focused on issues of interdependence and interaction in social life and have identified historical linkages between the structure of interpersonal conduct and the overall structure of society. Unlike other theoretical approaches, figurational sociology traditionally has given a high priority to the study of sport. Figurational analyses have emphasized sports as a sphere of social life in which the dichotomies between seriousness and pleasure, work and leisure, economic and noneconomic phenomena, and mind and body can be shown to be false and misleading. Before the mid-1980s, research done by figurational sociologists focused primarily on the historical development of modern sport and the interrelated historical processes of state formation, functional democratization, and expanding networks of international interdependencies. Their best known early work focused on linkages between the emergence of modern sports and the dynamics of civilizing processes, especially those associated with the control of violence in society (Elias and Dunning 1986).

Since the mid-1980s, the sociology of sport has been characterized by theoretical and methodological diversity. Fewer scholars use general theories of social life such as structural functionalism

and conflict theories. The theories more often used are various forms of critical theories, including feminist theories and hegemony theory; also used are interpretive sociology (especially symbolic interactionism), cultural studies perspectives, and various forms of poststructuralism (Rail 1998). Figurational sociology still is widely used, especially by scholars outside North America. A few scholars have done research informed by the reflexive sociology of Pierre Bourdieu (Laberge and Sankoff 1988; Wacquant 1995a, 1995b) and the structuration theory of Anthony Giddens (Gruneau 1999).

Methodological approaches also vary. Quantitative data and statistical analyses remain popular, although various qualitative methods and interpretive analyses have become increasingly popular, if not the dominant research approaches in the field (Donnelly 2000). Ethnography and in-depth interviewing, along with textual and discourse analysis, have emerged as common methodologies among many scholars studying sports and sport participation (Coakley and Donnelly 1999). Quantitative methods have been used most often to study issues and questions related to sport participation patterns, the attitudinal and behavioral correlates of participation, and the distribution of sports-related resources in society. Both quantitative and interpretive methods have been used to study questions and issues related to socialization, identity, sexuality, subcultures, the body, pain and injury, disability, deviance, violence, emotions, the media, gender relations, homophobia, race and ethnic relations, new and alternative sports forms, and ideological formation and transformation (Coakley and Dunning 2000).

FINAL NOTE

Sociologists study sports because they are prominent and socially significant cultural practices in contemporary societies. The sociology of sport contains an active, diverse, and slowly expanding collection of scholars united by professional organizations and academic journals. Continued growth of the field depends on whether these scholars continue to do research that makes meaningful contributions to the way people live their lives and recognized and visible contributions to knowledge in sociology as a whole.

STANDARDIZATION

Standardization is a technique used in comparing indicators from two or more populations. The goal of the standardization procedure is to control for compositional differences between these groups that may influence the indicator that is being examined. This method allows a researcher to determine the extent to which differences in the rates of events between populations are due to differences in population characteristics. Often sociologists ask questions, that require comparisons between groups of people: Which city has a

higher crime rate? Which country has lower mortality? Which ethnic group is more likely to coreside with elderly family members? In making these comparisons, one usually calculates a summary measure: crimes per capita, crude death rate, or the proportion of elders living with family members. However, any two groups of people are likely to differ along several dimensions, such as age, educational level, race, and income. These dimensions, or factors, also may be related to the event being explored. As a result, the summary measure to some extent reflects the compositional differences in the groups being studied.

Standardization historically has been a central aspect of demographic methods (Bogue 1969; Hinde 1998; Murdock and Ellis 1991; Shryock and Siegel 1980), but its importance extends beyond that use to a way of thinking about summary or aggregate measures. While offering the advantage of conciseness, aggregate measures mask underlying compositional differences, and the use of standardization represents an acknowledgment that population characteristics influence the rate at which events occur in a population. Summary indicators are very useful; they provide a single number for comparison rather than a whole series of numbers, and they are easily calculated. However, comparisons among population groups or among subgroups in a population should account for the differing compositional makeup of those groups. Demographers have been led to standardization for several reasons. First, there is a natural desire to make comparisons between groups along demographic indicators: crude death rates, crude birthrates, marriage rates, and employment, among others. Standardization allows these comparisons to reflect differences in the underlying processes, rather than being confounded by the effects of composition. Standardization procedures can accommodate the effects of a single factor or many factors, leaving the technique bounded only by the available data. Standardization also allows the estimation of indicators for groups for which data are incomplete or of poor quality.

Many demographic measures are affected by the composition of the population, particularly the age distribution. Age composition is especially critical in considering crude death rates, since mortality rates have a very distinctive age-specific pattern: high at very young and very old ages.

Populations with a large proportion of persons in those age groups experience a large number of deaths, regardless of age-specific rates of mortality. Two populations with identical sets of age-specific rates of mortality but different age distributions will have different crude death rates. The removal of the “interference” of age distribution from the summary measure—the crude death rate—is the goal of the standardization procedure. In the rest of this article, the standardization procedure will be explained using mortality rates, and then several other examples of standardization will be presented.

The first step in a comparison is to calculate a crude rate or proportion. Crude rates or proportions are calculated by the formula

$$CR = \frac{E}{P} \quad (1)$$

where E refers to the number of events of interest in the population during the time period and P refers to the population during that period. If the population is measured at the middle of the year and the events occur throughout the year, this proportion can be interpreted as a rate. In cases where this proportion is small, for instance, mortality rates, the crude rate commonly is multiplied by 1,000 and reported as the number of events per 1,000 people.

Crude rates or proportions are used to represent a variety of characteristics of a population. These rates have an advantage over a comparison of absolute numbers, since they account for differences in size between two populations. Obviously, in a comparison of the annual number of homicides in Chicago versus that in Seattle, one must account for the fact that the population of Chicago is 2.8 million people compared to about one-half million in Seattle. Similarly, comparing the number of deaths in the United States (over 2 million) to those in Sweden (about 90,000) in 1994 would be unreasonable without knowing that the population of the United States is three times that of Sweden.

Despite the advantage of crude rates over absolute numbers, crude rates are influenced by the composition of the populations being compared. If the event of interest varies by some factor and the two populations have varying levels of that

factor, the crude rates will partly reflect this compositional variation rather than only a difference in the rate at which the event is occurring. If the populations being compared are standardized with respect to the factor, any remaining difference between the crude rates can be attributed to a true difference in rates of occurrence. If the difference in the crude rate disappears, one can conclude that the compositional variation rather than a difference in the underlying rates of occurrence led to a difference in the crude of events.

To understand the rationale of standardization, it is necessary to recognize that in essence, the crude rate is a weighted average of a set of factor-specific rates, where the weights are the distribution of the factor in the population. Thinking in this manner, one can rewrite the crude rate as

$$CR = \sum \frac{e_a}{p_a} \frac{p_a}{P} \quad (2)$$

where p_a is the population in group a and e_a is the number of events occurring in group a . The sum of all e_a equals the total number of events, E , and the sum of all p_a equals the total population, P . Note that this equation has two components. The first, e_a/p_a , represents the group-specific rate of events or the group-specific proportion, which sometimes is expressed as m_a . The second component of the rate calculation, p_a/P , represents the proportion of the population in each of the a groups. These are the two series of elements needed to apply the direct standardization technique. Using this notation, the crude rate can be rewritten as

$$CR = \sum m_a \cdot \frac{p_a}{P} \quad (3)$$

When the formula for the crude rate is written in this manner, it is easy to see how the composition of the population, that is, its distribution among the a groups, affects the crude rate. If the group-specific rate m_a is high when the proportion of the population in that group, p_a/P , is large, more events will be observed in the total population than will be observed if p_a/P is small. Similarly, if m_a is small when p_a/P is small, few events will occur.

A comparison of the crude death rates in Sweden and the United States provides an example of the use of standardization. Sweden has one of the world's highest life expectancies at birth,

approximately 76 years for men and 81.4 years for women in 1994. The crude death rate of Sweden, however, was about 10.4 deaths per 1,000 in that year. In contrast, life expectancy at birth in the United States was 72.2 years for men and 78.8 years for women in 1993, and the crude death rate was about 8.6 deaths per 1,000 in that year (United Nations 1997). It seems natural to expect that the country with the longest life expectancy would also have the lowest crude death rate, so what accounts for this discrepancy? To understand the reason for this difference in the crude rates, it is necessary to observe the differing age distributions of the two populations. In the United States about 13 percent of the population is over age of 65; while in Sweden over 17 percent of people are over that age. Since death rates are highest in this age range, the larger proportion of the Swedish population in old age creates more deaths, even with lower age-specific death rates. Standardization demonstrates the extent to which these differences in age distribution account for the difference in the crude death rate.

As was mentioned above, this method of standardization—direct standardization—requires a standard population distribution and a set of factor-specific rates for the populations being studied. Direct standardization uses this standard population to calculate new standardized crude rates for the populations of interest. In this case, the population distribution of the standard population replaces the observed population distribution. Since each population's crude rate will be calculated with the same distribution, the effect of the compositional differences will be eliminated and each population will have the same composition. To apply direct standardization, the formula

$$DSR = \sum \frac{e_a^j \cdot p_a^s}{p_a^j \cdot P^s} \quad (4)$$

is used, where e_a^j represents the number of events occurring in group a in population j , p_a^j represents the population size of group a in population j , p_a^s represents the number of people in group a in the standard population s , and P^s represents the standard population. Comparing equations (2) and (4) shows the similarities. The second term in equation (2), the compositional distribution of the population of interest, p_a/P , has been replaced with the compositional distribution of the stan-

dard population, p_a^s/P^s . The first term in the crude rate calculation remains the factor-specific rate in the population of interest, population j .

Returning to the example of the United States and Sweden, using the age distribution of the United States as the standard distribution and computing a standardized crude death rate for Sweden by applying the age-specific death rates of Sweden yields a standardized crude death rate of 7.6 deaths per 1,000 for Sweden. Instead of being higher than the crude death rate in the United States, Sweden's crude death rate falls below that of the United States. At least part of the difference in the crude rates therefore is due to Sweden's older population rather than to a difference in age-specific death rates. In general, populations with a relatively old age distribution tend to have higher crude death rates than do populations with similar age-specific mortality patterns, since death rates are higher at older ages.

The data demands for direct standardization, while not overwhelming, can be difficult to meet if there is limited information on factor-specific rates in one of the populations of interest. For example, in many studies of mortality in less developed countries or in a historical perspective, information on age-specific death rates may be missing or unreliable. In these cases, an alternative method referred to as indirect standardization can be used. Indirect standardization requires knowledge only of the composition of the population and the total number of events of interest. Direct standardization involves the application of population-specific sets of rates to a standard population; conversely, indirect standardization involves the application of a standard set of rates to individual population distributions. In indirect standardization, a set of standard rates is applied to the population and the expected number of events is compared to the actual number. This standardizing ratio is estimated by the formula

$$SR = \frac{E^j}{\sum m_a^s p_a^j} \quad (5)$$

where E^j is the actual number of events in the population j , m_a^s is the factor-specific rate in the standard population s , and p_a^j is the number of people in population j who are in group a . The denominator of the ratio calculates the number of

events that would be expected in population j if the factor-specific rates of the standard population were applied to the population. When the event of interest is death, this ratio often is referred to as the standardized mortality ratio. To obtain the new indirectly standardized crude rate, this standardizing ratio is multiplied by the crude rate for the standard population:

$$ISR = SR \cdot CR^s \quad (6)$$

where CR^s is the crude rate in the standard population. These indirectly standardized crude rates then can be compared to each other. Obviously, when the standardizing ratio is greater than 1.0, the *ISR* will be larger than the crude rate for the standard population, and when the standardizing ratio is less than 1.0, the *ISR* will be smaller than the standard population's crude rate.

Indirect standardization does not control for composition as well as the direct standardization method does but should yield similar results in terms of direction and magnitude. Returning to the example of Sweden and the United States, the actual number of recorded deaths in Sweden would be greater than the observed number if U.S. age-specific death rates were applied to the Swedish population's age distribution. The resulting standardized mortality ratio would be 0.912, and when that was multiplied by the crude rate for the United States, the *ISR* for Sweden would be 7.8, very similar to the result obtained through direct standardization.

When indirect standardization is employed, there is no choice to be made about the standard population; this method is used when only one population distribution is available. The choice of the standard population for direct standardization should be considered carefully, but within reasonable bounds the choice of standard should not alter the conclusions radically. Researchers generally are interested in the direction and approximate size of differences between the groups, and these values are preserved with the choice of any of a number of reasonable standard populations. There are three general choices for the standard: use one of the populations being studied, use an average of the populations, or use a population outside those being studied. Each of these choices has advantages and disadvantages. Theoretically,

the choice of standard should be made to minimize the effects of that choice on the results.

Using one of the populations being studied eliminates the need to standardize that population and often makes the explication of comparisons easier. For instance, in comparing crime rates across several cities, choosing one city as the basis for comparison may be appropriate. When comparisons are made of a population over time, it is standard procedure to choose a distribution that is representative of the middle of the time period. For instance, in a study of mortality change between 1950 and 1990 in the United States, it would be appropriate to use the 1970 census for the standard age distribution. A drawback to using one of the study populations as the standard, however, can be that the population chosen has an unusual distribution of factors. This unusual distribution may skew the summary measures in a way that is inconsistent or difficult to interpret. Also, choosing one of the populations as a standard can carry implications that this distribution is the "ideal" or "correct" distribution and may place interpretational burdens on the results.

Using an average of the populations eliminates the problem of setting one population as the ideal and ameliorates the problem of unusual distributions. A comparison of racial differences in mortality in the United States, for example, might use the age distribution of the total U.S. population, an unweighted average of the distribution of each racial group, as the standard. This choice eliminates the assumption that any one population has a preferred distribution and allows for meaningful comparisons among groups. The use of an aggregate population as the standard is encountered frequently in comparisons of subgroups within a national population.

A third choice is to pick a population completely exogenous to the study as a standard. This choice most often involves an artificial population that is representative of a standard pattern of factor distributions. Several sources of standard populations exist. In the case of age, Coale and Demeny's (1983) set of regional model life tables contains sets of age distributions typical of a variety of mortality levels and patterns. The use of an external standard eliminates any value judgments associated with the choice of standard. An exter-

nal standard also can be chosen to minimize or eliminate extreme distributions of factors. The external standard also provides a way of comparing very diverse populations. Again, the choice of standard should match the populations being studied as closely as possible to minimize the effect of that choice on the results.

An exogenous standard also might be employed as a way to simulate the effects of a variety of changes in population composition on the crude rate. This use of the standardization technique highlights the underlying logic of the procedure by using the method to investigate the extent to which compositional changes influence aggregate comparisons. Here the technique is used as a methodological device to explore the effects of changes. For instance, a researcher might be interested in the effects on average wages of changing occupational structures among men and women. A testable hypothesis could be that as women approach men in terms of occupational distribution, the gender gap in wages will disappear. If a variety of simulated occupational structures are applied to a set of gender- and occupation-specific wage rates, the effect of occupational structure on the wage gap can be examined.

Since standardization developed in the field of demography, most applications involve the study of demographic phenomena. The example of the United States and Sweden involved comparisons of mortality rates. However, standardization is used widely in other areas as well. For example, the U.S. Census Bureau routinely reports the distribution of the American population aged 15 and older among marital states, and historical comparisons of this distribution are used to examine changes in marital behavior over time. However, the age composition of the population can greatly influence the distribution among marital states, particularly when the proportion of the population in the age range of 15 to 25 years is very large. In 1960, 65.6 percent of women aged 15 and older were married compared to 60.4 percent of similarly aged women in 1975 (United States Bureau of the Census 1976). At first glance, these comparisons seem to signal a retreat from marriage: A smaller proportion of women was married in 1975 than in 1960. However, when the age distribution of the population is standardized to the 1960 population, the proportion married in 1975 in-

creases to 63.5. While this is still a decline compared to 1960, the magnitude of the change is much less. The difference in the proportion married is due largely to a difference between 1960 and 1975 in the proportion of women just over the age of 15, the baby boomers, who were young teenage women who had not yet married.

Standardization can be used to control for characteristics other than age. Suppose, for instance, one is comparing the health status of two different groups: elderly white Americans and elderly African-Americans. If we compare the proportion of each group in poor health, we find that 34 percent of elderly whites and 50 percent of elderly African-Americans report their health as fair or poor. However, we know that health status varies by education and that the educational distributions of these two groups differ. Among elderly whites, about 12 percent have fewer than eight years of school, compared to 39 percent of elderly African-Americans. Clearly, since lower levels of education are associated with poorer health and elderly African-Americans have lower levels of educational attainment, some of the difference in observed health status between the groups can be expected to result from the different educational compositions.

It is desirable to compare these two groups without the influence of education. Using the educational distribution of the elderly white population as a standard and applying the observed education-specific rates of poor health among elderly African-Americans, one obtains an overall proportion of 42 percent in poor health, compared to the unstandardized proportion of 50 percent. Thus, if the African-American older population had an educational distribution similar to that of the more highly educated white elderly population, the expected health status of older African-Americans would improve.

Lichter and Eggebeen (1994) used standardization techniques to examine the effects of parental employment on rates of child poverty. In their work these researchers use direct standardization techniques in two different ways. In the first, they simulate the effects of a variety of assumptions about parental employment patterns on children's poverty rates. This is an illustration of using an "exogenous" or artificial population

distribution as a standard population. By changing the employment distribution of the parents of children in poverty, they determine that only modest declines in child poverty would result from increasing those levels of employment. Their second application of standardization compares the poverty rates of black children obtained by using the employment distribution of white parents as the standard to the rates directly observed. In this case, they have chosen one of the study populations as the standard and are interested in the extent to which differences in child poverty between blacks and whites are determined by factors other than parental employment distributions. They find in fact that parental employment differences among female-headed families account for a substantial portion of the observed differences in child poverty.

Standardization can control for more than one factor at a time and can be applied to more than two groups. Himes et al. (1996) standardize for age, sex, and marital status in an examination of the living arrangements of minority elderly in the United States. Living arrangements are known to be different for men and women, for married and unmarried, and for younger and older elderly. These factors—age, sex, and marital status—also are known to vary across racial and ethnic subgroups. Therefore, the observed differences in living arrangements are likely to be due in part to these underlying characteristics rather than being a reflection of differences in attitudes or beliefs. Standardization allows a comparison among groups without the influence of these compositional differences. In this research, the compositional distribution of the entire United States with respect to age, sex, and marital status was chosen as the standard. In this analysis, the standardization procedure had the greatest effect on comparisons of the African-American population and much smaller effects on the white, non-Hispanic, Hispanic, Asian, and Native American populations.

Standardization is widely used in a variety of sociological inquiries. While it originated in demographic analyses, it can be applied to a variety of questions in which a researcher wants to determine the extent to which compositional differences in population groups account for observed differences in summary measures. Standardization is also useful as a simulation technique, allow-

ing researchers to explore the effects of a variety of compositional changes on a summary indicator. Researchers should bear in mind, however, that the results of standardization are merely artificially constructed indicators; they do not represent a real population or circumstance.

CHRISTINE L. HIMES

STATE, THE

The term "state" denotes the complex of organizations, personnel, regulations, and practices through which political power is exercised in a territory. In simple societies organized as bands of families, as tribes, or as chiefdoms, political power is not separated from power relationships rooted in kinship structures or religion. Those societies also lack organizations and specialized personnel (beyond the chief) for exercising political authority

and therefore have no real states. The state emerged only with the development of more complex societies, either cities or tribal confederations, which formed the bases for city-states, monarchies, and empires. Monarchies and empires in turn have given way to liberal states, modernizing dictatorships, and one-party states as the most widespread current forms of states.

The “state” is a rather abstract term. Over time and space, the concrete organizational forms, the kinds of personnel, the specific laws and regulations, and the practices of states have varied greatly with the historical development of societies and across different cultures and regions. The modern nation-state is a very particular kind of state that developed in Europe in the eighteenth and nineteenth centuries and currently is spreading across the world (Poggi 1990). However, like other forms of the state, this organizational form is likely to have its day and then fade; already various kinds of supranational and international bodies have begun to take over some of the political power formerly monopolized by nation-states.

The basis of the state is political power. This article examines the roots of that power and then explores the various forms taken by states from their beginnings to the present day.

POLITICAL POWER

All forms of power involve the ability of powerholders to coerce others into giving up their property, their free choice of action, and even their lives. Political power, as opposed to economic power (based on money or other forms of wealth), religious power (based on relationships to transcendent forces), family power (based on sex, seniority, and kin relationships), and pure coercion (based on brute force), is rooted in the recognition of the rightful authority of the ruler (Weber 1968). That authority stems from the demands within a society for specialists with the ability to mediate and coordinate.

Any group of human beings in regular interaction among themselves is prone to conflict over possessions, decisions regarding group actions (to hunt or not, to camp here or there, to fight or flee from a threat), and individual actions that give offense (insults, injury, infidelity). In small groups,

such conflicts usually can be settled through the arbitration of respected family members or elders, but in larger groups or groups in which much interaction occurs among nonkin, those conflicts produce demands for justice that require a more broadly recognized form of mediation. Individuals who are particularly skilled at mediating such conflicts, who gain a reputation for wisdom and justice, can acquire the role of a specialist in settling conflicts. In addition, every group of human beings faces external threats from wild animals, the weather, and other human groups. Individuals who are particularly skilled at coordinating actions within a group for the purposes of attack, hunting, and defense can gain a reputation that translates into a calling as a specialist in coordinating group actions to meet threats.

The functions of mediation to produce internal justice and of coordination to deal with external threats are distinct; indeed Native American tribes sometimes had a “peace chief” and a “war chief” who specialized in those functions. Modern societies have legal-judicial systems and executive-military systems that show a similar division of functions. However, these functions tended to merge because in both cases it was necessary to have mechanisms to compel compliance with the arbitration decisions of the mediator or the action directives of the coordinator. Once a society develops regular means to compel compliance with those decisions and directives (generally armed warriors closely attached to or under the direct supervision of the mediator or coordinator), that society is on its way to developing a state. Political power is thus the authority given to a recognized leader (whether judge or general) to compel compliance with his or her decisions.

Political power, however, is a two-edged sword. On the one hand, the power of the leader must be sufficient to ensure that arbitration is enforced and that the coordination of military, hunting, or building activities is effective. The larger a society is, the more complex its economy is, the stronger its enemies are, and the more threatening and varied its environment is, the greater are the tasks facing the state. Thus, for a society to avoid turmoil and defend itself, it must grow in organizational size, complexity, and power along with the society of which it is a part. On the other hand, as the leaders acquire control of larger and richer

organizations and larger and more powerful coercive forces, there is a danger that that organizational and coercive force will be used to enrich and serve the desires of the ruler, not to meet the demands for justice and protection of the population (Mann 1986).

The history of the state is thus a history of balancing acts and often of overreaching. State rulers frequently use their organization and authority to expand their power and wealth. Some rulers invest heavily in conquest, acquiring power over new regions and peoples by brute force and then setting up organizations and laws to acquire and enforce political authority. Other rulers have sought to distinguish themselves primarily as lawgivers or (e.g., King Solomon) paragons of justice. Still others have simply taken their power as given and abused it. Sometimes they gain mightily from such abuse, but at other times—under very particular conditions—they may become the object of elite revolts or popular revolutions.

For sociologists, the key to understanding the state is knowledge about the shifting relationships between state rulers, their organizations and resources, and their societies. Much of the history of the development of state forms comes from the competition between rulers seeking to extend their control of political organizations and coercive force and elite and popular groups seeking to limit or channel political authority into socially acceptable goals and actions.

CITY-STATES, EMPIRES, AND FEUDALISM

Although cities and states initially may have developed independently, with both gradually moving forward between 8000 and 3000 B.C., by the third millennium B.C., the conjunction between urbanization and state making was firmly established in the Middle East. Elsewhere—in sub-Saharan Africa and southeast Asia (especially Java and Cambodia)—states and even empires developed without true cities; those states operated through dense clusters of villages that often centered on great temple complexes. By contrast, in the Middle East and the New World, large cities grew up around the temple complexes that served as the headquarters and ceremonial centers of the new states. Several of those city-states had great success in

expansion and became the nucleus of larger empires, such as Sumer, Akkad, Assyria, and the empire of the Aztecs.

City-states continued to emerge throughout history, especially in periods of early settlement of new lands (such as the Greek city-states that spread throughout the Mediterranean in the second millennium B.C.) or after the breakup of large empires (as occurred in Italy and along the Rhine in Germany after the collapse of Charlemagne's empire in the ninth century A.D.). The legacy of these city-states is that they experimented with a wide array of state forms. At various times, the Greek and Roman city-states of the eighth through fourth centuries B.C.—including Athens, Sparta, Thebes, Corinth, and Rome—were ruled by a single monarch, pairs of kings (or consuls), oligarchies of the wealthy or well-born aristocrats, and popular assemblies. The modern forms of democracy and monarchy can be traced back to the Greek and Roman city-states of that period. However, city-states generally did not survive in any area for more than a few centuries before being swallowed up by large territorial empires.

Those large territorial empires became the dominant form of the state in much of the world for the next 5,000 years, from roughly 3000 B.C. to A.D. 1900 (Eisenstadt 1963). In the Middle East, the major empires included of Sumer, Akkad, Egypt, Assyria, Babylonia, and Persia and the Hellenistic empires founded by the generals of Alexander the Great. These empires were followed by the Roman Empire, the Byzantine Empire, and the Islamic empires founded by the followers of Mohammed. These empires were followed by the vast empires of the Mongols and the Turks, the last of which was the Ottoman Empire, which ruled large portions of north Africa, the Middle East, and southeastern Europe and lasted until 1923. In Europe, after the fall of the Roman Empire there followed the empires of Charlemagne and his sons. That empire left as a legacy the Holy Roman Empire, which eventually evolved into the Austro-Hungarian Empire, which survived until 1918. After roughly A.D. 1500, much of eastern Europe and central Asia was under the control of the Russian Empire, which lasted until 1917. In China and India, large empires emerged in the third and fourth centuries B.C. In China, the Qin and Han dynasties initiated a pattern of imperial rule that lasted until the birth

of the Chinese Republic in 1911; in India, the Maurya and Gupta dynasties briefly unified the subcontinent and were followed by the Mughal Empire, which lasted until India came under British domination in the eighteenth century.

In Africa, there also were large Empires, including the Aksum Empire in Ethiopia which was (founded around 300 B.C. and whose successor empires and dynasties lasted until 1974), the Ghana Empire and Mali Empire in west Africa, Great Zimbabwe and Mutapa in southern Africa, and the Zulu Empire, which ruled over much of southeastern Africa until it was defeated by the British in the late nineteenth century. In the Americas, three major indigenous empires developed: the Maya and the Aztecs in what is today Mexico and the Incas centered in modern-day Peru. After defeating the Aztecs and Incas in the sixteenth century, Spain established an empire in the Americas extending from Chile to California that it ruled for nearly 300 years.

The vast majority of these empires were conquest empires in which strong imperial centers acquired territory, troops, and resources to build ever-larger empires and thus conquer ever more territory. However, many imperial rulers also were famous lawgivers renowned for establishing justice and order in their empires; they included Hammurabi of Babylonia, Justinian of Rome, and Suleyman the Magnificent of the Ottoman Empire. Their lawcodes were established not to give "rights" to subjects but to produce order by making a clear list of crimes and the penalties that would be imposed.

Though powerful, these empires were not immune to decay and disintegration. Even the longest-lived empires, such as those of Egypt and China, had periods of civil war and broke up into multiple states. Population growth that created pressure on the capacity of the land to yield taxes, military defeat by powerful neighbors, and conflicts among elite factions could all produce disorganization and decay of the imperial state administration. In times of decay, a locally based form of rule known as feudalism often arose.

Feudalism in the strict sense is a pattern of allegiance by oath taking in which a lord gives control of land (a "fief") to a vassal in return for a promise of service. This pattern may have one dominant lord controlling many vassals, or there

may be many lords and many vassals, with some vassals dispensing fiefs and thus becoming lords themselves. In this sense, feudalism is not a state, for no centralized administration has full control of the territory. However, if a single lord manages to emerge as dominant over all the other lords and vassals in a territory and is able to expand his own household and personal administration to exert his will throughout the territory, one can then speak of a state, which usually is described as a kingdom or monarchy. Kingdoms were known throughout the world and generally appear in periods in which large empires have broken down or before they are established. In most of the world, empires continued to reestablish themselves, often building on the strongest kingdom in a region. However, in western and central Europe, no empire ever reestablished lasting control over the area that had been controlled by the Romans. Instead, the period of feudalism in Europe (roughly A.D. 600 through 1300) was followed by many centuries in which a number of competing kingdoms controlled major portions of the European continent.

ABSOLUTISM AND BUREAUCRATIC-AUTHORITARIAN STATES

The early empires and kingdoms all had rudimentary administrations and relatively undifferentiated elites. That is, the officers of the state were mainly family members of the ruler or personal favorites appointed at the ruler's pleasure; many were also high-ranking officials in the church. They gained much of their income from the control of personal properties or privileges granted by the ruler. The mingling of state and church was based on a strong connection between religious and state power; there was usually an official state religion that supported the state and was in turn supported by the ruler.

By around the sixteenth century A.D., however, most of the kingdoms and empires of Europe and Asia had begun to develop into more impersonal and bureaucratic states. State offices were fixed in a "table of ranks," and officers were expected to undergo rigorous academic training to qualify for their positions. The number of state offices multiplied greatly, and while favorites still were chosen for key positions, an increasing number were chosen and promoted for their merit and

services. States also began to diversify their sources of income. Most early empires relied on various forms of tribute collection or taxes paid “in kind,” such as set amounts of grain, cloth, or labor services. In contrast, by the sixteenth century, most states had begun to specify and collect taxes in cash, with which they paid regular salaries to state officials. In those states, subjects still had few rights and no participation in politics; rulers remained absolute in authority. However, those states became “bureaucratic-authoritarian” in the sense that authority increasingly was exercised through uniform rules enforced by bureaucratic officials rather than through local and customary practices enforced by fairly autonomous local notables.

Dependence on cash meant that many states also placed a greater emphasis on trade and on taxes on commerce as an alternative to taxes on land. For some states (e.g., the Netherlands and Great Britain), taxes on trade and industry soon exceeded revenues from traditional land taxes (Tilly 1990). In the period 1500–1900, the promotion of trade and commerce led to a vast expansion of long-distance trade, both ocean-borne and land-based, across the globe. European kingdoms, stymied in creating empires in Europe, created them overseas. Seeking natural resources and new markets, European states (and later Japan) invested in colonies and overseas companies and administrations to control them in the Americas, Africa, India, southeastern Asia, Korea, and along the Chinese coast.

While this period remained one of kingdoms and empires, bureaucratic-authoritarian states faced two extensive periods of challenge. From the late sixteenth to the mid-seventeenth century and again from the late eighteenth to the mid-nineteenth century, all of Eurasia experienced several trends that reshaped states. First, in those two periods the population grew dramatically, doubling or more, while in other periods the population declined or was stable. These periods of population growth were also periods of rising prices as a result of more extensive commerce and a rising demand for basic goods. Pay to laborers and available land for peasants, however, declined as the population grew faster than did the agricultural economy. Population growth also led to factional conflicts among elite groups competing for control of state offices and to greater demands on state administrations. However, states were run-

ning into financial trouble, for population growth was reducing the surplus available for taxation and the rapid growth of commerce was shifting more resources into areas where traditional tax collection was weak, leaving more resources in the hands of merchants, local landowners, and urban and regional elites. Toward the end of those two periods—roughly 1580–1660 and 1770–1860—conflicts between state rulers and elites over the rulers’ prerogatives and resources triggered worldwide waves of revolutions and rebellions in kingdoms and empires; these included the English, American, and French revolutions, the anti-Habsburg revolts, and the revolutions of 1848 in Europe; the collapse of the Ming Empire and the Taiping rebellion in China; and the janissary, Balkan, and Egyptian revolts in the Ottoman Empire (Goldstone 1991).

REVOLUTIONS, NATIONALISM, AND NATION-STATES

Those revolutions and rebellions all involved popular uprisings and elite rebellions against the ruler and loyal elements of the state but had different outcomes in different areas. In most societies, the elites were deeply frightened by popular uprisings and sought to reestablish state power more firmly by tightening the reins of state power and enforcing allegiance to the state-sponsored religion. This was the case in Catholic Spain, Italy, and Austria under the Counter-Reformation; in Confucian China under the Qing dynasty; and in the Islamic Ottoman Empire. However, in England 1689, America in 1776, and France in 1789, the elites were more concerned that excessive state power would damage their positions and fuel future revolutions. Reviving ideas and institutions from the days of democratic Greece and republican Rome, they attempted to place limits on state power and reserve specific rights to elites and even to ordinary workers and peasants. Those limits and rights were codified in a variety of documents, including “declarations of rights”, and especially in constitutions that became the basis for state power. Those constitutions marked a distinctively modern turn in the history of state. Previously, state authority

had always rested on coercion and demands for the dispensation of order and been supported by religious belief and tradition, but from the age of constitutions, the legitimacy of state authority rested on whether the ruler abided by the limits in the constitution and recognized the rights of the elites and popular groups that had established that constitution.

Constitutions meant that a new relationship was forged between the state and the population of the territory it ruled. Under empires, the state established order and most people were simply economic producers, not political actors. By contrast, under constitutions, the people, or at least those involved in creating and establishing constitutional rule, were the ultimate controllers and beneficiaries of state power. This new relationship led to new demands by various groups.

One demand was for greater and more regular political participation by groups that had been excluded: religious and ethnic minority groups, women, and the poor. Though frequently resisted by elites and state rulers, in many areas those groups gained elite allies and acquired rights to regular political participation, most notably through voting (Reuschmeyer et al. 1992). States where voting rights are widespread and the state's power over its subjects has significant limits are commonly described as democratic or "liberal" states. By the late nineteenth century, most of the states in Europe west of Russia and in North and South America were liberal states.

Another demand came from professionals, merchants, and sometimes military officers who lived under empires and wanted to take control of their positions and territories under something like the relationship that prevailed in constitutional regimes, where the state was identified as an instrument of the people rather than the reverse. Those elites argued that every ethnic group should be entitled to its "own" state and its own rulers. The resulting ideology was known as "nationalism" (Calhoun 1998), and it spread widely throughout the world. Nationalism fueled the revolutions of 1830 in Poland and Greece; those of 1848 in Hungary, Germany, Italy, and Romania; the effort

to expel the Austro-Hungarians and unify Italy under Italian rule in the 1860s; and the Serb liberation movement that helped start World War I. Nationalist sentiments also fueled revolts in Ireland throughout the nineteenth and twentieth centuries; the Chinese Republican Revolution of 1911; the anticolonial revolutions in India, Algeria, Indonesia, and Vietnam after World War II; and a host of other anticolonial revolts in Africa and Asia.

Nationalism fostered the ideal that states should be "national" states, reflecting the identity and promoting the aspirations of their inhabitants as a united community rooted in shared traditions and culture (Anderson 1991). In fact, to comply with this ideal, many traditions had to be invented and national languages had to be created. Even today, it often is ambiguous whether a given nation-state reflects a nation (Is there is British nation or only English, Welsh, and Scottish nations plus portions of Scot-settled Ireland sharing the state of Great Britain?). However, the ideal of the nation-state spread widely, even to older states, so that it became expected that modern nation-states would have a national language, a national flag and anthem, national systems of schooling and communications (newspapers, radio, and television), national systems of transportation (highways, railways, and airlines), and a national army.

Nonetheless, since almost all existing states included members of more than one ethnic, linguistic, or cultural group within their boundaries, most nation-states inevitably failed to satisfy to a greater or lesser degree the aspirations of subnational groups, which in turn often developed their own nationalist ambitions. A large number of the violent conflicts in the world in recent years are the result of nationalist movements within nation-states, such as the Chechens in Russia, the Basques in Spain, the Kurds in Turkey, the Uighurs in China, and the Albanian Kosovars in Yugoslavia.

While nationalism seemed poised to bring more liberal, constitutional states into being, things did not develop that way. The defeat of many early nationalist movements led nationalist leaders to conclude that above all else, a people needed a

strong state to protect them from control by others, whether multinational empires or other nations. As a result, many nationalist movements gave rise to authoritarian, populist dictatorships. Those dictatorships often promulgated constitutions and claimed to draw their legitimacy—in the modern fashion—from their service to and identification with the people of the territories they ruled, but in fact they operated in as absolute a manner as any older imperial state, only now they were backed by the latest industrial and military technology. Thus, while nationalism was destroying the old traditional empires and replacing them with modern states, those modern states were following divergent paths into democracy and dictatorship.

DEMOCRACIES AND DICTATORSHIPS

The history of the state in the twentieth century has largely been one of a struggle between democracies and dictatorships. In the liberal states over the course of the twentieth century, the range of citizen rights has been expanding, the participation in politics of ordinary citizens (through rallies, financial contributions, petitions, and voting) has grown, and the obligations of the state to support its citizens (the modern “welfare state”) have been extended. A major result of these patterns is that women, the working class, and the poor are far more closely integrated into political life in liberal states as voters and direct recipients of state actions than ever before (O’Conner et. al, 1999). To accommodate and channel this political participation, most liberal states have a number of political parties that organize and control the competition for political power. At the end of the twentieth century, as a result of growing state obligations, the personnel and budget of modern liberal states has swollen to the point where state expenditures make up one-quarter to one-half of the entire national product of their societies.

However, the model of the liberal state did not triumph in every place where empires collapsed. In many regions, spurred by nationalist sentiment and the failure of liberal states to provide economic and military security under the chaotic

conditions that followed military defeat or economic crises, modern dictatorships emerged. Some of those dictatorships, such as those of Adolph Hitler and his Nazi Party in Germany and Benito Mussolini and his Fascist Party in Italy, did not outlast their founders. However, in Russia and China, Communist parties took on a dominant life of their own, and those countries became one-party states in which everything of economic, military, and political importance was controlled by the party-state. In other countries, notably in Africa (e.g., Nigeria), Latin America, and eastern Asia (e.g., Korea and Indonesia), military personnel seized power and held on for periods ranging from years to generations. For most of the twentieth century, such modern one-party and military dictatorships, all professing nationalist ideals and even staging (controlled) popular elections, controlled the vast majority of the states and peoples of the world.

In the last two decades of the twentieth century, however, the majority of those one-party states and military dictatorships collapsed (Walder 1995; Goldstone et al. 1991). Their extensive control of the economy stifled innovation and encouraged corruption, leading their revenues to fall well below those of the leading liberal states. Within dictatorial states, even the elites looked on the far greater material wealth and personal freedom of their counterparts in liberal states with envy. Efforts at reform in one-party and military states thus quickly turned into movements to establish liberal regimes. As a result, for the first time in history, it appears that humankind will enter a new millennium with a majority of its nations and populations living under liberal constitutional states (Huntington 1991).

BEYOND THE NATION-STATE

While the twentieth century has closed with the national, liberal state seemingly triumphant, there is no assurance that this form of state will endure. Constitutional states often have been overthrown by dictatorships, both military and populist, when they encounter severe military or economic setbacks. The Great Depression led a host of democ-

racies to collapse into dictatorships, and struggles with economic development led many Latin American and African states into communist takeovers and military coups in the 1960s and 1970s. In most of the world outside Europe and North America, liberal states are not firmly established and may be vulnerable if another major economic trauma sweeps the globe. Thus, the past threats to the continuance of liberal states may reemerge.

In addition, new threats to the primacy of the nation-state have arisen in the form of supranational organizations with genuine sovereignty and military power. The most notable of these organizations are NATO (a military alliance with a unified command embracing the forces of most European nations and the United States) and the European Union (a supranational body ruled by representatives from most European nations with taxing and legislative authority over certain aspects of its member states). A variety of cooperative multinational organizations established by treaty, such as the United Nations, the International Monetary Fund, the International Court of Justice, and various environmental commissions and human rights organizations, also have impinged on state sovereignty. The future may see still greater transfers of state power to such supranational bodies as the problems of establishing human rights, safeguarding the global environment, and maintaining stable and sound financial institutions may grow beyond the capacity of any single state or ad hoc arrangement of states to resolve.

STATISTICAL GRAPHICS

Statistical graphs present data and the results of statistical analysis, assist in the analysis of data, and occasionally are used to facilitate statistical computation. Presentation graphs include the familiar bar graph, pie chart, line graph, scatterplot, and statistical map. Data analysis employs these graphical forms as well as others. Computational graphs (“nomographs”) sometimes display data but usually show theoretical quantities such as power curves for determining sample size. Computational graphs are convenient when statistical tables would be unwieldy, but computer programs are even more convenient, and so nomographs are used with decreasing frequency. This article emphasizes the role of graphs in data analysis, although many of the considerations raised here also apply to graphical presentation.

Although it generally is recognized that the pictorial representation of information is a par-

Figure 1. Dot graph showing the fractional area devoted to graphs in fifty-seven journals in the natural, mathematical, and social sciences. Four sociology journals appear near the bottom of the graph. To construct the graph, fifty articles were sampled from each journal in 1980 and 1981.

ticularly effective mode of communication, statistical graphs seldom appear in sociological publications. Figure 1, from Cleveland (1984), shows the relative space devoted to graphs in leading scientific publications, including four sociology journals. Sociology, of course, is not a wholly quantitative discipline. Nevertheless, even a cursory examination of publications in the field reveals that sociologists much more frequently report numerical information in tabular than in graphical form. Informal observation also suggests that sociologists usually analyze numerical data without the assistance of statistical graphs, a situation that may be changing.

HISTORY

Broadly construed, graphic communication dates to the cave paintings of human prehistory and to the earliest forms of writing, which were pictorial or semipictorial. The first diagrams to communicate quantitative information—about location and distance—were maps: Egyptian cartographers employed coordinate systems in maps prepared 5,000 years ago, and cartography remains a relatively well developed area of graphical representation. Musical notation, which charts pitch as a function of time, also has an ancient origin and illustrates the spatial display of essentially nonspatial information. Rectilinear coordinate graphs are so familiar that it is easy to lose sight of the radical abstraction required to represent diverse quantities, such as pitch, as distances along an axis.

In the seventeenth century, the French mathematician and philosopher René Descartes established the relationship between algebraic equations and curves in a rectilinear coordinate space. The graphical representation of functions is not logically necessary for the display of empirical data as points in space, and there are isolated examples before Descartes of statistical graphs that employ abstract coordinate systems. Nevertheless, Descartes's analytic geometry no doubt provided the impetus for the development of statistical graphics, and the most common forms of statistical graphs evolved slowly over the subsequent three and a half centuries.

Among many individuals' contributions to this evolution, the work of William Playfair at the turn of the nineteenth century is of particular importance. First, Playfair either invented or popularized several common graphical forms, including the line graph, the bar graph, the pie chart, and the circle chart (in which areas of circles represent quantities). Second, Playfair employed statistical graphs to display social and economic data. Figure 2a, from Playfair's 1786 *Commercial and Political Atlas*, is a time series line graph of imports to and exports from England in the period 1771–1782. In the original graph, the space between the two curves is colored green when the balance of trade favors England (i.e., when the curve for exports is above that for imports) and red when the balance favors England's trading partners. Of the forty-two graphs in Playfair's atlas, all but one depict time series. The sole exception is a bar graph of imports to and exports from Scotland (Figure 2b), the data for which were available only for the year 1780–1781, precluding the construction of time series plots. Playfair's 1801 *Statistical Breviary* included a wider variety of graphical forms.

The first half of the nineteenth century was a period of innovation in and dissemination of statistical graphics, particularly in England and France. The ogive (cumulative frequency curve), the histogram, the contour map, and graphs employing logarithmic and polar coordinates all appeared before 1850. Later in the century, the British scientist Sir Francis Galton exploited an analogy to contour maps in his determination of the bivariate-normal correlation surface, illustrating the role of graphs in discovery.

The nineteenth-century enthusiasm for graphic representation of data produced many memorable and high-quality statistical graphs, such as those of Playfair, Florence Nightingale, E. J. Marey, and Charles Joseph Minard (several of which are reproduced in Tufte 1983). The same enthusiasm produced early abuses, however, including the graph from M. G. Mulhall's 1892 *Dictionary of Statistics* shown in Figure 3: The heights of the triangles indicate the accumulated wealth of each country, but their areas are wildly disproportionate to the quantities represented, conveying a misleading

impression of the data. Furthermore, the horizontal arrangement of the countries bears no relationship to the purpose of the graph and apparently was done for artistic effect: It would be more natural to order the countries by wealth. Many modern graphs have similar problems, a situation that has motivated a substantial literature of graphic criticism (such as the works by Schmidt, Tufte, and Wainer discussed below).

The evolution of statistical graphics paralleled the general growth of statistical science well into the twentieth century. This relationship changed radically in the 1930s as statisticians such as R. A. Fisher emphasized the development of procedures for statistical inference. Fisher's influential *Statistical Methods for Research Workers*, first published in 1925, includes a brief chapter on "diagrams"; this chapter incorporates line graphs, scatterplots, and a histogram with a superimposed normal-density

curve. The remainder of the book, however, contains many numerical tables but just five additional figures, none of which presents empirical information. Fisher's 1935 *The Design of Experiments* includes just three graphs, all of which are theoretical.

The rebirth of interest in statistical graphics may be traced to John W. Tukey's work on exploratory data analysis, beginning in the 1960s and culminating in the publication of his text on this subject in 1977. Tukey's coworkers and students, most importantly the group at Bell Laboratories and its successors associated with William S. Cleveland, continue to contribute to the modern development of statistical graphics (see, in particular, Chambers et al. 1983; Cleveland 1993, 1994). Further information on the history of statistical graphics can be found in Funkhouser (1937), Tufte (1983), and Beninger and Robyn (1978), the last of which contains a useful chronology and bibliography.

GRAPHIC STANDARDS

After several abortive efforts, the International Statistical Congresses held in Europe in the nineteenth century abandoned the attempt to formulate graphical standards. Since that time, many authors have proposed standards and principles for the construction of statistical graphs, but consensus on these matters remains elusive. Schmidt (1983, p. 17), for example, suggests that grid lines should always appear on rectilinear line graphs, while Tufte (1983, p. 112) maintains that grids "should usually be muted or completely suppressed," an instance of his more general principle that good graphs maximize the "dataink ratio" (the amount of ink devoted to the display of data as a proportion of all the ink used to draw the

graph) and eliminate "chartjunk" (extraneous graphical elements).

Disagreements such as this are due partly to the lack of systematic data on graphical perception (a situation that is improving), partly to differences in style and taste, and partly to the absence of adequate general theories of graph construction and perception (although there have been attempts, such as Bertin 1973). Also, good graphical display depends on the purposes for which a graph is drawn and on particular characteristics of the data, factors that are difficult to specify in advance and in a general manner.

Huff (1954, chap. 5), for example, argues that scales displaying ratio quantities should always start at zero to avoid exaggerating the magnitude

of differences between data values. This principle, however, often disguises patterns in data that are revealed clearly by graphical magnification. Consider Figure 4, a and b, which shows the relative value of the Canadian and U.S. dollars in the eight weeks surrounding the June 23, 1990, deadline for the ratification of the ill-fated "Meech Lake" amendment to the Canadian constitution. This period was widely interpreted, both domestically and abroad, as one of constitutional crisis and uncertainty for Canada. Because in the short term the Canadian dollar traditionally trades in a narrow range against the U.S. dollar, Figure 4a is essentially uninformative, while Figure 4b reveals that the Canadian dollar fell slightly as the Meech deadline approached and rose afterward.

Despite some areas of disagreement, commentators on the design of statistical graphs, such

as Tufte (1983, 1990, 1997), Schmidt, and Wainer, offer a great deal of uncontroversially sound advice. In a tongue-in-cheek essay (reprinted in Wainer 1997: chap. 1), Wainer enumerates twelve rules to help the reader "display data badly." Several of these rules are illustrated in Figure 5a, which appeared in the *Miami Herald* in 1984: "Rule 7, Emphasize the trivial (ignore the important)"; "Rule 11, More is murkier: (a) more decimal places and (b) more dimensions"; and "Rule 12, If it has been done well in the past, think of a new way to do it." The graph in Figure 5a is meant to show the presumably negative relationship between the success of the twenty-six major league baseball teams in the 1984 season and the average salaries paid to the players on those teams. The lengths of the bars represent average players' salaries, while the teams' records of wins and losses are hidden in parenthe-

Figure 4. The relative value of the Canadian and U.S. dollar in an eight-week period in 1990 surrounding the failure of the Meech Lake amendment to the Canadian constitution. (a) Beginning the vertical axis at zero. Note that the upper end point of one is arbitrary, since the Canadian dollar can (at least in theory) trade above par with the U.S. dollar. (b) Scaling the vertical axis to accommodate the range of the data. The vertical line in each graph is drawn at the June 23 deadline for ratifying the Meech Lake accord.

ses within the bars, making it essentially impossible to tell whether the two variables are related—ostensibly the point of the graph. The bars are drawn in three-dimensional perspective, apparently for artistic effect, but the result is that the quantities represented are slightly distorted: For example, the average salary of the New York Yankees, \$458,544, appears to be about \$410,000. A standard representation of these data appears in the scatterplot in Figure 5b, revealing a slight *positive* relationship between salary and success.

RESEARCH ON GRAPHIC PERCEPTION

The earliest psychophysical research on perception of graphs, conducted in the 1920s, focused on the relative merits of pie charts and bar charts for displaying percentage data and was inconclusive. More recently, statisticians and psychologists have undertaken systematic experimentation on graphical perception. Spence and Lewandowsky (1990) review the literature in this area up to 1990.

Cleveland and McGill (1984), for example, conducted a series of experiments to ascertain the

relative accuracy of ten elementary perceptual tasks that extract quantitative information from graphs, as represented schematically in Figure 6. Ranked in order of decreasing average accuracy, these tasks involve judgment of position along a common scale; position along nonaligned scales; length, direction, or angle; area; volume or curvature; and shading or color saturation. Similarly, Spence (reported in Spence and Lewandowsky 1990) has shown in an experiment that categorical information differentiating points on a scatterplot is encoded most effectively by colors and least effectively by confusable letters (e.g., E, F, H); other coding devices, such as different shapes (circles, squares, triangles), degrees of fill, and discriminable letters (H, Q, X), were intermediate in effectiveness.

Cleveland (1993) demonstrates that slope judgments are most accurate for angles close to forty-five degrees and least accurate for angles near zero or ninety degrees. Cleveland therefore suggests that the aspect ratio of graphs (the relative lengths of the axes) be set so that average slopes are close to forty-five degrees, a procedure he terms “banking to forty-five degrees.” This process is illus-

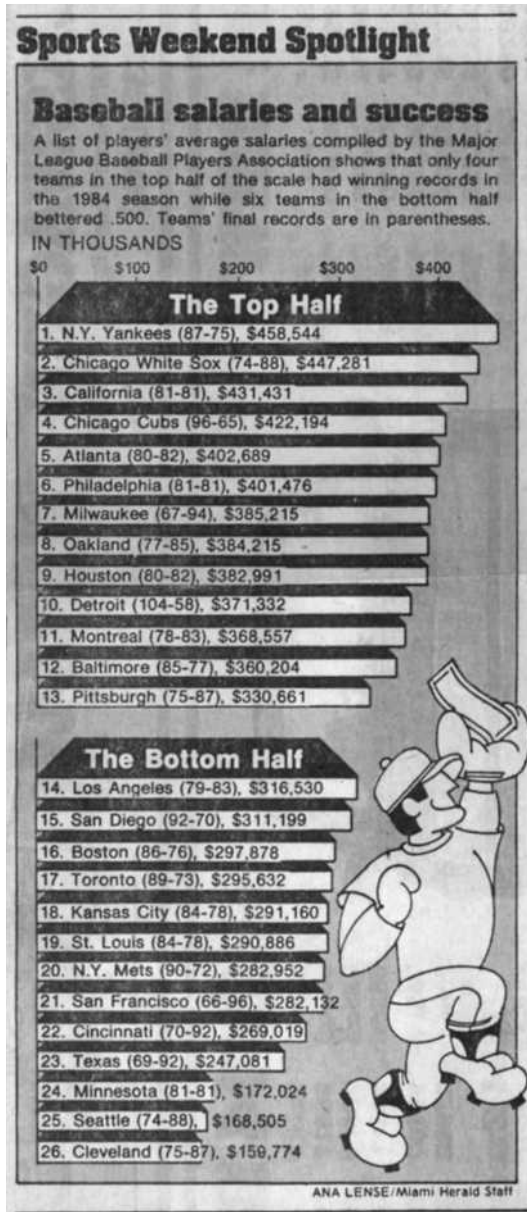

Figure 5a

trated in Figure 7. Both graphs in this figure plot the same data, but the periodic pattern of the data is nearly impossible to discern in Figure 7a because the average slope of the curve is too steep.

Cleveland and his colleagues have designed new graphical forms that apply these and similar findings by encoding important information through the employment of accurately judged graphic elements. One such form is the dot graph, an exam-

Figure 5b. Major League Baseball salaries and team success in the 1984 season. (a) As depicted in the Miami Herald. The lengths of the bars (slightly distorted) represent the average salaries paid to players from each team; the teams' won-lost records appear in parentheses within the bars. The apparent point of the graph is that there is a negative relationship between salaries and success. (b) The same data in standard scatterplot. The line on the plot, derived from a logistic regression of wins on average salaries, indicates a weak positive relationship between salaries and success.

ple of which appears in Figure 1. Similarly, Cleveland and McGill (1984) suggest the replacement of quantitative statistical maps that use shading or hue (e.g., Figure 8a) with maps that employ framed rectangles (Figure 8b), which exploit the more accurate judgment of position along nonaligned scales. Despite the inferiority of Figure 8a for judging differences in murder rates among the states, however, this map more clearly reveals regional variations in rates, illustrating the principle that the purpose for which a graph is drawn should influence its design.

The effectiveness of statistical graphs is rooted in the remarkable ability of people to apprehend, process, and remember pictorial information. The human visual system, however, is subject to distortion and illusion, processes that can affect the perception of graphs. Good graphical design can minimize and counteract the limitations of human vision. In Figure 9, for example, it appears that the difference between the hypothetical import and export series is changing when this difference

Figure 6. Ten elementary perceptual tasks for decoding quantitative information from statistical graphs.

SOURCE: Reprinted from Cleveland and McGill (1984) with the permission of the American Statistical Association.

actually is constant (cf., Playfair’s time series graph in Figure 2a). The source of the illusion is the tendency to attend to the least distance between the two curves rather than to the vertical distance. Thus, an alternative is to graph the difference between the two curves—the balance of trade—directly (cf. Figure 12, b and c, below), exploiting the relatively accurate judgment of position along a common scale, or to show vertical lines between the import and export curves, employing the somewhat less accurate judgment of position along nonaligned scales.

GRAPHS IN DATA ANALYSIS

Statistical graphs should play a central role in the analysis of data, a common prescription that is most often honored in the breach. Graphs, unlike numerical summaries of data, facilitate the perception of general patterns and often reveal unusual, anomalous, or unexpected features of the data—characteristics that might compromise a numerical summary.

Figure 7. Two scatterplots of the same data. Five hundred X-values were randomly generated in the interval $[0, 25\pi]$, and $Y = \sin X$. The periodic pattern of the data is clear in (b), where the aspect ratio of the plot is adjusted so that the average slope of the curve is not too steep, but not in panel (a).

The four simple data sets in Figure 10, from Anscombe (1973) and dubbed “Anscombe’s quartet” by Tufte (1983), illustrate this point well. All four data sets yield the same linear least-squares outputs when regression lines are fitted to the data, including the regression intercept and slope, coefficient standard errors, the standard error of the regression (i.e., the standard deviation of the residuals), and the correlation, but—significantly—not residuals. Although the data are contrived, the four graphs tell very different imaginary stories: The least-squares regression line accurately summarizes the tendency of y to increase with x in Figure 10a. In contrast, the data in Figure 10b clearly indicate a curvilinear relationship between y and x , a relationship the linear regression does not capture. In Figure 10c, one point is out of line with the rest and distorts the regression. Perhaps the outlying point represents an error in recording the data or a y -value that is influenced by factors other than x . In Figure 10d, the ability to fit a line

Figure 9. Despite appearances, the vertical separation between the curves for imports and exports is constant. The “data” are contrived.

and the line’s specific location depend on the presence of a single point.

Diverse graphical forms are adapted to different purposes in data analysis. Many important applications appear in the figures below, roughly in order of increasing complexity, including graphs for displaying univariate distributions, bivariate relationships, diagnostic quantities in regression analysis, and multivariate data.

Particularly useful for graphically screening data are methods for displaying the distributions of quantitative variables. Several univariate displays of the distribution of infant mortality rates for 201 countries are shown in Figure 11, using data compiled by the United Nations.

Figure 11a is a traditional histogram of the infant mortality data, a frequency bar graph formed by dissecting the range of infant mortality into class intervals or “bins” and then counting the number of observations in each bin; the vertical axis of the histogram is scaled in percent. Figure 11b shows an alternative histogram that differs from Figure 11a only in the origin of the bin system (the bars are shifted five units to the left). These graphs demonstrate that the impression conveyed by a histogram depends partly on the

Figure 10. The four data sets have the same linear least-squares regression, including the regression coefficients, their standard errors, the correlation between the variables, and the standard error of the regression.

arbitrary location of the bins. Figure 11c is a stem-and-leaf display, a type of histogram (from Tukey) that records the data values directly in the bars of the graph, thus permitting the recovery of the original data. Here, for example, the values given as 1:2 represent infant mortality rates of 12 per 1,000.

Figure 11d is a kernel density estimate, or smoothed histogram, a display that corrects both the roughness of the traditional histogram and its dependence on the arbitrary choice of bin location. For any value x of infant mortality, the height of the kernel estimate is

$$\hat{f}(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x - x_i}{h}\right) \quad (1)$$

where n is the number of observations (here, 201); the observations themselves are $\chi_1, \chi_2, \dots, \chi_n$, h is the “window” half-width for the kernel estimate, analogous to bin width for a histogram; and K is

STATISTICAL GRAPHICS

Figure 11. Six univariate displays of the distribution of infant mortality rates in 201 nations. The histograms (a) and (b) both have bins of width ten, but the bars of (b) are five units to the left of those of (a). A stem-and-leaf display is shown in (c), a kernel density estimate in (d), a boxplot in (e), and a normal quantile comparison plot in (f).

some probability–density function, such as the unit-normal density, ensuring that the total area under the kernel estimate is one. A univariate scatterplot – another form of distributional display giving the location of each observation – is shown at the bottom of Figure 11d.

Figure 11e, a “boxplot” of the infant mortality data (a graphic form also from Tukey), summarizes a variety of important distributional information. The box is drawn between the first and third quartiles and therefore encloses the central half of the data. A line within the box marks the position of the median. The whiskers extend either to the most extreme data value (as on the bottom) or to the most extreme nonoutlying data value (as on the top). Four outlying data values are represented individually. The compactness of the boxplot suggests its use as a component of more complex displays; boxplots may be drawn in the margins of a scatterplot to show the distribution of each variable, for example.

Figure 11f shows a normal quantile comparison plot for the infant mortality data. As the name implies, this graph compares the ordered data with corresponding quantiles of the unit-normal distribution. By convention, the i th largest infant mortality rate, denoted $\chi_{(i)}$, has $P_i = (i - 1/2)/n$ proportion of the data below it. The corresponding normal quantile is z_i , located so that $Pr(Z \leq z_i) = P_i$, where Z follows the unit-normal distribution. If X is normally distributed with mean μ and standard deviation σ , then within the bounds of sampling error, $x_{(i)} \cong \mu + \sigma z_i$. Departure from a linear pattern therefore indicates nonnormality. The line shown in Figure 11f passes through the quartiles of X and Z . The positive skew of the infant mortality rates is reflected in the tendency of the plotted points to lie above the fitted line in both tails of the distribution.

While the skewness of the infant mortality data is apparent in all the displays, the possibly multimodal grouping of the data is clearest in the kernel density estimate. The normal quantile comparison plot, in contrast, retains the greatest resolution in the tails of the distribution, where data are sparse; these are the regions that often are problematic for numerical summaries of data such as means and regression surfaces.

Many useful graphs display relationships between variables, including several forms that ap-

peared earlier in this article: bar graphs (Figure 2b), dot graphs (Figure 1), and line graphs such as time series plots (Figures 2a and 4). Parallel boxplots are often informative in comparing the distribution of a quantitative variable across several categories. Scatterplots (as in Figure 10) are invaluable for examining the relationship between two quantitative variables. Other data-analytic graphs adapt these forms.

In graphing quantitative data, it is sometimes advantageous to transform variables. Logarithms, the most common form of transformation, often clarify data that extend over two or more orders of magnitude (i.e., a factor of 100 or more) and are natural for problems in which ratios of data values, rather than their differences, are of central interest.

Consider Figure 12, which shows the size of the Canadian and U.S. populations for census years between 1790 and 1990 in the United States and between 1851 and 1991 in Canada. The data are graphed on the original scale in Figure 12a and on the log scale in Figure 12b. Because the Canadian population is much smaller than that of the United States, it is difficult to discern the Canadian data in Figure 12a. Moreover, Figure 12b shows more clearly departures from a constant rate of population growth, represented by linear increase on the log scale, and permits a direct comparison of the growth rates in the two countries. These rates were quite similar, with the U.S. population roughly ten times as large as the Canadian population throughout the past century and a half. Figure 10c, however, which graphs the difference between the two curves in Figure 10b (i.e., the log population ratio), reveals that the United States was growing more rapidly than Canada was before 1900 and more slowly afterward.

Graphs also can assist in statistical modeling. Least-squares regression analysis, for example, which fits the model

$$Y_i = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \dots + \beta_k x_{ki} + \epsilon_i \quad (2)$$

makes strong assumptions about the structure of the data, including assumptions of linearity, equal error variance, normality of errors, and independence. Here Y_i is the dependent variable score for the i th of n observations; $\chi_{1i}, \chi_{2i}, \dots, \chi_{ki}$ are independent variables; ϵ_i is an unobserved error that is assumed to be normally distributed with zero ex-

Figure 12. Canadian and U.S. population figures are plotted directly in (a) and on a log scale in (b). The difference between the two log series is shown in (c).

pectation and constant variance σ^2 , independent of the x 's and the other errors; and the β 's are regression parameters, which are to be estimated along with the error variance from the data.

Graphs of quantities derived from the fitted regression model often prove crucial in determining the adequacy of the model. Figure 13, for example, plots a measure of leverage in the regression (the "hat values" h_i) against a measure of discrepancy (the "studentized residuals" t_i). Leverage represents the degree to which individual observations can affect the fitted regression, while discrepancy represents the degree to which each observation departs from the pattern suggested by the rest of the data. Actual influence on the estimated regression coefficients is a product of leverage and discrepancy and is displayed on the graph by Cook's D_i , represented by the areas of the plotted circles. The data for this graph are drawn from Duncan's (1961) regression of the rated prestige of forty-five occupations on the educational and income levels of the occupations. The plot suggests that two of the data points (the occupations "minister" and "conductor") may unduly affect the fitted regression.

Figure 14 is a scatterplot of residuals against fitted Y -values,

$$\hat{Y}_i = b_0 + b_1x_{1i} + b_2x_{2i} + \dots + b_kx_{ki} \quad (3)$$

where the b 's are sample estimates of the corresponding β 's. If the error variance is constant as assumed, the variation of the residuals should not change systematically with the fitted values. The data for Figure 14 are drawn from work by Ornstein (1976) relating the number of interlocking directorate and executive positions maintained by 248 dominant Canadian corporations to characteristics of the firms. The plot reveals that the variation of the residuals appears to increase with the level of the fitted values, casting doubt on the assumption of constant error variance.

Figure 15 shows a partial residual (also called a component plus residual) plot for the relationship between occupational prestige and income, a diagnostic useful for detecting nonlinearity in regression. The plot is for a regression of the rated prestige of 102 Canadian occupations on the gender composition, income level, and educational level of the occupations (see Fox and Suschnigg

Figure 13. Influence plot for Duncan's regression of the rated prestige of forty-five occupations on their income and educational levels. The hat values measure the leverage of the observations in the regression, while the studentized residuals measure their discrepancy. The plotted circles have area proportional to Cook's D , a summary measure of influence on the regression coefficients. Horizontal lines are drawn at plus and minus 2; in well-behaved data, only about 5 percent of studentized residuals should be outside these lines. Vertical lines are drawn at two and three times the average hat value; hat values greater than two or three times the average are noteworthy. Observations that have relatively large residuals or leverages are identified on the plot.

1989). The partial residuals are formed as $e_{1i} = b_1\chi_{1i} + e_i$, where b_1 is the fitted income coefficient in the linear regression, χ_{1i} is the average income of incumbents of occupation i , and e_i is the regression residual. The nonlinear pattern of the data, which is apparent in the graph, suggests modification of the regression model. Similar displays are available for generalized linear models such as logistic regression. Further information on the role of graphics in regression diagnostics can be found in Atkinson (1985), Fox (1991, 1997), and Cook and Weisberg (1994).

Scatterplots are sometimes difficult to interpret because of visual noise, uneven distribution of the data, or discreteness of the data values. Visually ambiguous plots often can be enhanced by smoothing the relationship between the variables, as in Figure 15. The curve drawn through this plot was determined by a procedure from

Figure 14. Plot of residuals by fitted values for Ornstein's regression on interlocks maintained by 248 dominant Canadian corporations on the characteristics of the firms. The manner in which the points line up diagonally at the lower left of the graph is due to the lower limit of zero for the dependent variable.

Cleveland (1994) called *locally weighted scatterplot smoothing* ("lowess"). Lowess (also called "loess," for local regression) fits n robust regression lines to the data, with the i th such line emphasizing observations whose χ -values are closest to χ_i . The lowess fitted value for the i th observation, \hat{y}_i , comes from the i th such regression. Here x and y simply denote the horizontal and vertical variables in the plot. The curve plotted on Figure 15 connects the points (χ_i, \hat{y}_i) . Lowess is one of many methods of nonparametric regression analysis, including methods for multiple regression, described, for example, in Hastie and Tibshirani (1990) and Fox (forthcoming *a* and *b*). Because there is no explicit equation for a nonparametric regression, the results are most naturally displayed graphically.

Scatterplots for discrete data may be enhanced by paradoxically adding a small amount of random noise to the data to separate the points in the plot. Cleveland (1994) calls this process "jittering." An example is shown in Figure 16a, which plots scores on a vocabulary test against years of education; the corresponding jittered plot (Figure 16b) reduces the overplotting of points, making the relationship much clearer and revealing other characteristics

Figure 15. Partial residual (component+residual) plot for income in the regression of occupational prestige on the gender composition and income and education levels of 102 Canadian occupations in 1971. The broken line gives the linear least-squares fit, while the solid line shows the lowess (nonparametric regression) fit to the data.

of the data, such as the concentration of points at twelve years of education.

Because graphs commonly are drawn on two-dimensional media such as paper and computer screens, the display of multivariate data is intrinsically more difficult than that of univariate or bivariate data. One solution to the problems posed by multivariate graphic representation is to record additional information on a two-dimensional plot. Symbols such as letters, shapes, degrees of fill, and color may be used to encode categorical information on a scatterplot, for example (see Figure 19, below). Similarly, there are many schemes for representing additional quantitative information, as shown in Figures 8 and 13.

A scatterplot matrix is the direct graphic analogue of a correlation matrix, displaying the bivariate relationship between each pair of a set of quantitative variables and thus providing a quick overview of the data. In contrast to a correlation matrix, however, a scatterplot matrix can reveal nonlinear relationships, outlying data, and so on. The scatterplot matrix in Figure 17 is for rates of seven different categories of crime in the thirty largest U.S. cities (excluding Chicago) in 1996.

The regression curve shown in each scatterplot was determined by the lowess procedure described above.

A limitation of the scatterplot matrix is that it displays only the *marginal* relationships between the variables, while *conditional* (or *partial*) relationships are more often the focus of multivariate statistical analysis. This limitation sometimes can be overcome, however, by highlighting individual observations or groups of observations and following them across the several plots (see the discussion of “brushing” in Cleveland 1994). These methods are most effective when they are implemented as part of an interactive computer system for graphic data analysis.

One approach to displaying conditional relationships is to focus on the relationship between the dependent variable and each independent variable fixing the other independent variable (or variables) to particular, possibly overlapping ranges of values. A nonparametric regression smooth then can be fitted to each partial scatterplot. Cleveland (1993) calls this kind of display a “conditioning plot” or “coplot.” The strategy breaks down, however, when there are more than two or three independent variables, or when the number of observations is small.

Many of the most useful graphical techniques for multivariate data rely on two-dimensional projections of the multivariate scatterplot of the data. A statistical model fitted to the data often determines these projections. An example of a display employing projection of higher-dimensional data is the partial residual plot shown in Figure 15. Another common application of this principle is the similarly named but distinct partial regression (or added-variable) plot. Here the dependent variable (Y) and one independent variable in the multiple regression model (say, x_1) are each regressed on the other independent variables in the model (i.e., χ_2, \dots, χ_k), producing two sets of residuals (which may be denoted $y_{(1)}$ and $\chi_{(1)}$). A scatterplot of the residuals (that is, $y_{(1)}$ versus $\chi_{(1)}$) is frequently useful in revealing high-leverage and influential observations. Implementation on modern desktop computers, which can exploit color, shading, perspective, motion, and interactivity, permits the effective extension of projections to three dimensions (see Monette 1990; Cook and Weisberg 1994; Cook 1998).

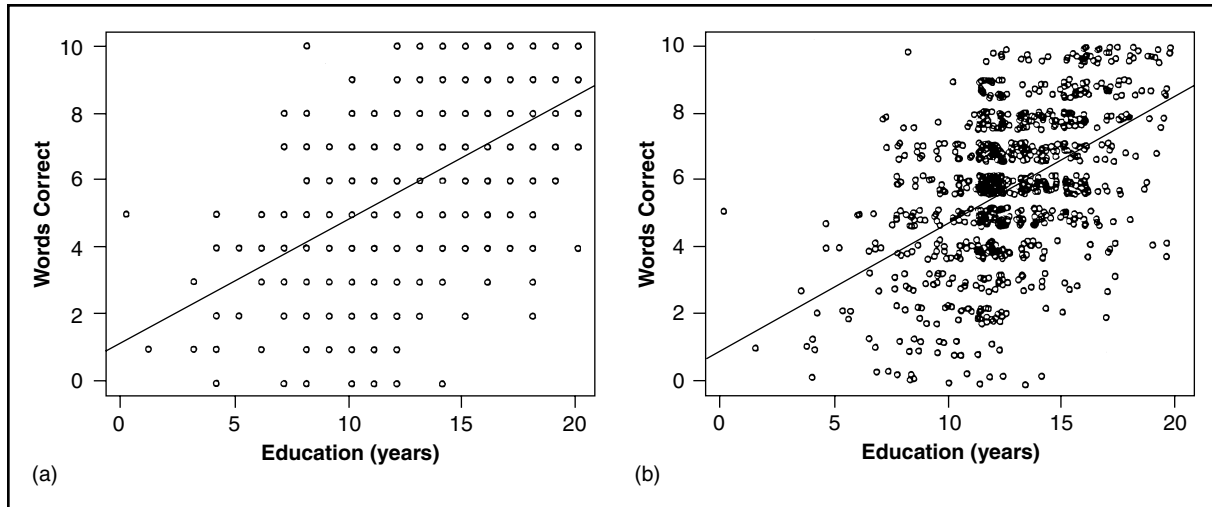

Figure 16. Randomly “jittering” a scatterplot to clarify discrete data. The original plot in (a) shows the relationship between score on a ten-item vocabulary test and years of education. The same data are graphed in (b) with a small random quantity added to each horizontal and vertical coordinate. Both graphs show the least-squares regression line.

SOURCE: 1989 General Social Survey, National Opinion Research Center.

When there are relatively few observations and each is of separate interest, it is possible to display multivariate data by constructing parallel geometric figures for the individual observations. Some feature of the figure encodes the value of each variable. One such display, called a “star plot,” is shown in Figure 18 for the U.S. cities crime rate data. The cities are arranged in order of increasing general crime rate.

Other common and essentially similar schemes include “trees” (the branches of which represent the variables), faces (whose features encode the variables), and small bar graphs (in which each bar displays a variable). None of these graphs is particularly easy to read, but judicious ordering of observations and encoding of variables sometimes can suggest natural clusterings of the data or similarities between observations. Note in Figure 18, for example, that Oklahoma City and Jacksonville have roughly similar “patterns” of crime, even though the rates for Oklahoma City are generally higher. If similarities among the observations are of central interest, however, it may be better to address the issue directly by means of clustering or ordination (also called multidimensional scaling); see, e.g., Hartigan (1975), and Kruskal and Wish (1978).

THE PRESENT AND FUTURE OF STATISTICAL GRAPHICS

Computers have revolutionized the practice of statistical graphics much as they earlier revolutionized numerical statistics. Computers relieve the data analyst of the tedium of drawing graphs by hand and make possible displays—such as lowess scatterplot smoothing, kernel density estimation, and dynamic graphs—that previously were impractical or impossible. All the graphs in this article, with the exception of several from other sources, were prepared with widely available statistical software (most with *S-Plus*, the graphical and other capabilities of which are ably described by Venables and Ripley 1997). Virtually all general statistical computer packages provide facilities for drawing standard statistical graphs, and many provide specialized forms as well.

Dynamic and interactive statistical graphics, only a decade ago the province of high-performance graphics workstations and specialized software, are now available on inexpensive desktop computers. Figure 19 illustrates the application of Cook and Weisberg’s (1999) state-of-the-art *Arc* package to Duncan’s occupational prestige data.

Figure 17. Scatterplot matrix for the rates of seven categories of crime in the thirty largest U.S. cities in 1996 (Chicago is omitted because of missing data). The rate labeled “Murder” represents both murder and manslaughter. The line shown in each panel is a lowess scatterplot smooth.

SOURCE: *Statistical Abstract of the United States: 1998*.

Arc, programmed in Tierney’s (1990) *Lisp-Stat* statistical computing environment, is freely available software that runs on Windows computers, Macintoshes, and Unix workstations. Standard statistical packages such as *SAS* and *SPSS* are gradually acquiring these capabilities as well.

The other edge of the computing sword cuts in the direction of ugly, poorly constructed graphs that obfuscate rather than clarify data: Modern software facilitates the production of competent (if not beautiful) statistical graphs. Nevertheless, a data analyst armed with a “presentation graphics” package can, with little effort or thought and less taste, produce elaborate, difficult to read, and misleading graphs.

STATISTICAL INFERENCE

Making an inference involves drawing a general conclusion from specific observations. People do this every day. Upon arising in the morning, one observes that the sun is shining and that the day will be nice. The news reports the arrest of a military veteran for child abuse, and a listener infers that military veterans have special adjustment problems. Statistical inference is a way of formalizing the process of drawing general conclusions from limited information. It is a way of stating the degree of confidence one has in making an inference by using probability theory. Statistically based research allows people to move beyond speculation.

Suppose a sociologist interviews two husbands. Josh, whose wife is employed, does 50 percent of the household chores; Frank, whose wife does not work for pay, does 10 percent. Should the sociologist infer that husbands do more housework when their wives are employed? No. This difference could happen by chance with only two cases. However, what if 500 randomly selected husbands with employed wives average 50 percent of the chores and randomly selected husbands with nonemployed wives average 10 percent? Since this difference is not likely to occur by chance, the sociologist infers that husbands do more housework when their wives are employed for pay.

Researchers perform statistical inferences in three different ways. Assume that 60 percent of the respondents to a survey say they will vote for Marie Chavez. The *traditional hypothesis testing* approach infers that Chavez will win the election if chance processes would account for the result (60 percent support in this survey) with less than some a priori specified statistical significance level. For example, if random chance could account for the result fewer than five times in a hundred, one would say the results are statistically significant. Statistical significance levels are called the *alpha*

(e.g., $\alpha = .05$ for the 5 percent level). If Chavez would get 60 percent support in a sample of the size selected less than 5 percent of the time by chance, one would infer that she will win. The researcher picked the 5 percent level of significance before doing the survey. (The test, including the α level, must be planned *before* one looks at the findings.) If one would get this result 6 percent of the time by chance, there is no inference. Note that not making the inference means just that: One does not infer that Chavez's opponent will win.

A second strategy involves stating the *likelihood of the result occurring by chance* without an a priori level of significance. This strategy reports the result (60 percent of the sample supported Chavez) and the probability of getting that result by chance, say, .042. This gives readers the freedom to make their inferences using whatever level of significance they wish. Sam Jones, using the .01 level ($\alpha = .01$) in the traditional approach would see that the results do not meet his criterion. He would not conclude that Chavez will win. Mara Jabar, using the .05 level, would conclude that Chavez would win.

The third strategy places a *confidence interval around a result*. For example, a researcher may be 95 percent confident that Chavez will get between 55 percent and 65 percent of the votes. Since the entire interval—55 percent to 65 percent—is enough for a victory, that is, is greater than 50 percent one infers that Chavez will win.

Each approach has an element of risk attached to the inference. That risk is the probability of getting the result by chance alone. Sociologists tend to pick low probabilities (e.g., .05, .01, and even .001), because they do not want to conclude that something is true when it is at all likely to have occurred by chance.

TRADITIONAL TESTS OF SIGNIFICANCE

Traditional tests of significance involve six steps. Three examples are used here to illustrate these steps: (1) A candidate will win an election, (2) mothers with at least one daughter will have different views on abortion than will mothers with only sons, and (3) the greater a person's internal political efficacy is, the more likely that person is to vote.

Step 1: State a hypotheses (H_1) in terms of statistical parameters (characteristics such as means, correlations, proportions) of the population:

$H1$: $P(\text{vote for the candidate}) < .50$. [Read: The mean for mothers with daughters is not equal to the mean for mothers with sons.]

$H2$: μ mothers with daughters \neq μ mothers with sons. [Read: The means for mothers with daughters is not equal to the mean for mothers with sons.]

$H3$: $\rho < 0.0$. [Read: The population correlation ρ (rho) between internal political efficacy and voting is greater than zero.]

$H2$ says that the means are different but does not specify the direction of the difference. This is a two-tail hypothesis, meaning that it can be significant in either direction. In contrast, $H1$ and $H3$ signify the direction of the difference and are called one-tail hypotheses.

These three hypotheses are not directly testable because each involves a range of values. *Step 2* states a null hypothesis, which the researcher usually wishes to reject, that has a specific value.

$H1_0$: $P(\text{vote for the candidate}) = .50$.

$H2_0$: μ mothers with daughters = μ mothers with sons.

$H3_0$: $\rho = 0$.

An important difference between one-tail and two-tail tests may have crossed the reader's mind. Consider $H1_0$. If 40 percent of the sample supported the candidate, one fails to reject $H1_0$ because the result was in the direction opposite of that of the one-tail hypothesis. In contrast, whether mothers with daughters have a higher or lower mean attitude toward abortion than do mothers with sons, one proceeds to test $H2_0$ because a difference in either direction could be significant.

Step 3 states the a priori level of significance. Sociologists usually use the .05 level. With large samples, they sometimes use the .01 or .001 level. This paper uses the .05 level ($\alpha = .05$). If the result would occur in fewer than 5 percent (corresponding to the .05 level) of the samples if the null hypothesis were true in the population, the null hypothesis is rejected in favor of the main hypothesis.

Suppose the sample correlation between internal political efficacy and voting is .56 and this would occur in fewer than 5 percent of the samples this size if the population correlation were 0 (as specified in H_0). One rejects the null hypothesis, H_0 , and accepts the main hypothesis, H_1 , that the variables are correlated in the population. What if the sample correlation were .13 and a correlation this large would occur in 25 percent of the samples from a population in which the true correlation were 0? Because 25 percent exceeds the a priori significance level of 5 percent, the null hypothesis is not rejected. One cannot infer that the variables are correlated in the population. Simultaneously, the results do not prove that the population correlation is .00, simply that it could be that value.

Step 4 selects a test statistic and its critical value. Common test statistics include z , t , F , and χ^2 (chi-square). The *critical value* is the value the test statistic must exceed to be significant at the level specified in step 3. For example, using a one-tail hypothesis, a z must exceed 1.645 to be significant at the .05 level. Using a two-tail hypothesis, a z , must exceed 1.96 to be significant at the .05 level. For t , F , and χ^2 , determining the critical value is more complicated because one needs to know the degrees of freedom. A formal understanding of degrees of freedom is beyond the scope of this article, but an example will give the reader an intuitive idea. If the mean of five cases is 4 and four of the cases have values of 1, 4, 5, and 2, the last case must have a value of 8 (it is the only value for the fifth case that will give a mean of 4, since $1 + 4 + 5 + 2 + x = 20$, only if $x = 8$ and $20/5 = 4$). Thus, there are $n - 1$ degrees of freedom. Most test statistics have different distributions for each number of degrees of freedom.

Figure 1 illustrates the z distribution. Under the z distribution, an absolute value of greater than 1.96 will occur by chance only 5 percent of the time. By chance a $z > 1.96$ occurs 2.5 percent of the time and a $z < -1.96$ occurs 2.5 percent of the time. Thus, 1.96 is the critical z -score for a two-tail .05 level test. The critical z -score for a one-tail test at the .05 level is 1.645 or -1.645 , depending on the direction specified in the main hypothesis.

Step 5 computes the test statistic. An example appears below.

Step 6 decides whether to reject or fail to reject the null hypothesis. If the computed test statistic

exceeds the critical value, one rejects the null hypothesis and makes the inference to accept the main hypothesis. If the computed test statistic does not exceed the critical value, one fails to reject the null hypothesis and make no inference.

Example of Six Steps Applied to H_1 . A random sample of 200 voters shows 60 percent of them supporting the candidate. Having stated the main hypothesis (step 1) and the null hypothesis (step 2), step 3 selects an a priori significance level at $\alpha = .05$, since this is the conventional level. Step 4 selects the test statistic and its critical level. To test a single percentage, a z test is used (standard textbooks on social statistics discuss how to select the appropriate tests statistics; see Agresti and Finlay 1996; Loether and McTavish 1993; Raymondo 1999; Vaughan 1997). Since the hypothesis is one-tail, the critical value is 1.645 (see Figure 1).

The fifth step computes the formula for the test statistic:

$$z = \frac{p_s - p}{\sqrt{\frac{pq}{n}}}$$

- where p_s is the proportion in the sample
- p is the proportion in the population under H_0
- q is $1 - p$
- n is the number of people in the sample.

Thus,

$$z = \frac{.6 - .5}{\sqrt{(.5 \times .5) / 200}}$$

$$z = 2.828$$

The sixth step makes the decision to reject the null hypothesis, since the difference is in the predicted direction and $2.828 > 1.645$. The statistical inference is that the candidate will win the election.

REPORTING THE PROBABILITY LEVEL

Many sociological researchers do not use the traditional null hypothesis model. Instead, they report the probability of the result. This way, a reader knows the probability (say, .042 or .058) rather than the significant versus not significant status. Reporting the probability level removes the “magic

Figure 1. Normal deviate (z) distribution.

of the level of significance.” A result that is significant at the .058 level is not categorically different from one that is significant at the .042 level. Where the traditional null hypothesis approach says that the first of these results is not significant and the second is, reporting the probability tells the reader that there is only a small difference in the degree of confidence attached to the two results. Critics of this strategy argue that the reader may adjust the significance level post hoc; that is, the reader may raise or lower the level of significance after seeing the results. It also is argued that it is the researcher, not the reader, who is the person testing the hypotheses; therefore, the researcher is responsible for selecting an a priori level of significance.

The strategy of reporting the probability is illustrated for *H1*. Using the tabled values or functions in standard statistical packages, the one-tail probability of a $z = 2.828$ is .002. The researcher reports that the candidate had 60 percent of the vote in the sample and that the probability of getting that much support by chance is .002. This provides more information than does simply saying that it is significant at the .05 level. Results that could happen only twice in 1,000 times by chance

(.002) are more compelling than are results that could happen five times in 100 (.05).

Since journal editors want to keep papers short and studies often include many tests of significance, reporting probabilities is far more efficient than going through the six-step process outlined above. The researcher must go through these steps, but the paper merely reports the probability for each test and places an asterisk along those which are significant at the .05 level. Some researchers place a single asterisk for results significant at the .05 level, two asterisks for results significant at the .01 level, and three asterisks for results significant at the .001 level.

CONFIDENCE INTERVALS

Rather than reporting the significance of a result, this approach puts a confidence interval around the result. This provides additional information in terms of the width of the confidence interval.

Using a confidence interval, a person constructs a range of values such that he or she is 95 percent confident (some use a 99 percent confi-

dence interval) that the range contains the population parameter. The confidence interval uses a two-tail approach on the assumption that the population value can be either above or below the sample value.

For the election example, $H1$, the confidence interval is

$$p_s \pm z_{\alpha/2} \sqrt{\frac{pq}{n}}$$

where $z_{\alpha/2}$ is the two-tail critical value for the alpha level

p_s is the proportion in the sample

p is the proportion in the population under H_0

q is $1 - p$

n is the number of people in the sample

$$\begin{aligned} &= .6 \pm 1.96 \sqrt{\frac{.5 \times .5}{200}} \\ &= .6 \pm 1.96 \times .03535 \\ &= .6 \pm .0693 \end{aligned}$$

upper limit	.669
lower limit	.531

The researcher is 95 percent confident that the interval, .531 to .669, contains the true population proportion. The focus is on the confidence level (.95) for a result rather than the low likelihood of the null hypothesis (.05) used in the traditional null hypothesis testing approach.

The confidence interval has more information value than do the first two approaches. Since the value specified in the null hypothesis ($H_0: P = .50$) is not in the confidence interval, the result is statistically significant at the .05 level. Note that a 95 percent confidence level corresponds to a .05 level of significance and that a 99 percent confidence interval corresponds to a .01 level of significance. Whenever the value specified by the null hypothesis is not in the confidence interval, the result is statistically significant. More important, the confidence interval provides an estimate of the range of possible values for the population. With 200 cases and 60 percent support, there is confidence that the candidate will win, although it may be a close election with the lower limit indicating 53.1 per-

cent of the vote or a landslide with the upper limit indicating 66.9 percent of the vote. If the sample were four times as large, $n = 800$, the confidence interval would be half as wide (.565-.635) and would give a better fix on the outcome.

COMPUTATION OF TESTS AND CONFIDENCE INTERVALS

Table 1 presents formulas for some common tests of significance and their corresponding confidence intervals where appropriate. These are only a sample of the tests that are commonly used, but they cover means, differences of means, proportions, differences of proportions, contingency tables, and correlations. Not included are a variety of multivariate tests for analysis of variance, regression, path analysis, and structural equation models. The formulas shown in Table 1 are elaborated in most standard statistics textbooks (Agresti and Finlay 1996; Blalock 1979; Bohrnstedt and Knoke 1998; Loether and McTavish 1993; Raymondo 1999; Vaughan 1997).

LOGIC OF STATISTICAL INFERENCE

A formal treatment of the logic of statistical inference is beyond the scope of this article; the following is a simplified description. Suppose one wants to know whether a telephone survey can be thought of as a random sample. From current census information, suppose the mean, μ , income of the community is \$31,800 and the standard deviation, σ , is \$12,000. A graph of the complete census enumeration appears in Panel A of Figure 2. The fact that there are a few very wealthy people skews the distribution.

A telephone survey included interviews with 1,000 households. If it is random, its sample mean and standard deviation should be close to the population parameters, μ and σ , respectively. Assume that the sample has a mean of \$33,200 and a standard deviation of \$10,500. To distinguish these sample statistics from the population parameters, call them M and s . The sample distribution appears in Panel B by Figure 2. Note that it is similar to the population distribution but is not as smooth.

One cannot decide whether the sample could be random by looking at Panels A and B. The distributions are different, but this difference might

Common Tests of Significance Formulas

What is Being Tested?	H_1	H_0	Test Statistic	Large-Scale Confidence Interval
Single mean against value specified as χ in H_0	1-tail: $\mu > \chi$ 2-tail: $\mu \neq \chi$	$\mu = \chi$	t with $n - 1$ degrees of freedom $t = \frac{M - \chi}{s/\sqrt{n}}$	$M \pm t_{\alpha/2} \sigma / \sqrt{n}$
Single proportion against value specified as χ in H_0	1-tail: $P > \chi$ 2-tail: $P \neq \chi$	$P = \chi$	$z = \frac{P_s - \chi}{\sqrt{PQ/N}}$	$P_s \pm z_{\alpha/2} \sqrt{\frac{PQ}{n}}$
Difference between two means	1-tail: $\mu_1 > \mu_2$ 2-tail: $\mu_1 \neq \mu_2$	$\mu_1 = \mu_2$	t with $n_1 + n_2$ degrees of freedom: $t = \frac{M_1 - M_2}{\sqrt{s^2 \left(\frac{1}{n_1} + \frac{1}{n_2} \right)}}$ where $s^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2}$	$M_1 - M_2 \pm t_{\alpha/2} \sigma_{M_1 - M_2}$ where $\sigma_{M_1 - M_2}$ is defined as the denominator of the t -test in the cell to the immediate left
Difference between two proportions	1-tail: $P_1 > P_2$ 2-tail: $P_1 \neq P_2$	$P_1 = P_2$	$z = \frac{Ps_1 - Ps_2}{\sqrt{PQ} \sqrt{\frac{n_1 + n_2}{n_1 n_2}}}$	$Ps_1 - Ps_2 \pm z_{\alpha/2} \sigma_{Ps_1 - Ps_2}$ where $\sigma_{Ps_1 - Ps_2}$ is defined as the numerator of the z -test in the cell to the immediate left
Significance of contingency table	The level on one variable depends on the level on the second variable	No dependency between the variables	$\chi^2 = \frac{\Sigma(F_o - F_e)^2}{F_e}$	Not applicable
Single correlation	1-tail $\rho > 0$ 2-tail $\rho \neq 0$	$\rho = 0$	F with 1 and $n - 2$ degrees of freedom: $F = \frac{r^2(n - 2)}{1 - r^2}$	Complex, since it is not symmetrical

Table 1

have occurred by chance. Statistical inference is accomplished by introducing two theoretical distributions: the sampling distribution of the mean and the z -distribution of the normal deviate. A theoretical distribution is different from the population and sample distributions in that a theoretical distribution is mathematically derived; it is not observed directly.

Sampling Distribution of the Mean. Suppose that instead of taking a single random sample of 1,000 people, one took two such samples and determined the mean of each one. With 1,000 cases, it is likely that the two samples would have means that were close together but not the same. For instance, the mean of the second sample might be \$30,200. These means, \$33,200 and \$30,200, are pretty close to each other. For a sample to have a mean of, say \$11,000, it would have to include a

greatly disproportionate share of poor families; this is not likely by chance with a random sample with $n = 1,000$. For a sample to have a mean of, say, \$115,000, it would have to have a greatly disproportionate share of rich families. In contrast, with a sample of just two individuals, one would not be surprised if the first person had an income of \$11,000 and the second had an income of \$115,000.

The larger the samples are, the more stable the mean is from one sample to the next. With only 20 people in the first and second samples, the means may vary a lot, but with 100,000 people in both samples, the means should be almost identical. Mathematically, it is possible to derive a distribution of the means of all possible samples of a given n even though only a single sample is observed. It can be shown that the mean of the

Figure 2. Four distributions used in statistical inference: (A) population distribution; (B) sample distribution; sampling distribution for $n=100$ and $n=1,000$; and (D) normal deviate (z) distributions

sampling distribution of means is the population mean and that the standard deviation of the sampling distribution of the means is the population standard deviation divided by the square root of the sample size. The standard deviation of the mean is called the *standard error of the mean*:

$$\text{Standard error of the mean (SEM)} = \sigma_M = \frac{\sigma}{\sqrt{n}}$$

This is an important derivation in statistical theory. Panel C shows the sampling distribution of the mean when the sample size is $n = 1,000$. It also shows the sampling distribution of the mean for $n = 100$. A remarkable property of the sampling distribution of the mean is that with a large sample

size, it will be normally distributed even though the population and sample distributions are skewed.

One gets a general idea of how the sample did by seeing where the sample mean falls along the sampling distribution of the mean. Using Panel C for $n = 1,000$, the sample $M = \$33,200$ is a long way from the population mean. Very few samples with $n = 1,000$ would have means this far from the population mean. Thus, one infers that the sample mean probably is based on a nonrandom sample.

Using the distribution in Panel C for the smaller sample size, $n = 100$, the sample $M = \$33,200$ is not so unusual. With 100 cases, one should not be surprised to get a sample mean this far from the population mean.

Being able to compare the sample mean to the population mean by using the sampling distribution is remarkable, but statistical theory allows more precision. One can transform the values in the sampling distribution of the mean to a distribution of a test statistic. The appropriate test statistic is the distribution of the normal deviate, or z -distribution. It can be shown that

$$z = \frac{M - \mu}{\sigma/\sqrt{n}}$$

If the z -value were computed for the mean of all possible samples taken at random from the population, it would be distributed as shown in Panel D of Figure 2. It will be normal, have a mean of zero, and have a variance of 1.

Where is $M = \$33,200$ under the distribution of the normal deviate using the sample size of $n = 1,000$? Its z -score using the above formula is

$$\begin{aligned} z &= \frac{33,200 - 31,800}{12,000/\sqrt{1,000}} \\ &= 3.689 \end{aligned}$$

Using tabled values for the normal deviate, the probability of a random sample of 1,000 cases from a population with a mean of \$31,800 having a sample mean of \$33,200 is less than .001. Thus, it is extremely unlikely that the sample is purely random.

With the same sample mean but with a sample of only 100 people,

$$\begin{aligned} z &= \frac{33,200 - 31,800}{12,000/\sqrt{100}} \\ &= 1.167 \end{aligned}$$

Using tabled values for a two-tail test, the probability of getting the sample mean this far from the population mean with a sample of 100 people is .250. One should not infer that the sample is nonrandom, since these results could happen 25 percent of the time by chance.

The four distributions can be described for any sample statistic one wants to test (means, differences of means, proportions, differences of proportions, correlations, etc). While many of the calculations will be more complex, their logic is identical.

MULTIPLE TESTS OF SIGNIFICANCE

The logic of statistical inference applies to testing a single hypothesis. Since most studies include multiple tests, interpreting results can become extremely complex. If a researcher conducts 100 tests, 5 of them should yield results that are statistically significant at the .05 level by chance. Therefore, a study that includes many tests may find some “interesting” results that appear statistically significant but that really are an artifact of the number of tests conducted.

Sociologists pay less attention to “adjusting the error rate” than do those in most other scientific fields. A conservative approach is to divide the Type I error by the number of tests conducted. This is known as the Dunn multiple comparison test, based on the Bonferroni inequality. For example, instead of doing nine tests at the .05 level, each test is done at the $.05/9 = .006$ level. To be viewed as statistically significant at the .05 level, each specific test must be significant at the .006 level.

There are many specialized multiple comparison procedures, depending on whether the tests are planned before the study starts or after the results are known. Brown and Melamed (1990) describe these procedures.

POWER AND TYPE I AND TYPE II ERRORS

To this point, only one type of probability has been considered. Sociologists use statistical inference to minimize the chance of accepting a main hypothesis that is false in the population. They reject the null hypothesis only if the chances of it’s being true in the population are very small, say, $\alpha = .05$. Still, by minimizing the chances of this error, sociologists increase the chance of failing to reject the null hypothesis when it should be rejected. Table 2 illustrates these two types of error.

Type I, or α , error is the probability of rejecting H_0 falsely, that is, the error of deciding that H_1 is right when H_0 is true in the population. If one were testing whether a new program reduced drug abuse among pregnant women, the H_1 would be that the program did this and the H_0 would be that the program was no better than the existing one. Type I error should be minimized because it would be wrong to change programs when the new program was no better than the existing one. Type I

Type I (α) and Type II (β) Errors

Decision Made by the Researcher	True Situation in the Population	
	H_0 , the null hypothesis, is true	H_1 , the main hypothesis, is true
H_0 , the null hypothesis is true	$1 - \alpha$	β
H_1 , the main hypothesis is true	α	$1 - \beta$

Table 2

error has been described as “the chances of discovering things that aren’t so” (Cohen 1990, p. 1304). The focus on Type I error reflects a conservative view among scientists. Type I error guards against doing something new (as specified by H_1) when it is not going to be helpful.

Type II, or β , error is the probability of failing to reject H_0 when H_1 is true in the population. If one failed to reject the null hypothesis that the new program was no better (H_0) when it was truly better (H_1), one would put newborn children at needless risk. Type II error is the chance of missing something new (as specified by H_1) when it really would be helpful.

Power is $1 - \beta$. Power measures the likelihood of rejecting the null hypothesis when the alternative hypothesis is true. Thus, if there is a real effect in the population, a study that has a power of .80 can reject the null hypothesis with a likelihood of .80. The power of a statistical test is measured by how likely it is to do what one usually wants to do: demonstrate support for the main hypothesis when the main hypothesis is true. Using the example of a treatment for drug abuse among pregnant women, the power of a test is the ability to demonstrate that the program is effective if this is really true.

Power can be increased. First, get a larger sample. The larger the sample, the more power to find results that exist in the population. Second, increase the α level. Rather than using the .01 level of significance, a researcher can pick the .05 or even the .10. The larger α is, the more powerful the test is in its ability to reject the null hypothesis when the alternative is true.

There are problems with both approaches. Increasing sample size makes the study more costly. If there are risks to the subjects who participate,

adding cases exposes additional people to that risk. An example of this would be a study that exposed subjects to a new drug treatment program that might create more problems than it solved. A larger sample will expose more people to these risks.

Since Type I and Type II errors are inversely related, raising α reduces β thus increasing the power of the test. However, sociologists are hesitant to raise α since doing so increases the chance of deciding something is important when it is not important. With a small sample, using a small α level such as .001 means there is a great risk of β error. Many small-scale studies have a Type II error of over .50. This is common in research areas that rely on small samples. For example, a review of one volume of the *Journal of Abnormal Psychology* (this journal includes many small-sample studies) found that those studies average Type II error of .56 (Cohen 1990). This means the psychologist had inadequate power to reject the null hypothesis when H_1 was true. When H_1 was true, the chance of rejecting H_0 (i.e., power) was worse than that resulting from flipping a coin.

Some areas that rely on small samples because of the cost of gathering data or to minimize the potential risk to subjects require researchers to plan their sample sizes to balance α , power, sample size, and the minimum size of effect that is theoretically important. For example, if a correlation of .1 is substantively significant, a power of .80 is important, and an $\alpha = .01$ is desired, a very large sample is required. If a correlation is substantively and theoretically important only if it is over .5, a much smaller sample is adequate. Procedures for doing a power analysis are available in Cohen (1988); see also Murphy and Myous (1998).

Power analysis is less important for many sociological studies that have large samples. With a large sample, it is possible to use a conservative α error rate and still have sufficient power to reject the null hypothesis when H_1 is true. Therefore, sociologists pay less attention to β error and power than do researchers in fields such as medicine and psychology. When a sociologist has a sample of 10,000 cases, the power is over .90 that he or she will detect a very small effect as statistically significant. When tests are extremely powerful to detect small effects, researchers must focus on the substantive significance of the effects. A correlation of

.07 may be significant at the .05 level with 10,000 cases, but that correlation is substantively trivial.

STATISTICAL AND SUBSTANTIVE SIGNIFICANCE

Some researchers and many readers confuse statistical significance with substantive significance. Statistical inference does not ensure substantive significance, that is, ensure that the result is important. A correlation of .1 shows a weak relationship between two variables whether it is statistically significant or not. With a sample of 100 cases, this correlation will not be statistically significant; with a sample of 10,000 cases, it will be statistically significant. The smaller sample shows a weak relationship that might be a zero relationship in the population. The larger sample shows a weak relationship that is all but certainly a weak relationship in the population, although it is not zero. In this case, the statistical significance allows one to be confident that the relationship in the population is substantively weak.

Whenever a person reads that a result is statistically significant, he or she is confident that there is some relationship. The next step is to decide whether it is substantively significant or substantively weak. Power analysis is one way to make this decision. One can illustrate this process by testing the significance of a correlation. A population correlation of .1 is considered weak, a population correlation of .3 is considered moderate, and a population correlation of .5 or more is considered strong. In other words, if a correlation is statistically significant but .1 or lower, one has to recognize that this is a weak relationship—it is statistically significant but substantively weak. It is just as important to explain to the readers that the relationship is substantively weak as it is to report that it is statistically significant. By contrast, if a sample correlation is .5 and is statistically significant, one can say the relationship is both statistically and substantively significant.

Figure 3 shows power curves for testing the significance of a correlation. These curves illustrate the need to be sensitive to both statistical significance and substantive significance. The curve on the extreme left shows the power of a test to show that a sample correlation, r , is statistically significant when the population correlation, ρ (rho), is .5. With a sample size of around 100, the power

of a test to show statistical significance approaches 1.0, or 100 percent. This means that any correlation that is this strong in the population can be shown to be statistically significant with a small sample.

What happens when the correlation in the population is weak? Suppose the true correlation in the population is .2. A sample with 500 cases almost certainly will produce a sample correlation that is statistically significant, since the power is approaching 1.0. Many sociological studies have 500 or more cases and produce results showing that substantively weak relationships, $\rho = .2$, are statistically significant. Figure 3 shows that even if the population correlation is just .1, a sample of 1,000 cases has the power to show a sample result that is statistically significant. Thus, any time a sample is 1,000 or larger, one has to be especially careful to avoid confusing statistical and substantive significance.

The guidelines for distinguishing between statistical and substantive significance are direct but often are ignored by researchers:

1. If a result is not statistically significant, regardless of its size in the sample, one should be reluctant to generalize it to the population.
2. If a result is statistically significant in the sample, this means that one can generalize it to the population but does not indicate whether it is a weak or a strong relationship.
3. If a result is statistically significant and strong in the sample, one can both generalize it to the population and assert that it is substantively significant.
4. If a result is statistically significant and weak in the sample, one can both generalize it to the population and assert that it is substantively weak in the population.

This reasoning applies to any test of significance. If a researcher found that girls have an average score of 100.2 on verbal skills and boys have an average score of 99.8, with girls and boys having a standard deviation of 10, one would think this as a very weak relationship. If one constructed a histogram for both girls and boys, one would find them almost identical. This difference is not substantively significant. However, if there was a sufficiently

Figure 3. Power of test of r , $\alpha = .05$

large sample of girls and boys, say, $n = 10,000$, it could be shown that the difference is statistically significant. The statistical significance means that there is some difference, that the means for girls and boys are not identical. It is necessary to use judgment, however, to determine that the difference is substantively trivial. An abuse of statistical inference that can be committed by sociologists who do large-scale research is to confuse statistical and substantive significance.

NONRANDOM SAMPLES AND STATISTICAL INFERENCE

Very few researchers use true random samples. Sometimes researchers use convenience sampling. An example is a social psychologist who has every student in a class participate in an experiment. The students in this class are not a random sample of the general population or even of students in a university. Should statistical inference be used here?

Other researchers may use the entire population. If one wants to know if male faculty members are paid more than female faculty members at a particular university, one may check the payroll for every faculty member. There is no sample—one has the entire population. What is the role of statistical inference in this instance?

Many researchers would use a test of significance in both cases, although the formal logic of statistical inference is violated. They are taking a “what if” approach. If the results they find could have occurred by a random process, they are less confident in their results than they would be if the results were statistically significant. Economists and demographers often report statistical inference results when they have the entire population. For example, if one examines the unemployment rates of blacks and whites over a ten-year period, one may find that the black rate is about twice the white rate. If one does a test of significance, it is unclear what the population is to which one wants

to generalize. A ten-year period is not a random selection of all years. The rationale for doing statistical inference with population data and nonprobability samples is to see if the results could have been attributed to a chance process.

A related problem is that most surveys use complex sample designs rather than strictly random designs. A stratified sample or a clustered sample may be used to increase efficiency or reduce the cost of a survey. For example, a study might take a random sample of 20 high schools from a state and then interview 100 students from each of those schools. This survey will have 2,000 students but will not be a random sample because the 100 students from each school will be more similar to each other than to 100 randomly selected students. For instance, the 100 students from a school in a ghetto may mostly have minority status and mostly be from families that have a low income in a population with a high proportion of single-parent families. By contrast, 100 students from a school in an affluent suburb may be disproportionately white and middle class.

The standard statistical inference procedures discussed here that are used in most introductory statistics texts and in computer programs such as SAS and SPSS assume random sampling. When a different sampling design is used, such as a cluster design, a stratified sample, or a longitudinal design, the test of significance will be biased. In most cases, the test of significance will underestimate the standard errors and thus overestimate the test statistic (z , t , F). The extent to which this occurs is known as the “design effect.” The most typical design effect is greater than 1.0, meaning that the computed test statistic is larger than it should be. Specialized programs allow researchers to estimate design effects and incorporate them in the computation of the test statistics. The most widely used of these procedures are WesVar, which is available from SPSS, and SUDAAN, a stand-alone program. Neither program has been widely used by sociologists, but their use should increase in the future.

STATISTICAL METHODS

In the 1960s, the introduction, acceptance, and application of multivariate statistical methods transformed quantitative sociological research. Regression methods from biometrics and economics; factor analysis from psychology; stochastic modeling from engineering, biometrics, and statistics; and methods for contingency table analysis from sociology and statistics were developed and combined to provide a rich variety of statistical methods. Along with the introduction of these techniques came the institutionalization of quantitative methods. In 1961, the American Sociological Association (ASA) approved the Section on Methodology as a result of efforts organized by Robert McGinnis and Albert Reiss. The ASA’s yearbook, *Sociological Methodology*, first appeared in 1969 under the editorship of Edgar F. Borgatta and George W. Bohrnstedt. Those editors went on to establish the quarterly journal *Sociological Methods and Research* in 1972. During this period, the National Institute of Mental Health began funding training

programs that included rigorous training in quantitative methods.

This article traces the development of statistical methods in sociology since 1960. Regression, factor analysis, stochastic modeling, and contingency table analysis are discussed as the core methods that were available or were introduced by the early 1960s. The development of additional methods through the enhancement and combination of these methods is then considered. The discussion emphasizes statistical methods for causal modeling; consequently, methods for data reduction (e.g., cluster analysis, smallest space analysis), formal modeling, and network analysis are not considered.

THE BROADER CONTEXT

By the end of the 1950s, the central ideas of mathematical statistics that emerged from the work of R. A. Fisher and Karl Pearson were firmly established. Works such as Fisher's *Statistical Methods for Research Workers* (1925), Kendall's *Advanced Theory of Statistics* (1943, 1946), Cramér's *Mathematical Methods of Statistics* (1946), Wilks's *Mathematical Statistics* (1944), Lehman's *Testing Statistical Hypotheses* (1959), Scheffé's *The Analysis of Variance* (1959), and Doob's *Stochastic Processes* (1953) systematized the key results of mathematical statistics and provided the foundation for developments in applied statistics for decades to come. By the start of the 1960s, multivariate methods were applied routinely in psychology, economics, and the biological sciences. Applied treatments were available in works such as Snedecor's *Statistical Methods* (1937), Wold's *Demand Analysis* (Wold and Juréen, 1953), Anderson's *An Introduction to Multivariate Statistical Analysis* (1958), Simon's *Models of Man* (1957), Thurstone's *Multiple-Factor Analysis* (1947), and Finney's *Probit Analysis* (1952).

These methods are computationally intensive, and their routine application depended on developments in computing. BMD (Biomedical Computing Programs) was perhaps the first widely available statistical package, appearing in 1961 (Dixon et al. 1981). SPSS (Statistical Package for the Social Sciences) appeared in 1970 as a result of efforts by a group of political scientists at Stanford to develop a general statistical package specifically

for social scientists (Nie et al. 1975). In addition to these general-purpose programs, many specialized programs appeared that were essential for the methods discussed below. At the same time, continuing advances in computer hardware increased the availability of computing by orders of magnitude, facilitating the adoption of new statistical methods.

DEVELOPMENTS IN SOCIOLOGY

It is within the context of developments in mathematical statistics, sophisticated applications in other fields, and rapid advances in computing that major changes occurred in quantitative sociological research. Four major methods serve as the cornerstones for later developments: regression, factor analysis, stochastic processes, and contingency table analysis.

Regression Analysis and Structural Equation Models. Regression analysis is used to estimate the effects of a set of independent variables on one or more dependent variables. It is arguably the most commonly applied statistical method in the social sciences. Before 1960, this method was relatively unknown to sociologists. It was not treated in standard texts and was rarely seen in the leading sociological journals. The key notions of multiple regression were introduced to sociologists in Blalock's *Social Statistics* (1960). The generalization of regression to systems of equations and the accompanying notion of causal analysis began with Blalock's *Causal Inferences in Nonexperimental Research* (1964) and Duncan's "Path Analysis: Sociological Examples" (1966). Blalock's work was heavily influenced by the economist Simon's work on correlation and causality (Simon 1957) and the economist Wold's work on simultaneous equation systems (Wold and Juréen 1953). Duncan's work added the influence of the geneticist Wright's work in path analysis (Wright 1934). The acceptance of these methods by sociologists required a substantive application that demonstrated how regression could contribute to the understanding of fundamental sociological questions. In this case, the question was the determination of occupational standing and the specific work was the substantively and methodologically influential *The American Occupational Structure* by Blau and Duncan (1967), a work unsurpassed in its integration

of method and substance. Numerous applications of regression and path analysis soon followed. The diversity of influences, problems, and approaches that resulted from Blalock and Duncan's work is shown in Blalock's reader *Causal Models in the Social Sciences* (1971), which became the handbook of quantitative methods in the 1970s.

Regression models have been extended in many ways. Bielby and Hauser (1977) have reviewed developments involving systems of equations. Regression methods for time series analysis and forecasting (often called Box-Jenkins models) were given their classic treatment in Box and Jenkins's *Time Series Analysis* (1970). Regression diagnostics have provided tools for exploring characteristics of the data set that is to be analyzed. Methods for identifying outlying and influential observations have been developed (Belsley et al. 1980), along with major advances in classic problems such as heteroscedasticity (White 1980) and specification (Hausman 1978). All these extensions have been finding their way into sociological practice.

Factor Analysis. Factor analysis, a technique developed by psychometricians, was the second major influence on quantitative sociological methods. Factor analysis is based on the idea that the covariation among a larger set of *observed* variables can be reduced to the covariation among a smaller set of *unobserved* or latent variables. By 1960, this method was well known and applications appeared in most major sociology journals. Statistical and computational advances in applying maximum-likelihood estimation to the factor model (Jöreskog 1969) were essential for the development of the covariance structure model discussed below.

Stochastic Processes. Stochastic models were the third influence on the development of quantitative sociological methods. Stochastic processes model the change in a variable over time in cases where a chance process governs the change. Examples of stochastic processes include change in occupational status over a career (Blumen et al. 1955), friendship patterns, preference for job locations (Coleman 1964), and the distribution of racial disturbances (Spilerman 1971). While the mathematical and statistical details for many stochastic models had been worked out by 1960, they were relatively unknown to sociologists until the

publication of Coleman's *Introduction to Mathematical Sociology* (1964) and Bartholomew's *Stochastic Models for Social Processes* (1967). These books presented an array of models that were customized for specific social phenomena. While these models had great potential, applications were rare because of the great mathematical sophistication of the models and the lack of general-purpose software for estimating the models. Nonetheless, the influence of these methods on the development of other techniques was great. For example, Markov chain models for social mobility had an important influence on the development of loglinear models.

Contingency Table Analysis and Loglinear Models. Methods for categorical data were the fourth influence on quantitative methods. The analysis of contingency tables has a long tradition in sociology. Lazarsfeld's work on elaboration analysis and panel analysis had a major influence on the way research was done at the start of the 1960s (Lazarsfeld and Rosenberg 1955). While these methods provided useful tools for analyzing categorical data and especially survey data, they were nonstatistical in the sense that issues of estimation and hypothesis testing generally were ignored. Important statistical advances for measures of association in two-way tables were made in a series of papers by Goodman and Kruskal that appeared during the 1950s and 1960s (Goodman and Kruskal 1979). In the 1960s, nonstatistical methods for analyzing contingency tables were replaced by the loglinear model. This model made the statistical analysis of multiway tables possible. Early developments are found in papers by Birch (1963) and Goodman (1964). The development of the general model was completed largely through the efforts of Frederick Mosteller, Stephen E. Fienberg, Yvonne M. M. Bishop, Shelby Haberman, and Leo A. Goodman, which were summarized in Bishop et al.'s *Discrete Multivariate Analysis* (1975). Applications in sociology appeared shortly after Goodman's (1972) didactic presentation and the introduction of ECTA (Fay and Goodman 1974), a program for loglinear analysis. Since that time, the model has been extended to specific types of variables (e.g., ordinal), more complex structures (e.g., association models), and particular substantive problems (e.g., networks) (see Agresti [1990] for a treatment of recent developments). As with regression models, many early applications appeared in the area

of stratification research. Indeed, many developments in loglinear analysis were motivated by substantive problems encountered in sociology and related fields.

ADDITIONAL METHODS

From these roots in regression, factor analysis, stochastic processes, and contingency table analysis, a wide variety of methods emerged that are now applied frequently by sociologists. Notions from these four areas were combined and extended to produce new methods. The remainder of this article considers the major methods that resulted.

Covariance Structure Models. The covariance structure model is a combination of the factor and regression models. While the factor model allowed imperfect multiple indicators to be used to extract a more accurately measured latent variable, it did not allow the modeling of causal relations among the factors. The regression model, conversely, did not allow imperfect measurement and multiple indicators. The covariance structure model resulted from the merger of the structural or causal component of the regression model with the measurement component of the factor model. With this model, it is possible to specify that each latent variable has one or more imperfectly measured observed indicators and that a causal relationship exists among the latent variables. Applications of such a model became practical after the computational breakthroughs made by Jöreskog, who published LISREL (*linear structural relations*) in 1972 (Jöreskog and van Thillo 1972). The importance of this program is reflected by the use of the phrase "LISREL models" to refer to this area.

Initially, the model was based on analyzing the covariances among observed variables, and this gave rise to the name "covariance structure analysis." Extensions of the model since 1973 have made use of additional types of information as the model has been enhanced to deal with multiple groups, noninterval observed variables, and estimation with less restrictive assumptions. These extensions have led to alternative names for these methods, such as "mean and covariance structure models" and, more recently, "structural equation modeling" (see Bollen [1989] and Browne and

Arminger [1995] for a discussion of these and other extensions).

Event History Analysis. Many sociological problems deal with the occurrence of an event. For example, does a divorce occur? When is one job given up for another? In such problems, the outcome to be explained is the time when the event occurred. While it is possible to analyze such data with regression, that method is flawed in two basic respects. First, event data often are censored. That is, for some members of the sample the event being predicted may not have occurred, and consequently a specific time for the event is missing. Even assuming that the censored time is a large number to reflect the fact that the event has not occurred, this will misrepresent cases in which the event occurred shortly after the end of the study. If one assigns a number equal to the time when the data collection ends or excludes those for whom the event has not occurred, the time of the event will be underestimated. Standard regression cannot deal adequately with censoring problems. Second, the regression model generally assumes that the errors in predicting the outcome are normally distributed, which is generally unrealistic for event data. Statistical methods for dealing with these problems began to appear in the 1950s and were introduced to sociologists in substantive papers examining social mobility (Spilerman 1972; Sorensen 1975; Tuma 1976). Applications of these methods were encouraged by the publication in 1976 of Tuma's program RATE for event history analysis (Tuma and Crockford 1976). Since that time, event history analysis has become a major form of analysis and an area in which sociologists have made substantial contributions (see Allison [1995] and Petersen [1995] for reviews of these methods).

Categorical and Limited Dependent Variables. If the dependent variable is binary, nominal, ordinal, count, or censored, the usual assumptions of the regression model are violated and estimates are biased. Some of these cases can be handled by the methods discussed above. Event history analysis deals with certain types of censored variables; loglinear analysis deals with binary, nominal, count, and ordinal variables when the independent variables are all nominal. Many other cases exist that require additional methods. These methods are called quantal response models or models for categorical, limited, or qualitative dependent vari-

ables. Since the types of dependent variables analyzed by these methods occur frequently in the social sciences, they have received a great deal of attention by econometricians and sociologists (see Maddala [1983] and Long [1997] for reviews of these models and Cameron and Trivedi [1998] on count models).

Perhaps the simplest of these methods is logit analysis, in which the dependent variable is binary or nominal with a combination of interval and nominal independent variables. Logit analysis was introduced to sociologists by Theil (1970). Probit analysis is a related technique that is based on slightly different assumptions. McKelvey and Zavoina (1975) extend the logit and probit models to ordinal outcomes. A particularly important type of limited dependent variable occurs when the sample is selected nonrandomly. For example, in panel studies, cases that do not respond to each wave may be dropped from the analysis. If those who do not respond to each wave differ nonrandomly from those who do respond (e.g., those who are lost because of moving may differ from those who do not move), the resulting sample is not representative. To use an example from a review article by Berk (1983), in cases of domestic violence, police may write a report only if the violence exceeds some minimum level, and the resulting sample is biased to exclude cases with lower levels of violence. Regression estimates based on this sample will be biased. Heckman's (1979) influential paper stimulated the development of sample selection models, which were introduced to sociologists by Berk (1983). These and many other models for limited dependent variables are extremely well suited to sociological problems. With the increasing availability of software for these models, their use is becoming more common than even that of the standard regression model.

Latent Structure Analysis. The objective of latent structure analysis is the same as that of factor analysis: to explain covariation among a larger number of observed variables in terms of a smaller number of latent variables. The difference is that factor analysis applies to interval-level observed and latent variables, whereas latent structure analysis applies to observed data that are noninterval. As part of the American soldier study, Paul F. Lazarsfeld, Sam Stouffer, Louis Guttman, and others developed techniques for “factor ana-

lyzing” nominal data. While many methods were developed, latent structure analysis has emerged as the most popular. Lazarsfeld coined the term “latent structure analysis” to refer to techniques for extracting latent variables from observed variables obtained from survey research. The specific techniques depend on the characteristics of the observed and latent variables. If both are continuous, the method is called factor analysis, as was discussed above. If both are discrete, the method is called latent class analysis. If the factors are continuous but the observed data are discrete, the method is termed latent trait analysis. If the factors are discrete but the data are continuous, the method is termed latent profile analysis. The classic presentation of these methods is presented in Lazarsfeld and Henry's *Latent Structure Analysis* (1968). Although these developments were important and their methodological concerns were clearly sociological, these ideas had few applications during the next twenty years. While the programs ECTA, RATE, and LISREL stimulated applications of the loglinear, event history, and covariance structure models, respectively, the lack of software for latent structure analysis inhibited its use. This changed with Goodman's (1974) algorithms for estimation and Clogg's (1977) program MLLSA for estimating the models. Substantive applications began appearing in the 1980s, and the entire area of latent structure analysis has become a major focus of statistical work.

Multilevel and Panel Models. In most of the models discussed here, observations are assumed to be independent. This assumption can be violated for many reasons. For example, in panel data, the same individual is measured at multiple time points, and in studies of schools, all the children in each classroom may be included in the sample. Observations in a single classroom or for the same person over time tend to be more similar than are independent observations. The problems caused by the lack of independence are addressed by a variety of related methods that gained rapid acceptance beginning in the 1980s, when practical issues of estimation were solved. When the focus is on clustering with social groups (such as schools), the methods are known variously as hierarchical models, random coefficient models, and multilevel methods. When the focus is on clustering with panel data, the methods are referred to as models for cross-section and time series data, or simply

panel analysis. The terms “fixed and random effects models” and “covariance component models” also are used. (See Hsiao [1995] for a review of panel models for continuous outcomes and Hamerle and Ronning [1995] for panel models for categorical outcomes. Bryk and Raudenbush [1992] review hierarchical linear models.)

Computer-Intensive Methods. The availability of cheap computing has led to the rapid development and application of computer-intensive methods that will change the way data are analyzed over the next decade. Methods of resampling, such as the bootstrap and the jackknife, allow practical solutions to previously intractable problems of statistical inference (Efron and Tibshirani 1993). This is done by recomputing a test statistic perhaps 1,000 times, using artificially constructed data sets. Computational algorithms for Bayesian analysis replace difficult or impossible algebraic derivations with computer-intensive simulation methods, such as the Markov chain algorithm, the Gibbs sampler, and the Metropolis algorithm (Gelman et al. 1995). Related developments have occurred in the treatment of missing data, with applications of the EM algorithm and Markov chain Monte Carlo techniques (Schafer 1997).

Other Developments. The methods discussed above represent the major developments in statistical methods in sociology since the 1960s. With the rapid development of mathematical statistics and advances in computing, new methods have continued to appear. Major advances have been made in the treatment of missing data (Little and Rubin 1987). Developments in statistical graphics (Cleveland 1985) are reflected in the increasing number of graphics appearing in sociological journals. Methods that require less restrictive distributional assumptions and are less sensitive to errors in the data being analyzed are now computationally feasible. Robust methods have been developed that are insensitive to small departures from the underlying assumptions (Rousseeuw and Leroy 1987). Resampling methods (e.g., bootstrap methods) allow estimation of standard errors and confidence intervals when the underlying distributional assumptions (e.g., normality) are unrealistic or the formulas for computing standard errors are intractable by letting the observed data assume the role of the underlying population (Stine 1990). Recent work by Muthén (forthcom-

ing) and others combines the structural component of the regression model, latent variables from factor and latent structure models, hierarchical modeling, and characteristics of limited variables into a single model. The development of Mplus (Muthén and Muthén 1998) makes routine application of this general model feasible.

CONCLUSIONS

The introduction of structural equation models in the 1960s changed the way sociologists viewed data and viewed the social world. Statistical developments in areas such as econometrics, biometrics, and psychometrics were imported directly into sociology. At the same time, other methods were developed by sociologists to deal with substantive problems of concern to sociology. A necessary condition for these changes was the steady decline in the cost of computing, the development of efficient numerical algorithms, and the availability of specialized software. Without developments in computing, these methods would be of little use to substantive researchers. As the power of desktop computers grows and the ease and flexibility of statistical packages increase, the application of sophisticated statistical methods has become more accessible to the average researcher than the card sorter was for constructing contingency tables in the 1950s and 1960s. As computing power continues to develop, new and promising methods are appearing with each issue of the journals in this area.

Acceptance of these methods has not been universal or without costs. Critiques of the application of quantitative methods have been written by both sympathetic (Lieberman 1985; Duncan 1984) and unsympathetic (Cosser 1975) sociologists as well as statisticians (Freedman 1987) and econometricians (Leamer 1983). While these critiques have made practitioners rethink their approaches, the developments in quantitative methods that took shape in the 1960s will continue to influence sociological practice for decades to come.

STATUS ATTAINMENT

Status attainment is the process by which individuals attain positions in the system of social stratification in a society. If one thinks of social stratification as referring to the rewards society offers and the resources individuals use to obtain those rewards, education, occupation, and income are the key factors. The amount and kind of education people attain determine the kinds of jobs they get. The kind of work people do is the main determinant of their income. Moreover, the education, occupation, and income of parents largely determine the kinds of advantages or disadvantages they create for their children. Sociologists usually think of education, occupation, and income as the main aspects of socioeconomic status, and the study of status attainment is therefore the study of how these attributes of people are related both within and across generations.

ESTABLISHMENT OF THE FIELD

As a distinctive area of research, status-attainment research had its origins in the work of Otis Dudley Duncan in the 1960s. Duncan (1961) reconceptualized the study of intergenerational occupational mobility—which is concerned with the degree and pattern of association between the kinds of work done by parents and offspring (in practice, fathers and sons)—as the study of the factors that determine who gets what sort of job, with the father's occupation being only one of several determining factors. Other researchers extended Duncan's findings to take account of the factors that determine how much schooling people get and how much money they make.

Duncan's conceptual reformulation was accompanied by two important technical innovations. The first was the creation of a socioeconomic status scale for occupations. Unlike education and income, occupation has no intrinsic metric: No

natural ordering of occupations exists in terms of relative status. For many kinds of research, however, especially the study of status attainment, it is desirable to arrange occupations into some sort of status hierarchy, that is, a hierarchy of the relative socioeconomic advantage enjoyed by people in different occupations. Duncan created such an ordering of occupations for the categories of the 1950 U.S. Census classification by taking the weighted average of the education and income of typical incumbents, with the weights chosen to maximize the association between the resulting socioeconomic status scale and the relative prestige of occupations as measured by popular evaluations. He was able to do this because prestige and socioeconomic status are very highly correlated: Occupations that have high socioeconomic status (that is, that require a great deal of education and pay well) also tend to have high prestige, and jobs that require little education and pay poorly tend to have low prestige.

Second, Duncan introduced path analysis into sociology. Path analysis is a way of statistically representing the relative strength of different relationships between variables, both direct and indirect. For example, it is known that educated people tend to earn more than do uneducated people, but it is not clear whether this is the case simply because they have jobs of higher status or whether, among those who have jobs of similar status, the better educated earn more than do the less well educated. Path analysis provides a way of answering this question: Even among people doing the same sort of work, the better educated tend to earn more.

SUBSTANTIVE ISSUES

Four central issues have dominated research on status attainment. The first issue is the extent of "social reproduction," the tendency for class and socioeconomic status position to be perpetuated, or "reproduced," from generation to generation. A value assumption underlies this question. "Open" societies, that is, societies with low rates of social reproduction or, to put it differently, high rates of intergenerational social mobility, are regarded as desirable since they are assumed to have relatively high equality of opportunity and to emphasize "achievement" rather than "ascription" as the basis for socioeconomic success.

The second issue is the factors other than the status of parents that affect education, occupation, and income. Of course, some factors may be correlated with the status of parents and also may have an independent effect. For example, there is a modest negative correlation between socioeconomic status and fertility—high-status people tend to have fewer children—and there is also a tendency for people from large families not to go as far in school as people from small families do. Thus, part of the reason the children of high-status people go further in school is that such people have smaller families. However, it is also true that at any given level of parental status (e.g., for families where both parents are college-educated professionals), people from smaller families go further in school. Therefore, the number of siblings has an *independent* effect on educational attainment apart from its correlation with parental status. Sorting out such effects is facilitated by the application of path analysis.

The third issue is the extent to which there are sex and racial (or ethnic) differences in patterns of status attainment. With respect to gender, the questions are: Do men and women from similar social origins go equally far in school? Do equally qualified men and women get jobs of equal status? Are women paid as well as men doing similar work? The same set of questions is asked with respect to differences between racial and ethnic groups.

The fourth issue is whether the process of status attainment operates the same way in different countries or in the same country in different historical periods. What follows is a summary of what is known about each of these four issues with respect to educational attainment, occupational attainment, and income attainment.

EDUCATION

Reproduction. In regard to the extent of educational reproduction, the evidence in the United States in the late twentieth century is clear: America is an “open” society. Educational attainment (how far people go in school) is only weakly dependent on parental status. Only about 20 percent of the variability in years of school completed can be attributed to the level of education attained by one’s father or mother. When several different family background characteristics are taken into

account, the connection is not much stronger; at most, about one-third of the variability in educational attainment can be attributed to the status of the family one comes from. The rest is due to factors unrelated to social origins.

Other Factors. Apart from the social status of parents, the main factors that affect educational attainment are intelligence, the number of siblings (as was noted above, all else being equal, people from large families get less schooling), family stability (those from nonintact families, people whose parents have divorced or died—one or both—go less far in school), the influence of “significant others” (family members, friends, and teachers), and academic performance (the better people do in school, the longer they continue to go to school).

The question naturally arises as to why and how origin status and these other factors affect educational attainment. In a country such as the United States, where education up to the college level is free, parental wealth has relatively little effect on whether people stay in school. This claim is supported by the observation that the effect of social origins on educational attainment declines with each successive educational transition. That is, social origins have a stronger influence on whether people graduate from high school than on whether high school graduates go on to college and an even weaker influence on the graduation chances of those who begin college. If parental wealth is not important, what is?

There are two underlying factors: “Human capital” (sometimes called “cultural capital”) is the most important, but “social capital” is involved as well. Human capital refers to the knowledge, skills, and motivations of individuals. The basic argument here is that growing up in a high-status family enhances one’s human capital and that those with high human capital do better in school and therefore gain more education, which of course further enhances their human capital. The idea is that children who grow up in well-educated families or professional families learn the kinds of skills and acquire the kinds of motivations that enable them to do well in school. There are many books in such houses, and there are often computers. Schoolwork is familiar to these children because it is the same sort of thing they find at home.

Social capital refers to the social connections people have with others. Here the idea is that

people are strongly influenced by the company they keep. Young people whose friends drop out of high school are more likely to drop out of high school themselves than are others whose friends have a social background and academic performance level that encourage educational attainment. Similarly, those whose friends go to college are more likely to go themselves than are others whose friends go to work after high school, and those whose teachers encourage them to continue their education are more likely to do so than are others whose records are just as good. Since people with high-status origins tend to live in neighborhoods with others of similar origins, they tend to have greater social capital than do those with low-status origins.

Sex and Racial Differences. In the United States, there is little difference in the average amount of education attained by men and women, but more men than women tend to be very well educated or very poorly educated; that is, more men than women graduate from college, but more men than women drop out of high school. However, the effect of social origins and other factors on educational attainment is very similar for men and women. Race and ethnicity are a different story. Blacks are substantially less well educated than are whites and those of other races. In part, this is the case because the parents of blacks are poorly educated. However, blacks are also less able to convert whatever advantage they do have into a corresponding advantage for their children. In particular, blacks do not go as far in school as would be predicted from their parents' status. The sharp difference between blacks and other groups is a continuing legacy of slavery. While there are differences in the educational attainment levels of other ethnic groups, those differences are largely the result of differences among those groups in the average status of parents.

In nations such as South Africa, where until 1994 racial distinctions were embedded in law and social institutions (as in the American South before 1964), racial differences in educational attainment are much larger than they are in the United States. Whereas in the United States in 1990 whites averaged 13.1 years of schooling and blacks averaged 12.3 years, a difference of 0.8 year in South Africa in 1991 whites averaged 10.0 years of schooling and blacks averaged 4.5 years, a difference of 5.5 years, with the other racial groups falling be-

tween these values. This was a direct consequence of government policies that created separate and unequal school systems for South Africa's four "official" racial groups.

Cross-Cultural and Cross-Temporal Variations. Differences between countries in the educational attainment process are due both to general factors such as the level of industrialization and to specific differences in the way education is organized. In general, in places where the level of educational inequality in the parents' generation is high, educational attainment is more dependent on social origins than it is in countries where the level of educational inequality in the parents' generation is low. This is a consequence of the effect of human capital acquired at home. In a country such as the United States, where janitors have about ten years of school and high school teachers have about sixteen, the son of a janitor will be able to compete in school much more effectively with the son of a high school teacher than is the case in a society such as India where high school teachers also have about sixteen years of schooling but janitors have no schooling at all and are illiterate. Second, in highly industrialized countries schooling is less dependent on social origins than it is in less industrialized countries, in part because schooling tends to be free in industrialized countries. Third, in countries where the state provides not only free education but financial subsidies to students, as has been done in eastern Europe and in some western European countries, education tends to be less dependent on social origins than it is in countries without such subsidies.

There is a worldwide trend for educational attainment to become less "ascriptive" over time. That is, in almost all countries educational attainment has become less and less dependent on social origins throughout most of the twentieth century. The reason for this is straightforward. As was mentioned above, the effect of social origins on the probability that people will move from one level of education to the next declines with each higher level of education. Therefore, since the average *level* of educational attainment has been steadily increasing in most countries, it follows that more and more people are in educational categories where social origins matter relatively little.

An important distinction in educational systems is that between divided and unitary systems.

In the United States, there is, with only modest exceptions, a single path to educational attainment: primary school, to secondary school, to college or university, to graduate or professional school. Students achieve a certain level of education and then leave school to take up other pursuits. Thus, years of schooling is a very good indicator of educational attainment. In Europe and elsewhere, schooling tends to be divided into parallel tracks. In particular, a distinction is made between academic and vocational tracks, beginning in secondary school. Thus, in Europe, educational attainment must be measured not only by the amount of schooling but by the type of schooling a student has. In general, academic credentials have more value in the labor market than do vocational credentials in that they lead to jobs with higher status and higher income.

Among nations at a similar level of economic development, there often are substantial variations in the dependence of education on social origins. For example, in the 1970—the latest period for which there are systematic comparative data—55 percent of French male university graduates were the sons of managers or professionals, while in Great Britain this was true of only 35 percent. In general, at every selection point, social origins mattered more in France than they in Great Britain. In this sense, one can say that the British educational system was (and probably still is) substantially more egalitarian than the French system.

Finally, particular historical events can have a major impact on educational attainment. For example, the 1966–1977 Cultural Revolution in China caused massive disruptions in almost all aspects of social life. Secondary schools were closed from 1966 to 1968; universities were closed until 1972 and, when they reopened, accepted students on the basis of political status rather than academic merit until 1977. The results were twofold. First, the educational advantage of high-status origins—particularly growing up in a professional family—were very reduced substantially for those who would have entered secondary school or university during that period. Second, the quality of education declined because even when the schools remained open, they were devoted largely to political indoctrination rather than conventional studies. The evidence indicates that those educated during the Cultural Revolution read less well than do

those with the same amount of schooling who were educated before or after the Cultural Revolution.

OCCUPATIONAL STATUS

Reproduction. Like educational status, occupational status is only weakly related to social origins. However, it is somewhat harder to pin this down than is true for education since, unlike education, which is completed by most people early in life, occupational status may vary over the life course, as people change jobs. The convention in most research on occupational attainment therefore is to restrict the analysis to men (since women not only change jobs but move in and out of the labor force for marriage or childbearing) and to compare the occupations held by men at the time they are interviewed with the occupations of their fathers when the interviewed men were teenagers, usually age 14. The relationship between fathers' and sons' occupational statuses turns out to be even weaker than the relationship between parents' and offspring's educational attainment. Thus, with respect to occupational statuses as well as educational attainment, America is an open society.

Other Factors. In the analysis of occupational attainment, an important issue has been to assess the relative importance of social origins (measured by the father's occupational status) and education as determinants of men's occupational status. The ratio of these two effects has been taken as an indicator of the degree of societal openness. In the United States and most industrial societies, education is by far the most important determinant of occupational status, while the direct effect of a father's occupational status is very limited. In the past, many people directly inherited their occupational position from their parents (for example, the sons of farmers were likely to take over their fathers' farms, the sons of shopkeepers to take over their fathers' shops, and so on), but in modern societies such as the United States, where people tend to work in large organizations, most jobs cannot be inherited directly. Instead, occupational status inheritance, insofar as it occurs at all, results mainly from the children of high-status people going further in school and those going further in school attaining better jobs. However, since, as was shown above, education is largely independent of social origins, the results is that education serves mainly as a vehicle of social mo-

bility rather than a mechanism of social reproduction or status inheritance.

Sex and Racial Differences. The most striking difference between men and women is that most men work most of the time once they complete their schooling, whereas the work lives of many women are interrupted for childbearing and child rearing. However, the labor-force participation rates of women and men are converging in the United States as more women remain in the labor force even when their children are very young. In general, men and women work at jobs of equal status, although the specific jobs held by men and women are very different. Most managers, skilled and unskilled manual workers, and farm workers are men; most clerical and service workers are women; and professional, sales, and semiskilled manual jobs tend to be performed by both men and women. The sex segregation of the labor force has important implications for income differences between men and women, as is discussed below.

Blacks tend to work at lower-status occupations than do whites and others. In part this is due to their lower levels of educational attainment, but in part it is due to the fact that blacks are not able to obtain jobs as good as those which can be obtained by equally well-educated members of other groups. Again, as in the case of education, differences in occupational status among nonblack ethnic groups are largely attributable to differences in educational attainment.

Cross-Cultural and Cross-Temporal Variations. In highly industrialized societies and in relatively egalitarian societies, there is little direct transmission of occupational status from one generation to the next; in those societies, occupational transmission is largely indirect, occurring through education. In less industrialized and less egalitarian societies, the importance of the father's occupation as a determinant of occupational status increases and the importance of education decreases, although education always remains more important than the father's occupation even in the least-developed societies.

Although the association between father's and son's occupational statuses has been declining over time and is weaker in industrialized societies, the *pattern* of intergenerational occupational mobility appears to be largely invariant, with only minor variations across societies caused by specific

historical circumstances, at least in industrialized societies and probably in nonindustrialized societies as well. That is, the relative chances that, say, the son of a professional and the son of a laborer will become professionals, rather than skilled workers, appear to be essentially similar in all societies.

Despite the commonality in intergenerational mobility patterns, there are substantial national variations in the strength of the linkage between schooling and career beginnings. In general, there is a tighter connection between education and the status of one's first job in countries, such as Germany and Switzerland, where there are separate vocational and academic tracks and assignment to one or the other is made early and where vocational secondary education provides occupation-specific skills than there is in countries, such as Great Britain, Japan, and the United States, where neither condition holds. Japan is, however, a special case. Japanese secondary schools and universities are highly stratified on the basis of prestige. Schools have close connections with large business firms and are able to place their students there. Students from the best schools go to the best firms, where they are trained by being rotated through a series of jobs. Thus, there is very tight schooling-first job connection in Japan, but of a kind not well captured by the association between the amount of schooling and the prestige of the first job.

There are also national differences in the sensitivity of career opportunities to the expansion or contraction of the economy, depending on institutional differences, particularly in welfare state policies and labor market structures. In the United States, for example, rates of job mobility show great sensitivity to structural change and to the labor market resources of individual workers, whereas in the Netherlands, jobs are largely insulated from structural forces.

Finally, careers can be strongly affected by specific historical events. The collapse of communism in eastern Europe in 1989 forced many political officials and administrators into early retirement. However, since the political transformation was accompanied by an economic collapse, with the economies of many former communist countries shrinking by about one-third in the early 1990s, unemployment increased and many women and older workers left the labor force. At the same time, there were substantial new opportunities,

particularly in the newly emerging private sector of the economy. Thus, there was a substantial increase in occupational mobility, at least in the short run.

As with education, the extent of reproduction of occupational status has been systematically decreasing over time in almost all societies. The reasons for this are not clear. There may be a worldwide shift toward an emphasis on achievement as opposed to ascription, although the likelihood that a shift in value orientations could have such a large and systematic effect does not seem great. More likely, the systematic increase in the average level of education in almost all countries is responsible, since it is known that the association between fathers' and sons' occupational statuses decreases for those who have obtained higher levels of education.

INCOME

Reproduction. Little is known about the extent of income reproduction because it is very difficult to measure income in the parents' generation. Most data used in intergenerational analyses are obtained by asking people to report on their parent's characteristics. While people tend to know how much schooling their parents had and what sort of work their fathers were doing when the respondents were teenagers, few people have a very good idea of what their parents' income were. However, one major study has obtained such information: a study of the graduating class of 1957 from Wisconsin high schools conducted by Sewell and Hauser (1975). This cohort of graduates has been followed up in a number of surveys over the years, so that information has become available about its members' occupations and incomes at various stages after completing school. In addition, with careful arrangements to guard confidentiality, the researchers were able to obtain information from the Wisconsin Department of Taxation and the Social Security Administration regarding the incomes of the parents at the time the students were in high school. These data suggest that the intergenerational transmission of income is even weaker than is true for education or occupation. Other ways of indirectly estimating this relationship yield similar results.

One possible reason for this is that income (measured in real dollars, that is, adjusted for

inflation) is highly variable over the life cycle and, for some workers—particularly those who are self-employed or whose jobs are dependent on the weather—even from year to year. Moreover, age differences in earnings vary systematically for different occupational groups. The earnings of professionals tend to increase steadily over the course of their careers, while at the other extreme, the earnings of unskilled laborers do not change at all. Thus, when they first start working, unskilled laborers earn as much as or more than do professionals just beginning their careers, but by the time they near retirement, professionals earn several times as much as laborers of the same age earn. Incomes are also highly variable from place to place, reflecting differences in the cost of living, and even within cities, different firms pay different wages or salaries for the same job. All these factors make individual variations in income rather unpredictable.

Other Factors. Unlike parental education and occupational status, which affect educational attainment but have little direct effect on occupational attainment or income, parental income directly affects the income of offspring even when education and occupational attainment are taken into account. In fact, parental income is nearly as important as occupational status in determining income and is more important than education. Apparently, there is a propensity to earn money, and this propensity is transmitted from generation to generation. Whether this reflects differences in values that transmitted from parents to their children—with some people choosing jobs on the basis of how well they pay and others choosing jobs on the basis of their intrinsic interest, how secure they are, and so on—or in another factor is not known.

Other factors that affect income even when parental education and the respondent's own education and occupational status are taken into account include ability, the quality of the college attended, and the kind of work people do. Doctors earn more than professors do even though the jobs are of similar status, and garbage collectors earn more than ditch diggers earn. There is an extensive, although inconclusive, literature on differences in earnings across industrial sectors, and there is some evidence that earnings are higher in more strongly unionized occupations and industries.

Sex and Racial Differences. Gender is the big story here. In the United States, among full-time year-round workers, women earn about 60 percent of what men earn, and this ratio has remained essentially unchanged since the 1950s. Of the 40 percent gender difference, about 20 percent can be accounted for by the greater work experience of men, differences in the kinds of education received, and similar factors. The other 20 percent is due in part to the fact that the jobs performed mainly by women tend to pay less than do the jobs performed mainly by men even though many of these jobs are similar with respect to the skill required, the effort involved, and the responsibility entailed, and in part to the fact that women tend to earn less than do men in the same occupations. This state of affairs is possible because of the extreme gender segregation of the labor force. Most jobs tend to be performed either mostly by men or mostly by women, with relatively few jobs open to both sexes.

One consequence of this is that, at least in the United States, poverty is concentrated in female-headed households, especially where there are young children present. Not only do women in such situations find it difficult to work because of their child care responsibilities, even when they do work, their earnings tend to be low. Thus, the total income of such households is often below the poverty line.

In the United States, racial differences in income are somewhat smaller than gender differences and have been declining steadily for the last half century, as has occupational segregation by race. There is little evidence that the racial composition of jobs affects their pay levels. Instead, racial differences in income are attributable both to the fact that many blacks tend to be less educated and to work at lower-status jobs than most whites and others and to the fact that blacks get a lower return on their education and occupational status than do whites and others. Interestingly, there appears to be an across-the-board difference between the earnings of black and other males at any given level of education, occupational status, and so forth. However, the racial difference in the earnings of women is somewhat more complicated. At low levels of education and occupational status, black women earn much less than do other women, but at high levels of education and occupational

status, there is little or no difference in earnings among women of all races.

Cross-Cultural and Cross-Temporal Variations. While international comparisons of the determinants of personal or family income are scarce, probably because of the difficulty in measuring income in a comparable way across countries, differences in the *distribution* of income across nations and over time are well established. Income inequality is related to the level of economic development in a curvilinear way: It is low for the least developed nations, where most people are peasants; high for nations at medium levels of development, which often display large regional differences as a result of uneven economic development; and low for the most developed nations, where a combination of tax and welfare policies tends to ensure that most of the population enjoys at least a moderately adequate standard of living and constrains opportunities to become extremely rich. Because of restrictions on the accumulation of private property in communist regimes, income inequality tends to be smaller than it is in capitalist nations at a corresponding level of economic development. Finally, rampant inflation, such as that which occurred in eastern Europe after the collapse of communism, may cause dramatic reversals of fortune, impoverishing those on fixed incomes, such as government employees and pensioners, and enriching sellers of goods and services whose prices keep pace with inflation.

DONALD J. TREIMAN

STATUS INCONGRUENCE

The phenomenon sociologists call "status incongruence" has equivalents in many languages. Expressions such as "*nouveau riche*," "*déclassé*," "*roturier*" and "*parvenu*" show that people in many societies perceive the incongruence between various statuses. The popular dictum "the heart on the left, the pocket on the right" expresses this incongruence between positions and feelings.

As a sociological concept, status incongruence is relatively recent. It was devised some time after the adoption of the notion of "status," following the discovery of Max Weber's writings on this subject by American sociologists in the late 1930s. In the 1950s, some twelve articles were published on "status inconsistency," most of them in the *American Sociological Review*. Those articles had a cumulative effect. At a certain point in the 1960s, it was felt that the debate on this topic had become saturated. In the absence of more empirical evidence, the theoretical discussion on status incongruence stagnated, but in the meantime the concept had been diffused in textbooks and compendiums.

After a period of neglect, the concept of status inconsistency has been reinvigorated over the last two decades as sociologists on both sides of the Atlantic have acknowledged a "decline of social classes." However despite the fact that the idea of social class has been dethroned, social inequalities persist.

The concept of status incongruence is a companion of the theory of cross-pressure. The first article focusing directly on status incongruence appeared in the same year (1944) as *The People's Choice* by Lazarsfeld, Berelson, and McPhee. The two notions nevertheless remain distinct in the

sociological literature because they respond to different analytic needs.

The incidence of status incongruence increases in times of social upheaval, such as the period of the Weimar Republic, the economic depression in the United States in the early 1930s, and that in Russia after the implosion of the Soviet regime. In the two decades before the French Revolution of 1789, the incidence of status incongruence was particularly high.

In emphasizing the revolutionary potential of downward mobility, which he called the "proletarianization of middle classes," Marx paid little attention to upward mobility and the effects of status incongruence. That neglect has been considered by some scholars to be one of his more glaring errors (Lopreato and Hazelrigg, 1972 p. 445). In contemporary sociological literature, the notion of status incongruence is related to role theory, rational theory, the theory of relative deprivation, and the theory of social movements.

This article considers only advanced Western societies, partly because the empirical evidence on status incongruence is available primarily for those countries and partly because social mobility and its impact on status incongruence are a less widespread phenomenon in developing countries.

STATUS INCONSISTENCY AS A CORRECTION OF WEAK CORRELATIONS

For a long time in sociological research, correlation between levels of social stratifications and other variables were rarely as significant as expected in light of the hypotheses and theoretical frameworks that had been adopted. Even when the rudimentary dichotomy of manual and nonmanual was abandoned and more categories were taken into consideration, the empirical results did not provide satisfactory explanations. Even when class as a rigid and restricted concept was largely replaced by the dimension of occupational status, the research strategy was not improved. Certainly, the emphasis on status groups is one of Weber and Pareto's chief corrections of Marx's theory (Lopreato and Hazelrigg 1972, p. 83). Nevertheless, an essential approach was missing until the 1950s, that of status inconsistency, which marked an advance in sociological thinking. It has been demonstrated that the consistency or

inconsistency of a person's status based on various criteria is a better predictor of social behavior than is the level of status based on a single criterion.

FROM SOCIAL CLASS TO STATUS INCONSISTENCY

Status incongruence is generated by gaps in income, occupation, education, and ethnic origin and other inconsistencies between a person's social position in one domain and that person's relatively lower status in another dimension. Status incongruence can be found in census results by cross-tabulating indicators such as education, income, professional hierarchical position, qualification, and racial origin. There is a logical relationship between the spread of status incongruencies and the weakening of social class consciousness.

Status inconsistency has become an essential aspect of social stratification in contemporary postindustrial society. It has been exacerbated by the growth of the middle classes and the decline of the peasantry and the industrial working class. Vertical mobility is the main source of status discrepancy. Most studies of social mobility have focused on upward mobility, particularly during the postwar period of economic development, but in more recent times, downward mobility has become equally important. Today, social mobility consists mostly in what Lipset and Zetterberg (1956, p. 563) called "the interchange of ranks." For every upward move, there must be a downward move. What was then only a hypothesis has been confirmed empirically: "[S]ome proportion of the children of the middle class fall in socio-economic status; some do not have the abilities to complete higher education or to get along in a bureaucratic hierarchy, and fall by the wayside. Whatever the reason that some persons of middle class origin move downward, they leave room for others of lower-class background to rise" (p. 570). Today, millions of Europeans and Americans born into the middle classes are in such incongruent situations. The downward move can be intragenerational or intergenerational.

Another source of status incongruence is liberation from primary social groups, particularly religious communities and families. More and more, through schooling, individual achievement negates the constraints of family background. For this

reason, status inconsistency is a fertile ground for individualistic tendencies.

The concept of status inconsistency raises the concept of status crystallization, which was proposed by Lenski (1954) as a nonvertical dimension of social status. Strong or weak status crystallization refers to the degree of incongruence or coherence of a person's ranking according to various criteria. A strong status crystallization implies that a person is rated consistently on all important criteria, whether the rating is high or low. Today, a large part of the population in Western societies finds itself in a situation of weak status crystallization. Solid social class can exist only if the majority of the population experiences strong status crystallization.

One of the most visible varieties of status incongruence occurs among schoolteachers, who are more numerous today than were workers in the heavy industry plants four decades ago. For many teachers there is a serious gap between the level of their education and their role in society and income level. The left-wing orientation of most teachers in European countries can be explained in terms of status incongruence, rather than class. Even some college professors experience this incongruence.

If one compares status incongruence today and in the past, two important categories have become prominent over the last two decades: the "intellectual proletariat" and the "ethnic achiever" (as opposed to the "skidder").

The spread of education in most advanced societies has highlighted the need of postindustrial economies for highly educated people. Today, two-thirds of people aged 18 are still in school. At the end of their college years, most of them do not find a job that corresponds to their expectations in terms of intellectual and economic rewards. It is in this category of the population—young educated people "with diplomas in their pockets"—that the rate of unemployment is the highest in most west European countries. This overabundance of graduates results from the incapacity of a highly technological society to absorb them in "interesting" occupations, with the existing jobs being protected by unions. This imbalance between the level of education, the quality of the job, and the amount of income generates status incongruences for "overeducated" young people. An advanced

postindustrial society in search of productivity replaces people with machines, producing a new kind of educated proletariat that was born into the middle class. In western Europe in the last decade (except in Germany), one of every four or five young people under age 25 was unemployed, and others were pushed down into "degraded" jobs. Those who accept jobs beneath their abilities, "degraded jobs," represent one of the most frequent varieties of status incongruence, a "reserve army" of alienated people.

The ethnic achiever is a new variety in western Europe and an old one in the United States. Status inconsistency can be found among ethnic and racial minorities in Great Britain, France, Germany, Belgium, the Netherlands, Switzerland, and Austria. Immigrants of European origin in Europe are integrated and assimilated in a single generation, with the best example being the eight million French citizens of Italian, Spanish, Portuguese, Polish, or Armenian origins. The children of these European immigrants are not normally in a position of status inconsistency. When language is combined with ethnicity and religion, as with immigrants from the southern rim of the Mediterranean, the integration process takes two generations and the younger generation often experiences status incongruence. When skin color is considered, the difficulties of integration are compounded. Many immigrants from southern Asia and Africa feel excluded from the host society. Nevertheless, a substantial minority are economically well integrated, and many climb the income ladder. They are ethnic achievers, more than completely assimilated immigrants. They are deeply rooted in status incongruences.

In Europe, these two varieties of status incongruence contrast with a social category of status crystallization at the bottom of society. According to a recent survey by the Organization for Economic Cooperation and Development (OECD), almost one-fourth of the adult population in Western advanced societies is functionally semi-illiterate and coexists with a high proportion of functionally overeducated younger adults. Strong status crystallization arises from the fact that these semi-illiterates are also those who receive the lowest salaries and perform the most menial work, and the large majority of them are of non-European origin. The status crystallization that occurs in

Europe has a similar and more deeply ingrained counterpart in the United States.

MINORITY STATUS AND STATUS INCONGRUENCE

In many studies of electoral behavior (which are preferred because of the availability of statistics), particularly those conducted by means of survey research, the issue of social context has been neglected. Only the characteristics of individuals are taken into consideration, while the parameters of the social milieu are ignored. With some notable exceptions, too many sociologists have forgotten that the behavior of people is conditioned by their social context. This mistake has been denounced by the German sociologist Scheuch (1969) as the "individualistic fallacy," a complement to the "ecological fallacy." The direct consequence of "individualistic research" is the dismissal of the notion of a "minority" in spite of the fact that its importance has been demonstrated repeatedly. Examples are found in the contrasting behaviors of the same "unidimensional category," whether they are a frustrated minority or a dominant majority. Examples include Irish Catholics who vote for the leftist party in Britain versus "good" Catholics who vote conservative in France or Catholics in Germany who vote for the Christian democratic party and industrial workers who live in densely populated working-class areas versus the same kind of workers who live in middle-class districts. These notions of "minority context" and "majoritarian context" are directly related to the issue of status incongruence, because in many places minorities live in a more or less hostile environment. In such cases, three concepts are involved: status incongruence, minority complex, and cross-pressure.

Contradictory propositions have been suggested concerning the political effects of upward and downward mobility in terms of status incongruence. According to some scholars, upward mobility favors a conservative orientation, and downward mobility a liberal-leftist tendency. Others scholars have arrived at the opposite conclusion. This confusing situation can be explained by the neglect of the social context by those who extrapolate at the national level the results obtained at the local level. Most studies of status incongruence have been conducted in individual

cities (including Lenski's 1954 and 1966 studies). It is misleading to generalize from a series of local monographs that do not represent a truly national sample: "Consistency theory seeks to show that predictable effects result from the combination or interaction of statuses, and that these effects differ from the effects of several independent variables" (Rossides 1976, p. 87). However, in practice it is difficult to weigh the importance of each variable in the social context. In one case, it may be a question of race; in another, income; and in still another, professional position. Extrapolated at national level, these variables conceal important variations across local social contexts.

STATUS INCONGRUENCE AND INDIVIDUALISM

Most frequently, status inconsistency refers to individuals, not to collectivities. Incongruence of status is a characteristic of a relationship between individuals. When an individual cannot raise the lower factors of the incongruence, he or she tends to avoid people who react to them (Malewski 1963, p. 306). He or she makes an individual move. If an individual can raise the lower factor, "he has a natural tendency to think of himself in terms of that status or rank which is highest, and to expect others to do the same, [but] others, who come in contact with him, have a vested interest in doing just the opposite, that is, in treating him in terms of the lowest status or rank" (Lenski 1966, p. 87). Even in this case, the relationship is between individuals. Vertical mobility separates ascending individuals from nonmobile peers who remain in their status of origin. A high rate of individual upward mobility breaks the unity of the social class by effectively promoting certain people and generating in the minds of others expectations of moving out of the class and into a better one. As Dahrendorf has noted, a high rate of upward mobility favors individualism to the detriment of class consciousness.

However, high rates of downward mobility may have the opposite effect, favoring, as Marx emphasized, the spread of class consciousness. In that case, the tendency is not to leave the group but to identify oneself with others in the same situation of incongruence of status. In some social contexts that aggregate individuals, such as large factories, mines, railways, working-class suburbs, and ghettos in large cities, the phenomenon of

individual status incongruence blooms into a collective social consciousness and a "minority complex."

CONFIGURATIONS OF STATUS INCONGRUENCES

The amount of status inconsistencies depends on the configuration of three dimensions that may be dichotomized for analytic purposes.

1. Culturally homogeneous societies versus heterogeneous societies. In recent decades, immigration in Western countries has differed from that of former times. In most cases, immigrants coming from Western Europe to the United States and Canada require only two generations for complete assimilation into the dominant culture. More recent immigrants in Western countries came from the southern rim of the Mediterranean and Africa. Not only are their distinctive characteristics not only religious and linguistic, they also differ in skin color. Their integration requests more than two generations, and many of them manifest a preference for multiculturalism, that is, for a recognition and institutionalization of ethnic diversity. Such diversity is currently a source of status inconsistencies but may have different effects in the future.
2. Segmented versus fluid societies. Heterogeneous countries may be segmented or fluid. Segmented societies are divided into religious or linguistic communities, as in Belgium and Northern Ireland, or into "pillars," as in the Netherlands until the middle of 1980s (Lijphart 1977). In these societies, there is little room for ethnic status inconsistency. By contrast, in fluid societies, the crossing of vertical and transversal cleavages is relatively common and generates incongruences.
3. High versus low vertical mobility. Another dichotomy is related to the amount of vertical social mobility on the economic scale, which may be relatively high or relatively low. The fact that high vertical mobility, either upward or downward, increases the frequency of incongruence of statuses is well established.

These three factors have a cumulative effect on the proportion of people who experience incongruence of status.

STATUS INCONGRUENCE AT THE ELITE LEVEL

What is missing in Pareto's "circulation of elites" is the concept of status incongruence. This is surprising in the writings of someone who emphasized the importance of upward and downward social mobility. If the concept of status incongruence was applied to the highest levels of society, elite studies would be enhanced. The psychological portrait of some of the world's most famous painters could be better understood in the light of status inconsistency. The biographies of masters such as Michelangelo, Bellini, Bosch, Goya, van Gogh, and Toulouse Lautrec could be enriched by an interpretation in terms of status incongruence. Many novelists, including Dostoevsky, Tolstoy, Stendhal, Balzac, de Lampedusa, Proust, and Dumas, have analyzed the psychological aspects of status inconsistency even if they have not used that sociological term. One of the main themes of *The Red and the Black* and *The Leopard* is status inconsistency. The most common case is that of the rich man's daughter who becomes enamored of a young man of lower status. No sociologist has explored the hundreds of cases of status incongruence described by famous writers, starting with Shakespeare's *Romeo and Juliet*.

The concept of status incongruence should be applied even to saints. The best analyses of the personality of the evangelist Paul have been written by theologians and religious historians, who have used the notion of status inconsistency implicitly. The subtitle of Dieter Hilbrand's *Saul-Paul: A Double Life* is significant. Baslez insists on the status incongruence of Saint Paul: Born as a Roman citizen but at the periphery, in Syria; he was a stranger in Ephesus; a polyglot Jew, an apostate, and the son of a Pharisee, he was rejected as a missionary in many communities. Paul accumulated many incongruences. Moses, as the nephew of the pharaoh, and Muhammad, as the poor husband of a rich wife, are examples of status inconsistencies.

The use of the concept of status incongruence is appropriate for a better understanding of political leaders from Spartacus to Robespierre and

from Trotsky to Castro. There are numerous examples of the status incongruence of athletes, clergymen, businessmen, politicians: poets, and movie stars, but this notion has been insufficiently used to explain the metamorphosis of labor leaders. The concept could even be applied to sociologists for a better understanding of the theories and motivations of scholars such as Pareto, Michels, Veblen, Sorokin, Mills, and Lazarsfeld.

THE RELEVANCE OF STATUS INCONGRUENCE TODAY

The incidence of status incongruence in advanced societies today is many times higher than it was in earlier generations. This upsurge is a result of increasing upward and downward economic mobility, the increasing ethnic heterogeneity of Western societies (as a consequence of massive non-European immigration), and a better perception of inequalities and the spread of "multiculturalism" as opposed to the doctrine of the melting pot, particularly among the so-called second generation, which is composed of the sons and daughters of immigrants.

Four decades ago, status incongruence was usually a question of an imbalance between education, income, occupation, religion, and gender. Today it originates primarily in ethnic and racial intermingling. Religious differences have become less prominent.

In most Western societies on both sides of the Atlantic, a homogeneous majority no longer exists. Any conceivable majority is necessarily composed of multiple minorities of all kinds. An advanced society is a multidimensional society that includes many parallel hierarchies. The political game consists precisely in building coalitions of minorities to crystallize a temporary and unstable political-electoral majority. In almost all these countries, the leftist party has become the party of amalgamated minorities, of those who experience frustrations generated by status incongruences and the psychological complex of belonging to a minority. In the United States, the electorate of the Democratic Party is much more ethnically heterogeneous than is its adversary. It is a conglomerate of minorities. In France, the leftist coalition has officially adopted the label "plural majority." Without the concept of status incongruence, it would be difficult to explain its electoral success.

Projections of demographic trends suggest that Western societies are becoming increasingly diversified along a noneconomic axis and that the amount of status incongruence nourished by ethnic and racial characteristics will increase.

A mountain of statistics has been collected showing that objective inequality and social consciousness explain only a relatively small part of the variance in studies of social stratification. What must be added is an interpretation in terms of status congruence-incongruence.

STRESS

NOTE: Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.

The theoretical interest in social epidemiology, the study of effects of social conditions on the diffusion of distress and diseases in the population, can be traced to Durkheim's study of suicide in 1897 (1951). Since then, theory and research have elaborated on the associations among the various forms of social integration and psychiatric disorder. Among the classic works are Faris and Dunham's study of the ecology of mental disorders in urban areas (1939), Hollingshead and Redlick's research on social class and mental illness in New Haven (1958), the midtown Manhattan studies (Srole et al. 1962; Langner and Michael

1962; Srole 1975), the Sterling County studies by the Leightons and their colleagues (A. H. Leighton 1959; C. C. Hughes et al. 1960; D. Leighton et al. 1963) and the British studies by Brown and his associates (Brown and Harris, 1978). Each study illuminates the linkage between social conditions and distress and advances theories, hypotheses and empirical evidence in the specification of the relationships.

A parallel theoretical development has also taken place, over the past thirty-five years, in the formulation of the life stress paradigm in social psychiatry. The birth of this paradigm can be dated to the work of Hans Selye (1956) whose study of the undifferentiated response (physiological and psychological) that is generated by diverse external stimuli (stressors) linked sociological constructs to the internal individualistic responses made by individuals to their environment. This stress-distress model provided impetus for a convergence between the earlier sociological concerns with consequences of social integration and the physiological modeling of internal responses to the external environment.

The stress research enterprise gained further momentum when Holmes and Rahe, and subsequently other researchers, developed measures of life experiences that require social adjustments, known as inventories of life events (Holmes and Rahe 1967; Dohrenwend and Dohrenwend 1974, 1981; Myers and Pepper 1972). The life events schedules provide a convenient instrument that can be applied to a wide range of populations and administered with ease. The instrument has shown a high degree of validity and reliability relative to many measures of distress across populations and time lags.

In general, the research shows that life stressors, as measured by the life events schedules, exert a significant but moderate influence on mental and physical well-being. In a simple zero-order correlation, the relationship between life stressors and well-being (e.g., depressive symptoms) ranges between .25 and .40 (Rabkin and Struening 1976). This figure is somewhat less for physical health (House 1981; Wallston et al. 1987; Ensel 1986). The magnitude of this relationship seems to hold up when other factors are taken into account (e.g., general socioeconomic status measures; age; gender; psychological resources such as self-esteem,

personal competence, and locus of control; physical health; and prior mental state).

MODIFICATIONS AND EXTENSIONS—THE MEDIATION PROCESSES

Modifications of the stressors-distress paradigm have taken several directions. In one direction, the conceptualization of stress as undifferentiated response has been modified so that the nature of stressors entails further specification. For example, in the analysis of life events, desirability, controllability, and importance are identified as dimensions exerting differential effects on distress (Thoits 1981; Tausig 1986). Research has shown that when only self-perceived undesirable life events are considered, the effect of the stressor instrument on distress increases marginally but significantly. It has also been shown that when items pertaining to psychological states (sleeping and eating problems) or illnesses are deleted, the magnitude of its effect is only marginally reduced (Ensel and Tausig 1982; Tausig 1982, 1986).

Conceptualization and operationalization of stressors have also been extended to include role strains (Pearlin and Schooler 1978) and daily hassles (Lazarus and Folkman 1984). Generally speaking, these stressors have demonstrated consistent but moderate effects on mental health, with zero-order correlations with various measures of mental health ranging from .15 to .35.

Another direction focuses attention on factors mediating or buffering the stressors-distress relationship. Researchers have identified three major components involved in the stress process: stressors, mediating factors, and outcome variables. Pearlin et al. (1981) viewed these constructs as multifaceted. Mediators consist of both external coping resources (i.e., social support) and internal coping resources (i.e., mastery and self-esteem). Outcome factors consist of psychological and physical symptomatology.

Social support, for example, has been considered a major candidate variable, and the cumulative evidence is that it exerts both direct and indirect effects on mental health (Cobb 1976; Cassel 1974, 1976; Nuckolls, Cassel, and Kaplan 1972; Dean and Lin 1977; Lin et al 1979; Turner 1981; Barrera and Ainlay 1983; Aneshensel and Huba 1984; Sarason and Sarason 1985; Kessler

and McLeod 1985; Lin, Dean, and Ensel 1986; Berkman 1985; Cohen and Wills 1985; House, Umberson, and Landis 1988). Coping has also received substantial research attention and been found to be an effective mediator (Pearlin et al, 1981; Wheaton 1983, 1989; Lazarus and Folkman 1984). This type of research has served as the prototype for the sociopsychological study of stress in the 1980s (Pearlin, 1989). Emphasis has been placed on the mechanisms by which social resources, provided or called upon in the presence of a stressor, operate to alter the effect of the stressor (House, Umberson, and Landis 1988; Kessler, Price, and Wortman 1985; Thoits 1985).

DEVELOPMENT OF INTEGRATIVE AND TIME-LAGGED MODELS

While conceptual analysis and research attention have been given to life stress, resources (social support and coping), and psychological stress for their potential effects on health and mental health, only recently have specific proposals emerged in integrating these elements into a coherent theoretical framework. Dohrenwend and Dohrenwend (1981) summarized various formulations of life stress processes involving stressors (life events) and the psychological and social contexts in which they occurred. These formulations were synthesized into six hypotheses, each of which was shown to provide viable conceptual linkages between stressors (life events) and health outcomes and to have received some empirical support. The hypotheses in these models share two common features: (1) The ultimate dependent variable is adverse health or adverse health change rather than mental health problems or disorders, and (2) each hypothesis delineates and explains the possible empirical association between life events and health. Some of the hypotheses affirm the primary role of life events as causing health problems, while others incorporate mediating factors to explain health problems. The Dohrenwends (1974) proposed that these hypotheses should be examined together for their relative merits. Golden and Dohrenwend (1981) outlined the analytic requirements for testing these causal hypotheses.

Further elaboration of these hypotheses formed the basis of an integrative life stress paradigm in which stressors and resources in three environments—social, psychological, and physiological—

are considered as the factors impinging on well-being (Lin and Ensel 1989). This model specifies the enhancing (resources) and detrimental (stressing) forces in each environment. These stressors and resources in the three environments interact in affecting one's physical and mental health. Empirical evidence suggests that social resources tend to mediate the stress process involving mental health, whereas psychological resources are more prominent in mediating the process involving physical health.

Another integrative attempt incorporates multidisciplinary and multilevel variables in the study of life stress. For example, Lazarus and Folkman (1984) and Trumbull and Appley (1986) have conceptualized cognitive mechanisms involved in the stress process. Lazarus and Folkman proposed a model in which three levels of analysis (social, psychological, and physiological) are conducted to understand the antecedent, mediating, and immediate as well as long-term effects on distress. Trumbull and Appley (1986) proposed the simultaneous assessment of the physiological system, psychological system, and social system functioning. These functionings have both intrasystem and intersystem reciprocal relationships and exert joint effects on distress. In the later paradigms, emphasis has been placed on personality factors and coping skills. Additionally, the importance of linking social, psychological, and physical factors in the study of the stress process has been noted. Causal antecedents of both depressive and physical symptomatology are viewed as coming from social, psychological, and physiological sources and are hypothesized to be mediated by a variety of coping factors and perceived social support.

Pearlin and Aneshensel have proposed a synthesized paradigm (Pearlin 1989; Pearlin and Aneshensel 1986) in which health behaviors and illness behaviors have been incorporated into the basic stress process and in which equal attention has been given to the potential mediating and moderating roles of social and psychological resources. Thus, in addition to mediating the effect of stressors on illness outcomes, coping and social support are viewed as having the potential to mediate health and illness behaviors. An important element of this synthesizing paradigm is the recognition that physical illness creates life problems that are reflected in an increase in undesir-

able life events—that is, in addition to stressors affecting physical illnesses, physical illness also has the potential to bring about the occurrence of stressors. In such a synthesized paradigm, stressors embedded in social structure (e.g., role strains and problems) interact with illness behavior and illnesses. These interactions are mediated by coping and social support.

Finally, growing attention has been given to the need for studying the stress process over time (Wheaton 1989). Not only have there been concerns with causal interpretations of cross-sectional data, but more importantly, a call for longer lags in the panel design to capture the stress process in the life course more realistically (Thoits 1982). Some of the earlier panel studies, such as the midtown Manhattan study (Srole and Fischer 1978), the Kansas City study (Pearlin et al. 1981), the New Haven study (Myers, Lindenthal, and Pepper 1975), and the Cleveland GAO study (Haug and Folmar 1986) have all made significant contributions to understanding the stress process in urban communities. More current efforts, incorporating prevailing models and variables, would substantially add to the knowledge about stress in the life course. Current panel studies, such as those mounted by Aneshensel in Southern California; House and his associates on a national sample; Berkman in New Haven; Murrell in Kentucky; and Lin, Dean, and Ensel in upstate New York have the potential to expand research programs into investigations of the life-course process of stress.

STRUCTURAL LAG

The concept of structural lag originally was suggested by the observation that in the late twentieth century there was a discrepancy between the growing number of older healthy people and the meaningful roles available to them. This simple empirical observation is only one instance of a more general phenomenon: a mismatch between the numbers and kinds of people of a given age and existing patterns in the social structures into which people must fit. This mismatch occurs because changes in people's lives and changes in social structures typically are not synchronic. When social structures fail to adapt to new cohorts with characteristics different from those of previous cohorts, there is a situation of structural lag (Riley et al. 1994).

PREMISES ABOUT AGE AND SOCIETY

How and why structural lags emerge and how they are dealt with can be better understood by considering the underlying principles of age as both an individual and a social phenomenon and its relationship to social change.

1. Age not only is a characteristic of people but is built into social structures in the form of criteria for entering or leaving social roles, expectations about behavior in those roles, and resources and rewards for role performance. Formal and informal rules govern the age at which children enter and stay in school, age patterns in the family such as the appropriate age at first marriage, and age of entry into and retirement from the work force. Age norms influence behavior and orientations in these roles, and conformity is buttressed by material rewards and social approval.
2. Both the process of aging from birth to death and social structures related to age are subject to change. The aging process is not the same for all cohorts, since members of each cohort (those born in the same period) grow up and grow older under unique social, political, and environmental circumstances. For example, cohorts of people born around the beginning of the twentieth century differ from those born a half century later in level of education, exposure to illness, size of the family, job skills, the likelihood of being married and divorced, and attitudes and worldviews. Cohorts born at the end of the twentieth century will differ from their predecessors in still other ways. For example, the birth weight of newborns in the 1980s and 1990s was greater than that of babies born in earlier times, and this undoubtedly will influence the way that members of those cohorts develop. Further, as the more recent cohorts grow up, it is likely that they will benefit from new medical advances. Age patterns in social structures have changed as well. To cite two examples, schools have raised the school-leaving age, and government and corporate policies have encouraged a decline in the typical age of retirement.
3. Changes in patterns of aging and in social structures affect each other; they are interdependent. As an example, by altering long-standing employment practices, restructuring, downsizing, and mergers of large firms in the United States have led to a shift in the work lives of employees. Thus, compared to previous cohorts of workers, fewer workers now can look forward to lifetime employment in one firm; many have to make multiple career changes, and some have to make do with temporary and part-time employment at some time in their working lives. In turn, new patterns of careers over the life course are likely to have an impact on societal institutions. Firms are likely to reduce their commitment to training workers, with educational institutions as-

suming greater responsibility for training and retraining.

While changing aging processes and social structures affect each other, the two processes of change are distinct, with each following its own dynamics. The aging process, while varying across cohorts, has a distinct rhythm, as people are born and then proceed through childhood, adolescence, adulthood, and old age. Social structures do not have a similar rhythm. The economy has ups and downs; political shifts follow their own paths; and cataclysmic events such as wars, depressions, famines, and epidemics affect all social institutions. Consequently, in any period there is likely to be a poor fit between lives and structures: an imbalance between what people of given ages have to offer, what they need and expect in their lives, and their motivations versus what social structures can accommodate or demand.

4. Lags can occur in either direction. Sometimes people's lives lag behind changes in social structures. For example, many older people may be reluctant to learn and use new technologies, or adolescents may not be motivated to take the science courses that will prepare them for technological changes. At the end of the twentieth century, however, a key form of imbalance is the lag of social structures behind changes in people's lives. As the examples discussed below indicate, structural lag is pervasive, affecting people of all ages and many social institutions.

STRUCTURAL LAG AT THE MILLENNIUM

A focus on the fit or misfit between people and structures in three major age strata shows how these principles play themselves out and how structural lags have emerged.

The Old. The increase in the number and proportion of older people in the twentieth century is a dramatic example of a change in people's lives that has posed numerous problems for societal institutions. By the end of the century people 65 years old and over represented 13 percent of the U.S. population compared to about 4 percent at the beginning of the century. More than 70

percent of Americans now live to age 65, almost three times the proportion at the beginning of the century. These changes are in large part the result of public and private health care measures that reduced infant mortality decades ago, increasing the proportion of individuals who could survive to the later years. Reductions in infant and child mortality were followed by reductions in death rates among older people, partly as a result of public health and scientific and medical innovations and partly because of healthy practices in diet and exercise undertaken by individuals. Indeed, old people at the end of the twentieth century are a relatively healthy lot. Most report that they have no disabilities; even among those over age 85, about 40 percent report being able to function in daily life (Rowe and Kahn 1998). Thus, not only are more people growing old, they are aging well.

Social institutions have been slow to accommodate to the needs of this new kind of older population, a lag that represents not only lost opportunities for the old but a loss of the productive capabilities of older people to society. Consider the organization of work and retirement. Although 65 is the age of eligibility for full Social Security benefits, most people in recent years have been retiring before that age. This pattern of early retirement was facilitated by Social Security regulations, devised in an earlier period, that exact little or no cost for retiring before age 65. On their part, many employing organizations, driven by changing personnel requirements, offer financial incentives for early retirement. Also, in the process of restructuring their firms or merging with others, employers let many long-term employees go, many of whom retired early rather than face the uncertainties of the job market. If they are assured of financial security in retirement, some workers welcome the opportunity to retire early, perhaps because of their health or because of the onerous or stultifying nature of their jobs. Nevertheless, surveys find that a sizable proportion of older workers prefer not to sever their ties to the labor force completely (Burkhauser and Quinn 1994). However, few firms permit workers to continue at their old jobs under the more flexible working conditions many workers prefer. Available part-time or temporary jobs typically have few, if any, of the benefits of workers' former employment, and the pay is generally low. The

result is that many older workers withdraw from the labor force completely—often unwillingly. Employing organizations thus lose the benefits that experienced workers can bring to their firms.

Paid employment is not the only way older workers can make productive contributions to society. A sizable minority of older people do volunteer work that has social value—in religious, charitable, and civic organizations, for example. Structural lag and resistance to new ideas and values consistent with a changed society may explain why more older persons do not volunteer. Volunteer organizations often do not have recruiting mechanisms to draw on the large pool of potential older volunteers. With respect to societal values, volunteer work is not accorded the same respect as paid employment (Kahn 1994).

Societal institutions are lagging behind the needs of an unfortunate sector of the older population: those in poor health who need support. Especially among the oldest old, there is a need for long-term care either in the home or in a nursing facility, but affordable arrangements for such care are inadequate. As a result some older people are not getting the care they need, and the burden for caring for them falls on their elderly spouses or their middle-aged offspring or other relatives. In such ways, structural lag in care institutions affects both the old and the middle-aged. Unless there are relevant structural changes in these care institutions and/or government programs to shore them up, there will be problems for the baby boom cohorts when they reach their later years. They will have fewer kin available to provide the needed support, since the baby boom cohorts were followed by relatively small cohorts.

Children. Children's lives also have changed dramatically; today they have vastly different growing up experiences than did earlier cohorts. As a consequence, children now differ from their predecessors in attitudes, capabilities, motivations, behaviors, and the choices they make. These dispositions will affect their paths of future development: their school careers, job choices and opportunities, and marriage and family decisions.

One development that has altered the lives of children has been the increase in single-parent families. On average, these families are poorer than two-parent families, and there are long-term consequences for children raised under condi-

tions of poverty. Experiencing poverty as infants and young children (zero to 5 years of age) affects people's subsequent educational achievement and employability (Duncan, et al. 1998). The increase in single-parent families thus does not bode well for the future of their young offspring, many of whom will not be prepared to fill the roles available in a technologically advanced and constantly changing society.

There has also been a marked increase in families where both the father and the mother work outside the home. Unless they have high incomes, dual-earner families, share with single-parent families the problem of finding adequate child care arrangements. A small proportion of mothers cope with both work and taking care of children, and a similarly small percentage of fathers care for children while mothers work away from the home. In some cases, grandparents or other relatives care for children outside the children's home. The well off can afford paid babysitters, and about one-quarter of preschoolers of working mothers are in some form of organized day care. Many of these facilities, however, have been judged unsafe or unsanitary and do not offer a warm and intellectually stimulating environment.

While the long-term outcome of these new socialization environments for infants and children cannot be known yet, social structures outside the family clearly are not filling the gaps created by changed family arrangements. Most important, there has been no institutionalization of satisfactory nonparental child care arrangements; social structures outside the family are lagging behind changes in children's lives and changes in the family.

There is also a gap between the lives of school-age children and social structures. Consider institutions of public education. Among the many undertakings of public schools at the end of the twentieth century, there are two major tasks: educating students raised in changed family environments and preparing those students for a changed society in which people increasingly will need the ability to adapt to continual changes and more jobs will require high levels of conceptual thinking.

By and large, experimental programs and various changes in schools notwithstanding, schools are falling behind in meeting these challenges. For example, many teachers have inadequate knowl-

edge of subject matter; curricula often lag behind new knowledge and are too often shaped by the nature of national or statewide tests; frequently there is administrative inertia and resistance to change; and students often are not challenged sufficiently in terms of, for example, the amount and nature of homework. These patterns militate against the goal of inculcating the kinds of thinking and other skills that will be needed in the next decades, when today's students will enter the labor force and take on adult responsibilities.

Adults. Structural lags affecting the old and the young have an impact on people in their middle years. It is those people years who must undertake the care of the young and the old when there are no alternatives, but it is precisely when people are in their prime years that they have heightened job and career responsibilities. Social structures are lagging in providing arrangements—such as flexible hours or flexible workplace settings and respite care from social agencies—that would ease the multiple burdens of those with career and family care responsibilities.

It is not only work organizations and social agencies that are not helping workers undertake their multiple responsibilities: Family structures are not adapting to the new realities either. It is women who typically bear the brunt of multiple burdens of work and family care. While most married women with children work outside the home, they still have the main responsibility for tasks in the home. More husbands—when they are present—are “helping” with household work than was the case in earlier times, but the norm of equal sharing has not been institutionalized. There is a gap between the changed lives of women and the way most families are structured.

Class, Gender, and Race Differences. There are differences within the several age strata (layers of people who differ in age and confront structures differentially appropriate for particular ages) in the degree of fit between changed people and changed institutions. The match or mismatch between people of given ages and institutions often depends on the gender, ethnicity, race, or class of the people involved.

Thus, the impact of structural lag is uneven. In some instances it is the most disadvantaged segments of the different age strata that are most likely to feel the brunt of the lag.

CLOSING THE GAP: PRESSURES FOR CHANGE

The gap between structures and the lives of the individuals in those structures creates tensions, inefficiencies, and other problems that are potent stimuli for change in both people and structures. Whatever the constraints, social structures tend to respond to these forces.

Social Structural Responses. Social structural responses to an increase in cohort size—a key source of pressure on structures—are illustrative. Beginning in midcentury, the pressure on social institutions came from the unexpectedly large number of people in the baby boom cohorts, whose large size created a lag in structures at every life stage. As Waring (1976) shows, social institutions coped with these large cohorts in myriad ways. When the baby boom cohorts were newborns, hospitals reduced the typical length of stay of new mothers and their babies to accommodate the flood of new births. When the baby boomers entered school, new schools were built and younger teachers were hired to compensate for the teacher shortage. In their college years, educational requirements were extended, with the result that entry into the labor force was delayed, helping to prevent a labor glut. These changes generally came piecemeal, but many of them, such as shorter maternal hospital stays, have turned out to be long-lasting.

As the number of old people has increased and as the baby boomers approach old age, there are signs that social institutions are making further changes. Indeed, as the changes made in many different institutional settings accumulate, new social meanings of age may arise. Age barriers to entry into a broad range of social roles are being relaxed and even breaking down. For individuals this means increased opportunities to intersperse periods of education, work, family time, and leisure over the life course, unlike the more rigid pattern of education in youth, work in adulthood, and retirement and leisure in old age that has been the typical shape of the life course (Riley et al. 1999). Within institutions, as more roles become available to people of all ages, cross-age interactions are likely to increase. Also, the pool of human capital available to varied social institutions will no longer be limited by rigid age norms.

Mechanisms of Change. Changes, whether piecemeal or encompassing, do not come about automatically. A number of processes operate singly or in combination to bring about change.

Actions of policymakers. Some individuals and agencies are in a good position to make and implement policy—government officials and company executives, for example—because they have an overview of their organizations and can propose or institute policies that will reduce the gap between people and structures.

One of the portents of more flexible age criteria has been the opening up of colleges and universities to older students. Educational administrators have played an important role in this development. They saw an opportunity to expand the pool of prospective students and felt a responsibility to offer access to their schools to older people. They have devised special degree programs for older people along with a wide range of nondegree classes. On a less formal level, other organizational leaders have developed elder hostel programs that give older people a chance to combine education and recreation, programs that have expanded beyond college settings and beyond the United States.

Undoubtedly, these policy initiatives were influenced by the actions of older people who were seeking avenues for enriching their lives or for filling in gaps in their education. Indeed, people inside social structures often act as agents of change, sometimes engaging in purposeful action with others and sometimes acting independently, as in the case of cohort norm formation, another mechanism of change.

Cohort norm formation. As formulated by Riley (1978), cohort norm formation is a process that occurs when the members of a cohort, reacting independently but in like fashion to changes in society, create new patterns of behavior and attitudes. These changes often spread to the succeeding cohorts, contributing to the establishment of new norms.

The centurylong increase in women's labor force participation is a prime example of this process. Since the early decades of the twentieth century, in successive cohorts, increasing proportions of women have worked outside the home. They were, of course, responding to broad social

forces that eased household burdens, facilitated control of family size, and introduced workplace technologies that women could manage efficiently. However, it was individual women who made the decision to enter and remain in the labor force after marriage. As they did so, norms for women's labor force participation changed. Early in the century the typical married woman did not hold a job outside the home and was not expected to, but as increasing numbers of women sought employment, it became acceptable for them to work for pay. At the end of the twentieth century, not only are high proportions of single and married women in the labor force, it is expected that women will have paying jobs regardless of their marital status. This norm was embodied in welfare legislation in the 1990s: Poor women were given time limits for welfare payments to support them and their dependent children. After that deadline, they were expected to be self-supporting.

Among older people at terminal stages of the life course, another set of norms has been forming (Riley 1990). Older people have been pressing for new norms that will help them avoid a prolonged, painful process of dying, provide palliative care, and give them more control of the way they die. New norms for the dying process and arrangements to implement them are being put in place. Hospice care that eschews heroic measures for those near death has been more widely accepted, more people are writing living wills detailing measures to be taken near the end, and hospitals have been forming medical ethics committees to deal with these issues. The "right to die" movement has gained power and, with it, some of the structural changes it supports. However, this movement has taken on a new cast as it has focused more on improving caretaking arrangements than on the psychosocial needs of patients (see "Death and Dying" in this encyclopedia).

What started out as individual but uncoordinated responses of numerous older people and others concerned about unacceptable practices in the American way of dying—an example of cohort norm formation—have taken on the shape of a social movement, a more organized effort to change customary practices.

Social movements. Social movements have played a role in effecting many age-related changes. These movements take several forms. They may involve

organized groups exerting pressure for change or may entail collective actions that arise more spontaneously. Whether organized or not, they bring issues of concern to public attention. Sometimes their actions lead to conflicts with groups that have different interests and agendas.

Organized social movements encompassing large segments particular age strata have emerged relatively infrequently. Most noteworthy was the Townsend movement in the 1930s, which organized older people to work for a publicly supported pension program for the elderly in the United States. At its height it had organized groups in almost every state. It played a role in the eventual enactment of Social Security legislation.

Although broad-based movements involving age-related issues are difficult to organize, more limited movements for structural change crop up. In the recent past there has been the "right to die" movement with its shifting emphases, as noted above, and organizations focusing on the problems of older women. At the other end of the age spectrum there is a children's rights movement concerned particularly about neglected children. By bringing problems to public attention and by lobbying policymakers directly, these social movements are able to stimulate at least piecemeal changes.

At times, social movements can trigger conflict among age strata. In the 1980s, for example, some pressure groups attempted to pit younger people against the old with dire predictions of intergenerational conflict in the future. Those groups argued that the elderly receive undue advantages from U.S. government programs and that younger adults are unfairly burdened with supporting those programs. Such age conflicts have not emerged, however, and challenges from younger adults that might provide the impetus for changes in government policies seem unlikely. The cross-age support for Social Security suggests why this is so. Younger adults want to maintain the Social Security program to safeguard their own future as well as to protect their parents' present status. Apart from affection for their parents, self-interest is involved. Without publicly supported pensions, those under age 65 would have to bear an increased financial burden to support their elderly parents. Moreover, many adults under age 65 benefit indirectly from gifts and ultimately

from inheritances made possible by the financial security afforded to the old by Social Security pensions. In short, the inevitability of growing old and the intergenerational bonds and exchanges within the family are powerful deterrents to conflicts between the young and the old (Foner 1974).

Obstacles to Change. Changing age-related components of social structures does not necessarily proceed smoothly. Long-held values, institutional rigidities, and the possible costs involved create impediments to effective change.

Proposals to make lifelong education a reality—not only educational opportunities for the old but also time off for retraining and sabbaticals for educational enrichment among those of working age—may seem simple to implement. However, many employers perceive that giving time off for sabbaticals is costly and often see no payoff from retraining mature workers when newly trained and cheaper young workers are available.

More equal sharing of household and child care responsibilities by young and middle-aged married adults can be thwarted by entrenched values about the appropriate roles of men and women.

Giving sick and dying patients increased autonomy in regard to their care does not comport with common practices such as rigid scheduling and beliefs of physicians and authorities in medical institutions that patients do not have the professional expertise needed to deal with their illness.

Unintended Consequences. Such obstacles notwithstanding, change does occur, but sometimes it has unforeseen results. For example, the spread of hospices that provide relief and palliative care for near-death patients has been a welcome alternative for people who do not want heroic—and often painful and expensive—measures. However, as the number of hospices and their patients has increased in the United States, federal regulatory agencies have found themselves hard put to monitor them and fraud has increased (New York Times 1998).

New norms about extending the work life will give healthy and eager older workers productive roles while at the same time addressing certain problems of the financial viability of the Social Security system. However, these new norms could undermine the right to retirement, discrediting those who are unable to work or those who need a

rest after long years of toil. Further, an increase in the number of older workers in the labor market looking for good part-time jobs could lead to competition with young and female workers also looking for such jobs. One result could be depressed wages in this sector of the labor market.

Viewed in their particulars, changes in social structures do not always neatly adjust social institutions to the changed lives of people. The change may be only partial, some changes may work out well for some people but not for others, and new problems may emerge, calling for additional changes. Viewed in the long run, however, structural lag turns out to be a frequently unrecognized but powerful force for change.

STRUCTURAL LAG AND THEORIES OF CHANGE

The concept of structural lag as a force for change has a ring of familiarity. Many analysts have put forth theories about discrepancies among the several parts of the society that press for change.

Perhaps the idea seemingly most similar to structural lag is Ogburn's (1932) concept of "cultural lag." Ogburn conceived of culture as complex, consisting of interdependent parts. There is the material culture with its technology, raw materials, manufactured products, and the like, and the nonmaterial culture that includes folkways, mores, social institutions, beliefs, laws, and governments. Ogburn thought that changes in the nonmaterial culture generally were dependent on changes in the material culture and often lagged behind changes in the material culture, hence the notion of cultural lag.

While Ogburn's concept of culture includes many of the same components of social structure posited in the theory of structural lag, his approach to social change differs from the analysis of structural lag in a number of ways. Ogburn's emphasis is on the relationship among elements in the culture. The theory of structural lag introduces the lack of fit between *people* and structures. Moreover, not only are changes in the lives of people not synchronized with changes in social structures, people act as agents of change in trying to align structures with their changing lives. A related difference is that Ogburn views the motive power of change as residing in the material culture. By

contrast, the analysts of structural lag consider changing lives and changing social structures as interdependent, with no claim for the priority of one over the other.

Others also have proposed that inconsistencies in social structures create pressures for social change. For example, Marx and Engels (1848) discussed contradictions within capitalism, and Merton (1938, 1957) analyzed the disjunction between culturally defined goals and socially differential access to the opportunity structure for achieving those goals, but these theories differ from the analysis of structural lag in a number of ways.

For Marx, change has its source in a fundamental contradiction of capitalism between private ownership of the means of production and the social nature of the production process, a contradiction that results in the exploitation of wage laborers employed by and dependent on capitalist employers. As workers struggle to improve their working conditions, their actions lead to fundamental change in the social relations of production. However, Marx's analysis of capitalist contradictions focuses on the crucial role of the productive sphere, whereas the analysis of structural lag does not give preeminence to any particular institution. Structural lag can and does occur in all societal structures, and pressures for change can emanate from all of them. Nor is social conflict the major mechanism of social change posited in the theory of structural lag, where, as was noted above, other mechanisms of change are generally more important.

In Merton's theory, the disjunction between goals and means leads to several modes of deviant adaptation, of which one, "rebellion", clearly augurs social change. In rebellion, one segment of the population rejects both goals and means as socially defined and seeks to replace them with a "greatly modified social structure" (Merton 1957, p. 155). Thus, this theory suggests a mechanism for changing the existing cultural and social structure. It is not concerned with the continuous entry into society of new cohorts whose changing lives confront social structures with the need for change, a central focus of the theory of structural lag.

In summary, the theory of structural lag, while rooted in the special qualities of age and aging as social phenomena—seemingly a narrow focus—is a broad theory that links age and aging to both

social structures and social change. In its structural aspects, it views age as a key element with which social structures must cope. From a dynamic perspective, it sees social forces bringing about change in people's lives, with those changing lives in turn causing pressure for changes in social structures. Structural lag thus is both a consequence of social change and an impetus for further change.

STUDENT MOVEMENTS

Student movements generally are thought of college student movements. These young adult movements have a long history in widely differing societies. Some have been characterized as direct student redress of situational grievances, such as the seventeenth-century sacking of the English Jesuit College of La Fleche to protest a rigid, strained regimen and the student protests led by African-American and Hispanic students on over a hundred campuses in the 1980s and 1990s to protest cutbacks in governmental aid and scholarships for lower-income students. Other student protest movements have been related to larger social movements. Examples are evident over time and space, including the nineteenth-century Russian revolutionary student movement, the American civil rights and antiwar student movements of the 1930s and 1960s, the 1970s Greek student Polytechnic protest that precipitated the downfall of that country's military dictatorship, and the ill-fated Chinese Tianenmen Square democratic movement in the late 1980s.

Student movements have the potential to generate major social change in the context of underlying economic, demographic, and other social forces. This makes student movement a strategic factor in assessing the nature of some consequential social change developments in society. The recent history of the United States exemplifies this idea. The far-reaching Civil Rights Act of 1964, the public shift from support of to opposition to the Vietnam War, and the pressure to diversify college student bodies and curricula racially and ethnically all involved student protest-induced changes that have affected the lives of people throughout American society and influenced student move-

ments in other societies, as movements in other societies have influenced American students.

Other examples of consequential student protest movements extend back a millennium or more. What is different about contemporary student movements is the combination of their frequency and their consequences for social change in society. This is a reflection of the central role of formal education in economic and social stability and development in both advanced technological and developing societies.

The massive growth of higher education, with the concomitant potential for student movements, is evident from the change in the proportion of young adults in their late teens and early twenties attending college. Before World War II, even in the advanced industrial nations of Japan, the United States, and Canada, as well as in Great Britain and western Europe, less than 10 percent of the young adult age cohort attended college. The figure was less than 1 percent in emerging, often formerly colonial, developing nations. In contrast, by the late twentieth century, close to half of young adults were in college in advanced technological societies, and the fastest growing student body in developing countries had become collegiate. Overall, instead of a few hundred or a few thousand students, major state universities in the United States now generally have between 20,000 and 40,000 or more students, with long-established private universities typically having over 10,000. Similarly, large national universities such as those in Beijing, Tehran, Madrid, Mexico City, and Moscow have student bodies larger than those of the largest U.S. state universities.

The growth of public education generally, and collegiate education in particular, has placed young adult students in a strategic position in respect to the potential of protest movements to induce social change. Prototypical examples at the end of the twentieth century range from the student protests that keyed the unexpected election of the former professional wrestler Jesse Ventura to the governorship of Minnesota and the overthrow of the authoritarian Suharto regime after over thirty years in Indonesia, the fourth most populous nation in the world.

The precipitating causes of these student protest activities were very different. In the case of

Minnesota, the economy was strong and played no discernible role. Key factors were the intense national political conflict between Republicans and Democrats over President Clinton's sexual scandal, charges of obstruction of justice, and partisan controversy over a presidential impeachment. This induced many students and other young people to change allegiance from the established national parties to a reform party candidate. In Indonesia, the Asian economic crisis of 1998 played a key role in the protest activity of students demanding a more democratic government and more equitable economic opportunities.

In terms of real or potential effects on the direction of society, it is not only that college students represent a high proportion of influential future economic, political, and social leaders. The growth of colleges since the middle of the twentieth century is also an international reflection of the general public's and democratic and authoritarian regimes' recognition of the importance of the educational training of students. This training represents a key element in the future of various societies in the modern cybernetic economic era.

There has been extensive research on what motivates consequential proportions of students to engage in protest movements. There is irony in the fact that students represent a relatively privileged and prospectively influential group in society. These characteristics generally are associated with support for the established social order, yet students are often in the activist forefront of protest movements aimed at changing that order.

This seeming contradiction has been addressed in intergenerational conflict terms since the time of Socrates and Plato. In sociology, Mannheim (1952) addressed specific attention to this phenomenon as part of his concern with the sociology of knowledge. Building on Mannheim's analyses, Feuer (1969) holds that the need for the emerging young to replace older adults in societies generates inherent intergenerational conflict that crystallizes in increasingly influential collegiate settings.

In this context, it is held that students act out their traditional intergenerational conflicts in a setting that is particularly conducive to challenging the older generation. Colleges, and to a lesser extent primary and secondary schools, remove students from familial and kinship settings. While

faculty members present an adult schooling influence, in the increasingly large school settings, students are placed in a peer-related situation removed from both direct familial influences and the later pressures of occupational positions.

This relatively separated, peer-influenced life pattern is evident in the precipitating protest actions of many student movements. Most sociological research has dealt with student participation in major protest movements involving civil rights, environmental protection, war, and other momentous public issues. However, a review of the student movement literature demonstrates that often the early motivation for student protest against university administrators and more general societal authorities has been related to specific student-experienced grievances over American-based situational concerns such as poor dormitory food in the 1950s and concerns among Italian and Chinese students in the 1960s and 1980s that growing numbers of college graduates were unemployed or were receiving lower pay than were undegreed manual laborers (Altbach and Peterson 1971; Lipset 1971).

Immediate student self-interest also can be seen in respect to student participation in larger social movements. This has been evident in respect to direct student concerns about conscription and being forced into combat situations. The 1860s Harvard University economic and social elite student anticonscription protests during the Civil War helped precipitate congressional modification of who was subject to the draft. Those with several hundred dollars were allowed to commute their draft status to the next young man called up who could not afford to commute being drafted. This was a central factor in the poor nonstudent Irish Catholic, conscription riots of 1863 in New York City that left several hundred dead.

Similar immediate self-interest was a part of the American Student Union antiwar movement before World War II in the 1930s as well as the anti-Vietnam War movement led by the Students for a Democratic Society (SDS) in the 1960s. These student protests partially reflected general public disagreement about war support, but the most common precipitating thread was immediate student interest. A particularly clear case of student self-interest was the high involvement of African-

American students in the civil rights movements of the 1960s, working for more openings and support for African-Americans, who had long been excluded from equal higher educational opportunity.

However, immediate self-interest does not explain the active involvement of most participants in student movements to support disadvantaged minority and low-income groups. This is seen in protest actions such as extensive involvement in the Student Non-Violent Coordinating Committee and other American civil rights organizations in the 1960s and the 1989 student effort to establish democracy in China. In this respect, students tend to activate parental ideals and values that are perceived to be falling short in their implementation (Davies 1969). What has become evident in the extensive empirical research on student movement participants since the 1960s is that the conflict of generations thesis advanced by Mannheim, Feuer, and others is less a conflict of generations than an active attempt among the student generation to realize the values to which they have been socialized by the parental generation.

Rather than challenging the values of the parental generation, student activists generally support those values and work to see them actualized (DeMartini 1985). A case in point is the background characteristics of students who were active in the politically liberal SDS, which was strongly against the Vietnam War, and that of those in the politically conservative Young Americans for Freedom (YAF), which was strongly supportive of that war. As Lipset (1971) reports, SDS students were mostly from high-status Protestant homes where secular, liberal values prevailed. In contrast, but in intergenerational concurrence, YAF student activists generally were drawn from strongly religiously observant and conservative homes in lower middle-class and working-class settings. Another example of this intergenerational confluence is Bell's (1968) documentation that the largest proportion of white student activists in the Congress of Racial Equality (CORE) were Jewish and were actively expressing their home-based familial values in support of minority rights.

Student movement concerns with actualizing ideals have been a dynamic aspect of those movements. The national student Free Speech Movement in 1964 was precipitated by University of

California at Berkeley students who protested a specific ban on allowing a CORE civil-rights-information table on the campus in an open mall area. While a relatively small number of students were actively involved with the CORE table, a large majority of students, first at Berkeley and then nationally, supported the First Amendment right of open expression, leading to the larger Free Speech Movement (Altbach and Peterson 1971).

Protest movements generally are time-delimited. Given the relatively short age dimensions of student status, student movements tend to have even shorter time spans. Even with time and leadership delimitations, student movements are sufficiently common and consequential that more systematic research is needed on not only who the student protestors are but also where they go after a student activist movement ends. Research is beginning to ascertain the extent to which former student protest activists' ideas and behaviors continue to reflect their protest values.

It is clear that most student activists enter into business and professional, high-socioeconomic-status positions. What is not as clear is the extent to which they continue to adhere to the values and related issues that motivated them to engage in student movements. Research in this area of student movements is suggestive of long-term consequences.

An analysis over time of 1960s student protest activists and nonactivists indicates that protest values continue to influence social, economic, and political behavior. Well over a decade after their civil rights and anti-Vietnam War activity, former activists continued to be more change-oriented than average, and given the nature of their protests, they were more liberal on issues of civil rights and civil liberties. Their orientation was to support more than did nonactivists government action to address a wide range of social problems and support specific policies such as abortion rights and affirmative action for minorities' and women's educational and employment opportunities (Sherkat and Blocker 1997). Further research may demonstrate additional social change consequences on society long after specific student movements have ended.

SUBURBANIZATION

Suburbanization is one aspect of the more general process of the expansion and spatial reorganization of metropolitan settlements. Settled areas that are beyond the historical boundaries of what have been considered cities but still are clearly functionally linked to the cities or may not be considered suburban. What is suburban is a matter of social definition. For example, when small cities are enveloped by the expansion of larger cities, at what point should they be considered suburbs, if they should be called suburbs at all? As some cities extend their boundaries outward, will the newly settled areas not be considered suburban if they are within the new boundaries?

Many researchers in the United States have chosen to adopt conventions established by the U.S. Bureau of the Census. The term "suburban" refers to the portion of a metropolitan area that is not in the central city. This definition depends on what is defined as metropolitan and central city,

and those definitions change over the years. Such changes are not simply technical adjustments; they respond (among other criteria) to assumptions about what cities and suburbs are. For example, as many U.S. "suburbs" have become employment centers in the last two decades, altering traditional patterns of commuting to work, Census Bureau scientists have adjusted the definition of "central city" to include some of those peripheral areas.

For many purposes, it may be preferable to avoid these categories altogether. "Suburban" may be intended to reflect distance from the city center, recency of development, residential density, or commuting patterns—all of which can be measured directly. The main substantive rationale for accepting definitions tied to the juridical boundaries of cities is to emphasize the differences between cities and suburbs (and among suburbs) that are related to municipal governance. An important class of issues revolves around disparities in public resources: In what parts of the metropolis are taxes higher, where are better schools available, where is police protection greater? What are the effects of these differences on the opportunities available to people who live in different parts of the metropolis? Another dimension concerns local politics: How do localities establish land use and budget policies, and what are the effects of those policies on growth?

Because many suburban residents have worked in central cities while paying taxes in the suburbs, John Kasarda has described the city-suburb relationship in terms of "exploitation." Political scientists in particular have studied this issue in terms of arguments for the reform of structures of metropolitan governance. The normative implications of their arguments have explicit ideological underpinnings. Some, such as Dennis Judd, emphasize the value of equality of life chances and interpret differences between cities and suburbs as disparities; others (public choice theorists such as Elinor Ostrom) emphasize freedom of choice and interpret differences as opportunities for the exercise of choice.

Sociologists on the whole have been less willing to be proponents of metropolitan solutions and have shown more interest in the causes than in the consequences of suburbanization. Nevertheless, there are differences in theoretical perspective that closely parallel those in political science,

and they hinge in part on the importance of political boundaries and the political process. The main lines of explanation reflect two broader currents in sociological theory: Structural functionalism is found in the guise of human ecology and neoclassical economics, and variants of Marxian and Weberian theory have been described as the "new" urban theory.

Ecologists and many urban economists conceptualize suburbanization as a process of decentralization, as is reflected in Burgess's (1967) concentric-zone model of the metropolis. Burgess accepted the postulate of central place theory that the point of highest interaction and most valued land is naturally at the core of the central business district. The central point is most accessible to all other locations in the metropolis, a feature that is especially valuable for commercial firms. At the fringes of the business district, where land is held for future commercial development, low-income and immigrant households can compete successfully for space, though only at high residential densities. Peripheral areas, by contrast, are most valued by more affluent households, particularly those with children and a preference for more spacious surroundings.

The key to this approach is its acceptance of a competitive land market as the principal mechanism through which locational decisions are reached. More specific hypotheses are drawn from theories about people's preferences and willingness (and ability) to pay for particular locations or structural changes (e.g., elevators, transportation technology, and the need for space of manufacturers) that affect the value of a central location. Many researchers have focused on gradients linking distance from the center to various compositional characteristics of neighborhoods: population density (Treadway 1969), household composition (Guest 1972), and socioeconomic status (Choldin and Hanson 1982). Comparatively little research has been conducted on the preferences of residents or the factors that lead them to select one location or another.

Other sociologists have argued that growth patterns result from conscious policies and specific institutional interventions in the land and housing markets. Representative of this view is the study done by Checkoway (1980), who emphasizes the role of federal housing programs and institu-

tional support for large-scale residential builders in the suburbanization process of the 1950s. The move to suburbs, he argues, was contingent on the alternatives offered to consumers. The redlining of inner-city neighborhoods by the Federal Housing Administration, its preference for large new subdivisions, and its explicit discrimination against minority home buyers are among the major forces structuring these alternatives.

There have been few studies of the housing market from an institutional perspective, although the restructuring of real estate financing and the emergence of new linkages between large-scale developers and finance capital have begun to attract attention. More consideration has been given to the explicitly political aspects of land development (Logan and Molotch 1987). Following Hunter (1953), who believed that growth questions are the "big issue" in local politics, later studies found that the most powerful voices in local politics are the proponents of growth and urban redevelopment and, in this sense, that a city is a growth machine.

In applying this model to suburbs, most observers portray suburban municipalities as "exclusionary." Suburban municipalities have long used zoning to influence the location and composition of land development. Since environmentalism emerged as a formidable political movement in the early 1970s, it has become commonplace to hear about localities that exercise their power to preserve open space and historic sites by imposing restraints or even moratoriums on new development. The "no-growth movement" is a direct extension of earlier exclusionary zoning policies.

SOCIOECONOMIC DIFFERENCES BETWEEN CITIES AND SUBURBS

These two theoretical perspectives can be illustrated through their application to research on socioeconomic differences between cities and suburbs. It is well known that central cities in most metropolitan regions have a less affluent residential population than do the surrounding suburbs. There is much debate, however, whether this class segregation between cities and their suburbs represents a natural sorting out of social classes through the private market or whether its causes are political and institutional. Similar debate surrounds the phenomenon of differentiation *within* suburbia,

where there is great variation in economic function, class and racial composition, and other characteristics of suburbs.

Research from an ecological perspective has stressed a comparison between the older, larger, denser cities of the North and the more recently growing cities of the South and West. The principal consistent findings have been that (1) the pattern of low central city relative to suburban social status is more pronounced in older metropolitan regions but that (2) controlling for metropolitan age, there appears to be a universal generalization of this pattern over time (Guest and Nelson 1978). These sociologists propose that suburbs have natural advantages over central cities. For example, their housing stock is newer, their land is less expensive, and they are more accessible to freeways and airports. The socioeconomic differences between cities and suburbs reflect those advantages.

Others argue that disparities are generated primarily by political structures that allocate zoning control and responsibility for public services to local governments and require those governments to finance services from local sources such as taxes on real property. They propose that the typical fragmentation of metropolitan government creates the incentive and opportunity for suburbs to pursue exclusionary growth policies (Danielson 1976).

Seeking to test these theories, Logan and Schneider (1982) found greater disparities in metropolitan areas where central cities were less able to grow through annexation (thus where suburban municipal governments were more autonomous) and where localities were more reliant on local property taxes (hence had greater incentive to pursue exclusionary policies). They also found a significant racial dimension: Greater disparities were evident in both 1960 and 1970 in metropolitan areas in the North with a larger proportion of black residents. (This did not hold for the South and West, however.) This disparity is due both to the concentration of lower-income blacks in central cities and to a greater propensity of higher-status whites to live in suburbs in those metropolitan areas. This finding is reinforced by Frey (see Frey and Speare 1988; Shihadeh and Ousey 1996), who reported that the central-city proportion of black residents is a significant predictor of white flight, independent of other causes.

If suburbs follow exclusionary growth policies, it seems counterintuitive that suburbs experienced much more rapid growth than did cities in the postwar decades. The findings on city–suburb disparities, of course, indicate that exclusion has selective effects. Nevertheless, it is surprising that in a study of northern California cities, Baldassare and Protash (1982), found that communities with more restrictive planning controls actually had higher rates of population growth in the 1970s. Similarly, Logan and Zhou (1989) found that suburban growth controls had little, if any, impact on development patterns (population growth, socioeconomic status, and racial composition). In their view, the exclusionary policies of suburbs may be more apparent than real. The more visible actions, such as growth moratoriums, often are intended to blunt criticisms by residents concerned with problems arising from rapid development. Unfortunately, few studies have looked in depth at the political process within suburbs; there is as little direct evidence on the role of local politics as there is on the operation of the land market. Most research from both the ecological and the political-institutional perspectives has inferred the *processes* for controlling growth from evidence about the *outcomes*.

SUBURBANIZATION OF EMPLOYMENT

A central problem for early studies of suburban communities was to identify the patterns of functional specialization among them. It was recognized that older industrial satellites coexisted with dormitory towns in the fringe areas around central cities. Both were suburban in the sense that they were integrated into a metropolitan economy dominated by the central city. Their own economic role and the nature of the populations they housed were quite distinct, however. The greatest population gains in the 1950s occurred in residential suburbs, communities that were wealthier, younger, newer, and less densely settled than the towns on the fringes of the region that had higher concentrations of employment. Schnore (see Schnore and Winsborough 1972) distinguished “suburbs” from “satellites” to acknowledge these different origins.

The metaphors of suburbs and satellites reflected the reality of early postwar suburbanization, a period when established towns and small cities

were surrounded by successive waves of new subdivisions. Those metaphors are no longer appropriate. Since the late 1950s, the bulk of new manufacturing and trade employment in the metropolis has been located in small and middle-sized cities in the suburban ring (Berry and Kasarda 1977, chap. 13). Downtown department stores compete with new suburban shopping malls. The highly developed expressway network around central cities frees manufacturing plants to take advantage of the lower land prices and taxes and the superior access to the skilled workforce offered by the suburbs. For the period 1963–1977, in the largest twenty-five metropolitan areas, total manufacturing employment in central cities declined by about 700,000 (19 percent), while their suburbs gained 1.1 million jobs (36 percent). At the same time, total central-city retail and wholesale employment was stagnant (dropping by 100,000). Trade employment in the suburbs increased 1.8 million (or 110 percent) in that period. Thus, total employment growth in the suburbs outpaced the growth of population (Logan and Golden 1986). This is the heart of the phenomenon popularized by Garreau (1991) as the creation of “Edge City.”

How has suburbanization of employment affected suburban communities? According to microeconomic and ecological models, locational choices by employers reflect the balance of costs and benefits of competing sites. New employment maintains old patterns because the cost–benefit equation is typically stable, including important considerations such as location relative to workforce, suppliers, markets, and the local infrastructure. In the terms commonly used by urban sociologists, this means that communities find their “ecological niche.” Stahura’s (1982) finding of marked persistence in manufacturing and trade employment in suburbs from 1960 to 1972 supports this expectation. Once it has “crystallized,” the functional specialization of communities changes only under conditions of major shifts in the needs of firms.

In this view, to the extent that changes occur, they follow a natural life cycle (Hoover and Vernon 1962). Residential suburbs in the inner ring, near the central city, tend over time to undergo two related transformations: to higher population density and a conversion to nonresidential development and to a lower socioeconomic status. Thus, inner suburbs that gain employment are—like older satellites—less affluent than residential suburbs.

By contrast, those who emphasize the politics of land development suggest very different conclusions. A growing number of suburbs perceive business and industry as a significant local resource. Once shunned by the higher-status suburbs, they now contribute to property values and the local tax base. Prestigious communities such as Greenwich, Connecticut, and Palo Alto, California, house industrial parks and corporate headquarters. The “good climate for business” they offer includes public financing of new investments, extensive infrastructure (roads, utilities, parking, police and fire protection), and moderate taxes (Logan and Molotch 1987).

Competition among suburbs introduces a new factor that has the potential to reshape suburban regions. Schneider (1989) reports that location of manufacturing firms is affected by the strength of the local tax base, suggesting that wealthy suburbs are advantaged in this competition. Logan and Golden (1986) find that newly developing suburban employment centers have higher socioeconomic status, as well as stronger fiscal resources, than other suburbs; this is a reversal of the pattern of the 1950s.

MINORITY SUBURBANIZATION

The suburbanization process also increasingly involves minorities and immigrants, and the incorporation of those groups into suburban areas has become an important topic for research on racial and ethnic relations. As Massey and Denton (1987) document, the rate of growth of nonwhites and Hispanics in metropolitan areas is far outstripping the rate of growth of non-Hispanic whites. Much of this growth is occurring in suburbs. During the 1970s, for example, the number of blacks in the non-central-city parts of metropolitan areas increased 70 percent compared with just 16 percent in central cities, and the number of other nonwhites in those locations shot up 150 percent compared with approximately 70 percent in central cities. One reason for the rapidly increasing racial and ethnic diversity of suburbs may be that some new immigrant groups are bypassing central cities and settling directly in suburbs. Equally important is the increasing suburbanization of older racial and ethnic minorities, such as blacks (Frey and Speare 1988).

This phenomenon has encouraged researchers to study suburbanization as a mirror on the social mobility of minorities. Consistent with classical ecological theory, suburbanization often has been portrayed broadly as a step toward assimilation into the mainstream society and a sign of the erosion of social boundaries. For European immigrant groups after the turn of the century, residential decentralization appears to have been part of the general process of assimilation (Guest 1980).

Past studies have found that suburbanization of Hispanics and Asians in a metropolitan area is strongly associated with each group’s average income level (Massey and Denton 1987, pp. 819–820; see also Frey and Speare 1988, pp. 311–315). Further, again for Hispanics and Asians, Massey and Denton (1987) demonstrate that suburban residence typically is associated with lower levels of segregation and, accordingly, higher probabilities of contact with the Anglo majority. However, these and other authors report very different results for blacks. Black suburbanization is unrelated to the average income level of blacks in the metropolitan area and does not result in higher intergroup contact for blacks. The suburbanization process for blacks appears largely to be one of continued ghettoization (Farley 1970), as is indicated by high and in some regions increasing levels of segregation and by the concentration of suburban blacks in communities with a high incidence of social problems (e.g., high crime rates), high taxes, and underfunded social services (Logan and Schneider 1984; Reardon 1997).

These findings regarding black suburbanization have been interpreted in terms of processes that impede the free mobility of racial minorities: steering by realtors, unequal access to mortgage credit, exclusionary zoning, and neighbor hostility (Foley 1973). Home ownership indeed may be one of the gatekeepers for suburban living. Stearns and Logan (1986) report that blacks were less likely to live in suburban areas where higher proportions of the housing stock were owner-occupied.

Further evidence is offered by Alba et al (1999), who based their conclusions on an analysis of individual-level data from the 1980 and 1990 censuses. They find that suburban residence is more likely among homeowners and persons of higher socioeconomic status. There are strong effects of

family status (marriage and the presence of children in the household), but for many immigrant groups, measures of cultural assimilation (English language use, nativity, and period of immigration) have declining relevance for suburban location. Assimilation traditionally has been a major part of the suburbanization process for most groups, especially those arising out of immigration, but large pockets of relatively new immigrants have now appeared in the suburban ring.

Parallel results are found for the racial and ethnic sorting process within a suburban region (the New York–New Jersey suburban region, as reported by Logan and Alba 1993; Alba and Logan 1993). Two sorts of analyses were conducted. First, members of different racial and ethnic groups were compared on the average characteristics of the suburbs in which they resided. Second, regression models were estimated for members of each major racial or ethnic group to predict several of these indicators of place advantages or community resources.

There are important differences between whites, blacks, Hispanics, and Asians in regard to the kinds of suburbs in which they live. As some researchers have suspected, suburban Asians have achieved access to relatively advantaged communities that are similar in most respects to those of suburban non-Hispanic whites. Hispanics in the New York region have not. Suburban Hispanic by and large live in communities that are about the same as black suburbs: communities with low average income levels and low rates of home ownership and, perhaps more important, high crime rates (Alba et al. 1994).

Is the disadvantage of blacks and Hispanics attributable to individual qualities of group members, or do these groups face collective disadvantages? Analysis of individual characteristics that may predict the quality of the suburb in which one resides shows that the same location process does not apply equally to all minorities. The pattern for whites, who are relatively advantaged in terms of access to community resources, lends clear support to assimilation theory. Human capital and indicators of cultural assimilation are strongly associated with access to higher-status suburbs. The same can be said of Asians (who are relatively advantaged overall), with the exception that cul-

tural assimilation variables seem not to be important for Asians.

The results for blacks call attention to processes of racial stratification. Even controlling for many other individual characteristics, blacks live in suburbs with lower ownership and income levels than do non-Hispanic whites. Further, most human capital and assimilation variables have a smaller payoff for blacks than they do for whites. The findings for Hispanics are supportive of the assimilation model in several respects. Hispanics gain more strongly than whites do from most human capital characteristics; therefore, at higher levels of socioeconomic achievement and cultural assimilation, Hispanics come progressively closer to matching the community resources of whites. It should be noted, however, that Hispanics begin from a lower starting point and that black Hispanics face a double disadvantage that is inconsistent with an assimilation perspective.

LOOKING TO THE FUTURE

Suburbanization continues to be a key aspect of metropolitan growth and is perhaps of growing importance in the global era (Muller 1997). The political boundaries between cities and suburbs accentuate interest in substantive issues of metropolitan inequality. They also create special opportunities for theories of urbanization to go beyond economic models and incorporate an understanding of the political process. Research on suburbanization has been most successful in describing patterns of decentralization and spatial differentiation. The movements of people and employment and the segregation among suburbs by social class, race, ethnicity, and family composition have been well documented. However, these patterns are broadly consistent with a variety of interpretations, ranging from those which assume a competitive land market (human ecology) to those which stress the institutional and political structuring of that market.

The principal gaps in knowledge concern the processes that are central to these alternative interpretations. Few sociologists have directly studied the housing market from the perspective of either demand (how do people learn about the alternatives, and how do they select among them?) or

supply (how does the real estate sector operate, how is racial and ethnic segmentation of the market achieved, how is the complex of construction industries, developers, and financial institutions tied to the rest of the economy?). Rarely have sociologists investigated government decisions (at any level) that impinge on development from the point of view either of their effects or of the political process that led to them. Of course, these observations are not specific to research on suburbanization. It is important to bear in mind that neither the theoretical issues nor the research strategies in this field distinguish suburbanization from other aspects of the urban process.

JOHN R. LOGAN

SUICIDE

To many people, suicide—intentional self-murder—is an asocial act of a private individual, yet sociology grew out of Durkheim's argument ([1897] 1951) that suicide rates are social facts and reflect variation in social regulation and social interaction. The concept of suicide derives from the Latin *sui* ("of oneself") and *cide* ("a killing"). Shneidman (1985) defines "suicide" as follows: "currently in the Western world a conscious act of self-induced annihilation best understood as a multidimensional malaise in a needful individual who defines an issue for which suicide is perceived as the best solution." Several conceptual implications follow from this definition.

Although suicidal types vary, there are common traits that most suicides share to some extent. (Shneidman 1985). Suicides tend to

- Seek a solution to their life problems by dying
- Want to cease consciousness
- Try to reduce intolerable psychological pain
- Have frustrated psychological needs
- Feel helpless and hopeless
- Be ambivalent about dying
- Be perceptually constricted and rigid thinkers
- Manifest escape, egression, or fugue behaviors
- Communicate their intent to commit suicide or die
- Have lifelong self-destructive coping responses (sometimes called "suicidal careers")

Completed suicides must be differentiated from nonfatal suicide attempts, suicide ideation, and suicide talk or gestures. Sometimes one speaks of self-injury, self-mutilation, accident proneness, failure to take needed medications, and the like—where suicide intent cannot be demonstrated—as "parasuicide." The most common self-destructive behaviors are indirect, such as alcoholism, obesity, risky sports, and gambling. There are also mass suicides (as in Jonestown, Guyana, in 1978 and in Masada in A.D. 72–73) and murder suicides. Individual and social growth probably require some degree of partial self-destruction.

Although most suicides have much in common, suicide is not a single type of behavior. Suicidology will not be an exact science until it specifies its dependent variable. The predictors or causes of suicide vary immensely with the specific type of suicidal outcome. Suicidologists tend to recognize three to six basic types of suicide, each with two or three of its own subtypes (Maris et al. 1992, chap. 4). For example, Durkheim ([1897] 1951) thought all suicides were basically anomic, egoistic, altruistic, or fatalistic. Freud (1917 [1953]) and Menninger (1938) argued that psychoanalytically, all suicides were based on hate or revenge (a "wish to kill"); on depression, melancholia, or hopelessness (a "wish to die"); or on guilt or shame (a "wish to be killed"). Baechler (1979)

added “oblativ” (i.e., sacrifice or transfiguration) and “ludic” (i.e., engaging in ordeals or risks and games) suicidal types.

EPIDEMIOLOGY, RATES, AND PREDICTORS

Suicide is a relatively rare event, averaging 1 to 3 in 10,000 in the general population per year. In 1996 (the most recent year for which U. S. vital statistics are available), there were 31,130 suicides, accounting for about 1.5 percent of all deaths. This amounts to an overall suicide rate of 11.6 per 100,000. Suicide is now the ninth leading cause of death, ranking just ahead of cirrhosis and other liver disease deaths and just behind human immunodeficiency virus (HIV) deaths. Suicide also has been moving up the list of the leading causes of death in this century (Table 1).

Suicide rates in the United States vary considerably by sex, age, and race (Table 2). The highest rates are consistently observed among white males, who constitute roughly 73 percent of all suicides. White females account for about 17 percent of all suicides. American blacks, especially females, rarely commit suicide (except for some young urban males). Some scholars have argued that black suicides tend to be disguised as homicides or accidents. In general, male suicides outnumber female suicides three or four to one. Generally, suicide rates gradually increase with age and then drop off at the very oldest ages. Female suicide rates tend to peak earlier than do those of males. Note in Table 3 that from about 1967 to 1977, there was a significant increase in the suicide rate of 15- to 24-year-olds and that suicide rates among the elderly seem to be climbing again.

Typically, marrying and having children protect one against suicide. Usually suicide rates are highest for widows, followed by the divorced and the never-married or single. Studies of suicide rates by social class have been equivocal. Within each broad census occupational category, there are job types with high and low suicide rates. For example, psychiatrists have high suicide rates, but pediatricians and surgeons have low rates. Operatives usually have low rates, but police officers typically have high rates.

The predominant method of suicide for both males and females in 1992 was firearms (Table 4).

Ten Leading Causes of Death in the United States, 1996 (total of 2,314,690 deaths)

Rank	Cause of Death	Rate per 100,000	No. of Deaths (all causes)
1	Disease of the heart	276.4	733,361
2	Malignant neoplasms	203.4	539,533
3	Cerebrovascular disease	60.3	159,942
4	Chronic obstructive pulmonary disease	40	106,027
5	Accidents	35.8	94,943
6	Pneumonia and influenza	31.6	83,727
7	Diabetes mellitus	23.3	61,767
8	HIV infection	11.7	31,130
9	Suicide	11.6	30,903
10	Chronic liver disease and cirrhosis	9.4	25,047

Table 1

SOURCE: Data from U.S. National Center for Health Statistics, 1998.

The second most common method among males is hanging, and among females it is a drug or medicine overdose. Females use a somewhat greater variety of methods than males do. Suicide rates tend to be higher on Mondays and in the spring-time (Gabennesch 1988).

Prediction of suicide is a complicated process (Maris et al. 1992). As is the case with other rare events, suicide prediction generates many false positives, such as identifying someone as a suicide when that person in fact is not a suicide. Correctly identifying true suicides is referred to as “sensitivity,” and correctly identifying true nonsuicides is called “specificity.” In a study using common predictors (Table 5) Porkorny (1983) correctly predicted fifteen of sixty-seven suicides among 4,800 psychiatric patients but also got 279 false positives.

Table 5 lists fifteen major predictors of suicide. Single predictor variables seldom correctly identify suicides. Most suicides have “comorbidity” (i.e., several key predictors are involved), and specific predictors vary with the type of suicide and other factors. Depressive disorders and alcoholism are two of the major predictors of suicide. Robins (1981) found that about 45 percent of all

**Rates of Completed Suicide per 100,000
Population by Race and Gender, 1996**

Race and Gender Group	No. of Suicides	Percent of Suicides	Rate per 100,000
White males	22,547	73	20.9
White females	5,309	17.1	4.8
Black males	(1,389)	(4.5)	(11.4)
Black females	(204)	(0.8)	(2.0)

completed suicides involved either depressed or alcoholic persons. Roughly 15 percent of all those with depressive illness and 18 percent of all alcoholics eventually commit suicide. Repeated depressive illness that leads to hopelessness is especially suicidogenic.

Nonfatal suicide attempts, talk about suicide or dying, and explicit plans or preparations for dying or suicide all increase suicide risk. However, for the paradigmatic suicide (older white males), 85 to 90 percent of these individuals make only one fatal suicide attempt and seldom explicitly communicate their suicidal intent or show up at hospitals and clinics. Social isolation (e.g., having no close friends, living alone, being unemployed, being unmarried) and lack of social support are more common among suicides than among controls. Suicide tends to run in families, and this suggests both modeling and genetic influences. Important biological and sociobiological predictors of suicide have been emerging, especially low levels of central spinal fluid serotonin in the form of 5-HIAA (Maris 1997).

HISTORY, COMPARATIVE STUDIES, AND SOCIAL SUICIDOLOGISTS

The incidence and study of suicide have a long history and were fundamental to the development

of sociology. The earliest known visual reference to suicide is Ajax falling on his sword (circa 540 B.C.). Of course, it is known that Socrates (about 399 B.C.) drank hemlock. In the Judeo-Christian scriptures there were eleven men (and no women) who died by suicide, most notably Samson, Judas, and Saul. Common biblical motives for suicide were revenge, shame, and defeat in battle. Famous suicides in art history include paintings of Lucretia stabbing herself (after a rape), Dido, and work by Edvard Munch and Andy Warhol.

Suicide varies with culture and ethnicity. Most cultures have at least some suicides. However, suicide is rare or absent among the Tiv of Nigeria, Andaman islanders, and Australian aborigines and relatively infrequent among rural American blacks and Irish Roman Catholics. The highest suicide rates are found in Hungary, Germany, Austria, Scandinavia, and Japan (Table 6). The lowest rates are found in several South American, Pacific Island, and predominantly Roman Catholic countries, including Antigua, Jamaica, New Guinea, the Phillipines, Mexico, Italy, and Ireland.

The sociological study of suicide started with Durkheim ([1897] 1951) and has continued to the present day primarily in the research and publications of the following sociologists: Short, (1954), J.P. Gibbs (1964), J.T. Gibbs (1988), Douglas (1967), Maris (1969, 1981), Phillips (1974), Phillips et al. (1991), Stack (1982), Wasserman (1989), and Pescosolido and Georgianna (1989). It is impossible in an encyclopedia article to do justice to the full account of the sociological study of suicide. For a more complete review, the reader is referred to Maris (1989).

Durkheim ([1897] 1951) claimed that the suicide rate varied inversely with social integration and that suicide types were primarily ego-anomic. However, Durkheim did not operationally define "social integration." Gibbs and Martin (1964) created the concept of "status integration" to correct this deficiency. They hypothesized that the less frequently occupied status sets would lead to lower status integration and higher suicide rates. Putting it differently, they expected status integration and suicide rates to be negatively associated. In a large series of tests from 1964 to 1988, Gibbs confirmed his primary hypothesis only for occupational statuses, which Durkheim also had said were of central importance.

Rates of Completed Suicide per 100,000 Population by Year and Age in the United States

Age*	YEAR				
	1957	1967	1977	1987	1992
5-14	0.2	0.3	0.5	0.7	0.9
15-24	4.0	7.0	13.6	12.9	12.9
25-34	8.6	12.4	17.7	15.4	14.6
35-44	12.8	16.6	16.8	15.0	15.1
45-54	18.0	19.5	18.9	15.9	14.7
55-64	22.4	22.4	19.4	16.6	14.9
65-74	25.0	19.8	20.1	19.4	16.6
75-84	26.8	21.0	21.5	25.8	23.1

Short (Henry and Short 1954) expanded Durkheim's concept of external and constraining social facts to include interaction with social psychological factors of "internal constraint" (such as strict superego restraint) and frustration-aggression theory. Short reasoned that suicide rates would be highest when external restraint was low and internal restraint was high and that homicide rates would be highest when internal restraint was low and external restraint was high.

A vastly different sociological perspective on suicide originated with the work of ethnomethodologist Douglas. Douglas, in the tradition of Max Weber's subjective meanings, argued that Durkheim's reliance on official statistics (such as death certificates) as the data base for studying suicide was fundamentally mistaken (Douglas 1967). Instead, it is necessary to observe the accounts or situated meanings of individuals who are known to be suicidal, not rely on a third-party official such as a coroner or medical examiner who is not a suicide and may use ad hoc criteria to classify a death as a suicide. There are probably as many official statistics as there are officials.

Maris (1981) extended Durkheim's empirical survey of suicidal behaviors, but not just by measuring macrosocial and demographic or structural

variables. Instead, Maris focused on actual interviews ("psychological autopsies") of the intimate survivors of suicides (usually their spouses) and compared those cases with control or comparison groups of natural deaths and nonfatal suicide attempts. Maris claimed that suicides had long "suicidal careers" involving complex mixes of biological, social, and psychological factors.

Phillips (1974) differed with Durkheim's contention that suicides are not suggestible or contagious. In a pioneering paper in the *American Sociological Review*, he demonstrated that front-page newspaper coverage of celebrity suicides was associated with a statistically significant rise in the national suicide rate seven to ten days after a publicized suicide. The rise in the suicide rate was greater the longer the front-page coverage, greater in the region where the news account ran, and higher if the stimulus suicide and the person supposedly copying the suicide were similar. In a long series of similar studies, Phillips et al. (1991) expanded and documented the suggestion effect for other types of behavior and other groups. For example, the contagion effect appears to be especially powerful among teenagers. Nevertheless, contagion accounts only for a 1 to 6 percent increase over the normal expected suicide rates in a population.

Percent of Completed Suicides in 1987 and 1992 by Method and Gender

METHOD	Gender			
	Male		Female	
	1987	1992	1987	1992
Firearms (E955.0–955.4)	64.0	65	39.8	39
Drugs/medications (E950.0–950.5)	5.2	–	25.0	–
Hanging (E953.0)	13.5	16	9.4	14
Carbon monoxide (E952.0–952.1)	9.6	–	12.6	–
Jumping from a high place (E957)	1.8	–	3.0	–
Drowning (E954)	1.1	–	2.8	–
Suffocation by plastic bag (E953.1)	0.4	–	1.8	–

Phillips’s ideas about contagion dominated the sociological study of suicide in the 1980s. Works by Stack (1982), Wasserman (1989), Kessler and Strip (1984), and others have produced equivocal support for the role of suggestion in suicide (Diekstra et al. 1989). Wasserman (1989) feels that the business cycle and unemployment rates must be controlled for. Some have claimed that imitative effects are statistical artifacts. Most problematic is the fact that the theory of imitation in suicide is underdeveloped.

The most recent sociologist to study suicide is the medical sociologist Pescosolido. She has claimed, contrary to Douglas, that the official statistics on suicide are acceptably reliable and, as Gibbs said earlier, are the best basis available for a science of suicide. Her latest paper (Pescosolido and Georgianna 1989) examined Durkheim’s claim that religious involvement protects against suicide. Pescosolido and Georgianna find that Roman Catholicism and evangelical Protestantism protect one against sui-

Common Single Predictors of Suicide

1. Depressive illness, mental disorder
2. Alcoholism, drug abuse
3. Suicide ideation, talk, preparation, religion
4. Prior suicide attempts
5. Lethal methods
6. Isolation, living alone, loss of support
7. Hopelessness, cognitive rigidity
8. Older white males
9. Modeling, suicide in the family, genetics
10. Work problems, economics, occupation
11. Marital problems, family pathology
12. Stress, life events
13. Anger, aggression, irritability, 5-HIAA
14. Physical illness
15. Repetition and comorbidity of factors 1–14, suicidal careers

Table 5

SOURCE: Maris et al. 1992, chap. 1.

cide (institutional Protestantism does not) and that Judaism has a small and inconsistent protective effect. Those authors conclude that with disintegrating network ties, individuals who lack both integrative and regulative supports commit suicide more often.

ISSUES AND FUTURE DIRECTIONS

Much of current sociological research on suicide appears myopic and sterile compared to the early work of Durkheim, Douglas, and Garfinkel. Not only is the scope of current research limited, there is very little theory and few book-length publications. Almost no research monographs on the sociology of suicide were written in the 1980s. Highly focused scientific journal articles on imitation have predominated, but none of these papers have been able to establish whether suicides ever were exposed to the original media stimulus. Since suicide does not concern only social relations, the study of suicide needs more interdisciplinary syntheses. The dependent variable (suicide) must include comparisons with other types of death and

violence as well as more nonsocial predictor variables (Holinger 1987).

A second issue concerns methods for studying suicide (Lann et al. 1989). There has never been a truly national sample survey of suicidal behaviors in the United States. Also, most suicide research is retrospective and based on questionable vital statistics. More prospective or longitudinal research design are needed, with adequate sample sizes and comparison or control groups. Models of suicidal careers should be analyzed with specific and appropriate statistical techniques such as logistic regression, log-linear procedures, and event or hazard analysis. Federal funds to do major research on suicide are in short supply, and this is probably the major obstacle to the contemporary scientific study of suicide.

Most studies of suicide are cross-sectional and static. Future research should include more social developmental designs (Blumenthal and Kupfer 1990). There is still very little solid knowledge about the social dynamics or "suicidal careers" of eventual suicides (Maris 1990). For example, it is well known that successful suicides tend to be socially isolated at the time of death, but how they came to be that way is less well understood. Even after almost a hundred years of research the relationship of suicide to social class, occupation, and socioeconomic status is not clear.

A major issue in the study of suicide is rational suicide, active euthanasia, the right to die, and appropriate death. With a rapidly aging and more secular population and the spread of the acquired immune deficiency (AIDS) virus, the American public is demanding more information about and legal rights to voluntary assisted death (see the case of Nico Speijer in the Netherlands in Diekstra et al. 1989). The right to die and assisted suicide have been the focus of a few recent legal cases (Humphry and Wickett 1986; Battin and Maris 1983). Rosewell Gilbert, an elderly man who was sentenced to life imprisonment in Florida for the mercy killing of his sick wife, was pardoned by the governor of Florida (1990). However, in 1990, the U.S. Supreme Court (*Cruzon v. the State of Missouri*) ruled that hospitals have the right to force-feed even brain-dead patients. The Hemlock Society has been founded by Derek Humphry to assist those who wish to end their own lives, make living wills, or pass living will legislation in their states

(however, see the *New York Times*, February 8, 1990, p. A18). Of course, the state must assure that the right to die does not become the obligation to die (e.g., for the aged). These issues are further complicated by strong religious and moral beliefs.

Should society help some people to die, and if so, who and in what circumstances? All people have to die, after all, so why not make dying free from pain, as quick as is desired, and not mutilating or lonely? One cannot help thinking of what has happened to assisted death at the other end of the life span, when help has not been available, in the case of abortion. Women often mutilate themselves and torture their fetuses by default. The same thing usually happens to suicides when they shoot themselves in the head in a drunken stupor in a lonely bedroom or hotel room. Obviously, many abortions and most suicides are not "good deaths."

Euthanasia is not a unitary thing. It can be active or passive, voluntary or involuntary, and direct or indirect. A person can be against one type of euthanasia but in favor of another. "Active euthanasia" is an act that kills, while "passive euthanasia" is the omission of an act, which results in death. For example, passive or indirect euthanasia could consist of "no-coding" terminal cancer or heart patients instead of resuscitating them or not doing cardiopulmonary resuscitation after a medical crisis.

"Voluntary euthanasia" is death in which the patient makes the decision (perhaps by drafting a living will), as opposed to "involuntary euthanasia," in which someone other than the patient (e.g., if the patient is in a coma) decides (the patient's family, a physician, or a nurse).

"Direct euthanasia" occurs when death is the primary intended outcome, in contrast to "indirect euthanasia," in which death is a by-product, for example, of administering narcotics to manage pain but secondarily causes respiratory failure.

All the types of euthanasia have associated problems. For example, active euthanasia constitutes murder in most states. It also violates a physician's Hippocratic oath (first do no harm) and religious rules (does all life belong to God?) and has practical ambiguities (when is a patient truly hopeless?).

Passive euthanasia is often slow, painful, and expensive. For example, the comatose patient Karen Anne Quinlan lived for ten years (she survived even after the respirator was turned off) and seemed to grimace and gasp for breath. Her parents and their insurance company spent thousands of dollars on what proved to be a hopeless case. The U.S. Supreme Court ruled in *Cruzan* (1990) that hospitals cannot be forced to discontinue feeding comatose patients.

In a case in which the author served as an expert, Elizabeth Bouvia, a quadriplegic cerebral palsy patient in California, sued to avoid being force-fed as a noncomatose patient. Her intention was to starve herself to death in the hospital. The California Supreme Court upheld Bouvia's right to refuse treatment, but others called the court's decision "legal suicide."

A celebrated spokesperson for euthanasia in the form of assisted suicide has been Derek Humphry, especially in his best-selling book *Final Exit* (1996). Rational assisted suicide (Humphry assisted in his first wife's death and in the death of his father-in-law), even for the terminally ill within six months of death, has proved highly controversial, particularly to Catholics and the religious right. Basically, Humphry has written a "how-to" book on the practicalities of suicide for the terminally ill.

His preferred rational suicide technique is to ingest four or five beta-blocker tablets and 40 to 60 100-mg tablets of a barbituate (perhaps in pudding or Jell-O), taken with Dramamine (to settle the stomach), vodka (or one's favorite whiskey), and a plastic bag over the head loosely fixed by a rubber band around the neck. Humphry recommends against guns (too messy), cyanide (too painful), hanging (too graphic), jumping (one could land on another person), and other mutilating, violent, painful, or uncertain methods.

One of the big questions about *Final Exit* is its potential abuses, for example, by young people with treatable, reversible depression. Having the lethal methods for suicide described in such vivid, explicit details worries many people that suicide will become too easy and thus often will be inappropriate. Yet Humphry shows that it is hard to get help with self-deliverance without fear of penalties. He argues that laws need to be changed to permit and specify procedures for physician-as-

sisted suicide for the terminally ill under highly controlled conditions.

A few states have undertaken such reforms to permit legal assisted death. For example, Initiative 119 in the fall of 1991 in Washington and Proposition 161 in the fall of 1992 in California would have provided "aid in dying" for a person if (1) two physicians certified that the person was within six months of (natural) death (i.e., terminally ill), (2) the person was conscious and competent, and (3) the person signed a voluntarily written request to die witnessed by two impartial, unrelated adults. Both referenda failed by votes of about 45 percent in favor and 55 percent against.

Humphry waged a similar legal battle in Oregon, first as president of the Hemlock Society and later as president of the Euthanasia Research and Guidance Organization (ERGO) and the Oregon Right to Die organization. On November 4, 1994, Oregon became the first state to permit a doctor to prescribe lethal drugs expressly and explicitly to assist in a suicide (see Ballot Measure 16). The National Right to Life Committee effectly blocked the enactment of this law until-1997, when the measure passed overwhelmingly again. On March 25, 1998, an Oregon woman in her mid-eighties stricken with cancer became the first known person to die in the United States under a doctor-assisted suicide law (most, if not all, of Dr. Jack Kervorkian's assisted suicides have probably been illegal).

Physician-assisted suicide has been practiced for some time in the Netherlands. On February 10, 1993, the Dutch Parliament voted 91 to 45 to allow euthanasia. To be eligible for euthanasia or assisted-suicide in the Netherlands, one must (1) act voluntarily, (2) be mentally competent, (3) have a hopeless disease without prospect for improvement, (4) have a lasting longing (or persistent wish) for death, (5) have assisting doctor consult at least one colleague, and (6) have written report drawn up afterward.

The Dutch law opened the door for similar legislation in the United States, although the U.S. Supreme court seems to have closed that door shut in Washington and New York. Box 1 discusses reviews of Dr. Herbert Hendin's *Seduced by Death*, which opposes physician-assisted death the United States and the Netherlands. While the idea of legal assisted suicide will remain highly contro-

versial and devisive, it is quite likely that bills similar to Oregon's Measure 16 will pass in other states in the next decade. A key issue will be safeguards against abuses (for example, Hendin argues that physicians in the Netherlands have decided on their own in some cases to euthanize patients).

THE DUTCH CASE

*The following are excerpts from reviews of Dr. Herbert Hendin's *Seduced by Death, Doctors, Patients, and the Dutch Cure* (Norton 1997). See *Suicide and Life-Threatening Behavior* 28:2, 1998.*

On June 26, 1997, the United States Supreme Court handed down a unanimous decision on physician-assisted suicide. All nine justices concurred that both New York and Washington's state bans on the practice should stand.

The picture [Hendin paints in the Netherlands] is a frightening one of excessive reliance on the judgment of physicians, a consensual legal system that places support of the physician above individual patient rights in order to protect the euthanasia policy, the gradual extension of practice to include administration of euthanasia without consent in a substantial number of cases, and psychologically naive abuses of power in the doctor-patient relationship.

[For example:] Many patients come into therapy with sometimes conscious but often more unconscious fantasies that cast the therapist in the role of executioner . . . It may also play into the therapist's illusion that if he cannot cure the patient, no one else can either." (Seduced by Death, p. 57)

Samuel Klagsburn, M.D., says of Hendin's argument: "He is wrong . . . suffering needs to be addressed as aggressively as possible in order to stop unnecessary suffering."

Hendin claims that in the Netherlands, "despite legal sanction, 60% of [physician-assisted suicide and death] cases are not reported, which makes regulation impossible."

Hendin goes on to argue that "a small but significant percentage of American doctors are now practicing assisted suicide, euthanasia, and the ending of patients' lives without their consent." But one also has to wonder: what

about all those patients being forced to live and suffer without the patients' consent?

Dr. Hendin is, after all, the former Executive Director and current Medical Director of the American Foundation for Suicide Prevention. What would really be news is if Hendin came out in favor of physician-assisted death. Certainly, there are abuses of any policy. But is that enough of a reason to fail to assist fellow human beings in unremitting pain to die more easily? Death is one the most natural things there is and often is the only relief.

One of the most controversial advocates of physician-assisted suicide ("medicide") has been Dr. Kervorkian (Kevorkian 1991). Public awareness of assisted suicide and whether it is rational has focused largely on Kervorkian, the "suicide doctor." As of early 1999, Kervorkian had assisted in over 100 suicides.

Initially, with Janet Adkins, Kervorkian used a suicide machine, which he dubbed a "mercitron." This machine provided a motor-driven, timed release of three intravenous bottles; in succession, they were (1) thiopental or sodium pentathol (an anesthetic that produces rapid unconsciousness), (2) succinylcholine (a muscle paralyzer like the curare used in Africa use in poison darts to hunt monkeys), and (3) potassium chloride to stop the heart. The metcitron was turned on by the would-be suicide. Because of malfunctions in the suicide machine, almost all of Kervorkian's suicides after Atkins were accomplished with a simple facial mask hooked up to a hose and a carbon monoxide cannister, with the carbon monoxide flow being initiated by the suicide. For most nonnarcotic users or addicts, 20 to 30 milligrams of intravenous injected morphine would cause death.

All of Kervorkian's first clients were women, and most were single, divorced, or widowed. Almost all were not terminally ill or at least probably would not have died within six months. The toxicology reports at autopsy (by Frederick Rieders; the author spoke with Dr. Dragovic, the Oakland County, Michigan, medical examiner to obtain these data) showed that only two of the eight assisted suicides had detectable levels of antidepressants in their blood at the time of death. It could be concluded that Kervorkian's assisted suicides were for the most part not being treated for depressive disorders.

Given Kervorkian's zealous pursuit of active euthanasia, one suspects that at least his early assisted suicides were not adequately screened or processed, for example, in accordance with the Dutch rules (above) or other safeguards. Strikingly, Hugh Gale is reputed to have asked Kervorkian to take off the carbon monoxide mask and terminate the dying process and perhaps was ignored by Kervorkian.

It is difficult to be objective about assisted suicide. Paradoxically, Kervorkian may end up setting euthanasia and doctor-assisted suicide back several years. Not only has he lost (1991) his Michigan medical license (he was a pathologist) and been charged with murder (after videotaping the dying of an assisted suicide for a television program), but Michigan and many other states (including South Carolina) have introduced bills to make previously legal assisted suicide a felony, with concurrent fines and imprisonment.

These new laws may have a chilling effect on both active and passive euthanasia, even in the case of legitimate pain control ("palliative care") previously offered to dying patients by physicians and nurses. For example, in Michigan it is now a felony to assist a suicide. People who want self-deliverance from their final pain and suffering will be more likely to mutilate themselves, die alone and disgraced, and feel generally abandoned in their time of greatest need.

Kervorkian needs to be separated from the issue of assisted suicide. However, the issue of physician-assisted suicide or death itself is not silly and transitory.

Everyone has to die eventually, and many people will suffer machine-prolonged debilitating illness and pain that diminishes the quality of their lives. Suicide and death and permanent annihilation of consciousness (if there is no afterlife) are effective means of pain control. This refers primarily to physical pain, but psychological pain also can be excruciating. Pain cannot always be controlled short of death. Most narcotics risk respiratory death. Furthermore, narcotics often cause altered consciousness, nightmares, nausea, panic, long periods of disrupted consciousness and confusion, and addiction.

Pain control technology is progressing rapidly (e.g., spinal implant morphine pumps). There are

hospices that encourage the use classic painkilling drinks such as Cicely Saunder's "Brompton's cocktail" (a mixed drink of gin, Thorazine, cocaine, heroin, and sugar). It is also possible to block nerves or utilize sophisticated polypharmacy to soften pain.

However, some pain is relatively intractable (e.g., that from bone cancer, lung disease with pneumonia, congestive heart failure in which patients choke to death on their own fluids, gastrointestinal obstructions, and amputation). A few physicians have made the ludicrous death-in-life proposal to give hopeless terminally ill patients general anesthesia to control their pain. People do always get well or feel better. Sometimes they just need to die, not be kept alive to suffer pointlessly. Anyone deserves to be helped to die in such instances.

SURVEY RESEARCH

Survey research is the method most frequently used by sociologists to study American society and other large societies. Surveys allow sociologists to move from a relatively small sample of individuals who are accessible as carriers of information about themselves and their society to the broad contours of a large population, such as its class structure and dominant values. Surveys conform to the major requirements of the scientific method by allowing a considerable (though by no means perfect) degree of objectivity in approach and allowing tests of the reliability and validity of the information obtained.

Like many other important inventions, a survey is composed of several more or less independent parts: sampling, questioning, and analysis of data. The successful combination of those elements early in the twentieth century gave birth to the method as it is known today. (Converse 1987 provides a history of the modern survey).

SAMPLING

The aspect of a survey that laypersons usually find the most mysterious is the assumption that a small sample of people (or other units, such as families or firms) can be used to generalize about the much larger population from which that sample is drawn. Thus, a sample of 1,500 adults might be drawn to represent the population of approximately 200 million Americans over age 18 in the year 2000. The sample itself is then used to estimate the extent to which numerical values calculated from it (for example, the percentage of the sample answering “married” to a question about marital status) are likely to deviate from the values that

would have been obtained if the entire population over age 18 had been surveyed. That estimate, referred to as “sampling error” (because it is due to having questioned only a sample, not the full population), is even stranger from the standpoint of common sense, much like pulling oneself up by one’s own bootstraps.

Although a sample of only 1,500 may be needed to obtain a fairly good estimate for the entire U.S. adult population, this does not mean that a much smaller sample is equally adequate for, say, a city of only 100,000 population. It is the absolute size of the sample that primarily determines the precision of an estimate, not the proportion of the population that is drawn for the sample—another counterintuitive feature of sampling. This has two important implications. First, a very small sample, for example, two or three hundred, is seldom useful for surveys, regardless of the size of the total population. Second, since it is often subparts of the sample, for example, blacks or whites, that are of primary interest in a survey report, it is the size of each subpart that is crucial, not the size of the overall sample. Thus, a much larger total sample may be required when the goal is to look separately at particular demographic or social subgroups.

All the estimates discussed in this article depend on the use of probability sampling, which implies that at crucial stages the respondents are selected by means of a random procedure. A nonprobability sampling approach, such as the proverbial person-in-the-street set of interviews, lacks scientific justification for generalizing to a larger population or estimating sampling error. Consumers of survey information need to be aware of the large differences in the quality of sampling that occur among organizations that claim to do surveys. It is not the case in this or other aspects of survey research that all published results merit equal confidence. Unfortunately, media presentations of findings from surveys seldom provide the information needed to evaluate the method used in gathering the data.

The theory of sampling is a part of mathematics, not sociology, but it is heavily relied on by sociologists and its implementation with real populations of people involves many nonmathematical problems that sociologists must try to solve. For example, it is one thing to select a sample of people according to the canons of mathematical

theory and quite another to locate those people and persuade them to cooperate in a social survey. To the extent that intended respondents are missed, which is referred to as the problem of nonresponse, the scientific character of the survey is jeopardized. The degree of jeopardy (technically termed “bias”) is a function of both the amount of nonresponse and the extent to which the nonrespondents differ from those who respond. If, for example, young black males are more likely to be missed in survey samples than are other groups in the population, as often happens, the results of the survey will not represent the entire population adequately. Serious survey investigators spend a great deal of time and money to reduce nonresponse to a minimum, and one measure of the scientific adequacy of a survey report is the information provided about nonresponse. In addition, an active area of research on the survey method consists of studies both of the effects of nonresponse and of possible ways to adjust for them. (for an introduction to sampling in social surveys, see Kalton 1983; for a more extensive classic treatment, see Kish 1965).

QUESTIONS AND QUESTIONNAIRES

Unlike sampling, the role of questions as a component of surveys often is regarded as merely a matter of common sense. Asking questions is a part of all human interaction, and it is widely assumed that no special skill or experience is needed to design a survey questionnaire. This is true in the sense that questioning in surveys is seldom very different from questioning in ordinary life but incorrect in the sense that many precautions are needed in developing a questionnaire for a general population and then interpreting the answers.

Questionnaires can range from brief attempts to obtain factual information (for example, the number of rooms in a sample of dwelling units) or simple attitudes (the leaning of the electorate toward a political candidate) to extensive explorations of the respondents’ values and worldviews. Assuming that the questions have been framed with a serious purpose in mind—an assumption not always warranted because surveys are sometimes initiated with little purpose other than a desire to ask some “interesting questions”—there are two important principles to bear in mind: one

about the development of the questions and the other about the interpretation of the answers.

The first principle is the importance of carrying out as much pilot work and pretesting of the questions as possible, because not even an experienced survey researcher can foresee all the difficulties and ambiguities a set of questions holds for the respondents, especially when it is administered to a heterogeneous population such as that of the United States. For example, a frequently used question about whether “the lot of the average person is getting worse” turned out on close examination to confuse the respondents about the meaning of “lot,”—with some taking it to refer to housing lots. Of course, it is still useful to draw on expert consultation where possible and to become familiar with discussions of questionnaire design in texts, especially the classic treatment by Payne (1951) and more recent expositions such as that by Sudman and Bradburn (1987).

Pilot work can be done in a number of ways, for example, by having a sample of respondents think aloud while answering, by listening carefully to the reactions of experienced interviewers who have administered the questionnaire in its pretest form, and, perhaps best of all, by having investigators do a number of practice interviews. The distinction between “pilot” and “pretest” questionnaires is that the former refer to the earlier stages of questionnaire development and may involve relatively unstructured interviewing, while the latter are closer to “dress rehearsals” before the final survey.

The main principle in interpreting answers is to be skeptical of simple distributions of results often expressed in percentage form for a particular question, for example, 65 percent “yes,” 30 percent “no,” 5 percent “don’t know.” For several reasons, such absolute percentages suggest a meaningfulness to response distributions that can be misleading. For one thing, almost any important issue is really a cluster of subissues, each of which can be asked about and may yield a different distribution of answers. Responses about the issue of “gun control” vary dramatically in the United States depending on the type of gun referred to, the amount and method of control, and so forth. No single percentage distribution or even two or three distributions can capture all this variation, nor are such problems confined to questions about

attitudes: Even a seemingly simple inquiry about the number of rooms in a home involves somewhat arbitrary definitions of what is and is not to be counted as a room, and more than one question may have to be asked to obtain the information the investigator is seeking. By the same token, care must be taken not to overgeneralize the results from a single question, since different conclusions might be drawn if a differently framed question were the focus. Indeed, many apparent disagreements between two or more surveys disappear once one realizes that somewhat different questions had been asked by each even though the general topic (e.g., gun control) may look the same.

Even when the substantive issue is kept constant, seemingly minor differences in the order and wording of questions can change percentage distributions noticeably. Thus, a classic experiment from the 1940s showed a large difference in the responses to a particular question depending on whether a certain behavior was said to be “forbidden” rather than “not allowed”: To the question, “Do you think the United States should forbid public speeches against democracy?” 54 percent said yes, [Forbid], but to the question, “Do you think the United States should allow public speeches against democracy?” 75 percent said no (do not allow). This is a distinction in wording that would not make a practical difference in real life, since not allowing a speech would have the same consequence as forbidding it, yet the variation in wording has a substantial effect on answers. Experiments of this type, which are called “split-ballot experiments,” frequently are carried out by dividing a national sample of respondents in half and asking different versions of the question to each half on a random basis. If the overall sample is large enough, more than two variations can be tested at the same time, and in some case more complex “factorial designs” are employed to allow a larger number of variations (see Rossi and Nock [1982] for examples of factorial surveys).

The proportion of people who answer “don’t know” to a survey question also can vary substantially—by 25 percent or more—depending on the extent to which that answer is explicitly legitimized for respondents by mentioning it along with other alternatives (“yes,” “no,” “don’t know”) or omitted. In other instances, the location of a question in a series of questions has been shown to affect answers even though the wording of the question

is not changed. For example, a widely used question about allowing legalized abortion in the case of a married woman who does not want more children produces different answers depending entirely on its position before or after a question about abortion in the case of a defective fetus. Thus, the context in which a question is asked can influence the answers people give. These and a large number of other experiments on the form, wording, and context of survey questions are reported by Schuman and Presser (1981) (see Turner and Martin [1984] for several treatments of survey questioning, as well as more recent volumes by Schwarz and Sudman [1996] and Sudman et al. [1996] with a cognitive psychological emphasis).

ANALYSIS

Although questioning samples of individuals may seem to capture the entire nature of a survey, a further component is vital to sociologists: the logical and statistical analysis of the resulting data. Responses to survey questions do not speak for themselves, and in most cases even the simple distribution of percentages to a single question calls for explicit or implicit comparison with another distribution, real or ideal. To report that 60 percent of a sample is satisfied with the actions of a particular leader may be grounds for either cheering or booing. It depends on the level of satisfaction typical for that leader at other times or for other individuals or groups in comparable leadership positions. Thus, reports of survey data should include these types of comparisons whenever possible. This is why for sociologists the collection of a set of answers is the beginning and not the end of a research analysis.

More generally, most answers take on clear meaning primarily when they are used in comparisons across time (for example, responses of a sample this year compared with responses of a sample from the same population five years ago), across social categories such as age and education, or across other types of classifications that are meaningful for the problem being studied. Moreover, since any such comparison may produce a difference that is due to chance factors because only a sample was drawn rather than to a true difference between time points or social categories, statistical testing is essential to create confidence that the difference would be found if the

entire population could be surveyed. In addition, individual questions sometimes are combined into a larger index to decrease idiosyncratic effects resulting from any single item, and the construction of this type of index requires other preliminary types of statistical analysis.

As an example of survey analysis, sociologists often find important age differences in answers to survey questions, but since age and education are negatively associated in most countries—that is, older people tend to have less education than do younger people—it is necessary to disentangle the two factors in order to judge whether age is a direct cause of responses or only a proxy for education. Moreover, age differences in responses to a question can represent changes resulting from the aging process (which in turn may reflect physiological, social, or other developmental factors) or reflect experiences and influences from a particular historical point in time (“cohort effects”). Steps must be taken to distinguish these explanations from one another. At the same time, a survey analyst must bear in mind and test the possibility that a particular pattern of answers is due to “chance” because of the existence of sampling error.

Thus, the analysis of survey data can be quite complex, well beyond, though not unrelated to, the kinds of tables seen in newspaper and magazine presentations of poll data. (The terms “poll” and “survey” are increasingly interchangeable, with the main difference being academic and governmental preference for “survey” and media preference for “poll.”) However, such thorough analysis is important if genuine insights into the meaning of answers are to be gained and misinterpretations are to be avoided. (A comprehensive but relatively nontechnical presentation of the logic of survey analysis is provided by Rosenberg [1968]. Among the many introductory statistical texts, Agresti and Finlay [1997] leans in a survey analytic direction.)

MODE OF ADMINISTRATION

Although sampling, questioning, and analysis are the most fundamental components, decisions about the mode of administering a survey are also important. A basic distinction can be made between self-administered surveys and those in which interviewers are used. If it is to be based on probability sampling of some sort, self-administration, usually is carried out by mailing questionnaires to respon-

dents who have been selected through a random procedure. For instance, a sample of sociologists might be chosen by taking every twentieth name from an alphabetical listing of all regular members of the American Sociological Association, though with the recognition that any such listing would be incomplete (e.g., not everyone with an advanced degree in sociology belongs to the association).

The major advantage of mail surveys is their relatively low cost, which is limited to payments to clerical employees, stamps, and perhaps financial incentive for the respondents. One disadvantage of mail surveys is that they traditionally have produced low response rates; many obtain only 25 percent or less of the target sample. However, Dillman (1978) argues that designing mail surveys in accordance with the principles of *exchange theory* can yield response rates at or close to those of other modes of administration. Whether this is true for a sample of the U.S. population remains in doubt for the reason given below, although Dillman has implemented some of his strategies in government census-type surveys. It is clear from numerous experiments that the use of two specific features—monetary incentives (not necessarily large) provided in advance and follow-up “reminders”—can almost always improve mail questionnaire response rates appreciably. However, another important disadvantage of mail surveys in the United States is the absence of an available centralized national listing of households for drawing a sample; because of this situation, it is difficult to say what response rate could be obtained from a nongovernmental national mail sample in this country.

Mail surveys generally are used when there is a prior list available, such as an organization’s membership, and this practice may add the benefit of loyalty to the organization as a motive for respondent cooperation. Other disadvantages of mail surveys are lack of control over exactly who answers the questions (it may or may not be the target respondent, assuming there is a single target), the order in which the questionnaire is filled out, and the unavailability of an interviewer for respondents who cannot read well or do not understand the questions. One compensating factor is the greater privacy afforded respondents, which may lead to more candor, although evidence of this is still limited. Sometimes similar privacy is attempted an interview survey by giving a portion

of the questionnaire to respondents to fill out themselves and even providing a separate sealed envelope to mail back to the survey headquarters, thus guaranteeing that the interviewer will not read the answers. This strategy was used by Laumann et al. (1994) in a major national survey of sexual behavior, but no comparison with data obtained in a more completely private setting was provided. Tourangeau and Smith (1996) provide a different type of evidence by showing that respondents who answer directly into a computer appear more candid than do respondents who give answers to interviewers. Recently, the Internet has been investigated as a vehicle for self-administered surveys, although there are formidable problems of sampling in such cases.

Because of these difficulties, most surveys aimed at the general population employ interviewers to locate respondents and administer a questionnaire. Traditionally, this has been done on a face-to-face (sometimes called “personal”) basis, with interviewers going to households, usually after a letter of introduction has been mailed describing the survey. The sample ordinarily is drawn by using “area probability” methods: To take a simple example, large units such as counties may be drawn first on a random basis, then from the selected counties smaller units such as blocks are drawn, and finally addresses on those blocks are listed by interviewers and a randomly drawn subset of the listed addresses is designated for the actual sample, with introductory letters being sent before interviewing is attempted. In practice, more than two levels would be used, and other technical steps involving “stratification” and “clustering” would be included to improve the efficiency of the sampling and data collection.

A major advantage of face-to-face interviewing is the ability of the interviewer to find the target respondent and persuade her or him to take part in the interview. Face-to-face interviewing has other advantages: Graphic aids can be used as part of a questionnaire, interviewers can make observations of a respondent’s ability to understand the questions and of other behavior or characteristics of a respondent, and unclear answers can be clarified. The major disadvantage of face-to-face interviewing is its cost, since much of the time of interviewers is spent locating respondents (many are not at home on a first or second visit). For every actual

hour spent interviewing, five to ten hours may be needed for travel and related effort. Furthermore, face-to-face surveys require a great deal of total field time, and when results are needed quickly, this is difficult to accomplish and may add more expense. Another disadvantage is the need for an extensive supervisory staff spread around the country, and yet another is that survey administrators must rely on the competence and integrity of interviewers, who are almost always on their own and unsupervised during interviews. This makes standardization of the interviewing difficult.

Increasingly since the early 1970s, face-to-face interviewing has been replaced by telephone interviewing, usually from a centralized location. Telephone surveys are considerably less expensive than face-to-face surveys, though the exact ratio is hard to estimate because they also are normally shorter, usually under forty-five minutes in length; the expense of locating people for face-to-face interviews leads to hourlong or even lengthier interviews, since these usually are tolerated more readily by respondents who are interviewed in person. Telephone surveys can be completed more rapidly than can face-to-face surveys and have the additional advantage of allowing more direct supervision and monitoring of interviewers. The incorporation of the computer directly into interviewing—known as computer-assisted telephone interviewing (CATI)—facilitates questionnaire formatting and postinterview coding, and this increases flexibility and shortens total survey time. Still another advantage of telephone surveys is the relative ease of probability sampling: Essentially random combinations of digits, ten at a time, can be created by computer to sample any telephone number in the United States (three-digit area code plus seven-digit number). There are a variety of practical problems to be overcome (e.g., many of the resulting numbers are nonworking, account must be taken of multiple phones per household, and answering machines and other devices often make it difficult to reach real people), but techniques have been developed that make such samples available and inexpensive to a degree that was never true of the area sampling required for face-to-face interviewing. Perhaps the largest problem confronting survey research is the proliferation of telemarketing, which makes many potential respondents wary of phone calls and reluctant to devote time to a survey interview.

Because speaking on the telephone seems so different from speaking face to face, survey methodologists initially thought that the results from the two types of survey administration might be very different. A number of experimental comparisons, however, have failed to find important differences, and those which do occur may have more to do with different constraints on sampling (telephone surveys obviously miss the approximately 8 percent of the American households without telephones and produce somewhat higher levels of refusal by the intended respondents). Thus, the remaining reasons for continuing face-to-face surveys have to do with the need for longer interviews and special additions such as graphic demonstrations and response scales. (Groves [1989] discusses evidence on telephone versus face-to-face survey differences, and Groves et al. [1988] present detailed accounts of methodological issues involving telephone surveys.)

Face-to-face and telephone surveys share one important feature: the intermediate role of the interviewer between the questionnaire and the respondent. Although this has many advantages, as was noted above, there is always the possibility that some behavior or characteristic of the interviewer will affect responses. For example, as first shown by Hyman (1954) in an effort to study the interview process, a visible interviewer characteristic such as racial appearance can have dramatic effects on answers. This is probably the largest of all the effects discovered, no doubt because of the salience and tension that racial identification produces in America, but the possibility of other complications from the interview process—and from the respondent's assumption about the sponsorship or aim of the survey—must be borne in mind. This is especially true when surveys are attempted in societies in which the assumption of professional neutrality is less common than in the United States, and some recent failures by surveys to predict elections probably are due to bias of this type.

THE SEQUENCE OF A SURVEY

Surveys should begin with one or more research problems that determine both the content of the questionnaire and the design of the sample. The two types of decisions should go hand in hand,

since each affects the other. A questionnaire that is intended to focus on the attitudes of different ethnic and racial groups makes sense only if the population sampled and the design of the sample will yield enough members of each group to provide sufficient data for adequate analysis. In addition, decisions must be made early with regard to the mode of administration of the survey—whether it will be conducted through self-administration or interviewing and, if the latter, whether in person, by telephone, or in another way—since these choices also influence what can be asked. Each decision has its trade-offs in terms of quality, cost, and other important features of the research.

After these planning decisions, the development of the questionnaire, the pretesting, and the final field period take place. The resulting data from closed, or fixed-choice, questions can be entered directly in numerical form (e.g., 1 = yes, 2 = no, 3 = don't know) into a computer file for analysis. If open-ended questions—questions that do not present fixed alternatives—are used and the respondents' answers have been recorded in detail, an intermediate step is needed to code the answers into categories. For example, a question that asks the respondents to name the most important problems facing the country today might yield categories for “foreign affairs,” “inflation,” “racial problems,” and so forth, though the words used by the respondents ordinarily would be more concrete. Finally, the data are analyzed in the form of tables and statistical measures that can form the basis for a final report.

MODIFICATIONS AND EXTENSIONS OF THE SURVEY METHOD

This discussion has concerned primarily the single cross-sectional or one-shot survey, but more informative designs are increasingly possible. The most obvious step now that surveys of the national population have been carried out for more than half a century is to study change over time by repeating the same questions at useful intervals. The General Social Survey (GSS) has replicated many attitude and factual questions on an annual or biennial basis since 1972, and the National Election Study (NES) has done the same thing in the political area on a biennial basis since the 1950s. From these repeated surveys, sociologists

have learned about substantial changes in some attitudes, while in other areas there has been virtually no change (see Niemi et al. [1989] and Page and Shapiro [1992] for examples of both change and stability). An important variant on such longitudinal research is the panel study, in which the same respondents are interviewed at two or more points in time. This has certain advantages; for example, even where there is no change for the total sample in the distribution of responses, there may be counterbalancing shifts that can be best studied in this way.

Surveys are increasingly being carried out on a cross-national basis, allowing comparisons across societies, though usually with the additional obstacle of translation to be overcome. Even within the framework of a single survey in one country, comparisons across different types of samples can be illuminating, for example, in an important early study by Stouffer (1955) that administered the same questionnaire to the general public and to a special sample of “community leaders” in order to compare their attitudes toward civil liberties. Finally, it is important to recognize that although the survey method often is seen as entirely distinct from or even opposite to the experimental method, the two have been usefully wedded in a number of ways. Much of what is known about variations in survey responses caused by the form, wording, and context of the questions has been obtained by means of split-ballot experiments, while attempts to study the effects of policy changes sometimes have involved embedding surveys of attitudes and behaviors within larger experimental designs.

ETHICAL AND OTHER PROBLEMS

As with other social science approaches to the empirical study of human beings, surveys raise important ethical issues. The success of survey sampling requires persuading individuals to donate their time to being interviewed, usually without compensation, and to trust that their answers will be treated confidentially and used for purposes they would consider worthwhile. A related issue is the extent to which respondents should be told in advance and in detail about the content and aims of a questionnaire (the issue of “informed consent”), especially when this might discourage their willingness to answer questions or affect the

kinds of answers they give (Singer 1993). The purely professional or scientific goal of completing the survey thus can conflict with the responsibility of survey investigators to the people who make surveys possible: the respondents. These are difficult issues, and there probably is no simple overall solution. There is a need in each instance to take seriously wider ethical norms as well as professional or scientific goals.

From within sociology, reliance on surveys has been criticized on several grounds. Sociologists committed to more qualitative approaches to studying social interaction often view surveys as sacrificing richness of description and depth of understanding to obtain data amenable to quantitative analysis. Sociologists concerned with larger social structures sometimes regard the survey approach as focusing too much on the individual level, neglecting the network of relations and institutions of societies. Finally, some see the dependence of surveys on self-reporting as a limitation because of the presumed difference between what people say in interviews and how they behave outside the interview situation (Schuman and Johnson 1976). Although there are partial answers to all these criticisms, each has some merit, and those doing survey research need to maintain a self-critical stance toward their own approach. However, the survey is the best-developed and most systematic method sociologists have to gather data. Equally useful methods appropriate to other goals have yet to be developed.

HOWARD SCHUMAN

SYMBOLIC INTERACTION THEORY

The term “symbolic interactionism” was invented by Blumer (1937) to describe sociological and social psychological ideas he presented as emanating directly from Mead, especially but not exclusively in *Mind, Self, and Society* (1934). “Symbolic interaction theory” is a term that is related to those ideas, though not necessarily in the specific forms presented by Blumer or Mead.

FUNDAMENTAL IMAGERY

The fundamental character of symbolic interactionist ideas is suggested by the theoretical proposition that the self reflects society and organizes behavior and by related imagery that addresses the nature of society and the human being, the nature of human action and interaction, and the relationship between society and the person. That imagery begins with a vision of society as a web of communication: Society *is* interaction, the reciprocal influence of persons who, as they relate, take into account each other’s characteristics and actions, and interaction is communication. Interaction is “symbolic,” that is, conducted in terms of the meanings persons develop in the course of their interdependent conduct. The environment of human action and interaction is symbolically defined: It is the environment as it is interpreted that is the context, shaper, and object of action and interaction. Persons act with reference to one another in terms of symbols developed through interaction and act through the communication of those symbols. Society is a label aggregating and summarizing such interaction. Society does not “exist”; it is created and continuously re-created as persons interact. Social reality is a flow of events joining two or more persons. More than simply being implicated in the social process, society and the person derive from that process: They take on their meanings as those meanings emerge in and through social interaction.

Neither society nor the individual is ontologically prior to the other in this imagery; persons create society through their interaction, but it is society, a web of communication and interaction, that creates persons as social beings. Society and the individual presuppose each other; neither exists except in relation to the other. This concep-

tion of society implicitly incorporates a view of the human being as “minded” and that “mindedness” as potentially reflexive. That is, people can and sometimes do take themselves as the object of their own reflection, thus creating selves, and do this from the standpoint of the others with whom they interact. Selves are inherently social products, although they involve more than reflected appraisals of others in the immediate situation of interaction; in particular, selves involve persons as subjects responding to themselves as objects. Thinking takes place as an internal conversation that uses symbols that develop in the social process. Mind arises in both the evolutionary and individual senses in response to problems (interruptions in the flow of activities) and involves formulating and selecting from symbolically defined alternative courses of action to resolve those problems. Choice is an omnipresent reality in the human condition, and the content of choices is contained in the subjective experience of persons as that experience develops in and through the social process.

Following from this imagery is a view of human beings, both collectively and individually, as active and creative rather than simply responsive to environmental stimuli. Since the environment of human action and interaction is symbolic; because the symbols attaching to persons (including oneself), things, and ideas are the products of interaction and reflexivity and can be altered and manipulated in the course of that interaction; since thought can be used to anticipate the effectiveness of alternative courses of action in resolving problems; and because choice among alternatives is an integral feature of social conduct, one arrives at an image of social interaction as literally constructed, although not necessarily anew in each instance, in the course of interaction. One also arrives at an image that entails a degree of indeterminacy in human behavior in the sense that the course and outcome of social interaction cannot as a matter of principle (not uncertain knowledge) be completely predicted from conditions and factors existing before that interaction.

THE SYMBOLIC INTERACTIONIST FRAMEWORK

Labeling the ideas of symbolic interactionism a “theory” is misleading. If one distinguishes between a systematic set of interrelated proposi-

tions about how a segment of the world is organized and functions and assumptions about and conceptualizations of the parts of that segment, symbolic interactionism has more the character of the latter than the former. That is, it is more a theoretical framework than a theory per se. While features of the framework appear to militate against attempts to formulate systematic theory by using it as a base and various proponents deny that possibility, a few sociologists have employed the framework in efforts to elaborate specific theories (e.g., Heise 1979; Stryker 1980, forthcoming; Stryker and Serpe 1982; Rosenberg 1984; Thoits 1983; MacKinnon 1994; Burke 1991). It is not possible to review such specific theories nor characterize the research that derives from that framework here. (For extensive references to classic literature and research literature before 1985, see Stryker and Statham [1985]. For more recent research, see one of the texts written from a symbolic interactionist perspective, such as Hewitt [1997], or *Symbolic Interaction*, a journal sponsored by the Society for the Study of Symbolic Interaction and devoted to work emanating from the framework.)

In the work of some (e.g., Blumer 1969), symbolic interaction “theory” is intended to be a general sociological frame that is applicable to the intellectual problems of sociology as a discipline from the most micro to the most macro levels. In the work of others (e.g., Stryker 1980), it is a frame restricted in utility to issues of social psychology. The first position does not seem defensible, because any framework brings into special focus particular variables and leaves unattended—at least relatively—other variables and because the symbolic interaction framework highlights interaction, social actors related through interaction, and subjective variables “internal” to those actors. It thus neglects features of the sociological landscape relating to large-scale social systems—the state, the economy, the “world system,” demographic variables, and so forth—and does not easily pose sociological questions involving interrelationships among those features of large-scale social systems. This neglect has led to criticism of the symbolic interactionist framework as lacking the social structural concepts needed for the analysis of power and consequently as an ideological apology for the status quo (see Meltzer et al. 1975; Stryker 1980; Reynolds 1990). Although many (e.g., Maines 1977) deny the validity of this criticism, pointing to work

by Hall (1972) and others, the criticism may be justified if the claim is that symbolic interactionism is a general sociological framework; it is not valid if the more restricted claim for its utility is made. However, there remains concern about the adequacy of the framework for problems of a distinctively *sociological* social psychology that centers on the reciprocal relationships of social units and social persons. There also is concern about whether the framework admits of and provides readily for the articulation of sociological and social psychology concepts. These concerns arise from the ways in which social structural concepts enter, or fail to enter, the symbolic interactionist frame (for presentations of an avowedly social structural version of the framework, see Stryker 1980, forthcoming). Whatever the intended coverage—from all of sociology to a limited social psychology—the framework traditionally has been conceived as knowing no cultural boundaries; that view, however, has been questioned (Hewitt 1990).

CENTRAL CONCEPTS

Implicated in the description of symbolic interactionist imagery provided above are many of the central concepts of the framework. The meaning of “meaning” is fundamental. By definition, social acts involve at least two persons taking each other into account in satisfying impulses or resolving problems. Since social acts occur over time, *gestures*—parts of an act that indicate that other parts are still to come—can appear. Vocal sounds, physical movements, bodily expressions, clothing, and so forth, can serve as gestures. When they do, they have meaning: Their meaning lies in the behavior that follows their appearance. Gestures that have the same meaning (implying the same future behavior) to those who make them and those who perceive them are *significant symbols*.

Things, ideas, and relationships among things and ideas can all be symbolized and enter the experience of human beings as objects; objects whose meanings are anchored in and emerge from social interaction constitute social reality. Although meanings are unlikely to be identical among participants, communication and social interaction presuppose significant symbols that allow meanings to be “sufficiently” shared. Because significant symbols anticipate future behavior, they entail plans of action: They organize behavior with

reference to what they symbolize. In the context of the ongoing social process, meanings must be at least tentatively assigned to features of the interactive situations in which persons find themselves; without the assignment of meanings, behavior in those situations is likely to be disorganized or random. The situation must be symbolized, as must its constituent parts; it must be defined or interpreted, and the products of that symbolization process are *definitions of the situation*. Those definitions focus attention on what is pertinent (satisfying impulses or resolving problems) in an interactive setting and permit a preliminary organization of actions appropriate to the setting. Tentative definitions are tested and may be reformulated through ongoing experience.

From the point of view of the actors involved, the most important aspects of a situation requiring definition are who or what they are in the situation and who or what the others with whom they interact are. Defining the others in the situation typically is accomplished by locating them as members of a socially recognized category of actors, one (or more) of the kinds of persons it is possible to be in a society (e.g., male or female, young or old, employed or unemployed). Doing this provides cues to or predictors of their behavior and permits the organization of one's own behavior with reference to them. When others are recognized as instantiations of a social category, behaviors are expected of them and actions that are premised on those expectations can be organized and directed toward them. Through this process, the introduction of early definitions of the situation can produce, although not inevitably, behavior that validates the definitions. This is an insight that underlies the notion of altercasting (Weinstein and Deutschberger 1963) and appears in the development of expectation states theory (Berger et al. 1974). When such behavior becomes routinized and organized, it also can serve to reproduce the existing social structure.

While some interactionists disdain the term, expectations attached to social categories—again, the kinds of persons it is possible to be in a society—are *roles*. Situations frequently allow one to locate others in multiple categories and open the possibility that conflicting expectations will come into play; in this circumstance, no clear means of organizing responses may be available. Defining oneself in a situation also involves locat-

ing oneself in socially recognized categories; to respond reflexively to oneself by classifying, naming, and defining who and what one is is to have a *self*. The self, conceived in this manner, involves viewing oneself as an object. The meaning of self, like that of any object, derives from interaction: To have a self is to view oneself from the standpoint of those with whom one interacts. The self, like any significant symbol, provides a plan of action. By definition, that plan implicates the expected responses of others.

People learn, at least provisionally, what they can expect from others through *role taking*, a process of anticipating the responses of the others with whom one interacts. In effect, one puts oneself in the place of those people to see the world as they do, using prior experience with them, knowledge of the social categories in which they are located, and symbolic cues available in interaction. On such bases, tentative definitions of others' attitudes are formulated and then validated or reshaped in interaction. Role taking permits one to anticipate the consequences of one's own and others' plans of action, monitor the results of those plans as they are carried out behaviorally, and sustain or redirect one's behavior on the basis of the monitoring. Because roles often lack consistency and concreteness while actors must organize their behavior as if roles were unequivocal, interaction is also a matter of *role making*: creating and modifying roles by devising performances in response to roles imputed to others (Turner 1962).

Many social acts take place within organized systems of action; consequently, both role taking and role making can occur with reference to a *generalized other*, that is, a differentiated but interrelated set of others (Mead's example involves baseball players anticipating the responses of other members of their team and those of their opponents). Not all others' perspectives are equally relevant to an actor; the concept of *significant other* indicates that some persons will be given greater weight when perspectives differ or are incompatible. It is implied here that meanings are not likely to be universally shared or shared in detail; if they are not, accuracy in role taking and difficulty in role making also will vary. It also is implied that smooth and cooperative interpersonal relations do not necessarily follow from accurate role taking: Conflict may result from or be sharpened by such accuracy.

The symbolic interactionist ideas reviewed here have a history. Many issue directly from Mead. Mead's ideas are part of a tradition of philosophical thought with roots in the Scottish moral philosophers Adam Smith, David Hume, Adam Ferguson, and Francis Hutcheson and, more proximately, in the American pragmatists Charles Peirce, William James, and John Dewey. They also contain important admixtures of evolutionary and dialectic premises. Mead's thought overlaps considerably with that of a number of sociologists who also wrote in the first decades of the twentieth century, in particular Charles Horton Cooley and William Isaac Thomas. Cooley's axiom that society and the person are two sides of the same coin (the coin, he added, is communication) and that of Thomas asserting that if humans define situations as real, the situations are real in their consequences, capture much of the essence of symbolic interactionism. A host of sociologists connect that past with the present; among others, Burgess, Blumer, Waller, Sutherland, Hughes, Shibutani, Kuhn, Cottrell, Hill, Lemert, Lindesmith, Mills, Miyamoto, and Stone are linked to a more contemporary set of persons that includes Goffman, Lofland, Becker, Lopata, Strauss, Geer, Weinstein, Farberman, Couch, Denzin, Bart, Maines, Reynolds, Turner, Daniels, Scheff, Wiseman, Heise, Stryker, Burke, Heiss, Fine, Hochschild, Weigert, McCall, Snow, and Hewitt. (For reviews of the history and literature of symbolic interactionism, see Stryker and Statham 1985; Meltzer et al. 1975; Reynolds 1990; Lewis and Smith 1980.) The presence of these researchers in a common listing does not indicate their adherence to a common credo; there may be much conceptual difference as well as similarity among them.

COMMONALITIES AND VARIATIONS

Thus, no single version of symbolic interaction theory satisfies all who find its core ideas appealing and useful in conducting research and analyses. There appear to be three fundamental premises of a symbolic interactionist perspective that are shared by those who acknowledge their intellectual roots in this tradition of sociological thought (Stryker 1988). The first holds that an adequate account of human social behavior must incorporate the perspective of participants in interaction and cannot rest entirely on the perspective of the observer. The second is that the self, that is, persons' reflex-

ive responses to themselves, links the larger social organization or structure to the social interaction of those persons. The third asserts that processes of social interaction are prior to both self and social organization, both of which derive and emerge from social interaction.

Each of these premises leaves open issues of considerable importance with respect to the content, methods, and objectives of interactionist analyses on which symbolic interactionists can differ. Some sociologists for whom the three core premises serve as a starting point believe that social life is so fluid that it can be described only in process terms, that concepts purportedly describing social structures or social organization belie the reality of social life. Relatedly, some believe that actors' definitions, which theoretically are central and powerful as generators of lines of action, are reformulated continuously in immediate situations of interaction, making it impossible to use preexistent concepts to analyze social life (Blumer 1969). Others accept the "reality" of social structural phenomena, viewing the social structure as relatively stable patternings of social interaction that operate as significant constraints on actors' definitions. Social structure is thought to make for sufficient continuity in definitions to allow the use of concepts derived from past analyses of social interaction in the analysis of present and future interaction (Stryker 1980). The first premise hides, in the term "*account*," the important difference between those who seem to believe that given the constructed character of social behavior, only an "after the fact" understanding of past events is possible (Weigert 1981) and those who believe that sociology can build testable predictive explanations of social behavior (Kuhn 1964). Similarly, some argue that the perspective of a sociological observer of human social behavior is likely to distort accounts of that behavior and so must be abjured in seeking to capture the perspectives of those who live the behavior that is observed (Denzin 1970), and others argue directly or by implication that the requirement that accounts incorporate the perspective of the actors whose behavior is observed dictates only that actors' definitions be included in developed explanations, not that they constitute those explanations (Burke 1991). The first group tends to argue that the best, if not the only "legitimate," methods are naturalistic, primarily observational (Becker and Geer 1957); the

second group tends to be catholic with respect to methods, refusing to rule out categorically any of the full range of possible social science methods and techniques (Heise 1979).

With respect to the second premise, interactionists differ in the degree to which they assign an independent "causal" role to the self as the link between social organization or structure and social behavior. For many, self can and does serve as an independent source of that behavior (McCall and Simmons 1978). For others, social organization or structure (as the residue of prior interaction) builds selves in its image, thus making the self essentially a conduit through which these structures shape behavior, not an independent source of that behavior (Goffman 1959). Similarly, there is variation among symbolic interactionists in the degree to which the self is seen as the source of creativity and novelty in social life, the degree to which creativity and novelty in social life are seen as probable as opposed to simply possible (occurring only under a specific and limited set of social circumstances), and the degree to which social life is constructed anew rather than "merely" reconstructed in the image of prior patterns (Turner 1962; Hewitt 1997; Stryker and Statham 1985).

The third premise is interpreted by some as denying that social organization and selves have sufficient constancy to permit generalized conceptualization or the development of useful a priori theory on the basis of any investigation that can carry over reasonably to any new investigation (Glaser and Strauss 1967). In the view of others, this premise does not deny that there is in social life a reasonable constancy that implies a sufficient constancy in both selves and social organization to permit the elaboration of useful theories employing general concepts that potentially are applicable to wide instances of social behaviors (Heise 1986). Some emphasize the behavioristic elements in their intellectual heritage from Mead, concentrating on how concerted lines of social action are constructed (Couch et al. 1986; McPhail and Wohlstein 1986), while others adopt a stance that attends primarily to the phenomenological worlds of the actors (or interactors) they study (Denzin 1984).

Clearly, these possibilities for important variations in symbolic interactionist thought are not independent of one another: Those who subscribe to a view emphasizing the fluidity of social life and

the moment-to-moment situated character of definitions also are likely to emphasize the degree to which social order continuously emerges from fluid process, the self organizes social behavior in an unconstrained fashion, and creativity and novelty characterize human behavior. They also tend to insist that the point of view of the observer contaminates reasonable accounts of social interaction, that there is little utility in an analysis of conceptualizations and theory emanating from earlier analyses, and that understanding, not explanation, is the point of sociological efforts.

The set of views presented in the preceding paragraph identifies symbolic interactionism for many of its most passionate adherents and perhaps for a majority of its critics. Those approaching their work from symbolic interactionism so defined tended to present what they did in both conceptual and methodological opposition to available alternatives in sociology. For example, Blumer (1969) devoted much of his career to championing direct and participant observation aimed at accessing the interpretations of those whose ongoing interaction sociologists sought to understand as opposed to both statistical and structural analyses, whose categories, data, and mathematical manipulations seemed to him devoid of actors' meanings. Critics of symbolic interactionism attacked it and its adherents for being nonscientific and asociological. To circumscribe symbolic interactionism in the manner of these adherents and critics belies the diversity in views on key issues represented in the work of those who use the framework.

CONTEMPORARY VITALITY

Interest in the symbolic interactionist framework within sociology has fluctuated. That interest was great from 1920 to 1950, reflecting in part the dominance of the University of Chicago in producing sociologists as well as the institutional structure of sociology. Through the 1950s and into the 1970s, interest waned, first as the structural functionalism of Parsons and Merton gained ascendance intellectually and Harvard and Columbia became institutionally dominant and later as Marxist and structuralist emphases on macro social processes swept the field. Symbolic interactionism, when not decried as reactionary or asociological, became the loyal opposition (Mullins 1973). Indeed, Mullins

predicted that it would disappear as a viable sociological framework.

More recent events contradict that prediction: Symbolic interactionism has had a remarkable revitalization in the past three decades (Stryker 1987), and there has been a corresponding resurgence of interest in the framework. The revitalization and resurgent interest reflect various sources. One is an emerging realization among sociologists with a structural orientation that their theories could benefit from the sociologically sophisticated theory of the social actor and action that symbolic interactionism can provide and the related increasing interest in linking micro to macro social processes. A second lies in a series of changing emphases in the work of contemporary symbolic interactionists. Although much recent work in a symbolic interactionist framework reflects traditional conceptual, theoretical, and methodological themes, on the conceptual level, newer work tends to adopt a "multiple selves" perspective, drawing on William James (Stryker 1989; McCall and Simmons 1978) rather than viewing the self as singular or unitary. Theoretically, there is greater attention to emotion, to affective dimensions of social life (Hochschild 1979; Thoits 1989; MacKinnon 1994; Ervin and Stryker, forthcoming), correcting for a "cognitive bias" in the framework; there is also greater appreciation for structural facilitators of and constraints on interaction and on self processes. While not yet prominent in contemporary interactionism, the groundwork has been laid (e.g., in Stryker and Statham 1985) for the reintroduction of the concept of habit, which was central in the writings of John Dewey and other forerunners of interactionism, in recognition that social life is not invariably reflexive and minded. Current symbolic interactionism is methodologically eclectic and tends to be more rigorous than it was in the past, whether the methods are ethnographic (Corsaro 1985) or involve structural equation modeling (Serpe 1987). Also contributing to the revitalization of symbolic interactionism is the attention to its ideas, often unacknowledged but sometimes recognized, paid by a psychological social psychology that is predominately cognitive in its orientation. For cognitive social psychology, concepts are mental or subjective structures formed through experience, and these structures affect recognizing, attending, storage, recall, and utilization of information impinging on the person; of prime significance

among concepts functioning in these ways are self-concepts. The link thus forged between cognitive social psychology and symbolic interactionism is mutually advantageous. Symbolic interactionism benefits from the "legitimacy" implicit in the attention given to its ideas and from the expanded pool of researchers focusing on those ideas; cognitive social psychology can benefit from understanding that cognitions are rooted in social structures and processes.

SHELDON STRYKES

SYSTEMS THEORY

NOTE: *Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.*

Systems theory is much more (or perhaps much less) than a label for a set of constructs or research methods. The term *systems* is used in many different ways (Boguslaw 1965; 1981, pp. 29–46). Inevitably this creates considerable confusion. For some it is a “way” of looking at problems in science, technology, philosophy, and many other things; for others it is a specific mode of decision making. In the late twentieth-century Western world it has also become a means of referring to skills of various kinds and defining professional elites. Newspaper “want ads” reflect a widespread demand for persons with a variety of “system” skills, for experts in “systems engineering,” “systems analysis,” “management systems,” “urban systems,” “welfare systems,” and “educational systems.”

As a way of looking at things, the “systems approach” in the first place means examining objects or processes, not as isolated phenomena, but as interrelated components or parts of a complex. An automobile may be seen as a system; a car battery is a component of this system. The automobile, however, may also be seen as a component of a community or a national transportation system. Indeed, most systems can be viewed as subsystems of more encompassing systems.

Second, beyond the idea of interrelatedness, systems imply the idea of control. This always includes some more or less explicit set of values. In some systems, the values involved may be as simple

as maintaining a given temperature range. The idea of control was implicit in Walter B. Cannon’s original formulation of the concept of homeostasis. Cannon suggested (Cannon 1939, p. 22) that the methods used by animals to control their body temperatures within well-established ranges might be adapted for use in connection with other structures including social and industrial organizations. He referred to the body’s ability to maintain its temperature equilibrium as *homeostasis*.

A third idea involved in the system way of looking at things is Ludwig von Bertalanffy’s search for a “general systems theory” (von Bertalanffy 1968; Boguslaw 1982, pp. 8–13). This is essentially a call for what many would see as an interdisciplinary approach. Von Bertalanffy noted the tendency toward increased specialization in the modern world and saw entire disciplines—physics, biology, psychology, sociology, and so on—encapsulated in their private universes of discourse, with little communication between any of them. He failed to note, however, that new interdisciplinary disciplines often quickly tend to build their own insulated languages and conceptual cocoons.

A fourth idea in the systems approach to phenomena is in some ways the most pervasive of all. It focuses on the discrepancy between objectives set for a component and those required for the system. In organizations this is illustrated by the difference between goals of individual departments and those of an entire organization. For example, the sales department wants to maximize sales, but the organization finds it more profitable to limit production, for a variety of reasons. If an entire community is viewed as a system, a factory component of this system may decide that short-term profitability is more desirable as an objective than investment in pollution-control devices to protect the health of its workers and community residents. Countless examples of this sort can be found. They all seem to document the idea that system objectives are more important than those of its subsystems. This is a readily understandable notion with respect to exclusively physical systems. When human beings are involved on any level, things become much more complicated.

Physical components or subsystems are not expected to be innovative. Their existence is ideal when it proceeds in a “normal” routine. If they wear out they can be replaced relatively cheaply,

and if they are damaged they can be either repaired or discarded. They have no sense of risk and can be required to work in highly dangerous environments twenty-four hours a day, seven days a week, if necessary. They do not join unions, never ask for increases in pay, and are completely obedient. They have no requirements for leisure time, cultural activities, or diversions of any kind. They are completely expendable if the system demands sacrifices. They thrive on authoritarian or totalitarian controls and cannot deal with the notion of democracy.

As a specific mode of decision making, it is this top-down authoritarianism that seems to characterize systems theory when it is predicated on a physical systems prototype. Computerization of functions previously performed by human beings ostensibly simplifies the process of converting this aspect of the theory into action. Computer hardware is presumably completely obedient to commands received from the top; software prepared by computer programmers is presumably similarly responsive to system objectives. Almost imperceptibly, this has led to a condition in which systems increasingly become seen and treated as identical to the machine in large-scale "man-machine systems." (The language continues to reflect deeply embedded traditions of male chauvinism.)

These systems characteristically have a sizable computerized information-processing subsystem that keeps assuming increasing importance. For example the U.S. Internal Revenue Service (IRS) obviously has enormous quantities of information to process. Periodically, IRS officials feel the necessity to increase computer capacity. To accomplish this, the practice has been to obtain bids from computer manufacturers. One bid, accepted years ago at virtually the highest levels of government, proposed a revised system costing between 750 million and one billion dollars.

Examination of the proposal by the congressional Office of Technology Assessment uncovered a range of difficulties. Central to these was the fact that the computer subsystem had been treated as the total system (perhaps understandably since the contractor was a computer corporation). The existing body of IRS procedures, internal regulations, information requirements, and law (all part of the larger system) was accepted as an immutable given. No effort had been made to

consider changes in the larger system that could conceivably eliminate a significant portion of the massive computer installation (Office of Technology Assessment 1972).

Almost two decades after attention had been called to these difficulties, system problems at the IRS continued to exist. A proposed Tax System Modernization was formulated to solve them. The General Accounting Office raised questions about whether this proposal, estimated to cost several billion dollars, was in fact "a new way of doing business" or simply intended to lower costs and increase efficiency of current operations. Moreover, the Accounting Office suggested that the lack of a master plan made it difficult to know how or whether the different component subsystems would fit together. Specifically, for example, it asked whether the proposal included a telecommunications subsystem and, if so, why such an item had not been included among the budgeted items (Rhile 1990).

To exclude the larger system from consideration and assume it is equivalent to a subsystem is to engage in a form of fragmentation that has long been criticized in related areas by perceptive sociologists (see Braverman 1974; Kraft 1977). Historically, fragmentation has led to *deskilling* of workers, that is, replacing craft tasks with large numbers of relatively simpler tasks requiring only semi-skilled or unskilled labor. This shields the larger system from scrutiny and facilitates centralization of control and power. It also facilitates computerization of work processes and even more control.

In the contemporary industrial and political worlds, power is justified largely on the basis of "efficiency." It is exercised largely through monopolization of information. Various forms of social organization and social structure can be used for the exercise of this power. Systems theory focuses not on alternative structures but, rather, on *objectives*, a subset of what sociologists think of as *values*. To hold power is to facilitate rapid implementation of the holder's values.

Fragmentation, in the final analysis, is an effort to divide the world of relevant systems into tightly enclosed cubbyholes of thought and practice controlled from the top. This compartmentalization is found in both government and private enterprises. The compartments are filled with those devoid of genuine power and

reflect the limitation of decisions available to their occupants. Those at the summit of power pyramids are exempt from these constraints and, accordingly, enjoy considerably more “freedom” (Pelton, Sackmann, and Boguslaw 1990).

An increasingly significant form of fragmentation is found in connection with the operation of many large-scale technological systems. Sociologist Charles Perrow has, in a path-breaking study, examined an enormous variety of such systems. He has reviewed operations in nuclear power, petrochemical, aircraft, marine, and a variety of other systems including those involving dams, mines, space, weapons, and even deoxyribonucleic acid (DNA). He developed a rough scale of the potential for catastrophe, assessing the risk of loss of life and property against expected benefits. He concluded that people would be better off learning to live without some, or with greatly modified, complex technological systems (Perrow 1984). A central problem he found involved “externalities,” the social costs of an activity *not* shown in its price, such as pollution, injuries, and anxieties. He notes that these social costs are often borne by those who do not even benefit from the activity or are unaware of the externalities.

This, of course, is another corollary to the fragmentation problem. To consider the technological system in isolation from the larger social system within which it is embedded is to invite enormous difficulties for the larger system while providing spurious profits for those controlling the subsystem.

Another interesting manifestation of the fragmentation problem arises in connection with two relatively new disciplines that address many problems formerly the exclusive province of sociology: operations research and management science. Each of these has its own professional organization and journal.

Operations research traces its ancestry to 1937 in Great Britain when a group of scientists, mathematicians, and engineers was organized to study some military problems. How do you use chaff as a radar countermeasure? What are the most effective bombing patterns? How can destroyers best be deployed if you want to protect a convoy?

The efforts to solve these and related problems gave rise to a body of knowledge initially

referred to as Operations Analysis and subsequently referred to as Operations Research. A more or less official definition of the field tells us Operations Research is concerned with scientifically deciding how to best design and operate man-machine systems usually under conditions requiring the allocation of scarce resources. In practice, the work of operations research involved the construction of models of operational activities, initially in the military, subsequently in organizations of all kinds. *Management science*, a term perhaps more congenial to the American industrial and business ear, emerged officially as a discipline in 1953 with the establishment of the Institute of Management Sciences.

In both cases, the declared impetus of the discipline was to focus on the entire system, rather than on components. One text points out that subdivisions of organizations began to solve problems in ways that were not necessarily in the best interests of the overall organizations. Operations research tries to help management solve problems involving the interactions of objectives. It tries to find the “best” decisions for “as large a portion of the *total system* as possible” (Whitehouse and Wechsler 1976).

Another text, using the terms *management science* and *operations research*, interchangeably defines them (or it) as the “application of scientific procedures, techniques, and tools to operating, strategic, and policy problems in order to develop and help evaluate solutions” (Davis, McKeown, and Rakes 1986, p. 4).

The basic procedure used in operations research/management science work involves defining a problem, constructing a model, and, ultimately, finding a solution. An enormous variety of mathematical, statistical, and simulation models have been developed with more or less predictable consequences. “Many management science specialists were accused of being more interested in manipulating problems to fit techniques than . . . (working) to develop suitable solutions” (Davis, McKeown, and Rakes 1986, p. 5). The entire field often evokes the tale of the fabled inebriate who persisted in looking for his lost key under the lamppost, although he had lost it elsewhere, because “it is light here.”

Under the sponsorship of the Systems Theory and Operations Research program of the National

Science Foundation, a Committee on the Next Decade in Operations Research (CONDOR) held a workshop in 1987. A report later appeared in the journal *Operations Research*. The journal subsequently asked operation researchers to comment on the report (Wagner et al. 1989). One of the commentators expressed what appears to be a growing sentiment in the field by pointing out the limitations of conventional modeling techniques for professional work. Criticizing the CONDOR report for appearing to accept the methodological status quo, he emphasized the character of models as “at best abstractions of selected aspects of reality” (Wagner et al. 1989). He quoted approvingly from another publication, “thus while exploiting their strengths, a prudent analyst recognizes realistically the limitations of quantitative methods” (Quade 1988).

This, however, is an unfortunate repetition of an inaccurate statement of the difficulty. It is not the limitations of quantitative methods that is in question but rather the recognition of the character of the situations to which they are applied. Sociologists distinguish between *established* situations, those whose parameters can be defined precisely and for which valid analytic means exist to describe meaningful relationship within them and *emergent* situations, whose parameters are known incompletely and for which satisfactory analytic techniques are not available within the time constraints of necessary action (Boguslaw [1965] 1981). In established situations mathematical or statistical models are quite satisfactory, along with other forms of rational analysis. In emergent situations, however, they can yield horrendous distortions. Fifty top U.S. corporation executives, when interviewed, recognized and acted upon this distinction more or less intuitively, although the situations presented to them were referred to as Type 1 and Type 2, respectively (Pelton, Sackmann, and Boguslaw 1990).

Individual persons, organizations, or enterprises may be viewed, on the one hand, as self-contained systems. On the other, they may be viewed as subsystems of larger social systems. Unfortunately, efforts are continually made to gloss over this dichotomy through a form of fragmentation, by treating a subsystem or collection of subsystems as equivalent to a larger system. It is this relationship between system and subsystem that

constitutes the core of the dilemma continuing to confront systems theory.

Achieving a satisfactory resolution of the discrepancy between individual needs and objectives of the systems within which individuals find themselves embedded or by which they are affected remains an unsolved problem as the twentieth century draws to a close.

T

TABULAR ANALYSIS

In its most general form, tabular analysis includes any analysis that uses tables, in other words, almost any form of quantitative analysis. In this article, however, it refers only to the analysis of categorical variables (both nominal and ordered) when that analysis relies on cross-classified tables in the form of frequencies, probabilities, or conditional probabilities (percentages). In general, the use of such cross-tabulated data is practical only with variables that have a limited number of categories. Therefore, this article deals with some of the *analytic* problems of *categorical data analysis*. Although it sometimes is difficult to separate analysis from methods of data presentation, the emphasis here is decidedly on analysis (see Davis and Jacobs 1968).

Tabular analysis can take many different forms, but two methods deserve special attention. The first is known as *subgroup analysis*. The underlying logic of this type of analysis was codified under the name “elaboration paradigm” by Lazarsfeld and his colleagues (Kendall and Lazarsfeld 1950; Lazarsfeld 1955; Hyman 1955; Rosenberg 1968; Lazarsfeld et al., 1972; Zeisel 1985). Because of the simplicity of the method and the ease with which it can facilitate communication with others, subgroup analysis has been the mainstay of research reports dealing with categorical data.

The second is based on the use of *log-linear* and related models and has become increasingly popular (Bishop et al. 1975; Goodman 1978;

Haberman 1978, 1979; Fienberg 1980; Agresti 1984; 1990; Clogg and Shihadeh 1994). (For other related models, see McCullagh and Nelder 1983; Thiel 1991; Long 1997; Press and Wilson 1998). This method is flexible, can handle more complex data (with many variables), and is more readily amenable to statistical modeling and testing (Clogg et al. 1990). For this reason, the log-linear method is rapidly emerging as the standard method for analyzing multivariate categorical data. Its results, however, are not easily accessible because the resulting tabular data are expressed as multiplicative functions of the parameters (i.e., log-linear rather than linear), and the parameters of these models tend to obscure descriptive information that often is needed in making intelligent comparisons (Davis 1984; Kaufman and Schervish 1986; Alba 1988; Clogg et al. 1990).

These two methods share a set of analytic strategies and problems and are complementary in their strengths and weaknesses. To understand both the promises and the problems of tabular analysis, it is important to understand the logic of analysis and the problems that tabular analyses share with the simpler statistical analysis of linear systems. As a multivariate analysis tool, tabular analysis faces the same problems that other well-developed linear statistical models face in analyzing data that are collected under less than ideal experimental conditions. It therefore, is important to have a full understanding of this foundation, and the best way to do that is to examine the simplest linear system.

STATISTICAL CONTROLS, CAUSAL ORDERING, AND IMPROPER SPECIFICATIONS

$$Y = Xd_{yx} + e \tag{2}$$

Consider the simplest linear multivariate system:

$$Y = Xb_{yxz} + Zb_{yzx} + e \tag{1}$$
