where all the variables, including the error term, are assumed to be measured from their respective means. When this equation is used merely to describe the relationship between a dependent variable Y and two other variables X and Z , the issue of misspecification—in other words, whether the coefficients accurately reflect an intended relationship—does not arise because the coefficients are well-known partial regression coefficients. However, when the linear model depicted in equation (1) is considered as a representation of an underlying theory, these coefficients receive meaning under that theory. In that case, the issue of whether the coefficients really capture the intended relationship becomes important. Causal relationships are not the only important relationships, but it is informative to examine this equation with reference to such relationships since this is the implicitly implied type of system.

Many different conceptions of causality exist in the literature (Blalock 1964, 1985a, 1985b; Duncan 1966, 1975; Simon 1954, 1979; Heise 1975; Mostetler and Tukey 1977; Bunge 1979; Singer and Marini 1987). However, the one undisputed criterion of causality seems to be the existence of a relationship between manipulated changes in one variable (X) and attendant changes in another variable (Y) in an ideal experiment. That is, a causal connection exists between X and Y if changes in X and X alone produce changes in Y . This is a very restrictive criterion and may not be general enough to cover all important cases, but it is sufficient as a point of reference. This definition is consistent with the way in which effects are measured in controlled experiments. In general, even in an ideal experiment, it is often impossible to eliminate or control all the variations in other variables, but their effects are made random by design. A simple linear causal system describing a relationship produced in an ideal experiment thus takes the following familiar form:

where e stands for all the effects of other variables that are randomized. The randomization makes the expected correlation between X and e zero. (Without loss of generality, it is assumed that all the variables [X , Y , and e] are measured as deviations from their respective means.) For the sake of simplicity, it is assumed for now that Y does not affect X . (For an examination of causal models dealing with reciprocal causation and with more complex systems in general, see Fisher 1966; Goldberger and Duncan 1973; Alwin and Hauser 1975; Duncan 1975; Blalock 1985a, 1985b.)

The coefficient d_{yx} measures the expected change in Y given a unit change in X . It does not matter whether changes in X affect other variables and whether some of those variables in turn affect Y . As long as all the changes in Y ultimately are produced by the manipulated initial changes in X and X alone, X receives total credit for them. Therefore, d_{yx} is a coefficient of *total causal effect* (referred to as an *effect coefficient* for short).

The customary symbol for a simple regression coefficient, b_{yx} is not used in equation (2) because b_{yx} is equivalent to d_{yx} only under these very special conditions. If one uses a simple regression equation in the form similar to equation (2) above and assumes that b_{yx} is equivalent to d_{yx} , the model is misspecified as long as the data do not meet all the assumptions made about the ideal experiment. Such errors in model specification yield biased estimates in general. Implications of some specification errors may be trivial, but they can be serious when one is analyzing nonexperimental data (see Kish 1959; Campbell and Stanley 1966; Leamer 1978; Cook and Campbell 1979; Lieberman 1985; Arminger and Bohrnstedt 1987).

Many underlying causal systems are compatible with the three-variable linear equation shown above. For the purpose at hand, it is enough to examine the simple causal systems shown in Figure 1. These causal systems imply critical assumptions about the error term and the causal ordering. If these assumptions are correct, there is a definite connection between the underlying causal parameters and the regression coefficients in equation (1). However, if some of these assumptions are wrong, equation (1) is a misrepresentation of

Figure 1. Some simplified linear causal systems

the assumed causal model (for a fuller description of other possible systems, see Duncan 1975).

The notation for causal hierarchy (\geq) means that the preceding variable may affect the variables after it, but variables after (\geq) may not affect the preceding variables. A connecting arrow between two variables indicates both the existence and the direction of effects; lack of a connecting arrow indicates no known effects. (For convenience, these diagrams do not show random errors, but their presence is assumed.)

For each causal system in Figure 1, the key relationships among simple regression coefficients, partial regression coefficients, and effect coefficients are listed below each causal diagram. Look at the simple causal chain (or a cascading system) shown in A1, for instance. The introduction of Z as a control variable has no effect on the observed

relationship between X and Y. Note also that the simple regression coefficient is equivalent to the effect coefficient ($b_{yx} = b_{yx \cdot z} = d_{yx}$); similarly, the simple b_{yz} is equivalent to d_{yz} , but the partial $b_{yz \cdot x}$ becomes zero. (If one were to control Y, the X-Z relationship would not change, but such control is superfluous given the assumptions about the causal ordering.) In fact, one could argue that these two conditions, given the assumptions about the causal hierarchy, uniquely define a simple causal chain. If the control variable Z enters the X-Y causal system only through X (or the effects of a set of variables are mediated completely through [an]other variable[s] in the system), there is no need to introduce Z (or a set of such variables) as a control to correctly specify the X-Y relationship.

In A2, the two partials ($b_{yx \cdot z}$ and $b_{yz \cdot x}$) are different from the respective bivariate coefficients (b_{yx}

and b_{yz}). The key point is that the partial b_{yxz} is equivalent to d_{yx} , while the partial between Z and Y ($b_{yz\cdot x}$) simply reflects the portion of the causal effect from Z to Y that is not mediated by X .

In A3, there is no direct connection between X and Y once the effect of Z is controlled: The observed bivariate relation between X and Y is spurious or, more accurately, the observed association between X and Y is explained by the existence of a common cause. In this case, the introduction of Z , controlling its effects on both X and Y , is critical in ascertaining the true causal parameter of the system (d_{yx}), which happens to be zero.

All the causal systems shown in B share similar patterns with A; the pattern of the relationship between the bivariate coefficients and the partials remains the same. For this reason, the X - Y relationship in particular is examined in the same way by introducing Z as a control variable regardless of the specification of causal hierarchy between X and Z . Note in particular that introducing Z as a control variable in B1 and B3 is a misspecification of the model, but such misspecifications (including an irrelevant variable in the equation) do not lead to biased estimation (for a related discussion, see Arminger and Bohrnstedt 1987).

The systems shown in C do not require additional comments. Except for the changes in the order of the two variables X and Z , they are exact replicas of the systems in A. The resulting statistics show the same patterns observed in A. Nevertheless, the attendant interpretation of the results is radically different. For instance, when the partial b_{yxz} disappears, one does not consider that there is no causal relationship between X and Y ; instead, one's conviction about the causal relationship is reinforced by the fact that an intervening causal agent is found.

In summary, the assumptions about the causal ordering play a critical role in the interpretation of the coefficients of the linear model shown in equation (1). The assumptions about the order must come from outside knowledge.

There is one more type to note. All the systems examined so far are linear and additive. The partial coefficients reflect the expected change in the dependent variable given a unit change in a given independent variable while the other independent variables are kept constant. If two or more inde-

pendent variables interact, such simplicity does not exist. A simple example of such a system is given below:

$$Y = X_1 \cdot b_1 + X_2 \cdot b_2 + (X_1 \cdot X_2) \cdot b_3 + e \quad (3)$$

which is the same as equation (1) except for the simplification of labels for the variables and coefficients and the addition of a multiplicative term ($X_1 \cdot X_2$).

The partial for X_i in such a system, for example, no longer properly represents the expected change in Y for a unit change in X_i , even if the assumptions about the causal order are correct. A partial differentiation of the equation with respect to X_i for instance, gives $b_1 + X_2 \cdot b_3$, which implies that the rate of change introduced by a change in X_i is also dependent on the values of the other causal variable (X_2) and the associated coefficient (b_3). One therefore cannot interpret the individual coefficients as measuring something independently of others. This point is important for a fuller understanding of the log-linear models introduced below, because a bivariate relationship is represented by interaction terms. The notion of control often invoked with *ceteris paribus* (other things being unchanged) also becomes ambiguous.

The logic of causal analysis for the additive systems can be extended easily to a system with more variables. If the assumptions about the causal order, the form of the relationship, and the random errors are correct, one can identify the causal parameters, such as d_{yx} , and decompose the linear connection between any set of variables into spurious (noncausal) and genuine (causal) components, d_{yx} , and the latter (d_{yx}) into indirect (mediated) and direct (residual) components.

To identify d_{yx} , one must control all the potentially relevant variables that precede X in causal ordering but not the variables that might intervene between X and Y . Under this assumption, then, the partial $b_{yx}(z\cdots)$, where the variables in parentheses represent all such "antecedent" variables, is equivalent to d_{yx} . In identifying this component, one must not control the variables that X may affect; these variables may work as mediating causal agents and transmit part of the effect of X to Y .

The partial of a linear system in which both antecedent variables (Z s) and intervening vari-

ables (W s) are included ($b_{yx} \cdot [x \cdots w \cdots]$) will represent the residual causal connection between X and Y that is not mediated by any of the variables included in the model. As more W s are included, this residual component may change. However, the linear representation of a causal system without these additional intervening variables is not misspecified. By contrast, if the introduction of additional Z s will change the X - Y partial, an omission of such variables from the equation indicates a misspecification of the causal system because some of the spurious components will be confounded with the genuine causal components.

For nonexperimental data, the problems of misspecification and misinterpretation are serious. Many factors may confound the relationships under consideration (Campbell and Stanley 1966; Cook and Campbell 1979; Lieberman 1985; Arminger and Bohrnstedt 1987; Singer and Marini 1987). There is no guarantee that a set of variables one is considering constitutes a closed system, but the situation is not totally hopeless. The important point is that one should not ignore these issues and assume away potentially serious problems. Selection biases, contagion effects, limited variations in the data, threshold effects, and so on, can be modeled if they are faced seriously (Rubin 1977; Leamer 1978; Hausman 1978; Heckman 1979; Berk 1983, 1986; Heckman and Robb 1986; Arminger and Bohrnstedt 1987; Long 1988; Bollen 1989; Xie 1989). Furthermore, this does not mean that one has to control (introduce) every conceivable variable. Once a few key variables are controlled, additional variables usually do not affect the remaining variables too much. (This observation is a corollary to the well-known fact that social scientists often have great difficulty finding any variable that can substantially improve R^2 in regression analysis.)

FREQUENCY TABLES, CONDITIONAL PROBABILITIES, AND ODDS RATIOS

To fix the ideas and make the following discussions concrete, it is useful to introduce basic notations and define two indicators of association for a bivariate table. Consider the simplest contingency table, one given by the cross-classification of two dichotomous variables. Let f_{ij} denote the observed frequencies; then the observed frequency distribution will have the following form:

		Observed Frequencies		
		Variable X		
		1	2	Total
Variable Y	1	f_{11}	f_{12}	$f_{1\cdot}$
	2	f_{21}	f_{22}	$f_{2\cdot}$
total		$f_{\cdot 1}$	$f_{\cdot 2}$	N

Note the form of marginal frequencies. Now let p_{ij} denote the corresponding observed probabilities: $p_{ij} = f_{ij}/N$. Let the uppercase letters, F_{ij} and P_{ij} , denote the corresponding expected frequencies and probabilities under same model or hypothesis.

If X and Y are statistically independent,

$$\frac{p_{ij}}{p_{\cdot j}} = \frac{p_{i\cdot} p_{\cdot j}}{p_{\cdot j}} = p_{i\cdot}$$

That is, the conditional probability of Y_i given X_j is the same as the marginal probability of Y_i . Thus, a convenient descriptive indicator of statistical independence is that $b_{yx} = p_{11}/p_{\cdot 1} - p_{12}/p_{\cdot 2} = 0$. The percentage difference is simply 100 times b_{yx} . The symbol b_{yx} is quite appropriate in this case, for it is equivalent to the regression coefficient. The fact that $b_{yx} \neq 0$ implies a lack of statistical independence between X and Y .

Another equally good measure is the odds ratio or cross-product ratio:

$$\begin{aligned} \text{Odds ratio } (t) &= \frac{F_{11}/F_{12}}{F_{21}/F_{22}} \\ &= \frac{F_{11}/F_{21}}{F_{12}/F_{22}} \\ &= \frac{F_{11}/F_{22}}{F_{12}/F_{21}} \end{aligned}$$

The first line shows that the odds ratio is a ratio of ratios. The second line shows that it is immaterial whether one starts with odds (ratio) in one direction or the opposite direction. The final line indicates that the odds ratio is equivalent to the cross-product ratio. In general, if all the odds ratios in a table for two variables are 1, the two variables are statistically independent; the converse is also true. The fact that t equals 1 implies that X is independent of Y . Therefore, both the odds ratio (t) and the percentage difference (b_{yx}) can serve equally

well as descriptive indicators of association between variables.

Given that observed frequencies are unstable because of sampling variability, it is useful to test the null hypothesis that $t = b_{yx} = 0$ in the population. Such a hypothesis is evaluated by using either the conventional chi-square statistic or the -2^* (likelihood ratio):

$$\begin{aligned} \chi^2 &= \sum \sum (f_{ij} - F_{ij})^2 / F_{ij} \\ L^2 &= -2 \sum \sum (f_{ij} \log(F_{ij}/f_{ij})) \\ &= 2 \sum \sum (f_{ij} \log(f_{ij}/F_{ij})) \end{aligned}$$

These values are evaluated against the theoretical distribution with the appropriate degrees of freedom. These two tests are equivalent for large samples. (For a related discussion, see Williams 1976; Tamas et al. 1994)

ELABORATION AND SUBGROUP ANALYSIS

The logic of linear systems that was presented earlier was introduced to social scientists through the elaboration paradigm and through an informal demonstration of certain patterns of relationship among variables (Kendall and Lazarsfeld 1950; Lazarsfeld 1955). Statistical control is achieved by examining relationships within each subgroup that is formed by the relevant categories of the control variable. The typical strategy is to start the analysis with an examination of the association between two variables of interest, say, X and Y. If there is an association of some sort between X and Y, the following two questions become relevant: (1) Is the observed relationship spurious or genuine? (2) If some part of the relationship is genuine, which variables mediate the relationship between the two? (The question of sampling variability is handled rather informally, relying on the magnitude of the percentage differences as a simple guide. Moreover, two variables that seemingly are unrelated at the bivariate level may show a stronger association after suppressor variables are controlled. Therefore, in some situations, applying such a test may be premature and uncalled for.)

To answer these questions adequately, one must have a fairly good knowledge of the variables under consideration and the implications of dif-

ferent causal systems. It is clear from the earlier examination of the linear causal systems that to answer the first question, one must examine the X-Y relationship while controlling for the factors that are antecedent to X (assuming that $X \geq Y$). To answer the second question, one also must control factors that X may affect and that in turn may affect Y. Controlling for many variables is possible in theory but is impractical for two quite different reasons: (1) One runs out of cases very quickly as the number of subgroups increases, and (b) as the number of subgroups increases, so does the number of partial tables to examine and evaluate. Nevertheless, it is quite possible that one might find a strategically critical variable that might help explain the observed relationship either by proving that the observed relationship is spurious or by confirming a causal connection between the two variables.

To make the discussion more concrete, consider the hypothetical bivariate percentage table between involvement in car accidents (Y) and the gender of the driver (X). The percentage difference (10% = 30% - 20%) indicates that men are more likely to be involved in car accidents while driving than are women. Because there are only two categories in Y, this percentage difference (b_{yx}) captures all the relationship in the table. Given the large sample size and the magnitude of the percentage difference, it is safe to assume that this is not an artifact of sampling variability.

Suppose a third variable (Z = amount of driving) is suspected to be related to both gender (X) and involvement in accidents (Y). It therefore is prudent to examine whether the X-Y relationship remains the same after the amount of driving is controlled or eliminated. Whether this conjecture is reasonable can be checked before one examines the three-variable subgroup analysis: There has to be some relationship between X and Z and between X and Y. Table 1b shows the bivariate relationship between gender (X) and driving (Z). Note that there is a very strong association: $b_{yx} = .333$ (33.3%) difference between the genders.

The conditional tables may show one of the following four patterns: (1) The observed relationship between X and Y disappears within each subgroup: $b_{yxz} = 0$, (2) the relationship remains the same: $b_{yxz} = b_{yx}$, (3) the relationships change in magnitude but remain the same across the groups:

Hypothetical Bivariate Tables

	Men	Women
a) Car Accidents (Y) by Gender (X)		
Had at least one accident while driving	30%	20%
Never had an accident while driving	<u>70%</u>	<u>80%</u>
Total	100%	100%
(Number of cases)	(3,000)	(3,000)
b) Amount of Driving (Z) by Gender (X)		
More than 10,000 miles	67.7%	33.3%
Less than 10,000 miles	<u>33.3%</u>	<u>67.7%</u>
Total	100%	100%
(Number of cases)	(3,000)	(3,000)

Table 1

SOURCE: Adapted from Ziesel (1985), p. 146.

$b_{yxz(1)} = b_{yxz(2)} \neq b_{yx}$, (4) the X-Y relationship in one group is different from the relationship in the other group: $b_{yxz(1)} \neq b_{yxz(2)}$. These examples are shown in Table 2. Compare these patterns with the corresponding causal systems shown in Figure 1.

Whether Z should be considered as antecedent or intervening depends on the theory one is entertaining. One's first interpretation might be that the original relationship has sexist implications in that it may mean that men are either more aggressive or less careful. Against such a hypothesis, the amount of driving is an extraneous variable. By contrast, one may entertain a social role theory stating that in this society men's roles require more driving and that more driving leads to more accidents. Then Z can be considered an intervening variable.

Pattern (1) will help undermine the psychological or biological hypothesis, and pattern (2) will enhance that hypothesis. Pattern (1) also will lend weight to the social role hypothesis. These patterns are the simplest to deal with but rarely are encountered in real life (see Lazarsfeld 1955; Rosenberg 1968; Zeisel 1985 for interesting examples). If one were lucky enough to come across such a pattern, the results would be considered important findings. Note that there are three causal systems in Figure 1 that share the same statistical pattern (the relationship between partials and origi-

nal coefficients) with each of these two. Of course, the choice must be dictated by the theory and assumptions about the causal ordering that one is willing to entertain.

Patterns (3) and (4) are more likely outcomes in real life. In (3), the magnitude of the X-Y relationship within each subgroup is reduced. (Sometimes the X-Y relationship may turn out to be even stronger.) This pattern is compatible with three causal systems—A2, B2, and C2—in Figure 1. Assume that one takes the causal order indicated in C; that is, one takes the gender role theory to account for the observed relationship. Part of the original relationship (.04 out of .10) is mediated by the amount of driving, but a greater part (.06) remains unexplained. If one believes that all the difference in the accident rate has nothing to do with psychological or biological differences between the genders, one has several other potential role-related connections to consider: Men may drive more during the rush hours than women do, men may drive during worse weather conditions than women do, and so on. One could introduce these variables as additional controls. By contrast, if one believes in the validity of the psychological explanation, one could collect data on the aggressiveness of each individual and introduce aggressiveness as a control variable.

Table 2d illustrates a pattern in which the effects of the two explanatory variables interact: X's effect on Y varies across the categories of Z, and Z's effect on Y varies across the categories of X. A corresponding example in linear systems was given by equation (3). One must consider both variables at the same time because the effect of one variable depends on the other.

In general, empirical data may exhibit patterns that are mixtures of 2c and 2d. In cross-tabulations of variables with more than two categories, it is often not easy, purely on the basis of eyeballing, to discern the underlying pattern. At this point, there is a need for more refined and systematic tools. Moreover, in some instances, an application of a log-linear model may indicate patterns that are different from what a linear model (such as using percentage tables) might indicate.

Before ending this section, it should be mentioned that some examples in the literature use the

TABULAR ANALYSIS

Percent Ever Had Accident (Y) by Gender (X) by Amount of Driving (Z)

a) Original X–Y Relationship Disappears

(Compatible with causal systems A3, B3, and C1)

Gender (X)	Amount of Driving (Z)		
	> 10,000 miles	< 10,000 miles	
Men	40% (2,000)	10% (1,000)	$b_{yxz} = 0$
Women	40% (2,000)	10% (1,000)	$b_{yzx} = .30$

b) Original X–Y Relationship Unchanged

(Compatible with causal systems A1, B1, and C3)

Gender (X)	Amount of Driving (Z)		
	> 10,000 miles	< 10,000 miles	
Men	30% (2,000)	30% (1,000)	$b_{yxz} = .10$
Women	20% (1,000)	20% (2,000)	$b_{yzx} = 0$

c) Original X–Y Relationship Diminishes

(Compatible with causal systems A2, B2, and C2)

Gender (X)	Amount of Driving (Z)		
	> 10,000 miles	< 10,000 miles	
Men	34% (2,000)	24% (1,000)	$b_{yxz} = .06$
Women	28% (1,000)	18% (2,000)	$b_{yzx} = .10$

d) X–Y Relationship Varies

Gender (X)	Amount of Driving (Z)		
	> 10,000 miles	< 10,000 miles	
Men	40% (2,000)	20% (1,000)	$b_{yxz(1)} = .20$
Women	20% (1,000)	20% (2,000)	$b_{yxz(2)} = 0$
			$b_{yzx(1)} = .20$
			$b_{yzx(2)} = 0$

Table 2

NOTE: Number of cases for the percentage base are in parentheses. Throughout these tables, $b_{xz} = .40$ and $b_{yx} = .10$ remain constant. Compare percents across the categories of that variable.

subgroup analysis as a full-fledged multivariate analysis tool. For instance, Davis (1984) shows how the logic of elaboration can be combined with the standardization technique to derive, among other things, the following decomposition of the relationship between the father’s and the son’s occupational statuses, where Zs represent the father’s education and the mother’s education and W represents the son’s education.

- a. Total observed relationship:
 $b_{yx} = .256$
- b. Spurious connection resulting from environmental variables (Zs) (a-c) .052
- c. Total causal effect: $b_{yxz...} = .204$

c1. Unmediated causal effect:

$$b_{yxz...w} = .138$$

c2. Effect mediated by education

$$(b_{yxz...} - b_{yxz...w}) = .066$$

The power of subgroup analysis comes mainly from the close analogy between the percentage differences and the coefficients of the linear system illustrated in Figure 1, but its uses need not be confined to the analysis of causal systems. There are various applications of this logic to survey data (Hyman 1955; Rosenberg 1968; Zeisel 1985). These accounts remain one of the best sources for learning the method as well as the art of pursuing research ideas through the use of percentage tables.

ODDS RATIOS AND LOG-LINEAR MODELS

A more formal approach to categorical data analysis is provided by the log-linear model and related models (Bishop et al. 1975; Goodman 1978; Haberman 1978, 1979; Fienberg 1980; Agresti 1984; Clogg and Shihadeh 1994; Long 1997). Some of these models are not even log-linear (Clogg 1982a, 1982b, Goodman 1984, 1990; Wong 1995; Xie 1992). Only the log-linear models are examined here.

By means of an ingenious device, the log-linear model describes the relationships among categorical variables in a linear form. The trick is to treat the logarithms of the cell frequencies as the (titular) dependent variable and treat design vectors as independent variables. The design vectors represent relevant features of the contingency table and hypotheses about them.

Once again consider a concrete example; the simplest bivariate table, in which each variable has only two categories. Such a table contains four frequencies. Logarithms of these frequencies (log-frequencies for short) can be expressed as an exact function of the following linear equation:

$$Y = b_0 + X_1 \cdot b_1 + X_2 \cdot b_2 + (X_1 \cdot X_2) b_3 \quad (4)$$

In this equation, Y stands for the log-frequencies ($\log(F_{ij})$). X_1 is a design vector for the first (row) variable, and X_2 is a design vector for the second (column) variable. The last vector ($X_1 \cdot X_2$) is a design vector for interaction between X_1 and X_2 , and it is produced literally by multiplying the respective components of X_1 and X_2 . It is important to note that the model is linear only in its parameters and that there is an interaction term. As is the case with linear models that contain interaction terms, one must be careful in interpreting the coefficients for the variables involved in the interaction term.

This type of model in which the observed frequencies are reproduced exactly also is known as a saturated model. (The model is saturated because all the available degrees of freedom are used up. For instance, there are only four data points, but this model requires that many parameters.) Of course, if one can reproduce the exact log-frequencies, one also can reproduce the actual frequencies by taking the exponential of $Y - F_{ij} =$

$\exp(Y_{ij})$. Note also the similarities between equations (3) and (4); both contain a multiplicative term as a variable. (For more general models, a maximum likelihood estimation requires an iterative solution, but that is a technical detail for which readers should consult standard texts (such as Nelder and Wedderburn 1972; Plackett 1974; Goodman 1978, 1984; Haberman 1978, 1979; Fleiss 1981; Agresti 1984). Many computer packages routinely provide solutions to these types of equations. Therefore, what is important is the logic underlying such analysis, not the actual calculation needed.)

It is no exaggeration to say that in more advanced uses of the model, what distinguishes a good and creative analysis from a mundane analysis is how well one can translate one's substantive research ideas into appropriate design vectors. Thus, it is worthwhile to examine these design vectors more carefully. Constructing a design matrix (the collection of vectors mentioned above) for a saturated model is easy, because one is not pursuing any specific hypothesis or special pattern that might exist in the relationship. Categories of each variable have to be represented, and there are many equivalent ways of doing that. This section will examine only the two most often used ones: effect coding and dummy coding. These design matrices for a 2×2 table are shown in Table 3.

The first column (X_0) in each coding represents a design vector for the constant term (b_0); X_1 is for the row categories, and X_2 is for the column categories. The last column (X_3) is the product of the preceding two, needed to represent interaction between X_1 , and X_2 . Note the pattern of these design vectors. In the effect coding, except for the constant vector, each vector or column sums to zero. Moreover, the interaction vector sums to zero for each column and row of the original bivariate table. This pattern assures that each effect is measured as a deviation from its respective mean.

In dummy coding, the category effect is expressed as a deviation from one reference category, in this case, the category that is represented by zero. Whatever codings are used to represent the categories of each variable, the interaction design vector is produced by multiplying the design vector for the column variable by the design

Design Vectors Used in Log-Linear Model for 2 × 2 Table

a) Design Matrices for Saturated Model

Frequency	Effect Coding				Dummy Coding			
	X_0	X_1	X_2	X_3	X_0	X_1	X_2	X_3
Y_{11}	1	1	1	1	1	1	1	1
Y_{12}	1	1	-1	-1	1	1	0	0
Y_{21}	1	-1	1	-1	1	0	1	0
Y_{22}	1	-1	-1	1	1	0	0	0

b) Representation of Log-Frequencies in Terms of Parameter

$b_0+b_1+b_2+b_3$	$b_0+b_1-b_2-b_3$	$b_0+b_1+b_2+b_3$	b_0+b_1
$b_0-b_1+b_2-b_3$	$b_0-b_1-b_2+b_3$	b_0+b_2	b_0

c) Representation of Frequencies in Terms of Multiplicative Parameters, where $t_i = \exp(b_i)$

$t_0^*t_1^*t_2^*t_3$	$t_0^*t_1/(t_2^*t_3)$	$t_0^*t_1^*t_2^*t_3$	$t_0^*t_1$

Table 3

vector for the row variable. Normally, one needs as many design vectors for a given variable as there are categories, minus one: (R-1) for the row variable and (C-1) for the column variable. In that case, there will be (C-1)(R-1) interaction design vectors for the saturated model. These interaction vectors are created by cross-multiplying the vectors in one set with those of the other set. There is only one vector for each of the three independent variables in equation (4) because both variables are dichotomous.

The names for these codings come from the fact that the first coding is customarily used as a convenient way of expressing factor effects in an

analysis of variance (ANOVA), while the second coding often is used in regression with dummy variables. As a result of coding differences in the representation of each variable, the constant term in each coding has a different meaning: In effect, coding it measures the unweighted grand mean, while in dummy coding, it measures the value of the category with all zeros (in this particular case, Y_{22}). (For other coding schemes, see Haberman 1979; Agresti 1984; Long 1984.) Some parameter estimates are invariant under different types of coding, and some are not (Long 1984); therefore, it is important to understand fully the implications of a particular design matrix for a proper interpretation of the analysis results.

Panel (b) of Table 3 expresses each cell as a product of the design matrix and corresponding parameters. Since the particular vectors used contain 1, -1, or 0, the vectors do not seem to appear in these cell representations. However, when design vectors contain other numbers (as will be shown below), they will be reflected in the cell representation. Panel (c) is obtained by exponentiation of the respective cell entries in (b), the individual t -parameter also being the corresponding exponential of the log-linear parameter in panel (b).

Panel (d) isolates parameters associated with the interaction design vector. Panel (e) contains corresponding antilogs or multiplicative coefficients. These parameters play a critical role in representing the degree and nature of association between the row variables and the column variables. If all the odds ratios are 1, one variable is statistically independent from the other; in other words, information about the association between variables is totally contained in the pattern of odds ratios. Panels (d) and (e) show that the odds ratio in turn is completely specified by the parameter(s) of the interaction vector(s). In forming the odds ratio, all the other parameters cancel out (in logarithms, multiplication becomes addition and division becomes subtraction).

In short, this is an indirect way to describe a pattern of association in a bivariate table. Unfortunately, doing this requires a titular dependent variable and multiplicative terms as independent variables. Also, in effect coding, the log-odds ratio is given by $4 \times b_3$, but in dummy coding, it is given by b_3 . This is a clear indication that one cannot assume that there is only one way of describing the parameters of a log-linear model. These facts make the interpretation of these parameters tricky, but the process is worth it for two reasons.

First, the advantage of this method for analyzing a 2 X 2 table is trivial, but the model can be generalized and then applied to more complex contingency tables. Because of the ANOVA-like structure, it is easy to deal with higher-level interaction effects. Second, the parameters of the log-linear models (obtained through the likelihood procedure) have very nice sampling properties for large samples. Therefore, better tools for statistical testing and estimating are available. Without this second advantage, the fact that the approach allows the construction of ANOVA-like models

may not be of much value, for the log-linear models only indirectly and by analogy reflect the relationship between variables.

Consider the bivariate tables in Table 4. In all these tables, the frequencies are such that they add up to 100 in each column. Thus, one can take these frequencies as percentages as well. The first table shows a 20 percent difference and an odds ratio of 2.25. The second table shows only half the percentage difference of the first but the same odds ratio. The last table shows the same percentage difference as the second one, but its odd ratio is greater at 6.68. These descriptive measures indicate that there is some association between the two variables in each table.

Whether this observed association is statistically significant can be tested by applying a model in which the coefficient for the interaction design vector is constrained to be zero. (Here one is utilizing the properties of the log-linear model that were asserted earlier.) Constraining the interaction parameter to zero is the same as deleting the interaction design vector from the model. This type of a design matrix imposes the model of statistical independence (*independence* model for short) on the data. If such a log-linear model does not fit the data (on the basis of some predetermined criteria), the observed association is accepted as significant. For large samples, both the conventional chi-square test and the likelihood ratio (L^2) test can be used for this purpose. The results of these tests are included in each table, and they indicate that all three associations are statistically significant at the conventional α level of .05.

Thus, to describe fully the underlying pattern of the association in Table 4, one needs to introduce the interaction parameter, which in these cases is the same as it is using the saturated model. The right-hand tables show the multiplicative parameters (t -parameters) for the interaction term. (Here only the results of applying effect coding are included.) First, examine the patterns of these parameters. In each of the three tables, the t -parameters indicate that the main diagonal cells have higher rates than do the off-diagonal cells. This tendency is slightly higher in the last table than it is in the first two. This interpretation follows from the fact that to reproduce the observed frequency in each cell, the respective t -

TABULAR ANALYSIS

Table 4

parameter must be multiplied to whatever value may be implied by other parameters in the model. In the first and second tables, the frequencies in the main diagonal are about 22 percent higher (1.22 times) than they would be without the interaction effect. The frequencies in the off-diagonal cells are about 18 percent lower than they otherwise would be. If one were to examine only the statistics generated by log-linear models, however, it would be easy to overlook the fact that the percentage of the first cell in the last table is only 12 percent (see Kaufman and Schervish 1986 for a more extended discussion). This is one of the reasons why it is advisable to examine the percentage tables even if one is using the log-linear model almost exclusively.

There are other reasons, too. By the linear standard (percentage difference), the first table shows a greater degree of association than does the second or the third. By the standard of a log-linear model or odds ratio, the last table shows the

greatest degree of association. In most cases, where the percentages remain within the range of 20 to 80 percent, these two standards are roughly comparable, and the linear and log-linear models may produce similar results (see Goodman 1981). More important, in examining three-way interactions, if two subtables have the patterns shown in Table 4a and 4b, log-linear models will indicate no three-way interaction, while linear models will indicate it. There are models in which a particular standard is justified explicitly by the phenomenon under consideration, but one should not adopt a standard merely because a particular statistical model does so. It is important to understand the differences in the implicit standards that are used in different methods.

SOME MODELS OF ASSOCIATION

The flexibility of log-linear models is not obvious until one deals with several variables. However, even in a bivariate table, if there is an underlying

order in the categories of variables involved and the pattern of association, the model allows some flexibility for exploring this pattern. Consider the hypothetical table shown in Table 5a. The marginal totals are such that each column may be read as percentages. There is a definite pattern in the direction of the relationship, although the tendency is fairly weak. If one were to apply a test of independence, such a null hypothesis would not be rejected. ($L^2 = 6.56$ with four degrees of freedom has a probability of .161.) Against an unspecified alternative hypothesis, the null hypothesis cannot be rejected at the conventional level of α .

Knowing that almost every society values these two variables in the same order, one may expect that the underlying pattern of association reflects the advantages of the upper class over the lower class in obtaining valued objects. Both the pattern of percentage differences and the odds ratios seem to indicate such an ordering in the pattern: The advantage the upper class has over the lower class is greater than the one it has over the middle class. Furthermore, the upperclass does better in relation to educational levels that are farther apart (the odds ratio involving the corner cells is 2.87).

A conjecture or hypothesis like this can be translated into a design vector. Assign any consecutive numbers to the categories of each variable, but to be consistent with the effect coding, express them as deviations from the mean. One such scaling is to use $(R+1)/2-i$ for the row variable and $(C+1)/2-j$ for the column variable. (The mean and category values can be reversed, but this scheme assigns a higher value to a higher class and a higher educational level to be consistent with everyday language.) Recalling once again that only the interaction terms are relevant for the description of association, one needs to create such an interaction term by multiplying these two vectors component by component. An example is shown in Table 6.

The log-linear model, then, will include design vectors for the constant term, two vectors for the row and two vectors for the column, and one vector for the "linear-by-linear" interaction. This type of model is known as a *uniform association* model (for a fuller discussion of this and related models, see McCullagh 1978; Haberman 1979; Clogg 1982a, 1982b; Anderson 1984; Goodman 1984, 1985, 1987, 1990, 1991 Clogg and Shihadeh 1994). The results of applying such a model to

Table 5a are presented in Table 5b and 5c. First, this model fits the data extremely well. Moreover, the reduction of the L^2 statistic ($6.557 - .008 = 6.549$) with one degree of freedom is statistically significant. Therefore, the null hypothesis cannot be accepted against this specific alternative hypothesis (see Agresti 1984 for a fuller discussion of hypothesis testing of this type). Note the pattern of the expected frequencies and the interaction parameters. Both indicate that the odds ratio for every consecutive four cells is uniform. Moreover, the other odds ratios are exact functions of this basic odds ratio and the distances involved. For instance, the odds ratio for the four corner cells is $2.87 = 1.303^{2 \times 2}$, with each exponent indicating the number of steps between respective categories in each variable. A degree of parsimony has been achieved in describing the pattern of association and some statistical power has been gained in proposing a more definite alternative hypothesis than the general one that stipulates any lack of statistical independence (and hence uses up four degrees of freedom).

The introduction of different design matrices allows one to explore different patterns very easily. Just two are examined here. Consider the hypothetical tables shown in Table 7. In the first table, the odds ratios remain the same across the columns but vary across the rows, perhaps indicating that the order inherent in the row categories is not uniform, while that in the column category is. Differently stated, the *distance* between two consecutive row categories varies, while it remains constant for the column categories. Such an association pattern is known as the *row-effects association* model not because the column variable does not have any effect but because an equal-interval scale works well for it. In this case, one needs two design vectors to accommodate the unequal distances in the row categories. In general, the most one needs is the number of categories in the row minus one. As is shown in Table 6, these design vectors are obtained by cross-multiplying the linear distance vector of the column and the two vectors that already have been used to represent the row categories. (It works just as well to use the dummy coding.) The *column-effects* model is obtained if one reverses the role of these variables.

Table 7b is an example of the simplest possible *homogeneous row-column effects* model. The odds

TABULAR ANALYSIS

A Hypothetical Table: Level of Educational Attainment (Y) by Social Class (X)

$df_1 - df_2 = 1;$

$p = .0109$

Table 5

ratios change across the row and across the column, but the corresponding pair of categories in the row and in the column share the same odds ratio. In this particular example, there is a greater distance between the first two categories than there is between the second two. In general, a homogeneous row-column effects model can accommodate different intervals in each variable as long as the corresponding intervals are homogeneous across the variables. The design matrix for such a pattern is easily obtained by adding the row-effects model vectors and the column-effects model vectors. This is also how two variables are constrained to have equal coefficients in any linear model. Such a design matrix for a 3x3 table is also contained in Table 6. The examples shown in that

table should be sufficient to indicate strategies for generalizing to a larger table.

There are many other possibilities in formulating specific hypotheses. These relatively simple models are introduced not only for their intrinsic value but also as a reminder that one can incorporate a variety of specialized hypotheses into the log-linear model (for other possibilities, see Goodman 1984; Clogg 1982a, 1982b; Agresti 1983, 1984). Before ending this section, it should be noted that when design vectors such as the ones for the homogeneous row-column effects model are used, the connection between the parameters for linear models indicated in this article and the usual ANOVA notation used in the literature is not

- T: design vector for the constant term.
- A: effect coding for row variable.
- B: effect coding for column variable.
- C: linear contrasts for row variable— $(R + 1)/2 - i$; any consecutive numbering will do; for variables with three categories, this is the same as the first code for the row variable.
- D: linear contrasts for column variable— $(C + 1)/2 - j$.
- E: design for the linear-by-linear interaction or uniform association, obtained by multiplying the linear contrast vector for the row and for the column.
- F: design vectors for the row effects model, obtained by multiplying the design vectors for the row categories and the linear contrast vector for the column.
- G: design vectors for column effects model, obtained by multiplying the design vectors for the column variable and the linear contrast for the row variable.
- H: homogeneous row-column effects model, obtained by adding each vector in the matrix for the row and the corresponding vector in the matrix for the column.
- I: row and column effects model—concatenation of F and G minus the redundant linear-by-linear interaction vector.
- J: interaction vectors for saturated model, obtained by multiplying each vector in A with each vector in B.

Design matrix for each type of model is obtained by concatenating relevant vectors from above, and the degrees of freedom by number of cells in the table minus the number of columns in the design matrix.

	<i>Vectors</i>	<i>df</i>
Independence model	T~A~B	4

obvious. Those parameters pertaining to each cell, denoted by t_{ij} , are equivalent to the product of the relevant part of the design matrix and the corresponding coefficients.

SOME EXTENSIONS

There are several ways in which one can extend the basic features of the log-linear models examined so far. Among these, the following three seem important: (1) utilizing the ANOVA-like structure

Hypothetical Tables Illustrating Some Association Models

a) Row-Effects Association Model

		Frequency			Odds Ratio		
		X

		-.693	.231	.462	.500	1.260	1.587

Table 7

of the log-linear model and the well-developed sampling theory to explore interaction patterns of multivariate categorical data, (2) manipulating the design matrices to examine more specific hypotheses and models, and (3) combining the strategic features of subgroup analysis and the flexibility and power of the log-linear models to produce more readily accessible analysis results. These three extensions are discussed below.

General Extension of Log-Linear Models. The most straightforward and widely used application of the log-linear model is to explore the interaction pattern of multivariate data by exploiting the ANOVA-like structure of the model. Given several variables to examine, especially when each variable contains more than two categories, it is almost impossible to examine the data structure in detail.

The ANOVA-like structure allows one to develop a convenient strategy to explore the existence of multiway relationships among the variables.

This strategy requires that one start with a design matrix for each variable (containing $k-1$ vectors, where k is the number of categories in the variable). It does not matter whether one uses dummy coding or effect coding. To examine all the possible interrelationships in the data, one needs design matrices corresponding to each two-way interaction to m -way interaction where m is the number of variables. To construct a design matrix for a two-way interaction between variable A and variable B , simply cross-multiply the design vectors for A with those for B . (This method is illustrated in Table 6.) This general approach to design matrices is extended to m -way. For example, a three-way

interaction is handled by cross-multiplying each two-way vector with the basic design vectors for a third variable, and so on.

If one includes in the model all the vectors covering up to m -way interactions, the resulting model is saturated, and each frequency in the multiway table is completely described. In general, one wants to explore and, if possible, find a parsimonious way to describe the data structure. One general strategy, perhaps overused, is to examine systematically the hierarchical pattern inherent in the design constraints and serially examine a nested set of models. To illustrate, consider that there are three variables and that the basic design vectors for each variable are represented by A , B , and C , respectively. Let T stand for the constant vector. Then an example of a nested set of models is illustrated below. The commas indicate concatenation, and two or more letters together indicate cross-multiplication of the basic design vectors for each variable.

- H_1 : T
- H_2 : T, A, B, C
- H_{3a} : T, A, B, C, AB
- H_{3b} : T, A, B, C, AB, AC
- H_{3c} : T, A, B, C, AB, AC, BC
- H_4 : $T, A, B, C, AB, AC, BC, ABC$
- (H_1) Equiprobability
- (H_2) Total independence
- (H_{3a}) One two-way interaction
- (H_{3b}) Two two-way interactions
- (H_{3c}) No three-way interaction
- (H_4) Saturated model

Each hypothesis is tested, using the appropriate degrees of freedom, which is given by the number of the cells in the frequency table minus the number of vectors contained in the design matrix and the χ^2 or L^2 statistics associated with each model. The sequence from the hypotheses in set (3) is arbitrary; one may choose any nested set or directly examine 3c. One usually would accept the simplest hypothesis that is compatible with the data.

If variables contain many categories, even the simplest two-way interactions will use up many

degrees of freedom. This type of generic testing does not incorporate into the design matrix any special relationships that may exist between variables. Models of this type are routinely available in standard computer packages and therefore are quite accessible. For that reason, they are overused. Moreover, the sequential nature of the testing violates some of the assumptions of classical hypothesis testing. Nevertheless, in the hands of an experienced researcher, they become a flexible tool for exploring the multivariate data structure.

The Uses of Constrained Models. The flexibility and power of log-linear models are fully realized only when one incorporates a specific hypothesis about the data into the design matrices. There are virtually endless varieties one can consider. Some of the simple but strategic models of association were introduced in the preceding section.

Incorporating such models into a multivariate analysis is not difficult if one views the task in the context of design matrices. For instance, suppose one suspects that a certain pattern of relationship exists between X and Y (for instance, the social class of origin and destination in intergenerational mobility). Furthermore, one may have an additional hypothesis that these relationships vary systematically across different political systems (or across societies with different levels of economic development). If one can translate these ideas into appropriate design matrices, using such a model will provide a much more powerful test than the generic statistical models described in the previous section can provide. Many social mobility studies incorporate such design matrices as a way of incorporating a special pattern of social mobility in the overall design (for some examples, see Duncan 1979; Hout 1984; Yamaguchi 1987 and for new developments, see DiPrete 1990; Stier and Grusky 1990; Wong 1990, 1992, 1995; Xie 1992).

In general, there are two problems in using such design matrices. The first, which depends in part on the researcher's creative ability, is the problem of translating theoretically relevant models into appropriate design matrices. The second is finding a way to obtain a good statistical solution for the model, but this is no longer much of a problem because of the wide availability of computer programs that allow the incorporation of design matrices (see Breen 1984 for a discussion of

preparing design matrices for a computer program that handles generalized linear systems).

One of the general problems has been that researchers often do not make the underlying design matrices explicit and as a result sometimes misinterpret the results. A solution for this problem is to think explicitly in terms of the design matrices, not in analogy to a generic (presumed) ANOVA model.

Use of Percentage Tables in Log-Linear Modeling. Multivariate analysis is in general complex. Categorical analysis is especially so, because one conceptual variable has to be treated as if it were ($k - 1$) variables, with k being the number of categories in the variable. Therefore, even with a limited number of variables, if each variable contains more than two categories, examining the multivariate pattern becomes extremely difficult. Therefore, the tendency is to rely on the general hypothesis testing discussed earlier.

It is useful to borrow two of the strategies of subgroup analysis: focusing on a bivariate relationship and using percentage distributions. After an acceptable log-linear model is identified, one therefore may display the relationship between two key variables while the effects of other variables are controlled or purged (Clogg 1978; Clogg and Eliason 1988a; Clogg et al. 1990; Kaufman and Schervish 1986). Furthermore, a percentage distribution for the bivariate distribution may be compared with the corresponding percentage distributions when different sets of variables are controlled in this manner. Fortunately, the log-linear modeling can provide a very attractive way in which the confounding effects of many variables can be purged from the relationship that is under special scrutiny (Clogg 1978; Kaufman and Schervish 1986; Clogg and Eliason 1988a; Clogg et al. 1990). Clogg et al. (1990) show a general framework under which almost all the known variations in adjustments can be considered a special case. Furthermore, they also describe statistical testing procedures for variety of statistics associated with such adjustments.

Tables 8 and 9 contain examples of traditional subgroup analysis, log-linear analysis, and the uses of standardization or purging methods. The upper panel of Table 8 contains a bivariate table showing (1) the race of the defendant (X) and (2) the

Death Penalty Verdict (Y) by Defendant's Race (X) and Victim's Race (Z)

		Death Penalty		
Victim's Race	Defendant's Race	Yes	No	Percentage Yes
Total	White	53	430	11.0
	Black	15	176	7.9
White	White	53	414	11.3
	Black	11	37	22.9
Black	White	0 [†]	16	0.0
	Black	4	139	2.8

Table 8

SOURCE: Radelet and Pierce (1991), p. 25, and Agresti (1996), p. 54.

NOTE: (1) For log-linear analysis, 0.5 is added to zero cell. (2) In the original data, there are two cases that involve both white and black victims. (3) The data do not consistently identify Spanish ancestry. Most defendants and victims with Spanish ancestry are coded as white. For detailed information, see Radelet and Pierce (1991).

verdict—death penalty versus other penalties (Y), while the lower panel contains the result of traditional three-variables subgroup analysis, in which the original relationship between X and Y is reanalyzed within the categories of the third variable, the race of the victims (Z). (These data are based on individuals who were convicted of multiple homicides in Florida. See Radelet and Peierce 1991; Agresti 1996.)

The original bivariate relationship seems to indicate that whites are more likely to receive the death penalty than are blacks. However, when the race of the victims is controlled, the partial relationship between X and Y is reversed: Within each category of victim, blacks are more likely to receive the death penalty than are whites. The underlying reasons for this reversal are two related facts: (1) There is a strong association between the race of the defendant (X) and the race of the victims (Z): white defendants are more likely to kill whites than blacks, while black defendants are more likely to kill blacks than whites, and (2) there is a strong relationship between the race of the victims and the death penalty: those who killed white victims are more likely to receive the death penalty than are those who killed blacks. Once these relation-

TABULAR ANALYSIS

Design Matrix, Expected Frequencies, and Standardized Percentages under the Model without Three-Way Interaction

a) Design Matrix and Coefficients for the Model without Three-Way Interaction

<i>I</i>	<i>Z</i>	<i>X</i>	<i>Y</i>	<i>XZ</i>	<i>YZ</i>	<i>XY</i>	Parameter	Coefficient	z-value
1	1	1	1	1	1	1	Constant (T)	2.959	21.0
1	1	1	-1	1	-1	-1	Z	1.039	6.9
1	1	-1	1	-1	1	-1	X	-0.135	-1.3
1	1	-1	-1	-1	-1	1	Y	-1.382	-11.1
1	-1	1	1	-1	-1	1	XZ	1.137	14.7
1	-1	1	-1	-1	1	-1	YZ	0.558	3.9
1	-1	-1	1	1	-1	-1	XY	-0.201	-2.2
1	-1	-1	-1	1	1	1	$L^2 = 0.284$	df = 1	Prob. = 0.594

b) Expected Frequencies under the Model without Three-Way Interaction

Victim's Race	Defendant's Race	Death Penalty		Percentage Yes
		Yes	No	
Total	White	53.5	430.0	11.1
	Black	15.0	176.0	7.9
White	White	53.3	413.7	11.4
	Black	10.7	37.3	22.3
Black	White	0.2	16.3	1.2
	Black	4.3	138.7	3.0

c) Direct Standardization

Total	White	35.87	447.62	7.4
	Black	28.16	162.84	14.7
White	White	33.58	260.67	11.4
	Black	25.91	90.33	22.3
Black	White	2.29	186.95	1.2
	Black	2.25	72.51	3.0

d) Purging XZ (= purging XZ and XYZ)

Total	White	17.7	183.2	8.8
	Black	34.9	160.9	17.8
White	White	17.0	132.3	11.4
	Black	33.5	116.6	22.3
Black	White	0.7	50.9	1.4
	Black	1.4	44.4	3.1

e) Purging XZ and YZ (= purging XZ, YZ, and XYZ)

Total	White	11.0	260.9	4.0
	Black	21.5	228.7	8.6
White	White	9.8	231.9	4.0
	Black	19.1	203.2	8.6
Black	White	1.2	29.0	4.0
	Black	2.4	25.4	8.6

Table 9

ships are taken into consideration, blacks receive a higher rate of the death penalty than do whites.

The log-linear analysis can supplement such a traditional subgroup analysis in several convenient ways. Panel (a) of Table 9 shows design matrix, coefficients, and standardized values under the model without three-way interaction. These statistics show several things that are not obvious in the conventional subgroup analysis: (1) The three-way interaction is not statistically significant, (2) all three bivariate relationships are statistically significant, and (3) in some sense, the association between X and Z is the strongest and that between X and Y is the weakest among the three bivariate relationships.

Panel (b) shows expected frequencies and relevant percentages under the model (where the three-way interaction is assumed to be zero). The pattern revealed in each subtable is very similar to that under the traditional subgroup analysis shown in Table 8. (This is as it should be, given no three-way interaction effect.) Within each category of victim's race, black defendants are more likely to receive the death penalty than are white defendants. The standardization or purging, then, allows one to summarize this underlying relationship between X and Y under the hypothetical condition that the effect of the third variable is controlled or purged. There are many different ways of controlling the effects of the third variable: (1) direct standardization, panel (c), (2) when the effects of XZ relationship are purged (in addition to the purging of the three-way interaction) panel (d), (3) when, in addition to the previous purging, the effects of the YZ relationship are also purged, panel (e). Although the percentage differences seem to vary, the underlying log-linear effect remains constant: Blacks are twice more likely to receive the death penalty than are whites when both kill a victim of the same race (see Clogg 1978; Clogg and Eliason 1988b; Clogg et al. 1990).

TERRITORIAL BELONGING

DEFINITION

Belonging is defined as the state of being part of something. Territorial belonging implies being part of a territory. The definition of a territory, although it is conditioned by the morphology of space, is essentially a social operation that is connected with the factors that induce the perception of boundaries. These are complex factors that researchers in the "psychology of form" (*Gestaltpsychologie*) have attempted to specify (Reusch 1956, pp. 340–361). Campbell has identified seven

of these factors. Those analytically most relevant to social systems are similarity and shared destiny or “common fate” (Campbell 1958), to which the ecological, economic, and sociological traditions (Hawley 1950, p. 258) add interdependence, which is related to Campbell’s (1958) notion of internal diffusion.

Territorial belonging is therefore a form of social belonging (for a detailed treatment, see Pollini 1987) that is displayed by a spatially defined collectivity. Spatial definition more or less precisely and more or less sharply delimits (where the concept of a boundary refers to a line or zone) a territory to which a name is given. Belonging to a spatially defined collectivity thus may be related to the name given to a territory, so that it becomes simply territorial without ceasing to be social as well. To emphasize its twofold nature, it also may be called “socioterritorial belonging” (Pollini 1992, pp. 55–58).

THE MULTIPLICITY OF TERRITORIAL BELONGINGS

Like any form of social belonging, territorial belonging may relate to objective or subjective elements and may be defined by the self or by others (Merton 1963). Like social belonging, it may be largely exclusive or admit to multiplicity and may be ascribed or acquired (Simmel 1908).

Workers in human ecology, human geography, sociology, and land economics have long attempted to provide a definition of the most suitable territorial units for social purposes. They have oscillated between emphasizing the principle of similarity (the morphology of the territory, the physical and cultural features of the individuals who inhabit it, the predominant type of economic activity, etc.) and emphasizing the principle of interdependence (on the basis of gravitational flows for work and services, areas of relatively intense exchange, etc.) (see Galtung 1968). The implementation of the political function of governing human communities, moreover, has led to the fixing of territorial boundaries that express (and produce) a common fate (Hawley 1950, p. 258).

Reciprocal relations are among the main criteria used to define territorial units (similarity, interdependence, and common fate, taking the proximity of elements for granted). As studies of “nation building” have shown (see Deutsch [1953] 1966), similarity tends to create relations of interdependence and interdependence generates perceptions of similarity (Simmel 1890, p. 40; Shils 1975, p. 17); in the same manner, a common fate induces perceptions of similarity and interdependence and similarity and interdependence heighten the perception of a common fate.

The most enduring and significant spatial units are those with multi-confirmed boundaries (Campbell 1958), that is, those for which the criteria of similarity, functional interdependence, and common fate are congruent. The European nation-states of the nineteenth and twentieth centuries exemplify the successful achievement of this congruence (Eisenstadt 1973, pp. 231–235).

In traditional nomadic and agricultural societies, similarity, interdependence, and common fate are properties that relate substantially to a single socioterritorial unit that includes everyday life almost in its entirety, except when extraordinary occasions (great feasts and celebrations, great markets, wars, etc.) demonstrate the importance of a broader socioterritorial unit that is ethnic and/or tribal in nature or sometimes is of state dimension (kingdoms and empires, churches and great religious organizations). This is the social order that is called the “segmentary society of mechanical solidarity” by Durkheim (1893), *Gemeinschaft* by Toennies (1887), and the “independent community” by Hawley (1950, pp. 223 ff) and is exemplified by numerous contemporary societies (Dyson Hudson 1966).

As a significant division of territorial labor develops—induced by the reduced spatial friction brought about by advances in transport and communications that allow more frequent exchanges over longer distances (the “mobiletic revolution” of Russett 1967) and by technical progress, which requires the greater accumulation of capital and is not uniformly distributed across the territory (industrial revolution)—the areas of interdependence

expand and are structured into several levels (Hawley 1950, pp. 236–257). This has evident effects on areas of common fate. Increased interdependence facilitates temporary or permanent movements across the territory and thus alters similarities and differences as well as the criteria for their definition and perception (Sola Pool 1965).

In short, mainly as a result of these phenomena, a socioterritorial structure grows more complex. Important socioterritorial units proliferate, intersect, and are organized into larger (Parsons 1961, pp. 123 ff) and relatively fluid systems, while the congruence among the three main principals of sociospatial structuring diminishes. These changes have been interpreted as the decay of *Gemeinschaft* (Toennies 1887) and of the territorial state (Herz 1957), as stages in an ongoing evolution into cosmopolitanism, and as the onset of a single overarching socioterritorial unit: the world in its entirety. Parsons (1951) introduced in his theoretical pattern of variables for the definition of roles the dichotomy between particularism and universalism. Although of general analytic significance, this dichotomy also has been used to characterize the process of modernization (Parsons 1971), which, with reference to territorial belonging, includes the localism–cosmopolitanism dichotomy. The term “globalization,” which now has general currency although it dates from the early 1970s (Kaufman 1974), has been employed more recently to define this trend.

The increased complexity of socioterritorial belonging is obviously correlated to the complexity of the social structuring of the territory. All individuals are involved in relational networks that may be micro-local (habitation), local, regional, national, continental, and global, and they shift easily and rapidly from one level to another by virtue of the ease of communications and transportation or simply pass subjectively from one role to another (Webber 1963, 1964).

Owing to the ease of communications and transport, every individual may encounter and assimilate elements of other cultures. Cultural diversity has dwindled before the advance of modern culture as it is interpreted by Western society.

Intellectual elements (“scientific” criteria for the reliability of knowledge) and most emotional (aspirations and values) and evaluative ones (ethics and hierarchies of values) are widely shared by humankind (Inglehart 1997). Consequently, similarities and differences are difficult to define in territorial terms, and when they are thus definable, they are increasingly so only as symbols (languages, flags, cultural artifacts, physical resemblances, etc.), since knowledge-evoking and evaluative elements have been reduced to being options that are private, individual, and socially irrelevant (ethical and gnoseological relativism, individualism) (Thomas and Znaniecki 1918–1920; Halman, et al. 1987).

The state itself, which is called on to define the conditions of the collective control of the collective destiny, although it is still characterized by distinct territorial boundaries, is undergoing profound change as a result of the erosion of its sovereignty and power by the rise of supranational political organizations (e.g., the United Nations) and, in centralized states, infrastate political organizations (Galtung 1967), as well as by the growth of multinational economic enterprises and other noneconomic associations over which it can exert little or no control.

Consequently, if the continuing determination of the territorial boundaries of political and/or administrative units (Herz 1968) allows belongings to be related to them, those belongings grow increasingly less socially significant in regards to not only interdependencies and similarities but also common destiny. This occurs because social relevance is divided among several units organized into a system of relationships that need not be hierarchical and may indeed compete with each other.

TERRITORIAL BELONGING SUBJECTIVELY DEFINED BY REFERENCE TO THE SELF (THE SENTIMENT OF TERRITORIAL BELONGING)

The localism–cosmopolitanism of territorial belonging: A single-or multidimensional concept?
The growing complexity of territorial belonging,

along with the hypothesis that it is the manifestation of an ongoing process whose final outcome is cosmopolitanism (or the erasure of any nonglobal, noncumenical sense of belonging), has prompted sociologists to study the phenomenon empirically by focusing on the subjective definition of belonging provided by individuals with reference to themselves. Taking the process of growing systemization at the “energetic” level for granted, attention has been focused on how the phenomenon is subjectively reflected in the subjective definition individuals give to their territorial belongings. The aim of these studies has been to single out the factors that induce a person to feel that she or he belongs primarily to one unit rather than to another and, more generally, why she or he expresses a primarily cosmopolitan sense of belonging rather than one anchored in a particular geographic unit. Other studies have explored attachment to units of a particular size (home and neighborhood, local community, region, nation, continent, etc.).

The data gathered in both types of studies have included highly modernized contexts. On the home and neighborhood, see Fried and Gleicher (1961), Galster and Hesser (1981), and Fried (1982). On the local community, see Kasarda and Janowitz (1974), Rojek et al. (1975), Taylor and Townsend (1976), Wasserman (1982), Fried (1982), Goudy (1990), and Beggs et al. (1996). On regional units, see Piveteau (1969) and Gubert (1997). On belongings and national pride, apart from studies of nationalism and ethnicity, see the European Values Study in Ashford and Timms (1992, pp. 89–91) and the World Values Study in Ingleheart (1997, pp. 303–305). On territorial belongings on the localism–cosmopolitanism continuum, see Treinen (1965), Gubert and Struffi (1987), Gubert (1992a), and Strassoldo and Tessarin (1992). These data confirm the complexity of the phenomenon of territorial belonging when it is defined subjectively (a sentiment of belonging). Subjectively felt belongings are multiple, and each has its own role to play; that is, they become socially important in accordance with the particular context, which may change rapidly. For example, the sense of national belonging is exalted during international sports events, but local and regional senses of belonging

emerge during sports events within a country. This multiplicity of territorial belongings therefore rules out their mutual exclusiveness; this emerges clearly when subjects are asked to declare the absolute level of attachment they feel to different territorial units (Gubert 1998).

It is probable that partly diversified belongings underlie this multiplicity. This diversity was not grasped in early empirical studies of the sentiment of belonging, which relied largely on relative measures of the strength of attachment to socioterritorial units arranged along a continuum, with the neighborhood and community at one extreme and cosmopolitanism at the other (Terhune 1965; Gubert 1972, p. 181). Relative measures also were used in later large-scale surveys such as the European Values Study and the World Values Study. It is difficult to imagine that a Pole’s identification with his or her nation is the same as his or her attachment to his or her place of residence. One may feel strongly Polish while also having close bonds with one’s local community, and this cannot be explained by a single-dimensional conception of localism–cosmopolitanism, which instead suggests a social experience in which the nation as a sociospatial unit has weaker emotional connotations.

Further evidence that feelings of belonging to diverse socioterritorial units differ is provided by analyses of the attitudes of subjects who declare that they do not feel attached to any particular territorial unit. These individuals may be called cosmopolitans, but their cosmopolitanism is not only the extreme position on the localism–cosmopolitanism continuum; it is also symptomatic of difficulties of social integration, or anomie (Bertelli 1992). The distribution of the strength of socioterritorial belonging therefore measures not only the territorial size of the main social collectivities of reference but also the intensity of social integration, which in the case of declared nonbelonging to any territorial unit is markedly diminished, perhaps more in some cases than in others; therefore, cosmopolitanism is internally differentiated or heterogeneous. Parsons’s assumption that there is social belonging (and therefore loyalty and attachment) if there is social conformity—if, that is,

the subject conforms with the institutional obligations of solidarity (Parsons 1951)—receives empirical support in that a lack of social integration is connected with a lack of belonging to any socioterritorial unit.

Localism–cosmopolitanism as a single-dimensional continuum. Taken for granted (or given) the multiplicity of socioterritorial belongings and their partly diverse nature a further finding of empirical surveys concerns the relative importance of each of these belongings with respect to the others. It is assumed here that, to some extent, they express the localism–cosmopolitanism dimension and therefore can be plotted along a continuum.

When asked about the matter, even interviewees in highly modernized contexts tend to assign more importance to local belongings than to national and supranational ones. Overall, the two units that predominate are the commune and the nation or state. The importance of the other subnational and supracomunal units (province, region) depends on the structure of the public powers (the federal or nonfederal structure of the state) (Gubert 1995) or on whether an ethnic and/or national minority constitutes the majority in a subnational unit (Gubert 1975, p. 305). By contrast, the emergence of subcommunal units (neighborhoods, districts) depends on the settlement pattern of a commune: When it is articulated into several settlements (districts), importance is more frequently ascribed to subcommunal units, while the neighborhood acquires more importance when it constitutes a “natural area” within the communal settlement and has weak links with the rest of the urban territory.

If, rather than proposing a predetermined set of spatial units largely defined in political-administrative terms, individuals who declare their attachment to a particular territory are asked to freely describe it, to give it a name or define its boundaries, the area of belonging is generally more circumscribed. Indeed, it is sometimes restricted to the domestic ambit and its immediate surroundings, with little consideration of supralocal spatial units (Gubert 1992b, pp. 266–277). One therefore may conclude that the immediate bond with a

territory is mainly local or microlocal and that only the mention of larger socioterritorial units prompts individuals to consider supralocal territorial attachments.

Between negation of the hypothesis of an evolution toward cosmopolitanism and the reasons for the persistence of localism in a modern society. Multiple regression analysis shows that the social conditions that orient people to cosmopolitan or supralocal belongings (e.g., higher educational level, greater geographic mobility, residence in a metropolis) attenuate local attachments, although they do not entirely eliminate them (Gubert 1992d, pp. 506–523). These conditions seeming to affect the intensity of territorial attachment, attenuating it all levels rather than eliminating its primacy at the local level. Residential mobility seems to multiply local attachments rather than creating a single cosmopolitan attachment (Rubinstein and Parmalee 1992, 1996; Gubert 1992b, pp. 326–330; Feldman 1996).

This phenomenon can be explained to some extent by the reasons adduced to account for the most important territorial attachments. These reasons mainly concern day-to-day living (Kasarda and Janowitz’s [1974] duration of residence) and the places of infancy and the family (Taylor and Townsend 1976); much less important are the physical characteristics of places (except for places which are morphologically very distinct, such as mountains and coastlines, partially confirming Fried’s [1982] argument) or utility and opportunity.

Therefore, the strongest territorial attachment is connected with strongly affective social relations or with affectively important individual experiences, such as those of a child who progressively establishes a relationship with his or her immediate surroundings.

It is evident that the geographic mobility for mainly utilitarian reasons (work, access to services, use of free time) typically induced by life in modern society does not affect this type of attachment greatly. For the same reason, little influence is exerted by educational level: Although it may extend relational ambits, it does so mainly for utilitarian reasons or ones tied to a person’s profes-

sional role (Webber 1964). This has evident consequences for the territorial area of matrimonial choice and the areas which contain a person's best friends or relatives; these areas have increased in size, but they are nevertheless of modest proportions. Also, as was found for residential mobility, the consequence of this extension is more to increase the number of places of particular attachment than to induce an attachment to broader spatial units. In other words, the elasticity of relational ambits to the reduced costs of overcoming distance is much greater for secondary instrumental relationships than it is for primary relationships, especially family ones, which are firmly anchored in residence (Parsons 1951, p. 180 ff; 1960, p. 250 ff).

Regression analysis not of the size of the area of main attachment but of the (absolute) intensity of the feeling of belonging to it reveals, as was already mentioned, that the social conditions most typical of modernity (residence in large cities, geographic mobility, residential mobility, higher levels of education, secularization, ethical relativism, individualism, etc.) tend to attenuate the intensity of local attachment but do not erase it. Another explanation for the continuing primacy of local attachments over cosmopolitan ones is therefore that modernity tends to reduce the intensity of territorial belongings, but not to such a varied extent across territorial units that it alters the hierarchy of subjective importance assigned to them by most individuals. This sheds light on why the indicators of localism and cosmopolitanism with regard to the territorial extension of main attachments are determined by a factor independent of the one that groups together the indicators of the intensity of attachment (in any case, the correlation between the indicators is weak).

In addition to intensity, the features that connote greater "modernity" of ecological social and cultural positions in individuals exert a certain amount of influence on the social importance of the sentiment of territorial belonging (Gubert 1992d). Perception of the boundaries that mark the zone of principal attachment are less sharp: The inside-outside boundary, unless it is marked by obvious physical barriers against communica-

tion and vision, is not connected with the perception of distinct sociocultural differences and tends to assume the features of a zone rather than those of a line. The identifying features of the collectivity on the other side of the boundary, except in the case of physical barriers against communication or vision, display not abrupt discontinuities but gradual variations. Stereotypes and the ingroup-outgroup opposition are not as marked as those which arise when racial or ethnic differences are involved.

Moreover, the multiplicity of territorial belongings and their dependence on the particular and contingent nature of the context prevent the onset of radical ingroup-outgroup conflicts. Factor analysis has shown that the intensity of territorial attachment and ingroup-outgroup opposition (which is measurable, for example, by acceptance or rejection of immigrants in the area of principal belonging) are independent factors. Feeling stronger attachment to a particular territory therefore is weakly correlated with greater hostility toward or less acceptance of outsiders. The explanation of variance in these attitudes has more to do with the sphere of interests than with that of territorial belongings.

Equally independent (or weakly correlated) are factors relative to the social significance of the sentiment of territorial belonging and indicators of the territorial extension of the most important units.

Expectations of a positive relation between modernity and cosmopolitanism are not borne out by the data, although cross-sectional analysis is not conclusive on this matter. Certainly contradicted are claims that cosmopolitan attachments predominate in contemporary societies. What the advance of modernity seems to have done is breed a plurality of territorial belongings and reduce their intensity and social significance.

Distribution models of territorial attachments.

Having ascertained that territorial attachment is felt mainly at the local level (the primary community of everyday life), one may inquire about the distribution pattern of the intensity of territorial attachment, extending the analysis to ambits that do not occupy the highest position in the hierarchy of spatial units.

Once again, the most detailed surveys have been carried out in Italy, a country where the dialectic among localism, nationalism, and cosmopolitanism is particularly lively. If one considers the first three positions in a decreasing scale of attachment from subcommunal units to the whole world, it is possible to identify the most common and significant rank orderings (Gubert 1992b, pp. 279–281). By far the most prevalent is a model one may call “lococentric:” Territorial units diminish in importance as they grow larger. In three-dimensional space, where a two-dimensional geographic plane constitutes the horizontal axes and the relative intensity of territorial attachment is the vertical axis, they assume a cone shape whose apex is the smallest spatial unit.

Two other patterns emerge: the opposite model (upside-down cone), where the importance of a territorial unit decreases as one moves from broader to narrower spatial units, and, more commonly, a volcano-shaped model, a variant of the cone where the greatest importance is attributed to intermediate units, the next greatest importance to smaller units, and the least importance to larger ones.

Despite the prevalence of the lococentric model, a model that might develop instead of the “cosmopolitan” one (upside-down cone) as a consequence of the continuing advance of modernity is the volcano model, which places greater emphasis on supralocal sociospatial units compared with smaller communal or subcommunal ones, but without the units assuming greater importance as they become more inclusive and extensive. This is a type of territoriality that reflects adaptation to the extension of relational spaces beyond the settlement of residence that assumes a form other than cosmopolitanism.

CONCLUSIONS

Sociological research into territorial belonging as it is subjectively defined by self-reference contradicts the claim that the extension of relational spaces and the increased frequency of relations across larger distances (continental and global) have led to the superseding of local or at least

noncosmopolitan attachments. Attachment to local ambits still largely predominates. If anything, one discerns adaptations of a different kind, such as the increased complexity of the subjectively felt territorial bond and its closer dependence on changing contexts, the diminished intensity and social significance of various kinds of attachment, and a shift of primary attachment from the local level to one midway between localness and ecumene (the inhabited world). Rejection of any particular territorial attachment that might represent the outcome of cosmopolitan development is at least partly due to a lack of social integration.

Predictions that the demise of Toennies’s *Gemeinschaft* and Durkheim’s segmentary society would indicate the end of the overriding importance of attachment to particular places is not supported by empirical inquiry. Toennies’s *Gemeinschaft* has disappeared from modern society, but territorially restricted areas still have social relations of a communitarian nature, that is, relation in which community action in Weber’s sense (Weber [1922] 1972, p. 21) predominates.

However, this may not explain the facts unless one refers to Pareto’s assertion (1916, vol. II, sections 112–120, 1023–1041; Treinen 1965) that the sentiment of territorial belonging is a “residue” that can be included among those of the “persistence of aggregates.” A sentiment springs from the psychological association between emotionally significant experiences and the context in which they happen. For example, emotionally positive experiences tied to childhood and the family and relationships involving sexuality are positively associated with the places in which they have occurred. This gives rise to deep emotional bonds with those places, bonds that lie beyond reasoning or rationalization. In Pareto’s account, the attachment to places thus depends not on the communitarian or societal nature of the collectivity settled in the place of residence but instead on the fact that the most emotionally significant experiences in a person’s life necessarily occur in a territorially limited context, if only because of the limits imposed by the perceptive horizon. This also explains why the dispersion of these emotionally significant experiences tends more to multiply

the places of attachment than to create broad and inclusive attachments.

The technical progress of the means of communications and the means of transportation that facilitate the expansion of relational ambits, the individualization and secularization of culture, and the proliferation of the utilitarian businesslike relationships of *Gesellschaft* have had little or no effect on the processes that, according to Pareto's theory, cause the birth and persistence of attachment to place. As the negation of a particular bond with a particular place, cosmopolitanism unless it is not an ideological position that is deliberately assumed and declared to the interviewer, therefore may be a symptom of social marginalization caused by a lack of emotionally significant positive experiences. It is thus only rarely caused by the extreme territorial dispersion of those experiences and much more frequently caused by other personal and family events.

There are a number of reservations about the premises of the phenomenon known as globalization. Although relational ambits certainly extend over broader areas or, more precisely, relations have increased in intensity in even the largest of those areas, there is little evidence that the relative intensity of relations has increased. One cannot rule out the possibility that a diminution in the "friction of space" has intensified relations with all the territorial levels into which social life is structured, and it is likely that the intensification at medium and low levels is even greater for certain types of relation than it is at higher and broader ones. The increase in international trade, for example, does not mean that the system is becoming increasingly globalized; the increase may be greater at the national and regional levels, and so in relative terms, regional and national systems have become more self-contained (Deutsch 1960; Deutsch and Eckstein 1960–1961). The unproven assumption that the increase in the absolute density of relations has been accompanied by an increase in their relative density is credited to the existence of globalization processes that may not exist or may exist only for particular types of relations. Moreover, it is evident that in subjective perception (and not only in this area), the importance of the various levels

depends much more on their relative density than on their absolute density.

If more detailed empirical research confirms the validity of these remarks, the persisting primacy of local, or at least noncosmopolitan, belongings may be explained not only by Paretian hypotheses but also by the predominance at the relational level of local, regional, and national systems compared with continental and global ones.

Belonging as being part of is a phenomenon of central importance in sociological analysis. Territorial belonging is only one way to manifest social belonging. It may be associated with (ethnic and national belonging) or in competition with (membership in universal religions or international interest groups) other forms of social belonging. It also is a complex phenomenon, but it nevertheless seems to be characterized by features more durable than those of other social or group belongings. It resembles ethnic and national belongings but may be less exposed to change if the Paretian hypothesis is correct. It is a phenomenon that probably is grounded in enduring features of human experience, in what once might have been called human nature. Even the dissolution of Toennies's *Gemeinschaft* into a nonorganic assembly of communitarian relations or the reduction of these relations to simple human relations confined to interindividual space has not severed the bond felt by individuals with the places where they had their most emotionally significant and gratifying personal experiences. Theories of modernity should take account of this fact, and the historicist paradigms that hypothesize a progressive evolution toward cosmopolitanism should be revised. Empirical research must continue, enrich itself with longitudinal surveys, and increase the number of cases observed. Feeling part of a territory and feeling tied to places are still important phenomena in numerous areas of social life.

RENZO GUBERT

TERRORISM

Terrorism became an issue of worldwide concern in the last third of the twentieth century. Terrorist tactics were not new; they had been used for centuries before being defined as terrorism. The word “terror” entered the political lexicon during the French Revolution’s “reign of terror.” In the late nineteenth century, at the beginning of the twentieth, and again in the 1920s and 1950s—all periods between major wars on the European continents—terrorism became a technique of revolutionary struggle. Stalin’s regime in the 1930s and 1940s was called a reign of terror, but from the late 1940s to the 1960s the word was associated primarily with the armed struggles for independence waged in Palestine and Algeria, from which later generations of terrorists took their inspiration and instruction. After World War II, “terror” emerged

as a component of nuclear strategy; the fear of mutual destruction that would deter nuclear war between the United States and the Soviet Union was referred to as a balance of terror.

In the 1970s, "terrorism" became a fad word, promiscuously applied to a wide spectrum of conditions and actions. Bombs in public places were one form of terrorism, but some people asserted that oppression, poverty, hunger, racism, gang violence, spousal or child abuse, environmental destruction, and even medical malpractice were also forms of terrorism. Some governments labeled as terrorism all violent acts committed by their opponents, while antigovernment extremities claimed to be, and often were, the victims of government terror.

In an effort to get a firm hold on a slippery subject, those studying the phenomenon of terrorism were obliged to define it more precisely. Terrorism could be described simply as the use or threat of violence to create an atmosphere of fear and alarm and thus bring about a political result. But making this definition operative in political debate, rules of war, or criminal codes was anything but easy. Is all politically motivated violence terrorism? How does terrorism differ from ordinary crime? Should terrorism be considered a crime at all, or should it be seen as simply another form of armed conflict that is no less legitimate than any other form of war? Is the term properly reserved for those trying to overthrow governments, or can governments also be terrorists?

Definition was crucial because it ultimately determined the way in which terrorism has been studied. A major problem was that terrorism almost always has a pejorative connotation and thus falls in the same category of words as "tyranny" and "genocide," unlike such relatively neutral terms such as "war" and "revolution." One can aspire to objective and dispassionate research, but one cannot be neutral about terrorism any more than one can be neutral about torture. Thus, defining terrorism became an effort not only to delineate a subject area but also to maintain its illegitimacy. Even the most clinical inquiry was laden with values and therefore political issues. The very

study of terrorism implied to some a political decision.

Terrorism can be defined objectively by the quality of the act, not by the identity of the perpetrators or the nature of their cause. All terrorist acts are crimes, and many also would be war crimes or "grave breaches" of the rules of war if one accepted the terrorists' assertion that they wage war. All terrorist acts involve violence or the threat of violence, sometimes coupled with explicit demands. The violence is directed against noncombatants. The purposes are political. The actions often are carried out in a way that will achieve maximum publicity, and the perpetrators are usually members of an organized group.

Terrorist organizations are by necessity clandestine, but unlike other criminals, terrorists often but not always claim credit for their acts. Finally—the hallmark of terrorism—the acts are intended to produce psychological effects. This introduces a distinction between the actual victims of terrorist violence and the target audience. The connection between the victim and the target of terrorism can be remote. The identity of the victims may be secondary or even irrelevant to the terrorist cause. "Pure terrorism" is entirely indiscriminate violence.

Terrorism differs from ordinary crime in its political purpose and its primary objective. However, not all politically motivated violence is terrorism, nor is terrorism synonymous with guerilla war or any other kind of war.

Terrorist techniques can be used by governments or those fighting against governments: however, scholars generally use the term "terror" when discussing fear-producing tactics employed by governments and "terrorism" when referring to tactics used by those fighting against governments. The distinction is primarily semantic. Both groups may use threats, assassinations, or abductions, but government terror also may include arbitrary imprisonment, concentration camps, torture, mind-affecting techniques, and the use of drugs for political purposes. Antigovernment terrorists generally lack the infrastructure for such tactics. Government terror produces more victims than terrorism does. Terrorists tend to seek more publicity than do governments.

Although a prerequisite to empirical research, the attempt to define terrorism inevitably lent greater coherence to disparate acts of violence than did any analysis offered by the terrorists themselves, few of whom thought of assassinations, bombings, kidnappings, and airline hijackings as elements of a unified tactical repertoire, let alone the basis of a strategy. Ironically, in an effort to understand a phenomenon, researchers ran the risk of attributing to terrorists a level of strategic thinking they may not have possessed.

The term “international terrorism” refers to terrorist attacks on foreign targets or the crossing of national frontiers to carry out terrorist attacks. It was the dramatic rise in international terrorism—especially in the form of attacks on diplomats and commercial aviation in the late 1960s—that caused mounting alarm on the part of governments not directly involved in those local conflicts.

Although terrorist tactics were centuries old, contemporary terrorism, especially in its international form, emerged in the late 1960s from a unique confluence of political circumstances and technological developments. The political circumstances included the failure of the rural guerrilla movements in Latin America, which persuaded the guerrilla movements to take their armed struggles into the cities, where, through the use of dramatic actions such as kidnappings, they could be assured of attracting national and international attention. Their actions also provoked terrorist responses by governments that resorted to using “disappearances” of suspected guerrillas and their supporters, torture, and other tactics of terror.

In the Middle East, the failure of the Arab armies in the Six-Day War in 1967 caused the Palestinians to abandon dependence on Arab military power to achieve their aims and rely more heavily on the tactics of terrorism with the approval of some Arab governments. Israel retaliated with both military attacks and assassinations of suspected terrorist leaders.

The third political root of contemporary terrorism grew from widespread antigovernment demonstrations in universities in western Europe, Japan, and the United States that were provoked in

large measure but not exclusively by the war in Vietnam. By no stretch of the imagination could these antigovernment protests be called acts of terrorism, but the mass marches spawned extremist fringes that were inspired by third world guerrilla movements to carry on an armed struggle even after the student movements subsided.

Technological advances were equally important. Developments in communications—radio, television, communication satellites—made possible almost instantaneous access to global audiences, which was critical for a mode of violence aimed at publicity. Modern air travel provided terrorists with worldwide mobility and a choice of targets. Modern society’s dependence on technology created new vulnerabilities. Global weapons production guaranteed a supply of guns and explosives.

Once the tactics of terrorism were displayed worldwide, they provided inspiration and instruction for other groups, and terrorism became a self-perpetuating phenomenon.

The 1980s saw a new form of international terrorism: state-sponsored terrorism. Some governments began to use terrorist tactics or employ those tactics as a mode of surrogate warfare. Unlike government-directed terror, which is primarily domestic, state-sponsored terrorism is directed against foreign governments or domestic foes abroad. International diplomacy, economic sanctions, and in some cases, military actions brought about a reduction in this type of terrorism in the 1990s.

Despite great differences in political perspectives and outlook toward armed conflict, the international community gradually came to accept at least a partial definition of terrorism and prohibited certain tactics and attacks on certain targets. This approach reflected that of the academic community, focusing on the terrorist act and rejecting judgment based on the political objective or cause behind an act. Thus, by 1985, the United Nations General Assembly unanimously condemned international terrorism, including but not limited to acts covered by previous treaties against airline hijacking, sabotage of aircraft, attacks at civil air-

ports, attacks against maritime navigation and offshore platforms, attacks in any form against internationally protected persons (i.e., diplomats), and the taking of hostages.

By 1998, there were ten multilateral counterterrorism agreements that covered roughly half of all incidents of international terrorism but omitted primarily bombings of targets other than airlines or diplomatic facilities. One difficulty in delineating this type of terrorist act was distinguishing between terrorist bombings and aerial bombardment, which is considered a legitimate form of war. The rules of war prohibit indiscriminate bombing, thus providing at least a theoretical distinction between war and terrorism, although even with modern precision-guided munitions, collateral civilian casualties from aerial bombing in populated areas may vastly exceed casualties caused by the deliberate, indiscriminate bombs of terrorists.

In 1998, an International Convention for the Suppression of Terrorist Bombings attempted to address this lacuna. Unable to draw a clear distinction between terrorist bombings and other types of bombings, the treaty stated that the “activities of armed forces during an armed conflict . . . and the activities undertaken by military forces by a state in the exercise of their official duties, inasmuch as they are governed by other rules of international law, are not governed by this Convention.”

Terrorism is a subject matter, not a discipline. It has been approached by scholars from various academic perspectives with political scientists in the lead. Psychologists and psychiatrists have examined individual and group behavior, while jurists have formulated international legal approaches. Sociologists have not played a major role in research focusing specifically on terrorism but have addressed it in the broader context of deviance or social control.

Much research on terrorism has focused more narrowly on the topic. In part, this reflects the desire of researchers to avoid the murky, politically loaded area of underlying causes, where any discussion might be seen as condemnation or rationalization of terrorist violence. Nonetheless, there have been excellent case studies of individual groups and their tactics.

Defining terrorism in terms of the act has enabled researchers to maintain a theoretically objective approach and conduct at least some primitive quantitative analysis. Event-based analysis has enabled them to discern broad patterns and trends and chart the growth of terrorism and its diffusion around the globe. They have been able to demonstrate statistically that as terrorism has increased in volume, it has also become bloodier. Researchers were able to illustrate a clear trend toward incidents of large-scale indiscriminate violence in the 1980s and infer that terrorists tend to be more imitative than innovative in their tactics. Event-based analysis also has permitted researchers to distinguish the operational profiles of specific terrorist groups, and these profiles have been useful in identifying changes in a group’s *modus operandi*.

At the same time, event-based analysis has led the analysts into some methodological traps. An exclusive focus on terrorist actions, for example, resulted in terrorists being viewed first as if they were all part of a single entity and second as if they were almost extraterrestrial. While there are connections and alliances among some terrorist groups, the only thing the terrorists of the world have in common is a propensity for violence and certain tactics. Moreover, each group is rooted in its own social, political, and cultural soil, and cross-national comparisons are difficult. This has led to the question of whether there is such a thing as a terrorist-prone society.

It is, however, dangerous to attribute the actions of a few to perceived political defects or cultural flaws of a society as a whole, and researchers’ attempts to discern deeper causes or conditions that lead to high levels of terrorism in certain societies have produced meager results. Terrorism is not demonstrably a response to poverty or political oppression. The liberal democracies of western Europe have suffered high levels of terrorist violence, while totalitarian states are virtually free of terrorism. Overall, countries with perceived terrorist problems tend to be comparatively advanced politically and economically. They are more highly urbanized and have higher per capita incomes, larger middle classes, more university stu-

dents, and higher rates of literacy. One may ask whether political and economic advancement simply brings a more modern form of political violence.

One obstacle to linking high levels of terrorism with environmental factors is the problem of measuring terrorism. For the most part, this has been done by counting terrorist incidents, but international terrorism was narrowly and, more important, artificially defined to include only incidents that cause international concern, a distinction that has meant very little to the terrorists. Counting *all* terrorist incidents, both local and international, is better but still inadequate. Terrorist tactics, narrowly defined, represent most of what some groups, particularly those in western Europe, do but for other groups, terrorism represents only one facet of a broader armed conflict. In civil war situations, such as that in Lebanon in the 1970s, separating incidents of terrorism from the background of violence and bloodshed was futile and meaningless. And what about the extensive unquantified political and communal violence in the rural backlands of numerous third world countries? Broad statements about terrorist-prone or violence-prone societies simply cannot be made by measuring only a thin terrorist crust of that violence, if at all. The problem, however, is not merely one of counting. Although terrorists arise from the peculiarities of local situations, they may become isolated in a tiny universe of beliefs and discourse that is alien to the surrounding society. German terrorists were German, but were they Germany? In the final analysis, one is forced to dismiss the notion of a terrorist-prone society.

If terrorism cannot be explained by environmental factors, one must look into the mind of the individual terrorist for an explanation. Are there individuals who are prone to becoming terrorists—a preterrorist personality? Encouraged by superficial similarities in the demographic profiles of terrorists—many of them have been urban middle and upper class (not economically deprived) males in their early twenties with university or at least secondary school educations—researchers searched for common psychological features.

Behavioral analysts painted an unappealing portrait: The composite terrorist appeared to be a

person who was narcissistic, emotionally flat, easily disillusioned, incapable of enjoyment, rigid, and a true believer who was action-oriented and risk seeking. Psychiatrists could label terrorists as neurotic and possibly sociopathic, but they found that most of them were not clinically insane. Some behavioral analysts looked for deeper connections between terrorists' attitude toward parents and their attitudes toward authority. A few went further in claiming a physiological explanation for terrorism based on inner ear disorders, but these assertions were not given wide credence in the scientific community. The growing number of terrorists apprehended and imprisoned in the 1980s permitted more thorough studies, but while these studies occasionally unearthed tantalizing similarities, they also showed terrorists to be a diverse lot.

Much research on terrorism has been government-sponsored and therefore oriented toward the practical goal of understanding terrorism in order to defeat it. While social scientists looked for environmental or behavioral explanations for terrorism, other researchers attempted to identify terrorist vulnerabilities and successful countermeasures. They achieved a measure of success in several areas. Studies of the human dynamics of hostage situations led to the development of psychological tactics that increased the hostages' chances of survival and a better understanding (and therefore more effective treatment) of those who had been held hostage. In some cases, specific psychological vulnerabilities were identified and exploited. With somewhat less success, researchers also examined the effects of broader policies, such as not making concessions to terrorists holding hostages and using military retaliation. The conclusion in this area were less clear-cut.

Another area of research concerned the effects of terrorism on society. Here, researchers viewed terrorism as consisting of not only the sum of terrorist actions but also the fear and alarm produced by those actions. Public opinion polls, along with measurable decisions such as not flying and avoiding certain countries, provided the measure of effect.

Some critics who are skeptical of the entire field of terrorism analysis assert that the state and

its accomplice scholars have “invented” terrorism as a political issue to further state agendas through manipulation of fear, the setting of public discourse, preemptive constructions of “good” and “evil,” and the creation of deliberate distractions from more serious issues. “Terrorism,” a pejorative term that is useful in condemning foes, has generated a lot of fear mongering, and the issue of terrorism has been harnessed to serve other agendas, but one would have to set aside the reality of terrorist campaigns to see terrorism solely as an invention of the hegemonic state. While such deconstructions reveal the ideological prejudices of their authors, they nonetheless have value in reminding other analysts to be aware of the lenses through which they view terrorism.

Over the years, research on terrorism has become more sophisticated, but in the end, terrorism confronts people with fundamental philosophical questions: Do ends justify means? How far does one go on behalf of a cause? What is the value of an individual human life? What obligations do governments have toward their own citizens if, for example, they are held hostage? Should governments or corporations ever bargain for human life? What limits can be imposed on individual liberties to ensure public safety? Is the use of military force, as a matter of choice, ever appropriate? Can assassination ever be justified? These are not matters of research. They are issues that have been dictated through the ages.

THEOCRACY

See Religion, Politics, and War; Religious Organizations.

TIME SERIES ANALYSIS

Longitudinal data are used commonly in sociology, and over the years sociologists have imported a wide variety of statistical procedures from other disciplines to analyze such data. Examples include survival analysis (Cox and Oakes 1984), dynamic modeling (Harvey 1990), and techniques for pooled cross-sectional and time series data (Hsiao 1986). Typically, these procedures are used to represent the causal mechanisms by which one or more outcomes are produced; a stochastic model is provided that is presumed to extract the essential means by which changes in some variables bring about changes in others (Berk 1988).

The techniques called *time series analysis* have somewhat different intellectual roots. Rather than try to represent explicit causal mechanisms, the goal in classical time series analysis is “simply” to describe some longitudinal stochastic processes in summary form. That description may be used to inform existing theory or inductively extract new

theoretical notions, but classical time series analysis does not begin with a fully articulated causal model.

However, more recent developments in time series analysis and in the analysis of longitudinal data more generally have produced a growing convergence in which the descriptive power of time series analysis has been incorporated into causal modeling and the capacity to represent certain kinds of causal mechanisms has been introduced into time series analysis (see, for example, Harvey 1990). It may be fair to say that differences between time series analysis and the causal modeling of longitudinal data are now matters of degree.

CLASSICAL TIME SERIES ANALYSIS

Classical time series analysis was developed to describe variability over time for a single unit of observation (Box and Jenkins 1976, chaps. 3 and 4). The single unit could be a person, a household, a city, a business, a market, or another entity. A popular example in sociology is the crime rate over time in a particular jurisdiction (e.g., Loftin and McDowall 1982; Chamlin 1988; Kessler and Duncan 1996). Other examples include longitudinal data on public opinion, unemployment rates, and infant mortality.

Formal Foundations. The mathematical foundations of classical time series analysis are found in difference equations. An equation “relating the values of a function y and one or more of its differences $\Delta y, \Delta^2 y, \dots$ for each x -value of some set of numbers S (for which each of these functions is defined) is called a difference equation over the set S ” ($\Delta y = y_t - y_{t-1}$, $\Delta^2 = \Delta(y_t - y_{t-1}) = y_t - 2y_{t-1} + y_{t-2}$, and so on) (Goldberg 1958, p. 50). The x -values specify the numbers for which the relationship holds (i.e., the domain). That is, the relationships may be true for only some values of x . In practice, the x -values are taken to be a set of successive integers that in effect indicate *when* a measure is taken. Then, requiring that all difference operations Δ be taken with an interval equal to 1 (Goldberg 1958, p. 52), one gets the following kinds of results (with t replacing x): $\Delta^2 y_t + k y_t = 2k + 7$, which can be rewritten $y_t - 2y_{t-1} + (1-k)y_{t-2} = 2k + 7$.

Difference equations are deterministic. In practice, the social world is taken to be stochastic. Therefore, to use difference equations in time series analysis, a disturbance term is added, much as is done in conventional regression models.

ARIMA Models. Getting from stochastic difference equations to time series analysis requires that an observed time series be conceptualized as a product of an underlying substantive process. In particular, an observed time series is conceptualized as a “realization” of an underlying process that is assumed to be reasonably well described by an unknown stochastic difference equation (Chatfield 1996, pp. 27–28). In other words, the realization is treated as if it were a simple random sample from the distribution of all possible realizations the underlying process might produce. This is a weighty *substantive* assumption that cannot be made casually or as a matter of convenience. For example, if the time series is the number of lynchings by year in a southern state between 1880 and 1930, how much sense does it make to talk about observed data as a representative realization of an underlying historical process that could have produced a very large number of such realizations? Many time series are alternatively conceptualized as a population; what one sees is all there is (e.g., Freedman and Lane 1983). Then the relevance of time series analysis becomes unclear, although many of the descriptive tools can be salvaged.

If one can live with the underlying world assumed, the statistical tools time series analysis provides can be used to make inferences about which stochastic difference equation is most consistent with the data and what the values of the coefficients are likely to be. This is, of course, not much different from what is done in conventional regression analysis.

For the tools to work properly, however, one must at least assume “weak stationarity.” Drawing from Gottman’s didactic discussion (1981, pp. 60–66), imagine that a very large number of realizations were actually observed and then displayed in a large two-way table with one time period in each column and one realization in each row. Weak stationarity requires that if one computed the

mean for each time period (i.e., for each column), those means would be effectively the same (and identical asymptotically). Similarly, if one computed the variance for each time period (i.e., by column), those variances would be effectively the same (and identical asymptotically). That is, the process is characterized in part by a finite mean and variance that do not change over time.

Weak stationarity also requires that the covariance of the process between periods be independent of time as well. That is, for any given lag in time (e.g., one period, two periods, or three periods), if one computed all possible covariances between columns in the table, those covariances would be effectively the same (and identical asymptotically). For example, at a lag of 2, one would compute covariances between column 1 and column 3, column 2 and column 4, column 3 and column 5, and so on. Those covariances would all be effectively the same. In summary, weak stationarity requires that the variance-covariance matrix across realizations be invariant with respect to the displacement of time. Strong stationarity implies that the joint distribution (more generally) is invariant with respect to the displacement of time. When each time period's observations are normally distributed, weak and strong stationarity are the same. In either case, history is effectively assumed to repeat itself.

Many statistical models that are consistent with weak stationarity have been used to analyze time series data. Probably the most widely applied (and the model on which this article will focus) is associated with the work of Box and Jenkins (1976). Their most basic ARIMA (autoregressive-integrated moving-average) model has three parts: (1) an autoregressive component, (2) a moving average component, and (3) a differencing component.

Consider first the autoregressive component and y_t as the variable of interest. An autoregressive component of order p can be written as $y_t - \Phi_1 y_{t-1} - \dots - \Phi_p y_{t-p}$.

Alternatively, the autoregressive component of order p (AR[p]) can be written in the form $\Phi(B)y_t$, where B is the backward shift operator—that is, $(B)y_t = y_{t-1}$, $(B^2)y_t = y_{t-2}$ and so on—and $\phi(B) =$

$1 - \phi_1 B - \dots - \phi_p B^p$. For example, an autoregressive model of order 2 is $y_t - \phi_1 y_{t-1} - \phi_2 y_{t-2}$.

A moving-average component of order q , in contrast, can be written as $\epsilon_t - \theta_1 \epsilon_{t-1} - \dots - \theta_q \epsilon_{t-q}$. The variable ϵ_t is taken to be “white noise,” sometimes called the “innovations process,” which is much like the disturbance term in regression models. It is assumed that ϵ_t is not correlated with itself and has a mean (expected value) of zero and a constant variance. It sometimes is assumed to be Gaussian as well.

The moving-average component of order q (MA[q]) also can be written in the form $\Theta(B)\epsilon_t$, where B is a backward shift operator and $\Theta(B) = 1 - \theta_1 B - \dots - \theta_q B^q$. For example, a moving-average model of order 2 is $\epsilon_t - \theta_1 \epsilon_{t-1} - \theta_2 \epsilon_{t-2}$.

Finally, the differencing component can be written as $\Delta^d y_t$, where the d is the number differences taken (or the degree of differencing). Differencing (see “Formal Foundations,” above) is a method to remove nonstationarity in a time series mean so that weak stationarity is achieved. It is common to see ARIMA models written in general form as $\Theta(B)\Delta^d y_t = \Phi(B)\epsilon_t$.

A seasonal set of components also can be included. The set is structured in exactly the same way but uses a seasonal time reference. That is, instead of time intervals of one time period, seasonal models use time intervals such as quarters. The seasonal component usually is included multiplicatively (Box and Jenkins 1976, chap. 9; Granger and Newbold 1986, pp. 101–114; Chatfield 1996 pp. 60–61), but a discussion here is precluded by space limitations.

For many sets of longitudinal data, nonstationarity is not merely a nuisance to be removed but a finding to be highlighted. The fact that time series analysis requires stationarity does not mean that nonstationary processes are sociologically uninteresting, and it will be shown shortly that time series procedures can be combined with techniques such as multiple regression when nonstationarity is an important part of the story.

ARIMA Models in Practice. In practice, one rarely knows which ARIMA model is appropriate

for the data. That is, one does not know what orders the autoregressive and moving-average components should be or what degree of differencing is required to achieve stationarity. The values of the coefficients for these models typically are unknown as well. At least three diagnostic procedures are commonly used: time series plots, the autocorrelation function, and the partial autocorrelation function.

A time series plot is simply a graph of the variable to be analyzed arrayed over time. It is always important to study time series plots carefully to get an initial sense of the data: time trends, cyclical patterns, dramatic irregularities, and outliers.

The autocorrelation function and the partial autocorrelation function of the time series are used to help specify which ARIMA model should be applied to the data (Chatfield 1996, chap. 4). The rules of thumb typically employed will be summarized after a brief illustration.

Figure 1 shows a time series plot of the simulated unemployment rate for a small city. The vertical axis is the unemployment rate, and the horizontal axis is time in quarters. There appear to be rather dramatic cycles in the data, but on closer inspection, they do not fit neatly into any simple story. For example, the cycles are not two or four periods in length (which would correspond to six-month or twelve-month cycles).

Figure 2 shows a plot of the autocorrelation function (ACF) of the simulated data with horizontal bands for the 95 percent confidence interval. Basically, the autocorrelation function produces a series of serial Pearson correlations for the given time series at different lags: 0, 1, 2, 3, and so on (Box and Jenkins 1976, pp. 23–36). If the series is stationary with respect to the mean, the autocorrelations should decline rapidly. If they do not, one may difference the series one or more times until the autocorrelations do decline rapidly.

For some kinds of mean nonstationarity, differencing will not solve the problem (e.g., if the nonstationarity has an exponential form). It is also important to note that mean nonstationarity may be seen in the data as differences in level for

different parts of the time series, differences in slope for different parts of the data, or even some other pattern.

In Figure 2, the autocorrelation for lag 0 is 1.0, as it should be (correlating something with itself). Thus, there are three spikes outside of the 95 percent confidence interval at lags 1, 2, and 3. Clearly, the correlations decline gradually but rather rapidly so that one may reasonably conclude that the series is already mean stationary. The gradual decline also usually is taken as a sign autoregressive processes are operating, perhaps in combination with moving-average processes and perhaps not. There also seems to be a cyclical pattern, that is consistent with the patterns in Figure 1 and usually is taken as a sign that the autoregressive process has an order of more than 1.

Figure 3 shows the partial autocorrelation function. The partial autocorrelation is similar to the usual partial correlation, except that what is being held constant is values of the times series at lags shorter than the lag of interest. For example, the partial autocorrelation at a lag of 4 holds constant the time series values at lags of 1, 2, and 3.

From Figure 3, it is clear that there are large spikes at lags of 1 and 2. This usually is taken to mean that the p for the autoregressive component is equal to 2. That is, an AR[2] component is necessary. In addition, the abrupt decline (rather than a rapid but gradual decline) after a lag of 2 (in this case) usually is interpreted as a sign that there is no moving-average component.

The parameters for an AR[2] model were estimated using maximum likelihood procedures. The first AR parameter estimate was 0.33, and the second was estimate -0.35. Both had t -values well in excess of conventional levels. These results are consistent with the cyclical patterns seen in Figure 1; a positive value for the first AR parameter and a negative value for the second produced the apparent cyclical patterns.

How well does the model fit? Figures 4 and 5 show, respectively, the autocorrelation function and the partial autocorrelation function for the residuals of the original time series (much like

Figure 1. Unemployment Rate by Quarter

residuals in conventional regression analysis). There are no spikes outside the 95 percent confidence interval, indicating that the residuals are probably white noise. That is, the temporal dependence in the data has been removed. One therefore can conclude that the data are consistent with an underlying autoregressive process of order 2, with

coefficients of 0.33 and -0.35. The relevance of this information will be addressed shortly.

To summarize, the diagnostics have suggested that this ARIMA model need not include any differences or a moving-average component but should include an autoregressive component of

Figure 2. Unemployment Series: Autocorrelation Function

order 2. More generally, the following diagnostic rules of thumb usually are employed, often in the order shown.

1. If the autocorrelation function does not decline rather rapidly, difference the series one or more times (perhaps up to three) until it does.
2. If either before or after differencing the autocorrelation function declines very abruptly, a moving-average component probably is needed. The lag of the last large spike outside the confidence interval provides a good guess for the value of q . If the autocorrelation function declines rap-

Figure 3. Unemployment Series: Partial Autocorrelation Function

idly but gradually, an autoregressive component probably is needed.

3. If the partial autocorrelation function declines very abruptly, an autoregressive component probably is needed. The lag of the last large spike outside the confidence interval provides a good guess for the value of p . If the partial autocorrelation

function declines rapidly but gradually, a moving-average component probably is needed.

4. Estimate the model's coefficients and compute the residuals of the model. Use the rules above to examine the residuals. If there are no systematic patterns in the residuals, conclude that the model

Figure 4. Residuals Series: Autocorrelation Function

is consistent with the data. If there are systematic patterns in the residuals, respecify the model and try again. Repeat until the residuals are consistent with a white noise process (i.e., no temporal dependence).

Several additional diagnostic procedures are available, but because of space limitations, they

cannot be discussed here. For an elementary discussion, see Gottman (1981), and for a more advanced discussion, see Granger and Newbold (1986).

It should be clear that the diagnostic process is heavily dependent on a number of judgment calls about which researchers could well disagree. Fortunately, such disagreements rarely matter. First, the disagreements may revolve around differences

Figure 5. Residuals Series: Partial Autocorrelation Functions

between models without any substantive import. There may be, for instance, no substantive consequences from reporting an MA[2] compared with an MA[3]. Second, ARIMA models often are used primarily to remove “nuisance” patterns in time series data (discussed below), in which case the particular model used is unimportant; it is the result that matters. Finally and more technically, if

certain assumptions are met, it is often possible to represent a low-order moving-average model as a high-order autoregressive model and a low-order autoregressive model as a high-order moving-average model. Then model specification depends solely on the criteria of parsimony. That is, models with a smaller number of parameters are preferred to models with a larger number of parame-

ters. However, this is an aesthetic yardstick that may have nothing to with the substantive story of interest.

USES OF ARIMA MODELS IN SOCIOLOGY

It should be clear that ARIMA models are not especially rich from a substantive point of view. They are essentially univariate descriptive devices that do not lend themselves readily to sociological problems. However, ARIMA models rarely are used merely as descriptive devices (see, however, Gottman 1981). In other social science disciplines, especially economics, ARIMA models often are used for forecasting (Granger and Newbold 1986). Klepinger and Weiss (1985) provide a rare sociological example.

More relevant for sociology is the fact that ARIMA models sometimes are used to remove “nuisance” temporal dependence that may be obstructing the proper study of “important” temporal dependence. In the simplest case, ARIMA models can be appended to regression models to adjust for serially correlated residuals (Judge et al. 1985, chap. 8). In other words, the regression model captures the nonstationary substantive story of interest, and the time series model is used to “mop up.” Probably more interesting is the extension of ARIMA models to include one or more binary explanatory variables or one or more additional time series. Nonstationarity is now built into the time series model rather than differenced away.

Intervention Analysis. When the goal is to explore how a time series changes after the occurrence of a discrete event, the research design is called an interrupted time series (Cook and Campbell 1979). The relevant statistical procedures are called “intervention analysis” (Box and Tiao 1975). Basically, one adds a discrete “transfer function” to the ARIMA model to capture how the discrete event (or events) affects the time series. Transfer functions take the general form shown in equation (1):

$$(1 - \delta_1 B - \dots - \delta_r B^r) y_t = (\omega_0 - \omega_1 B - \dots - \omega_s B^s) x_{t-b}$$

If both sides of equation (1) are divided by the left-hand side polynomial, the ratio of the two polynomials in B on the right-hand side is called a transfer function. In the form shown in equation (1), *r* is the order of the polynomial for the “dependent variable” (*y_t*), *s* is the order of the poly-

nomial for the discrete “independent variable” (*x_t*), and *b* is the lag between when the independent “switches” from 0 to 1 and when its impact is observed. For example, if *r* equals 1, *s* equals 0, and *b* equals 0, the transfer function becomes $\omega_0 / (1 - \delta_1 B)$. Transfer functions can represent a large number of effects, depending on the orders of the two polynomials and on whether the discrete event is coded as an impulse or a step. (In the impulse form, the independent variable is coded over time as 0, 0, . . . 0, 1, 0, 0, . . . , 0. In the step form, the independent variable is coded over time as 0, 0, . . . 1, 1 . . . 1. The zeros represent the absence of the intervention, while the ones represent the presence of the intervention. That is, there is a switch from 0 to 1 when the intervention is turned on and a switch from 1 to 0 when the intervention is turned off.) A selection of effects represented by transfer functions is shown in Figure 6.

In practice, one may proceed by using the time series data before the intervention to determine the model specification for the ARIMA component, much as was discussed above. The specification for the transfer function in the discrete case is more ad hoc. Theory certainly helps, but one approach is to regress the time series on the binary intervention variable at a moderate number of lags (e.g., simultaneously for lags of 0 periods to 10 periods). The regression coefficients associated with each of the lagged values of the intervention will roughly trace out the shape of the time path of the response. From this, a very small number of plausible transfer functions can be selected for testing.

In a sociological example, Loftin et al. (1983) estimated the impact of Michigan’s Felony Firearm Statute on violent crime. The law imposed a two-year mandatory add-on sentence for defendants convicted of possession of a firearm during the commission of a felony. Several different crime time series (e.g., the number of homicides per month) were explored under the hypothesis that the crime rates for offenses involving guns would drop after the law was implemented. ARIMA models were employed, coupled with a variety of transfer functions. Overall, the intervention apparently had no impact.

Figure 6. A Sampler of Intervention Effects. *I* = Intervention

Multiple Time Series. ARIMA models also may be extended to more than one time series (Chatfield 1996, Chap. 10) Just as the goal for the univariate case was to find a model that transformed the single time series into white noise, the goal for the multivariate case is to find a model that will transform a *vector* of time series into a white noise vector. In effect, each series is regressed simultaneously not only on lagged functions of itself and the disturbance term but on functions of all other time series and their disturbance terms. In practice, this sometimes reduces to building transfer function models that include a single response time series and several input time series, much as in multiple regression. For exam-

ple, Berk et al. (1980) explored how water consumption varied over time with the marginal price of water, weather, and a number of water conservation programs.

The mathematical generalization from the univariate case is rather straightforward. The generalization of model specification techniques and estimation procedures is not. Moreover, multivariate time series models have not made significant inroads into sociological work and therefore are beyond the scope of this chapter. Interested readers should consult Chatfield (1996) for an introduction or Granger and Newbold's (1986) for a more advanced treatment.

CONCLUSIONS

Time series analysis is an active enterprise in economics, statistics, and operations research. Examples of technical developments and applications can be found routinely in a large number of journals (e.g., *Journal of the American Statistical Association*, *Journal of Business and Economic Statistics*, *Journal of Forecasting*). However, time series analysis has not been especially visible in sociology. Part of the explanation is the relative scarcity of true time series for sociological variables collected over a sufficiently long period. Another part is that time series analysis is unabashedly inductive, often making little use of substantive theory; time series analysis may look to some a lot like “mindless empiricism.” However, in many sociological fields, true time series data are becoming increasingly available. Under the banner of “data analysis” and “exploratory research,” induction is becoming more legitimate. Time series analysis may well have a future in sociology.

RICHARD A. BERK

TIME USE RESEARCH

Time provides the organizational key to action at the level of individuals, groups, and institutions. It also defines a normative framework that regulates interpersonal relationships and allows synchronized operations in different parts of society. In the concept of time, structural as well as symbolic facets assume significance. In fact, as it is conceived in sociological theory, time is a means of social coordination as well as a dimension that assigns value to action schemes in a system assuring social order (Pronovost 1989; Sue 1994).

The empirical study of the temporal organization of human action reveals the functional charac-

teristics of social roles and the societal division of social tasks. For instance, indicators of inequality and social exclusion can be derived and compared by referring to estimates of the amount of time involved in gender-related activities such as market work and housework. The time use of populations or subpopulations is studied mostly by means of diary procedures that assess individual "time budgets:" the sequence, timing, and duration of activities performed by individuals over a specified period. It is misleading to think that the aim of time budget research is time as either a physical or a subjectively perceived entity. As stressed by the major postwar promoter of this area of study, the Hungarian sociologist Szalai, the object of studying time is to discover the use people make of their time, or "the arrangement and the fit of people's activities in a temporal frame of reference, the temporal order and structure of everyday life" (1984, p. 20).

From this point of view, time is a special kind of resource. As with material goods and more symbolic commodities such as money, people have a "fund" of time at their disposition and make decisions on how to use, "spend," or "invest" it. However, time is a far more democratic resource in that every person deals with the same basic "stock" of it, such as the twenty hours in a day and the seven days in a week. This means that a shared reference of differential time allocation patterns can facilitate coherent comparisons and meaningful interpretations. It is this particular aspect that has made time use an important topic in quantitative social research. Both academic scholars and national statistical offices have shown a growing interest in time-budget data because those data permit policy-oriented microanalyses of changing lifestyles at the individual or household level as well as macroanalyses of social and economic inequalities in the context of cross-national comparative studies.

In contrast to the physical notion that attributes equivalent temporal resources to all people and therefore facilitates systematic accounts, from a subjective point of view, the length of a day is not always the same. Some people seem to have more time than others. This phenomenon reveals the sociopsychological dimension of time in which concepts such as stress and alienation are relevant. In a world where the quality of life depends largely

on what one gets out of the time at one's disposal, coping with time and compressing multiple activities into the same time slot have become important skills. Furthermore, it is a universal observation that boring periods during a day, week, or year can seem long, whereas other, quantitatively equivalent but exciting periods of time are perceived as a passing moment. However, in studying social time, time-budget research adopts an activity-oriented approach and focuses only indirectly on subjective experiences. In substance, this means that observable patterns of behavior are selected as primary evidence and, in methodological terms, standard time units are chosen for measurement purposes.

THE TIME USE RESEARCH TRADITION

Although social time is not intrinsically quantitative, the use of standard time units for the purposes of analyzing the structure of everyday life seems legitimate, since the transfer of human work from agriculture to artificially controlled industrial environments and the subsequent changes in civilization have largely transformed natural time (tied to seasonal conditions and biological needs) into conventional, rational time (Elias 1988). As a corollary to this process, social life has become dominated by timekeeping. This chronometric function is characterized by a universally accepted "time" language that coordinates rhythms of action in the public and private spheres (Zerubavel 1982). Therefore, time budgets, which are concerned with different kinds of schedules for structuring the flow of events, are a key to the systematic investigation of the complex interdependencies and trade-offs of modern life.

The historical origins of the study of social time lie in both sociological theory and empirical research. With regard to theory, the early French school of sociology was interested in this phenomenon from the point of view of the historical and anthropological dimensions of social change (Pronovost 1989). Around the turn of the century, Hubert, Mauss, Durkheim, and Halbwachs conceived of social time as an intrinsically qualitative phenomenon that was relevant for the characterization of the sacred-profane symbolic dichotomy in the evolution of the collective consciousness or

the formation of a collective memory. Their focus was a macro one, and their main interest was to explain long-term cultural change.

In contrast, Mead in the early 1930s chose an individualistic, micro-oriented approach that offered a philosophical rationale for studying time in the present. The present was conceived of as the context for the emergence and assimilation of various social time systems in interplay with the definition of different notions of "the self." Thus, the French and American approaches represent polar opposites, with one conceiving time within the matrix of historical societal relationships, and the other from the perspective of mutable configurations of symbolic interactions in small groups. The somewhat later work of Sorokin reflects both approaches. He presents the functionalist idea that the plurality of individual time schemes requires extensive synchronization to achieve social cohesion and that time expresses the sociocultural "pulsation" of a society.

In the 1960s, Gurvitch gave new impetus to the study of time after a considerable period of neglect. He was the first to conceive of time as an important source of contradictions and potential conflict. In particular, he stressed the hierarchically diversified aspects of the phenomenon (e.g., social time, time in organizations, time in special social groups) and raised the issues of power and legitimacy. More recently, Merton introduced the concept of "socially expected durations" that highlight the normative aspects of the embeddedness of time in social structures. In contrast, Elias stressed the role of time as a symbolic means of social regulation but also of increasingly unpredictable individual self-expression.

The historical origins of empirical investigations of social time are even older, going back to the middle of the nineteenth century. Three lines of research are significant: the research conducted by Friedrich Engels on the English working class, where the temporal organization of daily life was the issue; the studies undertaken by Frédéric LePlay, in which the economic "family-budgets" of workers in several European countries were assessed (similar to what "time budgets" do today); and the experimental work on time and motion performed by Frederick Taylor, based on carefully collected chronometric data. Taylor's aim was to introduce

strategies of scientific time management in industry. In regard to the adoption of time-budget methodologies, there were Bevans's pioneering studies (1913) of how workers spent their spare time and early Soviet inquiries by Strumilin into time use as the basis for rational social programming. Lundberg and Komarovsky's research into the organization of time within the realm of community research was conducted along the lines of American cultural anthropology.

Of more enduring interest, however, were two studies published in the 1930s. Jahoda et al.'s *Marienthal: The Sociography of an Unemployed Community* (1933) was a substantial contribution to the study of time use. It explores changes in the meaning of time for German working-class families when work, as a dominant regulating and legitimizing criterion for time use, has disappeared. Male workers tended to become severely disoriented and alienated after losing their work-based prestige, whereas their wives were successful in mastering that situation because they had much more positive attitudes based on more complex sources of social recognition. This research also shows how important it is to be aware that similar circumstances can assume diverse meanings for different groups.

The other study, whose importance lies in its methodological ideas, is Sorokin and Berger's *Time-Budgets and Human Behavior* (1939). Here the aim was to explore meaningful criteria for decision making conducive to different time structures. Information on motivations and the kinds of experiences associated with certain practices and future projects was collected to acquire a deeper understanding of how people deal with their time. Even more important, this research raised the crucial epistemological question of how to divide essentially continuous strings of behavior into activity segments that, beyond commonsense classifications, can be grouped into homogeneous and mutually exclusive categories (Kurtz 1984). The difficulty was that some activities that from an external viewpoint seemed identical could assume unequal functions in the eyes of those concerned, or conversely, that substantially different activities could assume similar functions. This means that any classification of activities presupposes an interpretive act. With this fundamental problem

in mind, these authors were forced to approach earlier and purely descriptive assessments of time allocation with skepticism and spell out the methodological issues in their research.

After World War II, research took different directions in accordance with divergent political ideologies. The assessment of living conditions, which involved obtaining background data for economic planning and monitoring centrally initiated social change, continued to be of pivotal importance in research in eastern Europe's communist countries. Prudensky's time-budget studies in the Soviet Union in the 1960s not only followed the direction of Strumilin's work but also reflected these ideological concerns. The need to broaden data gathering to obtain effective guidance for public policy at the national level led Hungary's statistical office to begin the first microcensus research in this field.

In capitalist societies, time use research was concerned principally with mass media and leisure culture. Pioneering time use studies of audiences were undertaken by the BBC as well as NHK, the Japanese radio and television system, using large-scale survey techniques. From 1960 onward, NHK conducted regular five-year follow-up rounds of research to obtain time series statistics that showed long-term longitudinal development. This was a useful strategy because it produced an interesting account of how, in terms of time use, traditional ways of life are supplanted by innovative, primarily television-centered styles.

This was the situation in 1963, when the idea of conducting a Multinational Comparative Time Budget Research Project emerged. This was an ambitious sociological initiative in light of the organizational and data-processing difficulties of those years. Launched by a group of scholars directed by Szalai, sponsored by UNESCO's International Social Science Council, and coordinated by the Vienna Centre, this project attempted to obtain an interculturally valid body of knowledge that would shed light on regularities or variations in the functioning of human societies with regard to time use. This information was to be derived from a database of twelve different countries by using methodological instruments that assured a high level of analytic precision (Szalai 1977). In organizing the initiative, the basic concern was to

avoid the emergence of a single central vantage point regarding the collection, elaboration, and interpretation of information. Therefore, research sites had considerable autonomy in studying the uniform data sets collected by means of strictly standardized survey instruments from probability samples of urban populations in the twelve countries under investigation.

From a positivist point of view, the focus on chronometric evidence and on an array of "hard" time use indicators enhanced the scientific character of the study and facilitated the collaboration of teams from such culturally and sociopolitically different environments as the United States and the Soviet Union. Of course, collaboration entailed the acceptance of common working hypotheses such as the expected influence of the major independent variables of industrialization and urbanization on the modalities of the division of market work and nonmarket work in households. By contrast, time for leisure was thought to be correlated with superior levels of modernization and democratization. These hypotheses clearly reflected the research traditions of the day, and so to connect the ideologically distant worlds of the 1960s, it was necessary to choose highly conventionalized and neutral time indicators as empirical evidence.

The Twelve Country Project, characterized by a strong belief in the "scientific *and* social import of cross-national comparative research" (Szalai 1977), did not go without criticism. Some thought that it was most important for cross-national research to contribute findings on general theoretical problems (Przeworski and Teune 1970). However the promoters were convinced that the discovery of the empirical peculiarities of cultural settings was at least as important as the verification of a priori hypotheses on common characteristics and trends. That the pragmatic point of view prevailed meant that the problem of a lack of reliable, relevant, and usable data had to be overcome.

In retrospect, it seems that this project did not contribute much to general theory, but it did produce an elaborate methodology whose essential lines are applied to basic and official survey research in many countries today. In fact, as Szalai hoped, the homogenization of time-budget methods now permits the drawing of "maps" of collec-

tive daily activity schemes at different levels of definition that have proved to be useful diagnostic elements for many policymakers and grassroots organizations. When economic indicators are insufficient, statistical information regarding the use of time can open up new policy perspectives and guide substantial change, especially when gaps in the quality of life manifest themselves and corrective action is needed to improve the conditions of disadvantaged social groups.

METHODOLOGICAL ASPECTS OF TIME-BUDGET RESEARCH

Since the work of Szalai, the methodology of time use research has been further refined. Under the auspices of the International Association of Time Use Research, in particular under the guidance of Harvey (1984, 1993), who has repeatedly codified the best practices, statistical bodies have reached a consensus on the format of official survey research.

The task of discovering the temporal order and structure of everyday life by means of time-budget methods involves far more complex activities than gathering simple answers to questions of who does what, when, where, and with whom. In the design of a time-budget study, methodological issues such as the scope and scale of the research, the population from which the sample is to be drawn, the format of the data-gathering instruments, the classification and coding of activities, the choice of basic indicators, and the validity and reliability of the data must be resolved.

Defining the scope of a study also means fixing its scale. In fact, a time use survey may deal with a special group of persons, such as working women or teenagers, or with comprehensive national populations, perhaps excluding preschoolers. Or it may focus on a daily activity such as housework and child care or leisure. Alternatively, it may attribute equal weight to all everyday pursuits. Finally, the study may be aimed at discovering how the time of a special kind of day is spent, may take into account the rhythm of the week by distinguishing workdays from Sundays, or may be interested in longer periods such as the year with its seasonal differences and, in the extreme case, the life cycle (which of course would have to be studied on the basis of long-term recollections). Theo-

retically grounded sociological research is, for economic reasons, more likely to have circumscribed objectives, whereas national statistical offices have all-encompassing multipurpose datasets available. However, in both cases, the predominant tendency is to focus on the twenty-four hours of one or more single days in the life of the respondent. When these days are distributed over the week, month, or year, the average profiles of the period can be synthetically reconstructed. Such profiles most often refer to uninterrupted sequences of nonoverlapping main or "primary" activities. When there is interest in "secondary" activities or, more precisely, in contemporaneous activity episodes, the respondent usually is asked to designate the elements that represent the principal flow, which typically covers the 1,440-minute arc of the day. In fact, leaving secondary activity out of focus furnishes an unduly simplified picture of what is going on, since it ignores efficiency strategies that enable people who are short of time to deal simultaneously with multiple jobs. This frequently criticized weakness is compensated for by the heuristically valid fact that strict 24-hour accounts produce agile descriptive models. With such models, whatever time is saved on one kind of activity is strictly accredited, using zero-sum logic, to one or more other activities. Therefore "time set free" and the equivalent "time gained" concept furnish concise indicators of social change. Tracing the balance of the two magnitudes gives a dynamic slant to the analysis of time use and sheds light on the spectrum of strategic options.

Depending on the scope of the study, populations and samples are variously defined. From this point of view, the most significant difference between time use studies regards the choice of the sampling unit, which may be the individual or the household. In earlier studies, individual time use was of primary concern, and so estimates were obtained by classifying persons by their sociodemographic characteristics. More recent research, however, has looked more into how different types of families, as molecular units, manage time allocation with regard to income generation as well as work in the sphere of home and child care. Statistical offices now use very large probability samples of households to be able to generate cross-tabulated data on specific territorial areas and particular social groups. In Italy, for instance,

the last national time use survey, conducted by Istat in 1988 and 1989, consisted of more than 38,000 persons belonging to almost 14,000 households. A survey conducted in Germany in 1991 and 1992 by the Statistisches Bundesamt included 7,200 households. One of the most difficult problems in time-budget research is the sample units' frequent refusal to respond once they see how much time is involved. In fact, nonresponse rates tend to be high and in some official surveys amount to almost 30 percent. This problem is easier to handle in smaller-scale studies, which often use quota sampling.

Data gathering in time use research begins with an interview (Scheuch 1972) to record the characteristics of the respondent and his or her family, contractual work arrangements, normal labor supply, and housing or other assets and to inquire into irregularities in the day designated for collecting the time-budget information. The time budget itself is registered in a protocol, a diary, or modular display where the beginning and the end of each activity can be indicated together with other information. The resulting datasets show for each day and respondent (1) the number of different activities performed and the frequency of each activity in separate episodes (for instance, the series of daily meals or the periods passed in front of the television set) and (2) the timing, duration, and sequence of activities or activity episodes. Most often, the interviewees register activities by using their own words. A grid of minimal time intervals is given (the "fixed interval" solution), where the task is to fill each interval with an activity, or the interviewee is asked to specify the exact time points of his or her schedule (the "open interval" solution). To obtain the essential elements of the interviewee's context, there is usually room to indicate contemporaneous activities (for instance, reading while using public transport or listening to music while doing homework); participation in activities with family members, neighbors, friends, and colleagues; and where the activity takes place. The least expensive method of data collection is the condensed telephone interview, which explores time use on the previous day. For field studies, there are other procedures, such as single face-to-face interviews and two personal interviews. In the first case, the person is asked to recall what he or she did the preceding day. This

procedure is complicated when a lot of detail is required. The second procedure involves two personal interviews. During the first, background information is collected and the time use diary is left behind, to be filled in the next day. During the second interview, on the day after the respondent's observation of his or her time use, the interviewer checks and refines the registrations. In Scandinavian countries, people were asked to return diaries by mail. This saves a second visit, but it is advisable only when intelligent and conscientious collaboration can be assumed.

The greatest methodological challenge in time use research is the choice of the scheme of classification of activities in terms of which the structure of everyday life is represented. Sorokin started to tackle this problem, but convincing theoretical or empirical criteria for constructing typological keys have not been found, and using conventional categories of ordinary language is not entirely satisfactory. Normative and/or contractual work arrangements suggest a fairly unambiguous specification of "market work," but there are some activities in the home that, according to circumstances, can be classified as either housework or leisure. This difficulty could be overcome if the respondent did the coding himself or herself, but usually the log of daily routines is described in the respondent's own words and codification is done by someone else, following criteria that exclude personal and/or subjective meanings. An even more fundamental issue is whether current classifications can be assumed to be meaningful in cross-cultural terms. Time use studies distinguish the minimal basic activity groupings of personal needs, formal work or education, household work, and leisure. The hidden dimension that is postulated by such groupings is obviously a reflection of the Western opposition between necessity and freedom of choice. It places market work immediately after biological needs and before domestic work, which is placed near leisure. This implicitly individualistic and work-oriented, contractual rationale probably is not well suited to representing the more solidarity-oriented temporal orders of everyday life in traditional societies (Bourdieu 1963).

Another difficulty concerns the level of specificity at which a common array of activities is reported at the collective level. The daily pursuits

of persons who lead a busy life can be meaningfully recorded in great detail, whereas those of persons tied to the home usually have much less texture. One way to approach this difficulty is to construct hierarchical coding frameworks in which the first column in a multiple-digit code divides the day in terms of major classes of activities. Additional columns focus on increasingly more complex but exhaustive time accounts. The time use project coordinated by Szalai identified in its time-budget protocols ninety-six activity categories. For some purposes, these were reduced to thirty-seven and, for others, to the following ten main groups: work, housework, child care, shopping, personal needs, education, organizational activity, entertainment, active leisure, and passive leisure. Today the coding schemes for official statistical surveys often include many more basic activity categories because they have to accommodate the heterogeneity of lifestyles across gender groupings, generations, occupational categories, and rural versus urban residential environments.

Once time-budget data have been collected and coded, decisions about data processing and indicator construction can be made. According to the complexity of statistical data elaborations, there are three different levels of analysis (Stone 1972, pp. 96-97). First, activity arrays in terms of frequencies or durations, possibly taking company or locations into account, are cross-tabulated with the sociodemographic characteristics of the actors. Second, single activities and their positioning during the course of the day are studied. Finally, stochastic activity sequences are analyzed, focusing on the structure and rhythm of chronological daily routines. Since the 1960s, the following set of indicators generally have been used in computations: (1) the generic average duration of an activity, where the numerator refers to the total sample, disregarding whether there was involvement in the activity, (2) the rate of participation, or the percentage of interviewees who were involved in an activity, and (3) the specific average duration of an activity, where the denominator includes only those who have engaged in it.

Another issue in these surveys is the validity and reliability of data sets. Questions of validity can be raised by difficulties in recall and incorrect identification of activities among respondents or

by possible alterations of spontaneous behavior after observation and the consequent distortions in reports or by research instruments that inadequately reflect the specificities of the observed sociocultural context. Research directed at data quality (Juster 1985; Niemi 1993) has shown that results obtained by means of time budgets present at the aggregate level a high correlation with those obtained by means of other forms of observation, such as interviews, workplace or school statistics, and telephone surveys. Moreover, the hypothesis that the desirability or social prestige of certain activities or lifestyles could influence time use reports has not been confirmed. In general, it seems that the twenty-four-hour frame of reference helps reduce such effects and brings informal and often undeclared work commitments to light. Certainly, activities that are assumed to be of secondary importance, such as conversations and listening to the radio, are under represented in current summary tables that restrict the attention to "primary" time allocations. However, this cannot be considered an invalidating shortcoming. Nevertheless, to assure validity, time budgets presuppose the concept of rational time. If a population does not live by the clock, any calculation of time budgets is meaningless.

CONTRIBUTIONS OF TIME USE RESEARCH

Time use research has gained momentum because of interest on the part of international agencies in comparing the functioning of societies in their national settings, the need to connect demographic change and social development, the need to focus on gender-related or generational variables to understand the changing role of the family, the awareness that economic variables reflect wealth and well-being only in very partial ways and that household and care activities must be brought into focus, and the need to construct articulated databases for decision making about social policy.

Since the late 1980s, nationally representative time use data sets have been available for several countries, but the evidence is not easy to compare because activity classifications do not always coincide. Therefore, with the hope that many European Union countries will participate in the very

Daily Time Use, in Hours and Minutes, for Primary Activities in the United States, France and Hungary, by Gender and Employment Status (1965–1966)

	United States (44 cities)	France (6 cities)	Hungary (Gyorz)

expensive data-gathering process, Eurostat is preparing a standardized survey. Up to the present, only Japan has truly comparable five-year time series data to indicate trends and changes in lifestyle since 1970 (NHK 1991). In terms of Monday-to-Friday behavior, for instance, sleeping time and housework have decreased while market work has not. Over the years, leisure on all weekdays, especially hobbies, private lessons, and sports activities have grown steadily. Television viewing time reached a peak in 1975 (probably because of the advent of color television) but returned in 1990 to the 1970 level. The illustrations confirm the rule that trend-setting evidence of new life styles is found not so much in the main activity categories but in apparently marginal activities.

To demonstrate the interest of time-budget data in a comparative assessment of the different logics of time structurization, it is best to choose an example from the uniform data set gathered in the Twelve Country Study.

In Table 1, the patterns of daily urban time allocation ascertained in 1965–1966 for the United

States, France, and Hungary are presented in the most synthetic form. The data refer to an average weekday and compare time use for personal needs (mostly sleep and meals), market work or study, household work, leisure, and non-work-related travel among adults aged 18–65, subdivided by gender and employment status.

When one compares the starkly different research contexts of those days (market economy, welfare state, state-controlled system), a set of clear-cut differences in time use emerge from these different ways of life; at one extreme the United States and at the other Hungary, with France in between. The average duration of market work was much shorter in American cities than in Hungarian ones; this was due mainly to the fact that employed women were more likely to hold part-time jobs in the United States, while in Hungary they held full-time jobs. Across the three countries, household work and leisure show systematic secular trends. Employed American men enjoyed one hour more of leisure and contributed half an hour less to housework than did their

Hungarian counterparts. For employed American women, housework lasted one hour less, and leisure lasted one and a half hours more than was the case for employed Hungarian women. Finally, household work among unemployed American women required two hours less time and leisure benefits lasted two hours longer than was the case for the corresponding group in Hungary. The uneven availability of household appliances and unequal access to leisure amenities (in particular, television) were the causes of these differences in lifestyles. In addition, the table reveals well-known inequalities in gender and employment status. If one combines the time invested in market work and housework, it appears, though less significantly in the west than in the east, that women in the labor force contributed a considerably larger share of work and enjoyed much less leisure than did employed men.

Table 2 shows that gender differences are clearly implicated in the discrepancies in the number of hours of economic activity and housework per week between men and women, indicating that there are analogous patterns of inequality in developing countries such as Bangladesh, India, and Nepal. In these countries, women are more likely to spend their time in subsistence activities, whereas men tend to have a monopoly of paid jobs. In addition, women's time investment in housework is six times that of men in Bangladesh and three times that of men in the other two countries. However, the gap in overall work hours, though disadvantaging women, is less evident. In fact, in Bangladesh they contribute 54 percent of the total micro-productive time input, in India 55 percent, and in Nepal 58 percent.

Data from the French national survey (Insee 1989) on the effect of cumulative social roles among women are much more analytic. In France, for mothers with husbands under 45 years of age and at least one child younger than 25 years old, increasing from one child to three and more children means, if they are unemployed, an increase of one hour and fifteen minutes of house work and, if they are employed, an increase of fifty-two minutes. Where does this extra time come from? In the case of especially pressured employed mothers, the time investment in human capital in the form of caring for additional children implies a

reduction of one hour and thirteen minutes in the duration of market work, including a seven-minute reduction in free time and fourteen minutes less of sleep. Especially for women with more than one child, this negatively affects their competitive position in the professional world. Data such as these should be of interest to policymakers.

This example also shows that considerable caution is required in interpreting time use data. In general, estimates of differential time allocations for men and women in certain activities do not reflect only gender differences. Demographic variables, especially family composition, the structure of the labor force, and the availability of household help, intervene in causal links between gender and time use. Particular attention must be paid to these influences in longitudinal analyses such as that of Gershuny and Robinson (1988), which analyzed U.S. and British time-budget data over three decades. Statistically controlling for female labor force participation, male unemployment, and declining family sizes, those authors concluded that in the 1980s, women did substantially less housework while men did a little more than in the 1960s. In another study that analyzed data from repeated surveys in eight Western countries, a general reduction in time dedicated to all kinds of work was found, along with a convergence of time use models among males and females and a growing international similarity in the patterns of the division of time between work and leisure (Gershuny 1992).

In recent decades, considerable progress has been made in representing the multidimensionality of time use phenomena because official data, instead of regarding samples of randomly chosen individuals, have been collected from all members of households. This has made it possible to observe how husbands' time management affects their wives and vice versa and to determine what it means for families if both husband and wife are employed and if children come into the family nucleus.

In Table 3, pertinent data on couples from the national time use survey conducted in Germany in 1990-1991 are presented. It shows time use models for types of families defined by employment status and the presence of children. Assuming the operation of compensatory mechanisms, it also

Time Use in Three Southern Asian Countries (1982–1992)

Countries:	Social Groups:	Hours per week of economic activity			Hours per week of housework	Total work hours per week
		Paid	Subsistence	Total		
Bangladesh	Ages 5+ Women	14	8	22	31	53
	Men	38	3	41	5	46
India	Ages 18+ Women	28	7	35	34	69
	Men	43	4	47	10	57
Nepal	Ages 15+ Women	18	17	35	42	77
	Men	29	12	41	15	56

Table 2

SOURCE: United Nations, *The World's Women 1995: Trends and Statistics*, Chart 5.3, 1995, New York.

takes the weekly rhythm of time use into account by distinguishing workdays (Monday to Friday) from weekends (Saturday and Sunday).

One model regards more traditional couples in which only husbands are employed and wives do most of the housework. Husbands increase their market work when there are children, but regardless of the presence of children, they defend their daily leisure and contribute to housework mostly on weekends. The other model concerns couples in which both partners are employed. In this case, it is not surprising that the wives' market work is considerably shorter than the husbands', but what is important is that in the presence of children, both partners increase their market work by more than one hour each. The housework of mothers increases on all days, whereas fathers limit increases in their domestic chores to the weekends.

From a micro perspective, what the German example shows are the implications of decisions made within the family. Here the family is seen as the institutional arena where partners search for a suitable compromise in their interlocking role definitions. From a macro perspective, the implications of gendered time use arrangements for the changing division of labor and the growing interaction between the market sector and the household sector are important. Sociologists and economists have often criticized the fact that mostly female domestic and caring activities, mostly male "do-it-yourself" repair initiatives, and voluntary

and other socially useful work done by both men and women go unrecorded in labor statistics and national accounts. These are "productive activities" insofar as they can be delegated to persons other than those who benefit from them.

Table 4 shows a selection of the results of a United Nations Development Programme analysis of a posteriori standardized time budget data from the most recent national surveys conducted in fourteen different countries (Goldschmidt-Clermont and Pagnossin-Aligisakis 1995). This analysis distinguishes between market oriented System of National Accounts (SNA) activities considered in the UN System of National Accounts and non-SNA activities, and introduces the necessary controls for the demographic structures of the populations.

Despite the nonhomogeneous social structures and value systems of France, Germany, Great Britain, and the United States, everywhere statistically unrecorded (non-SNA) activities absorb about as much labor time as do recorded (SNA) activities. Furthermore, total economic time allocations (SNA plus non-SNA) tend to be equal among men and women. Although this demonstrates social equality in general terms, it can be seen that very strong gendered divisions of tasks prevail in all cases. In fact, in these four countries, women contribute only one-third of total market-oriented productive time, whereas they contribute two-thirds of total non-market-oriented productive time.

The availability of comparable time budget data is a prerequisite for official statistics that aim

Workday and Week-End Time Use of Husbands and Wives in German Households defined by the Employment Status of the Couple and the Presence of Children in the Family (1990-1991).

Activity categories	Husbands				Wives

to include the production value of nonmonetized activities, through “satellite accounts,” in their quantitative frameworks. The most recent national time use surveys have been conducted with these applications in mind.

THE RELEVANCE OF TIME-BUDGET DATA SETS FOR SOCIAL POLICY

Sociologists have often been skeptical about the utility of time-budget research. Time budgets are thought to provide data that are “broad but shallow” (Converse 1972, p. 46) and offer no more than static, tendentially commonsense descriptions of only the manifest aspects of everyday life. From a theoretical point of view, it is argued that there is a lack of explanatory hypotheses and relevant concepts that could bring norms, experiences, attitudes, and values to the fore. On the methodological side, the main criticism is that classification schemes of activities are imprecise, are unevenly general or detailed, and have barely changed since the 1920s (Pronovost 1989, pp. 78-80). Implicit in these observations is the dilemma Szalai faced earlier: whether priority should be assigned to the

testing of hypotheses or to multipurpose database construction. With the latter option comes the question of how to reconcile, in designing the studies, cross-national and longitudinal comparability and adherence to sociocultural settings and historically changing conditions.

Time-budget research is applied research that has increasingly been aimed at the design and evaluation of social policy. Its relevance in this context derives from the fact that in modern affluent societies, citizens often value scarce time more than material or monetary resources; thus, time use rationalization and efficient time management in the personal, family, and public sphere have become matters of general concern. Contingencies curtailing time use evidently are distributed unequally in the social world. For instance, health checks in public institutions often involve waiting times that private medical care does not, and not owning a means of transportation makes long commuting times unavoidable. Hence, social policies and their provisions try to make circumstances or opportunities more equal for everyone. Part-time employment, flexible worktimes, and compressed workweeks have been introduced mostly for pressured working mothers with small chil-

Distribution of Economic Time in Four Countries Between SNA and Non-SNA Activities, by Gender. Indices Showing Unequal Participation of Men and Women in Each Group of Activities

dren. Shop-opening hours and office schedules have been changed to permit effective coordination and a better reconciliation of tasks. The effectiveness these measures can be monitored with the help of time-budget procedures.

The complexity of time-budget data sets has often been insufficiently exploited. Initially this was due to limitations in handling enormous data sets, but increased technological resources and new multivariate statistical techniques have opened new frontiers. Almost exclusive attention has been given to average durations and frequencies of primary activities, but the study of configurations emerging from an association of these activities with other contemporaneous activities promises a better understanding of modern time regimes. Until now, not much research has been done on routinized rhythms or the strategic sequencing of activities. Also, the collaborative or conflicting interface of the various schedules of family members, the reconstruction of networks of participative personal contacts (a topic of great significance in regard to lonely children, the ill, and the elderly), and the relationship of the use of urban spaces to

time use (a problem studied by human geographers) are all interesting areas for future research because of the greater availability of important data sets.

Activity classifications will have to undergo critical study to better reflect changes in the activity patterns of everyday life. Statistical offices are presently reconceptualizing their taxonomies. Paid work might be broken down into its constituent parts and examined analytically, but other activities need redefinition. For example, some kinds of domestic work have been absorbed by the market; care activities now regard the elderly more than children; dealing with service bureaucracies has become a time-consuming task; there is a new spectrum of voluntary forms of participation at the social, political, and cultural levels; and leisure behavior has changed in relationship with new media.

However, the problem is not just a technical one regarding exclusively descriptive coding schemes. Time use data assume importance only when they provide a valid epistemological key for the interpretation of social change. As has already been

pointed out, earlier lines of research identified two central components of time use: market work and leisure. Today, time use studies based on data from household samples may help identify other valid criteria of time use to better understand how families cope with growing structural unemployment and increasing social insecurity.

ELKE KOCH-WESER AMMASSARI

TOURISM

Tourism is an economic phenomenon with important sociocultural implications that acquired a fundamental significance in the last decades of the twentieth century. It is one of the economic sectors with the highest rates of growth, together with transportation, communications, and the computer industry, with which it works in a synergistic way.

According to a classic definition, tourism can be identified in the complex of relations and manifestations that rise from the travel and stay of foreigners when the stay is temporary and is not motivated by a lucrative occupation (Hunziker and Krapf 1942). "Foreigners" are persons who do not reside habitually in the zone in which the tourist activity is carried out; depending on whether the zone of residence is in the same state, one can distinguish between internal tourism and international tourism.

Other elements have to be considered in distinguishing fully-fledged tourism from similar activities. First, two "fundamental actors" have to be dealt with. On one side, there are tourists (*active tourism*), who decide to undertake this activity because of several motivations. This is one of the primary topics in the sociopsychological analysis of tourism. On the other side, there is *passive* (or receptive) *tourism* constituted by the technical and socioeconomic structures that exist in the zones of reception with the aim of hosting tourists. In modern tourism, a third actor, consisting of agents of tourist intermediation (travel agencies, tour operators, carriers, etc.), has assumed greater importance by connecting the demand for and the supply of tourism. The tourism described here is essentially a mass phenomenon that exists alongside elite tourism, which was the first type to appear.

Merchant writers such as Marco Polo, traveler-explorers, and missionaries, often accompanied by anthropologists and ethnologists, were the forerunners of tourists, but only after the "Grand Tours" of the eighteenth and nineteenth centuries can one speak of the emergence of the tourist phenomenon. The grand tour was considered a fundamental stage in the formation of young aristocrats and later of the children of the emergent high bourgeoisie. It consisted of a visit to the more centers of the culture of the age, with a predilection for southern Europe, in particular Italy and its remnants of classic culture.

Toward the end of nineteenth century, with the inauguration of the first seaside resorts, tourism began to acquire mass characteristics, a phenomenon that was facilitated by the improvement of transportation systems, especially the extension of the railway network (Urry 1990).

The transformation of elite tourism into a phenomenon that involved wide strata of the popu-

lation did not occur until after the end of World War II and, in the more economically developed countries, the possession of the automobile as an individual and family means of transportation and the expansion of transcontinental and transoceanic flights.

Tourism is therefore facilitated, in addition to the elevation of individual incomes and better tariff conditions, by technical, political, and social factors. It also involves a psychological evolution in society, especially in the richer countries, where it provides an escape from the stresses of city life and the daily routine. A stronger desire for social intercourse has grown along with a desire for physical activity to compensate for a sedentary lifestyle.

Certain forms of travel have a demonstrative scope, since "to tour," in particular elite tourism but also mass tourism, may be thought of as an expression of one's prestige and social position.

Urry (1990) introduced the concept of the "tourist gaze," stating that "part at least of that experience is to gaze upon or view a set of different scenes, of landscapes or townscapes which are outside of the ordinary" (1990, p. 1). As Urry describes it:

1. "tourism is a leisure activity which presupposes its opposite, namely regulated and organized work, . . .
2. tourist relationships arise from a movement of people to, and their stay in, various destinations. This necessarily involves some movement through the space, that is the journey, and a period of stay in a new place or places,
3. the journey and stay are to, and in, sites which are outside the normal places of residence and work. Periods of residence elsewhere are of a short-term and temporary nature, . . .
4. the places gazed upon are for purposes which are not directly connected with the paid work and normally they offer some distinctive contrasts with work (both paid or unpaid);
5. a substantial proportion of the population of modern societies engages in such tourist practices, new socialized forms of

provision are developed in order to cope with the mass character of the gaze of tourist (as opposed to the individual character of “travel”)

6. places are chosen to be gazed upon because there is an anticipation, especially through daydreaming and fantasy, of intense pleasures, either on a different scale or involving different senses from those customarily encountered, . . .
7. the tourist gaze is directed to features of landscape and townscape which separate them off from everyday experience. Such aspects are viewed because they are taken to be in some sense out of the ordinary, . . .
8. the gaze is constructed through signs, and tourism involves the collection of signs, . . .
9. an array of tourist professionals develop who attempt to reproduce ever-new objects of the tourist gaze. . . (Urry 1990, pp. 2-3 passim).

THE DIMENSIONS OF THE PHENOMENON

The modern growth of tourism (Prosser 1994, p. 19) has been referred to ironically by Lodge (1992) as the “new global religion,” and a work on this phenomenon is entitled “*The Golden Hordes*” (Turner and Ash 1975). Prosser also supplies some data on a “phenomenon” that he describes by using the metaphor of the tsunami: By the mid-1990s, the tourism sector constituted 6 percent of world gross national product and 13 percent of the money spent for consumption and could be defined as the fastest-growing industry. According to the forecasts of the World Tourism Organization, in the year 2005, the tourist industry will involve 40 million persons.

Taking into account only persons who cross their state borders for tourism (perhaps equally important is the internal tourist movement), more recent data show, in approximately a decade, a near doubling of the phenomenon and also indicate that total revenues have increased to three times their original amount (Table 1).

The distribution of tourism in a wide range of countries has occurred in time span of only a few years. Tourism in the industrialized countries, while

Arrivals and Revenues in International Tourism

1995	566	393
1996	592	423

Table 1

SOURCE: World Tourism Organization.

declining in relative terms, accounts for ever 50 percent of the total, but the share of the developing countries has grown and now accounts for almost a third of the total. The countries of central and eastern Europe still suffer from the backwardness of decades of relative inaccessibility, but after the fall of the Berlin wall, their proportion of the world tourism has grown (Table 2).

France is the leader in tourist presence, followed by the United States and two countries of Mediterranean Europe, Spain and Italy. In fifth place is China, a country only recently opened to international tourism that has a large potential that has been limited by a deficiency of infrastructure and receptive structures.

The forecasts of an increase of tourism are plausible because some countries of the former communist bloc already play an important role. Other developing countries (e.g., Brazil and South Africa), apart from China, have potential and will be able to play a more important role in international tourism if they stabilize their political and/or economic situation.

There currently is a remarkable concentration of tourist destinations in which the top ten countries together account for over 50 percent of tourism and top twenty countries account for over two-thirds (Table 3).

These figures suggest that the market for tourism will grow and become more differentiated, that there will be more specialization and segmentation of that market, and that organized travel

Percentage Distribution of Tourist Presences

	1990 (%)	1996 (%)
Industrialized countries	61.5	55.8
Developing countries	28.3	31.0
Central and eastern Europe	10.2	13.2

packages will become more personalized to cope with the desire for greater individual freedom through a modular design of the product (Schwaninger 1989).

THE NATURE OF TOURISM

Mass tourism is the main concern of this article inasmuch as the current growth of the tourism industry essentially has resulted from it. Mass tourism is a “fickle” market in which status-elevating motivations are important. “If people do not travel, they lose status: travel is the maker of status” (Urry 1990, p. 5). The concept of conspicuous consumption (Veblen [1899] 1970) is operative here because in choosing a vacation, one takes into account the attributions of status defined on the basis of the place one visits and the characteristics of the other visitors.

One therefore is dealing with a market that is very sensitive to fashion and changes in values. The relative loss of importance of seaside resorts, which were the preferred destinations at the beginning of mass tourism, can be cited in this regard:

In the post-war period it has been the sun, not the sea, that is presumed to produce health and sexual attractiveness. The ideal body has come to be viewed as one that is tanned. This viewpoint has been diffused downwards through the social classes with the result that many package holidays present this as almost the reason for going on holiday. . . . Seaside resorts have also become less distinctive because of the widespread de-industrialization of many towns and cities so that there is less need to escape from them to the contrasting seaside. As the everyday has changed, as towns and cities have become de-industrialized and many have themselves become objects for the tourist gaze, with wave machines and other features of the

beach, so seaside resorts are no longer extraordinary. (Urry 1990, pp. 37–38)

Tourism is therefore a fashion phenomenon that goes through all the typical phases of a product of that type, from discovery and emergence, to increasing popularity, saturation, attenuation of its appeal, and eventually decline. It is sensitive to the relationship between demand and supply, based on perceptions, expectations, attitudes, and values of people, and therefore is subject to cultural filters:

The various contents and destinations of tourism, from the nineteenth Century to our days, seem to follow a standardized route . . . They are invented by individuals that live in conditions of originality and marginality in relationship to the ‘world.’ Subsequently they are consecrated by the notables: the monarchs and their families, followed by the artists and the celebrities . . . Finally they are diffused through the capillary imitation of the behavior of one social layer by the immediately inferior one. As soon as a place or a tourist fashion is known, there begins an emulation process that leads quickly to congestion; processes of distinction are then activated by groups that address to other places and invent other activities, reopening a new cycle. The succession of dissemination and invention cycles leads to the need for distinction to introduce more and more far and unusual goals. (Savelli 1998, pp. 92–93).

One can speak of the “pleasure periphery,” as in the case of the increase of Antarctic tourism (Prosser 1994, p. 22). For this aspect, the model of Plog (1973) is relevant. Plog analyzes the personality of the tourist: Along a continuum, one can go from psycho-centered, expectant subjects preoccupied with the small daily problems and escaping to adventures, to subjects who are as allocentered, confident in themselves, curious, and adventurous. The places visited by these varied subjects are obviously very different. In the survey conducted by Plog among the inhabitants of New York, while the psychocentered subjects do not venture beyond Coney Island, the midcentered travel to Europe and the allocentered do not dare to face the Pacific or Africa.

In dealing with tourism from a socioeconomic point of view, the “positional goods” concept

International Arrivals by Country, 1996

Country	Thousands of tourists	Country	Thousands of tourists

Table 3

SOURCE: World Tourism Organization.

(Hirsh 1978) can be used. This term refers to social goods, services, jobs, positions, and other relations that are scarce or subject to congestion and/or crowding. The competition is zero-sum: When someone consumes these kinds of goods in excess, someone else is forced to consume less. The supply is limited because quality would lessen as a result of quantitative growth.

One also can trace a conflict of interest between the actors described in the first part of this article (tourists, agencies, and the tourism industry in the hosting countries) and environmentalists. Since natural and cultural resources may be irremediably spoiled, there is thus a conflict of interest between present and future generations (Mishan 1969).

Another peculiar characteristic of tourism is that “almost all the services provided to tourists have to be delivered at the time and place at which they are produced. As a consequence the quality of the social interaction between the provider of the service, such as the waiter, flight attendant or hotel receptionist, and the consumer, is part of the ‘product’ being purchased by the tourist. If aspects of that social interaction are unsatisfactory (the offhand waiter, the unsmiling flight attendant, or the rude receptionist), then what is purchased is in effect a different service product” (Urry 1990, p. 40). Production of services for the consumer, in fact, cannot be done entirely behind the scenes, far away from the tourist gaze. Moreover, tourists have high expectations about what they will receive, since the search for the extraordinary is an essential aspect of the choice to travel.

“Spatial fixity” is a crucial characteristic of tourist services (Bagguley 1987), and customers are more mobile and now consume tourist services on a global scale. This means that “part of what is consumed is in effect the place in which the service producer is located. If the particular place does not convey appropriate cultural meanings, the quality of the specific service may well be tarnished” (Urry 1990, p. 40).

Since the services offered are intrinsically labor-intensive, employers try to diminish the costs. However, this may undermine the extraordinary character of the tourist experience (Urry 1990, p. 41).

TOURISTS AND THEIR MOTIVATIONS

In an attempt to grasp the features that distinguish tourists from other kinds of travelers, Cohen (1974) singles out certain dimensions that are thought to be essential: duration of the travel, voluntariness, direction, distance, recurrence, and purpose. On the basis of these elements, a tourist may be defined as a traveler who moves voluntarily and for a limited period of time to obtain pleasure from the experience of novelty and change, following a relatively long and non-recurring route.

For the sake of clarity, distinctions are introduced in the form of a dichotomy. However, one can assume that in many cases there are different degrees of distance from “full-fledged tourism.”

When the *duration* of the travel and stay is short (less than twenty-four hours in the definition of the UN Conference on International Travel and

Tourism), there are trips and excursions. There is also an upper limit, more difficult to determine, beyond which one can speak of permanent travelers (wanderers, nomads).

When the element of *voluntariness* is lacking, one is dealing with the exile (sometimes voluntary), the slave, the prisoner of war, or the political refugee. The pilgrim also can be considered a type of traveler who differs from the full-fledged tourist inasmuch as in many cases there is a lack of voluntariness. This is the case because social expectations can determine the decision to travel and the stay (e.g., pilgrimages to Mecca by Muslim believers).

In terms of *direction*, tourists return to their countries of origin, while immigrants make a one-way trip. There are also intermediate categories that are less easy to classify, such as "tourist immigrants" and "permanent tourists." These people leave home as tourists but decide to stay for a longer time span in a foreign country. Persons such as the "expatriates" (e.g., the many foreign artists who reside in cities such as Paris) are also difficult to define. They decide to live in a foreign country for indefinite periods without completely cutting their ties with the country of origin.

If the *distance* is short, one can speak of excursionists and hikers, while if the distance is much longer, one could have spoken in the past of explorers. Today, nearly all the possible destinations on the face of the earth seem to be within the reach of the tourist. If the distance implies crossing a national border, there is the already mentioned distinction between internal tourism and international tourism.

When travel and stay have a season or weekend regularity (*recurrence*), one is dealing with the *habitué*, who often is the owner of a summer house. This person is not properly a tourist, because the elements of novelty and change are lacking.

Finally, the *purpose* for the tourist does not have to be instrumental but can involve the seeking of pleasure. If the purpose is instrumental or has another specific nature different from the search for novelty and change, one is dealing with students, old country visitors, conventioners, business travelers, tourist employees, and the like.

However, this criterion is not as precise as it might appear at a first glance. The noninstrumental character of the purpose and the search for novelty and change has to be considered from a social point of view. When an individual takes a vacation for reasons of prestige, this travel is socially defined as a pleasure trip even if that individual will not enjoy the experience. More likely, there will be the opposite case: The purpose is declared as instrumental, but other instrumental (and not) purposes are also relevant (Savelli 1998, p. 57).

Tourists' motivations also can be analyzed by distinguishing the *push* factors that lead to the desire to go on vacation from the *pull* factors that the various areas of attraction exercise on the tourist (Savelli 1986, p. 2269).

To show the "versatility" of the tourism phenomenon, a relationship can be seen between some of its forms and the fundamental needs listed by Maslow. Therapeutic tourism satisfies physiological needs, while the needs of security and belonging are satisfied by familiar and "identity" tourism. The need for social recognition is catered to by tourism *à raconter*, (The French expression *à raconter* refers to a tourist who leads you to extraordinary places where extraordinary things happen that one is very pleased to narrate to friends, thereby obtaining social status.) and people satisfy the need for self-esteem through sport and cultural tourism (Kovacshazy and people 1998, p. 58).

To describe the psychological and social situation experienced by the tourist, some authors propose an interesting analogy between the tourist and the pilgrim. Both move from a familiar place to a distant one and then come back. In faraway localities, they dedicate themselves—although in different ways—to the "worship" of sacred places. These can be described as "liminoid" situations in which daily obligations are suspended (Turner and Turner 1978): "There is license for permissive and playful 'non-serious' behavior and the encouragement of a relatively unconstrained 'communitas' or social togetherness" (Urry 1990, p. 10). The purpose of a vacation thus consists of overturning the daily routine: Middle-class tourists try to be a "peasant for a day," while tourists with a lower social rank try to be "king/queen for a day" (Gottlieb 1982).

In a survey carried out in Italy (Isnart 1997) by interviewing only persons who go on vacation habitually, only the expenses for food and daily living were judged “more necessary” than those for traveling. The expenses for car use and maintenance and those undertaken to dress were lower than those for the consumption of vacations.

There often exists a link among subjective motivations, perception of the visited localities, and the objective connotations of those localities. Some connotations are always valid (effectiveness and efficiency, a proper quality–price ratio, a satisfactory environmental quality, the hospitality and warmth of the residents). Other connotations assume a nearly cyclical course: They gain a special reputation for one or two seasons and then fade out.

However, five major categories of motivations more or less summarize what this article has described so far:

1. *Subjectivity*: the sense of curiosity, interest, discovery, opportunity, and “digression” of the vacation
2. *Security*: the sense of confidence that vacation places must transmit and the possibility of relaxing (nearly the opposite of the insecurity of large cities)
3. *Transgression*: the willingness to have a good time, to push the limits, to have “extraordinary” and “sensual” experiences
4. *Budget*: the search for something that does not divert too many resources from other needs and opportunities
5. *Status*: the idea that travel is first of all social gratification, something to show, a reached goal (Isnart 1997, p. 16)

Among these categories of motivations, subjectivity prevails, with status and transgression not far behind. Obviously, budget is much more a concern of the elderly (who also appreciate security) and young people (who do not care much about status). Some of these differences are related to socioeconomic class.

THE IMPACT OF TOURISM

The tourist’s role is a total one: “He cannot hide his own externality from the local population and all his relations are imprinted and denoted, in the

first place, by the tourist role. In the same way, he is recognized as such from other tourists, regardless, in some manner, of his social condition, nationality, origin and race” (Savelli 1998, pp. 129–130).

The tourist’s presence therefore cannot pass unnoticed, and the increase of tourism can carry, besides the obvious economic advantages, some negative consequence in the countries that receive tourist flows. In this regard, there are pessimistic visions that are valid, especially for developing countries. These are the countries in which tourism can be expected to show steadily increasing rates of growth and in which there is more to earn from this development.

Tourist destinations are vulnerable, and one can even speak about economic colonialism, because investments and the largest part of demand are controlled by the developed countries. Exploitation can be not only economic but also social and environmental, inasmuch as community displacement, societal dislocation, and cultural transformation may occur (Ryan 1991): “Village farmland is appropriated, there is inter-generational stress as younger groups succumb to the ‘demonstration effect’ of tourist material wealth and behavior, intra-family stress as male-female role balance shifts, and community disharmony as religious ceremonies and artforms are commercialized” (Prosser 1994, p. 29).

Therefore, it is necessary to foster a sustainable tourism that tries “to sustain the quantity, quality, and productivity both of human and natural resources systems over time, while respecting and accommodating the dynamics of such systems” (Prosser 1994, pp. 31–32). This alternative form of tourism must “search for spontaneity, enhanced interpersonal relations, creativity, authenticity, solidarity, and social and ecological harmony” (Pearce 1989, p. 101).

The social relations between tourists and indigenous populations are complex and can lead to conflict as a result of several factors. Among the more important ones are the number of tourists who visit a place in relation to the size of the hosting population, the type of organization of the tourist industry, the effects of tourism on preexisting agricultural and industrial activities, economic and social differences between the visitors and the majority of the hosts, and the degree to which

visitors demand particular standards of lodging and service, that is, the expressed desire to be locked in an “environmental bubble” for protection from the “disappointing” characteristics of the hosting society (Urry 1990, p. 90).

As a counterbalance of these potential dangers, one has to consider that the cost of a new workplace in the tourist sector has been estimated at £4,000, compared with £32,000 in the manufacturing industry and £300,000 in mechanical engineering (Lumley 1988, cited by Urry 1990, p. 114). These are older figures, and therefore are not necessarily still valid, but the ratios probably continued to be valid. The “tourist prescription” therefore can be recommended particularly for countries that do not have many financial resources.

For tourism to be sustainable and respectful of the natural and social environment, the attitudes and behaviors of the three main actors must change:

- The attitudes of *tourists* must change. Tourists tend to believe that other tourists are the problem. Thus, their attitudes remain elitist and short-term.
- The *destination areas* must assume a longer-term attitude. An equilibrium between optimization of the revenues and protection of the resources must be found. Populations must be involved in all phases of development: ideation and planning, construction and implementation, conduction and management, and monitoring and modification.
- The *tourist industry* must find an equilibrium between opposing requirements. There is an unavoidable push for environmental control from foreign investors and operators in order to obtain greater profits that can be detrimental to local populations and governments. At the same time, the tourist industry feels the need to appear to be ecologically responsible (Prosser 1994, p. 32).

It has been proposed that tourism should be considered only a preliminary stage in which resources are obtained, that can be used later for “true” development through investment in other sectors. That is reasonable, because diversification is a key factor in economic security and stability, especially if tourism can be defined as a fashion

industry. However, one may question whether the impact of other industrial initiatives is less harmful and more sustainable than that of tourism. This opinion results from a dated attitude characterized by an ideologically rooted prejudice that is disappearing: “In the last few years in Britain many Labour councils have enthusiastically embraced local tourist initiatives, having once dismissed tourism as providing only ‘candy-floss jobs’” (Urry 1990, p. 115).

POSTMODERN TOURISM

While the countries that receive tourist flows need to find a balance between the advantages and disadvantages and search for a sustainable “receipt,” the benefits for tourists seem to be without shortcomings. Krippendorf (1987) speaks about “travel” that represents recuperation and regeneration, compensation and social integration, escape, and communication, intellectual expansion, freedom and self-determination, self-realization, and happiness.

The fact that the tourist industry continues to grow indicates that it is able to give a satisfactory answer to tourists’ expectations; otherwise there would be frustration, and the phenomenon would recede. One can ask why tourists continue to travel and their numbers continue to increase in spite of the “alarm bells” that call attention to the problem of overcrowding and the relative nonauthenticity of the tourist experience.

This article has dealt with the problem of overcrowding in its characterization of the tourist product as a “positional good.” This pessimistic thesis has been criticized by Beckerman (1974), who raises two interesting issues. First, the concern about the effects of the mass tourism is basically a “middle-class” anxiety (like many other environmental concerns) because the really rich “are quite safe from the masses in the very expensive resorts, or on their private yachts or private islands or secluded estates” (Beckerman 1974, pp. 50–51). Second, most people who are affected by mass tourism benefit from it, including the “pioneers,” who, when they return to a place, find services that were not available when the number of visitors was small.

One also can criticize the applicability of the scarcity concept to the tourist industry. The im-

PLICIT scarcities in the tourist industry are complex, and strategies can be adopted that allow the enjoyment of the same object by a greater number of persons. Thus, one must distinguish between the “physical capacity” and “perceptive capacity” of a tourist place (Walter 1982).

One also has to consider that in addition to the “romantic” tourist gaze, which emphasizes solitude, privacy, and a personal, quasi-spiritual relation with the observed object, there is an alternative “collective” gaze with different characteristics. The collective gaze demands the participation of wide numbers of other people to create a particular atmosphere: “They indicate that this is *the* place to be and that one should not be elsewhere.” (Urry 1990, p. 46). This is the case for major cities, whose uniqueness lies in their cosmopolitan character: “It is the presence of people from all over the world (tourists in other words) that gives capital cities their distinct excitement and glamour” (Urry 1990, pp. 46).

Some people prefer to move around in compact formations because otherwise they will not enjoy themselves, while others prefer to travel in solitude. Therefore, Hirsh’s (1978) thesis on scarcity and positional competition should be applied mainly to tourism characterized by the romantic gaze. When the collective gaze is more important, the problem of crowding and congestion is less marked. Moreover, the scarcity thesis would be totally applicable only if one maintained that there are severe limits to the number of “objects” worthy of the admiration of the tourist. However, “if Glasgow can be remade as a tourist attraction, one might wonder whether there are in fact any limits to the tourist, or post-tourist, gaze” (Urry 1990, p. 156).

Another issue refers to the nonauthenticity of the tourist experience. Turner and Ash (1975) describe a tourist who is placed at the center of a rigorously circumscribed world (the “environmental bubble”). Travel agents, couriers, and hotel managers are described as surrogate parents who relieve the tourist of every responsibility, protect the tourist from harsh reality, and decide for the tourist which objects are worthy to be admired.

Various types of tourists exist, and they are pushed by various needs and motivations for which various means are available to realize the tourist experience. In an age that is being defined as postmodern, the posttourist also is being redefined.

The post-tourist knows that they are a tourist and that tourism is a game, or rather a whole series of games with multiple texts and no single authentic tourist experience. The post-tourist thus knows that they will have to queue time and time again, that there will be hassles over foreign exchange, that the glossy brochure is a piece of pop culture, that the apparently authentic local entertainment is as socially contrived as an ethnic bar, and that the supposedly quaint and traditional fishing village could not survive without the income from tourism. (Urry 1990, p. 100).

The post-tourist knows that “he is not a time-traveller when he goes somewhere historic, not an instant noble savage when he stays on a tropical beach, not an invisible observer when he visits a native compound. Resolutely ‘realistic,’ he cannot evade his condition of outsider” (Feifer 1985, p. 271). This means that many travelers appreciate the “not-authenticity” of the tourist experience and “find pleasure in the multiplicity of tourist games. They know that there is *no* authentic tourist experience, that there are merely a series of games or texts that can be played” (Urry 1990, p. 11).

TRANSNATIONAL CORPORATIONS

A transnational corporation (TNC) is "any enterprise that undertakes foreign direct investment, owns or controls income-gathering assets in more than one country, produces goods or services outside its country of origin, or engages in international production" (Biersteker 1978, p. xii). Various terms multinational corporations (MNCs) and multinational enterprises (MNEs), transnational corporations are formal business organizations that have spatially dispersed operations in at least two countries. One of the most "transnational" major TNCs is Nestlé, the Swiss food giant; 91

percent of its total assets, 98 percent of its sales, and 97 percent of its workforce are foreign-based (UNCTAD 1998, p. 36).

TNCS AND THE GLOBAL ECONOMY

Although TNCs existed before the twentieth century (colonial trading companies such as the East India Company, the Hudson's Bay Company, and the Virginia Company of London were precursors of the modern TNC), only since the 1960s have they become a major force on the world scene (World Bank 1987, p. 45). Table 1 corroborates this by listing the foreign direct investment (FDI) stock of corporations by country from the beginning of the century to 1997. In 1900, only European corporations were major transnational players, but by 1930, American TNCs had begun to make their presence felt. The year 1960 marks the beginning of a new era in corporate transnationalization. In each of the decades from 1960 to the present, world FDI stock has more than tripled, whereas it only doubled during the first half of the century.

The phenomenal increase in transnational corporate activity in the latter part of the twentieth century can be accounted for in large part by technological innovations in transportation, communication, and information processing that have permitted corporations to establish profitable worldwide operations while maintaining effective and timely organizational control. The actual difference in foreign direct investment up to and after 1960 is even greater than the figures in Table 1 indicate. FDI for 1960 and before includes foreign *portfolio* investment, which is undertaken mainly by individuals, as well as foreign *direct* investment, which almost always is made by TNCs. These two types of investment were not reported separately for most countries before 1970. Thus, total FDI stocks are inflated. For example, Wilkins (1974, pp. 53–54) reports that in 1929–1930, U.S. foreign portfolio and direct investments were almost equal. American direct investment abroad was only \$7.5 billion; the remaining \$7.2 billion recorded in Table 1 was foreign portfolio investment.

Table 1 reveals that TNCs from only eleven countries accounted for almost 85 percent of all FDI in 1997. American TNCs accounted for more than one-quarter of total foreign investment, and

†Estimates.

‡World total, excluding former Comecon countries, except for 1997.

corporations based in the Triad (United States, European Union, and Japan) were responsible for nearly four-fifths of world FDI stock (UNCTAD 1998, pp. 379–384). Clearly, TNCs largely operate out of and invest in the developed countries of the global economy.

The magnitude of FDI flow in the world is revealed by the fact that worldwide sales of foreign affiliates in 1997 totaled \$9.5 trillion, almost one and a half times more than world exports of goods and services of \$6.4 trillion (UNCTAD 1998, p. 5). Global sales of affiliates are considerably more important than exports in delivering goods and services to markets worldwide, underlining the importance of TNCs in structuring international economic relations. In 1997, 53,607 TNCs controlled nearly 450,000 foreign affiliates throughout the world (UNCTAD 1998, p. 4).

Table 2 presents the top 30 TNCs ranked by foreign assets. Although fewer than one-quarter of these corporations are American in origin, most names are well known in the United States. It is the

nature of transnational enterprise to generate this degree of familiarity. Among the top 100 TNCs in terms of foreign assets, 41 originate in the European Union, 28 in the United States, and 18 in Japan (UNCTAD 1998, p. 317). Most FDI inflows and outflows take place within the Triad. In 1996, approximately one-quarter of all foreign sales was accounted for by these top 100 firms. Among the major industries in which these TNCs operate, electronics and electrical equipment account for the largest number (17), followed by chemicals and pharmaceuticals (16), automotive (14), petroleum and mining (14), and food and beverages (12). In 1996, these transnational giants employed nearly 6 million foreign workers (UNCTAD 1998, pp. 35–43).

**REASONS FOR BECOMING
TRANSNATIONAL**

The move toward integrated transnational investment can be seen as a logical and rational decision by business enterprises to adapt to their environ-

Reasons for Corporations Becoming Transnational

1. *Cost-Related Reasons*
 - a. To take advantage of differences in technological development, labor potential, productivity and mentality, capital market, and local taxes
 - b. Reduction of transport costs
 - c. Avoidance of high tariff barriers
 - d. To take advantage of local talents when establishing R&D overseas
2. *Sales Volume Reasons*
 - a. Foreign middlemen unable to meet financial demands of expanded marketing
 - b. For quicker adaptation to local market changes and better adaptation to local conditions
 - c. Following important customers abroad
 - d. Keeping up with competitors
 - e. Persuasion and coercion of foreign governments
 - f. To obtain a better international division of labor, larger production runs, and better utilization of available economies of scale
 - g. To avoid home country regulations, e.g., fiscal and antitrust legislation
3. *Reasons Related to Risk Factors*
 - a. To avoid exclusion from customers' and suppliers' markets, promoting forward and backward integration
 - b. To counter inflexibility and avoid country-specific recessions
 - c. To reduce risks of social and political disruption by establishing operations in a number of host countries

Table 3

SOURCE: Taylor and Thrift (1982), p. 21.

ment. Historically, there have been several distinct strategies: (1) expansion in the size of operations to achieve economies of scale, (2) horizontal integration, or the merging of similar firms to increase market share, (3) vertical integration, or the acquiring of firms that either supply raw materials (backward integration) or handle output (forward integration) to attain greater control, (4) spatial dispersion or regional relocation to expand markets, (5) product diversification to develop new markets, and (6) conglomeration or mergers with companies on the basis of their financial performance rather than what they produce (Chandler 1962, 1990; Fligstein 1990). Establishing an integrated TNC simply represents a new strategy in this evolutionary chain. Furthermore, depending on how a corporation is set up and with recent innovations in communications and information technology, a TNC can incorporate all these strategies so that the newly structured enterprise has far

greater control and a much less restricted market than it had previously.

Table 3 presents a list of reasons why it may be profitable for an organization to become transnational. First, direct costs for raw materials, labor, and transportation as well as indirect cost considerations such as tariff barriers and trade restrictions, local tax structures, and various government inducements obviously loom large in the decision to establish operations transnationally. Second, market factors may be equally important in that decision. Direct and easy access to local markets unfettered by foreign trade quotas and other legislative restraints can give TNCs an edge over their nontransnational competitors. Finally, the decision to become transnational may hinge on factors related to organizational control. Control over raw materials (backward integration) and markets (forward integration) and achieving sufficient regional and product diversification to withstand temporary economic downturns are other reasons for transnational relocation.

TNCS, NATION-STATES, AND GLOBALIZATION

Integrated TNCs traversing real-time electronic networks that span the global economy have produced a "borderless world" (Ohmae 1991). These technologically enhanced corporations also operate in the nonnationally controlled interstices of the planet (i.e., oceans, seabeds, airwaves, sky, and space), sometimes leaving toxic, life-threatening indicators of their presence. Existing in a sort of parallel world, they are responsible only to amorphous groups of shareholders. Gill and Law (1988, pp. 364–365) state that there is a "growing lack of congruence between the 'world economy,' with its tendencies to promote ever-greater levels of economic integration, and an 'international political system' comprised of many rival states." The rivalry between these two systems of world organization is revealed by the fact that 51 of the 100 largest economies in the world are TNCs (Karliner 1997).

The increasing domination of the world economy by TNCs directly challenges national sovereignty. Historically, the sovereignty and therefore the power of a nation-state lay in its ability to achieve compliance with whatever it commanded its territorially defined space. Borderlines physi-

cally defined what was territorially sovereign and what was not. If a state's sovereignty was challenged from outside its territory, it could resort to force to maintain control. However, as a result of various technological developments, the idea of a physically bounded and sealed state is now open to question. These developments underlie the transnational corporate threat to state sovereignty along the following three dimensions:

1. *Permeability of borders.* Borderlines between nation-states have been rendered permeable and porous in a number of innovative ways, erasing many of the traditional distinctions between "inside" and "outside." For example, what borders do electronic communications and atmospheric pollutants observe? Under whose borders do oil and gas reserves lie? Do space satellites invade territorial integrity? The new permeability of borders diminishes the capacity of nation-states to distinguish and determine what occurs "inside" their territory.
2. *Mobility across borders.* Developments in transportation, communication, and information technology not only have increased the rate of cross-border mobility among TNCs but also have increased the speed or velocity with which cross-border transactions take place. Concurrently measuring both the location and the velocity of TNC activity often produces "uncertain" results, generating "inderminacy" for a state.
3. *Border straddling.* To the extent that TNCs operate simultaneously in different sovereign jurisdictions, which jurisdiction has precedence over which corporate activities at what time? This complex issue blurs the legal boundaries between states. It also confuses the notion of "citizenship" and its attendant rights and responsibilities.

Through the use of these and other innovative strategies, TNCs have manipulated the concept of borders to their advantage. What exactly is the advantage that TNCs achieve through their cross-border flexibility? They gain between-border variability. The fact that different states have different laws and standards regarding all aspects of economic activity contributes to the power of TNCs that strategically play off one country's set of rules

against another's. For example, variations in national laws on tariffs, financing, competition, labor, environmental protection, consumer rights, taxation, and transfer of profits are all carefully weighed by TNCs in deciding where and how to conduct business. Together, these considerations form what has come to be known as "the policy environment" (UNCTAD 1993, pp. 173-175). In the international competition to attract foreign investment by creating a "favorable policy environment," between-border variability encourages a "race to the bottom" (Chamberlain 1982, p. 126), resulting in a continuing erosion of sovereignty. Whereas TNCs operate in a de facto borderless world created by technological ingenuity, de jure political and legal distinctions still mark the boundaries on a world map composed of nation-states. This represents the crux of the inherent conflict between TNCs and nation-states as they are currently structured.

Never before has there been a situation in which foreign organizations have been granted license almost as a matter of course to operate freely within the legally defined boundaries of a sovereign state. This, together with the fact that TNCs and nation-states are different organizational forms, established for different purposes, administered by different principles, and loyal to different constituencies, means that structural problems are bound to arise.

TNCS AND WORLD DEVELOPMENT

Although only 30 percent of FDI stock is in developing countries (UNCTAD 1998, p. 373), because of the immense power of many TNCs, great concern has arisen about the impact of TNCs on world development. Because the goals of transnational capitalist enterprise and indigenous national government are fundamentally different, many scholars have debated whether TNCs are an aid or a hindrance to world development. According to Biersteker (1978), the major points of contention in this debate are the degrees to which TNCs (1) are responsible for a net outflow of capital from developing countries, (2) displace indigenous production, (3) engage in technology transfer, (4) introduce capital-intensive, labor-displacing technologies, (5) encourage elite-oriented patterns of consumption, (6) produce divisiveness within local social structures owing to competing loyalties

to TNCs and nation-states, and (7) exacerbate unequal distributions of income.

In a study of many of these issues, Kentor (1998, p. 1025) analyzed a fifty-year data set consisting of seventy-five developing countries to determine whether the modernization thesis (i.e., FDI in developing countries promotes “economic growth by creating industries, transferring technology, and fostering a ‘modern’ perspective in the local population”) or dependency theory (i.e., FDI results in disarticulated economic growth, repatriation of profits, increased income inequality, and stagnation) better explains the long-term results of foreign direct investment. Kentor (p. 1042) summarizes his findings as follows:

The results of this study confirm that peripheral countries with relatively high dependence on foreign capital exhibit slower economic growth than those less dependent peripheral countries. These findings have been replicated using different measures of foreign investment dependence, GDP data, countries, time periods, and statistical methods. This is a significant and persistent negative effect, lasting for decades. Further, a structure of dependency is created that perpetuates these effects. The consequences of these effects, as described in the literature, are pervasive: unemployment, overurbanization, income inequality, and social unrest, to name a few.

Given current conditions, it would appear that overreliance on foreign investment by developing countries will widen the already huge global rift between rich and poor nations.

TNCS AND REGULATION

In the late 1960s, the United Nations (UN) reached the opinion that “transnational corporations had come to play a central role in the world economy and that their role, with its transnational character, was not matched by a corresponding understanding or an international framework covering their activities” (UNCTC 1990, p. 3). In the 1970s, the UN produced a draft “Code of Conduct on Transnational Corporations.” However, twenty years later, after much political wrangling, UN delegates concluded in 1992 that “no consensus was possible on the draft Code,” and thus the process of trying to achieve some effective legal

reconciliation between the goals of TNCs and those of host governments was brought to “a formal end” (UNCTAD 1993, p. 33).

Currently, although several international voluntary guidelines monitor the activities of TNCs, generally they have not been very successful (Hedley 1999). As of 1997, 143 countries had legislation in effect that specifically governs foreign direct investment (UNCTAD 1998, p. 53). Although initially most of those laws were framed to control the entry and regulate the activities of TNCs, legislative changes increasingly have become *more* favorable to foreign investment. For example, from 1991 to 1997, of the 750 changes to foreign investment policy made by countries worldwide, 94 percent were in the direction of liberalization (UNCTAD 1998, 57). In 1997, in attempts to ease high debt loads and survive a worldwide economic downturn, seventy-six developed and developing countries introduced 135 legislative inducements along the following lines: more liberal operational conditions and frameworks (61), more incentives (41), more sectoral liberalization (17), more promotion (other than incentives) (8), more guarantees and protection (5), and more liberal entry conditions and procedures (3) (UNCTAD 1998, p. 57). In their competition to attract foreign investment by creating favorable policy environments, these countries are yielding ever more control to TNCs.

Given the increasing dominance of TNCs in the global economy, the reasons why corporations become transnational, the diminishing sovereignty of nation-states, and the long-term effects of FDI on world development, one may question whether the move toward liberalization is in the interests of the countries and people who are encouraging it. What is called for is nothing short of a revolution in world governance. To regulate *transnational* corporations, it is necessary to introduce *trans-* or *supranational* legislation. To maintain national sovereignty in a global economy, authority must be coordinated and shared across borders. Legislative harmonization, although entailing an initial loss of sovereignty for participating states, can restore their authority over TNCs operating within their jurisdictions. By these means, corporate accountability can be imposed according to the needs and wishes of civil society. Whether or when such legislative harmonization will occur is open to question. However, in the view of the U.S. Tariff

Commission, "It is beyond dispute that the spread of multinational business ranks with the development of the steam engine, electric power, and the automobile as one of the major events of economic history" (cited in Lall and Streeton 1977, p. 15).

TYPOTOLOGIES

A typology is a multidimensional classification. The study of typological procedures is impeded by the use of a plethora of terms, some of which are used interchangeably. "Classification" can be defined as the grouping of entities on the basis of similarity. For example, humans can be classified into female and male. A related term is "taxonomy." According to Simpson (1961, p. 11), taxonomy "is the theoretical study of classification, including its bases, principles, procedures, and rules." Interestingly, the term "classification" has two meanings: One can speak of both the process of classification and its end product, a classification. The terms "classification," "typology," and "taxonomy" are all used widely and somewhat interchangeably in sociology.

Any classification must be mutually exclusive and exhaustive. This requires that there be only one cell for each case. For example, if humans are being classified by sex, this requires that every case

be placed in a cell (either male or female) but that *no* case be placed in more than one cell (no intermediate cases are allowed). It is assumed that the bases or dimensions for classification (such as sex) are clear and important (see Tiryakian 1968).

A type is one cell in a full typology. In sociology, emphasis often has been placed on one or a few types rather than on the full typology. The study of types developed largely as a verbal tradition in sociology and lately has been merged with a more recently developed quantitative approach.

In the verbal tradition, types were often defined as mental constructs or concepts, in contrast to empirically derived entities. Stinchcombe (1968, p. 43, original emphasis) says that “a *type concept* in scientific discourse is a concept which is constructed out of a *combination of the values of several variables*.” Lazarsfeld (1937, p. 120) says that “one is safe in saying that the concept of type is always used in referring to special compounds of attributes.” The variables that combine to form a type must be correlated or “connected to each other” (Stinchcombe 1968, pp. 44–45).

An important function of a type is to serve as a criterion point (for comparative purposes) for the study of other types or empirical phenomena. In this case, only a single type is formulated. The most famous single-type formulation is Weber’s ideal type:

An ideal type is formed by the one-sided accentuation of one or more points of view. . . . In its conceptual purity, this mental construct [Gedankenbild] cannot be found empirically anywhere in reality. It is a utopia. Historical research faces the task of determining in each individual case the extent to which this ideal-construct approximates to or diverges from reality, to what extent for example, the economic structure of a certain city is to be classified as a “city economy.” (1947, p. 90, original emphasis)

This strategy has been criticized. Martindale is startled by the suggestion that “we compare actual individuals with the (admittedly imaginary) ideal typical individuals to see how much they deviate from them. This is nothing but a form of intellectual acrobatics, for actual individuals ought to deviate from the ideal type just as much as one made them deviate in the first place” (1960, p. 382).

Seizing on Weber’s statement that the pure ideal type “cannot be found empirically anywhere in reality,” critics view the ideal type as hypothetical and thus without a fixed position, rendering it useless as a criterion point. A more realistic interpretation is that the ideal type represents a type that *could* be found empirically; it is simply that the purest case is the one most useful as a criterion, and this case is unlikely to be found empirically. As an example, a proof specimen of a coin is the best criterion for classifying or grading other coins, but it is not found empirically in the sense of being in circulation. If it were circulated, its features soon would be worn to the extent that its value for comparison with other coins would be greatly diminished.

The strategy of the ideal type is a sound one. Its logic is simple, and the confusion surrounding it is unfortunate, perhaps being due in part to the translation of Weber’s work. The genius of the ideal type lies in its parsimony. Instead of using a large full typology (say, of 144 cells, many of which may turn out to be empirically null or empty), a researcher can utilize a single ideal type. Then, instead of dealing needlessly with many null cells, the researcher need only fill in cells for which there are actual empirical cases and only as those cases are encountered. The ideal type is an accentuated or magnified version (or purest form) of the type. Although rarely found empirically in this pure form, the ideal type serves as a good comparison point. It usually represents the highest value on each of the intercorrelated variables or the end point of the continuum. While one could use the middle of the continuum as a referent (just as one uses the mean or median), it is convenient and perhaps clearer to use the end point (just as one measures from the end of a ruler rather than from its middle or another intermediate point).

Another single type that is used as a criterion is the constructed type. McKinney (1966, p. 3, original emphasis) defines the constructed type as “a *purposive, planned selection, abstraction, combination, and (sometimes) accentuation of a set of criteria with empirical referents that serves as a basis for comparison of empirical cases*.” The constructed type is a more general form of the ideal type.

In addition to formulations that use a single type, there are formulations that use two or more types. One strategy involves the use of two “polar”

types (as in the North and South poles). These types serve as two bracketing criteria for the comparison of cases. A famous set of types is Tönnies's (1957) *Gemeinschaft* and *Gesellschaft* ("community" and "society"). Another is introvert and extrovert. Still others are primary and secondary groups and localistic and cosmopolitan communities (see McKinney 1966, p. 101, for these and other examples).

SUBSTRUCTION

One problem with the common practice of using only a single type or a few types is that the underlying correlated dimensions on which they are based may not be clear. In some cases, it is possible to make these dimensions clear and extend them all to form a property space or attribute space; a set of axes representing the full range of values on each dimension. Then the existence of other potential related types that were not originally formulated, can be discerned. This process of extending the full property space and the resulting full typology from a single type or a few types is called *substruction* and was developed by Lazarsfeld (1937; Barton 1955). As an example, Barton (1955, pp. 51–52) performed a substruction in which the attributes underlying the four types of folkways, mores, law, and custom were extended to form a full property space. Barton found three underlying dimensions of the four types ("how originated," "how enforced," and "strength of group feeling") and combined them to form the property space.

REDUCTION

The opposite of substruction is *reduction*. Reduction is used when one has a full typology that is unmanageable because of its size. The three basic forms of reduction presented by Lazarsfeld (1937, p. 127) are functional, arbitrary numerical, and pragmatic. Lazarsfeld's functional reduction consists of discarding from the typology all empirically null and thus unnecessary cells.

The second form of reduction is arbitrary numerical. Lazarsfeld (1937, p. 128) provides an example: In constructing an index of housing conditions, one might weight plumbing without central heat or a refrigerator as being equal to the other two without plumbing. Coding the existence of an attribute by 1 and the lack of it by 0 and

taking variables in this order (plumbing, central heat, refrigerator), Lazarsfeld is saying that $(1, 0, 0) = (0, 1, 1)$. Thus, two previously different three-dimensional cells are equated and reduced to one.

Lazarsfeld's third form of reduction is pragmatic reduction. It consists of collapsing contiguous cells together to make one larger (but generally more heterogeneous) cell. As Lazarsfeld (1937, p. 128) says, "in the case of pragmatic reduction, certain groups of combinations are contracted to one class in view of the research purpose." For examples of these three forms of reduction, see Bailey (1973).

With Lazarsfeld's rigorous work as a notable exception, it can be said that most work in the typological tradition has been qualitative. Blalock, commenting on McKinney's (1966) constructive typology, says:

He [McKinney] also claims that there is nothing inherently anti-quantitative in the use of typologies. He notes that historically, however, researchers skilled in the use of typologies have not been statistically or mathematically inclined, and vice-versa. This may be one of the reasons for the existing gap between sociological theory and research. (1969, p. 33)

A persistent problem in the qualitative typological tradition has been the confusion over the status of the type as a heuristic device, a mental construct, or an empirical entity. Winch (1947) distinguished between heuristic and empirical types. He said that heuristic types are conceptually derived and may not have empirical examples. Empirical types, in contrast, result solely from data analysis, without prior conceptualization. A persistent problem with the conceptual types, such as the ideal type, has been the problem of inappropriate reification. If a type is a construct, concept, or model, it may not be found empirically but is designed only to be heuristically used in developing theory. However, there is often a tendency over time to reify the type or act as though it were actually found empirically. Figure 1 shows that the qualitative tradition has both heuristic and empirical types, while the quantitative tradition (discussed below) has primarily empirical types, as its types are derived from data analysis.

In other cases in the qualitative typological tradition, types are meant as empirical phenom-

	Qualitative	Quantitative
Heuristic	Ideal type	Probably null
Empirical	Ethnographic types	Types derived from cluster analysis or numerical taxonomy

Figure 1. A Typology of Typologies

ena rather than heuristic devices. This is particularly true in the area of social ethnography or field research, where researchers eschew statistical analysis but analyze data resulting from field studies by developing typologies based on observations recorded in their field notes (see Spradley and McCurdy 1972). Typologies in this case take the form of tables with names or labels in the cells rather than frequencies of occurrence as in statistical tables. Here the labels or types are generally inductively or empirically derived through intensive study of groups in the field. However, even here there may be a distinction between the types derived by the researcher and the types actually used by the people being studied. For example, the types that tramps identify among themselves (mission stiff, bindle stiff) may be different from the types identified by researchers or the lay public (bums, winos, homeless persons). For a discussion of taxonomies in ethnographic research and a number of examples of actual taxonomies (inducting the tramp example), see Spradley and McCurdy (1972).

EMPIRICAL DERIVATION

Computerization has brought on a new era of quantitative typology construction, which now coexists with the older qualitative tradition. This new approach often is called numerical taxonomy, cluster analysis, or pattern recognition (see Sneath and Sokal 1973; Bailey 1974). In contrast to the earlier verbal approach, which largely dealt with concepts and mental constructs, the newer quantitative approach is largely empirical and inductive.

It begins with a data set and derives empirical types from the data through a variety of quantitative procedures, many of them computerized.

This newer statistical approach to classification can be elucidated through the monothetic-polythetic distinction. A typology is monothetic if the possession of a unique set of features is both necessary and sufficient for identifying a specimen as belonging to a particular cell in the typology. That is, each feature is necessary and the set is sufficient. Thus, no specimen can be assigned to a particular type unless it possesses all the features (and no others) required of that type. This means that all the specimens in a given type are identical in every way (at least in all the features specified).

In contrast, a polythetic typology is constructed by grouping together the individuals within a sample that have the greatest number of shared features. No single feature is either necessary or sufficient (Sokal and Sneath 1963, p. 14). The objects or specimens are grouped to maximize overall similarity within each group. In a polythetic type, each individual possesses a large number of the classifying properties and each property is possessed by a large number of individuals. In the case where *no* single property is possessed by every individual in the group, the type is said to be fully polythetic.

While a verbal type (such as the ideal type) may be purely homogeneous (i.e., monothetic), it is unlikely that an empirically constructed type will be monothetic (except for some divisively derived types), especially if it contains a large number of cases grouped on a large number of variables. Thus, most empirically constructed types are polythetic, and some may be fully polythetic, without even a single feature being common to all the members of the group.

A basic distinction for all empirical classification techniques is whether one groups objects or variables. The former is known as Q-analysis, and the latter as R-analysis (Sokal and Sneath 1963, p. 124). In R-analysis, one computes coefficients (either similarity or distance coefficients) down the columns of the basic score matrix, which includes objects and variables (see Table 1 in Bailey 1972). In Q-analysis, one correlates rows. The interior data cells are the same in any case, and one form is the simple matrix transposition of the other. The difference is that Q-analysis correlates the objects

(e.g., persons), while R-analysis correlates the variables (e.g., age). While Q-analysis is the most common form in biology (see Sneath and Sokal 1973), it rarely is used in sociology (for an example, see Butler and Adams 1966). One problem is that Q-analysis requires a small sample of cases measured on a large number of variables, while R-analysis requires a large sample of cases with a smaller number of variables. Biology has the former sort of data; sociology, the latter.

Most sociologists have had little experience with Q-analysis. Most statistical analysis in sociology is concerned with relationships between two or more variables, with few studies making inferences concerning individuals rather than variables. Thus, the very notion of correlating individuals is alien to many sociologists.

Once the researcher has decided whether to pursue Q-analysis or R-analysis, the next step is to decide which measure of similarity to use. A researcher can measure similarity either directly, with a correlation coefficient, or indirectly, with a distance coefficient. While similarity coefficients show how close together two objects or variables are in the property space, distance coefficients show how far apart they are in that space. For a discussion of these measures, see Bailey (1974).

The next task of empirical typology construction is to parsimoniously group the cases into homogeneous types. There are two chief ways to proceed. One can envision all N cases as forming a single type. This is maximally parsimonious but maximizes within-group or internal variance. Grouping proceeds “from above” by dividing the cases into smaller groups that are more homogeneous. This is called the *divisive strategy*. Divisive classification generally proceeds by dividing the group on the basis of similarity on one or more variables, either simultaneously or sequentially. According to Sokal and Sneath (1963, p. 16), divisive classification is “inevitably largely monothetic.”

The alternative strategy (the *agglomerative strategy*) is to envision the N cases as forming N separate groups of one case each. Then each group is homogeneous (including only a single case), but parsimony is minimal. The strategy here is “classification from below” by agglomerating or grouping the most similar cases together, yielding some loss of internal homogeneity but gaining parsimony (as N groups are generally too unwieldy).

Unlike divisively formed types, agglomeratively formed types are generally polythetic and often fully polythetic.

The basic typological strategy is very straightforward and logically simple for divisive methods. All one must do is partition the set of cases in all possible ways and choose the grouping that maximizes internal homogeneity in a sufficiently small number of clusters. The problem is that the computation is prohibitive even for a modest number of cases measured on a modest number of variables.

A basic problem with empirically derived typologies is that they are generally static because the measures of similarity or distance that are used are synchronic rather than diachronic. While this is a problem, it is not a problem unique to classification but is shared by almost all forms of sociological analysis. Further, it is possible to deal with this issue by using diachronic data such as change coefficients or time series data.

Despite procedural differences, there are clear congruences between the qualitative and quantitative typological approaches. The ideal type is essentially monothetic, as are some types produced by quantitative divisive procedures. Quantitative procedures produce types that are polythetic, even fully polythetic. The results of quantitative procedures are generally not full typologies but reduced form that include fewer than the potential maximum number of types. Such polythetic types can be seen as analogous to the result of subjecting full monothetic typologies to reduction (either pragmatic or arbitrary numerical). Thus, contemporary typologists meet the need for reduction by using quantitative methods. Any correlational method of typology construction is by definition a method of functional reduction.

Further, the method usually will perform pragmatic reduction along with the functional reduction. Remember that pragmatic reduction collapses monothetic cells. The correlation coefficients utilized in typological methods are never perfect. The lower the correlations are, the more diverse the individuals in a group are. Placing diverse individuals in one group is tantamount to collapsing monothetic cells by means of pragmatic reduction. Thus, there are two basic avenues for constructing reduced types: Begin with monothetic types (such as ideal types) and subject them to the various forms of reduction to yield polythetic types

or construct polythetic types directly by using quantitative methods. Thus, the qualitative and quantitative procedures can produce similar results.

Given the breadth and diversity of sociological typologies (for example, from quantitative to qualitative procedures and from heuristic to empirical types), it is not surprising that there have been a number of criticisms of typologies. Some alleged problems are that typologies are not mutually exclusive and exhaustive, are treated as ends in themselves rather than as means to an end, are not parsimonious, are based on arbitrary and ad hoc criteria, are essentially static, rely on dichotomized rather than internally measured variables, yield types that are subject to reification, and are basically descriptive rather than explanatory or predictive. All these factors can be problems but are relatively easy for a knowledgeable typologist to avoid. The ones that cannot be easily avoided (such as the problem of cross-sectional data) often are seen as general problems for sociology as a whole and are not specific to typology construction.

MERITS

Even if pitfalls remain, the merits of carefully constructed typologies make them well worth the effort. One of the chief merits of a typology is parsimony. A researcher who is overwhelmed by thousands or even millions of individual cases can work comfortably with those cases when they are grouped into a few main types. A related merit is the emphasis on bringing simplicity and order out of complexity and chaos. A focus on the relative homogeneity of types provides an emphasis on order in contrast to the emphasis on diversity and complexity that is paramount in untyped phenomena. A third merit of a full typology is its comprehensiveness. There is no other tool available that can show not only all relevant dimensions but also the relationships between them and the categories created by the intersections. Such a typology shows the entire range of every variable and all their confluences. A fourth merit (as was noted above) is a typology's use of a type or types for comparative purposes. A fifth merit is a typology's use as a heuristic tool to highlight the relevant theoretical dimensions of a type. A sixth is a typology's ability to show which cells have empirical examples and which are empirically null. This can aid in hypothesis testing, especially when a

large number of variables have a small number of values that actually occur (Stinchcombe 1968, p. 47). A seventh merit is a typology's ability to combine two or more variables in such a way that interaction effects can be analyzed (Stinchcombe 1968, pp. 46-47).

TYPOLOGIES AND CONTINUOUS DATA

A clear but sometimes unstated goal of scientific development is to move past simple, nominal-variable analysis to the use of complex continuous-data models by employing ratio or interval variables. This has clearly been the case in sociology, which now depends on sophisticated regression models that work best with ratio (or at least interval) variables. Thus, some might argue that as science moves away from types toward the use of variables, typology construction becomes secondary.

Although the logic of moving from a reliance on types to a reliance on interval and ratio variables may seem irrefutable, this transition is not as smooth as some might wish. In fact, a number of obstacles to the transition from types to variables have arisen. Some researchers feel that once they have adopted sophisticated statistical techniques that use ratio variables, typologies are no longer needed. The reasoning here is that typologies are chiefly descriptive, arise at an early level of scientific analysis, and are essentially crude or unsophisticated formulations. In contrast, later models focus on explanation and prediction rather than description.

This notion belies the fact that science must constantly develop new ideas and theories to regenerate itself. As it does so, it must repeat the process of providing sound typologies that facilitate research by aiding in concept development and clarification and provide a comprehensive overview. Thus, it is a dangerous myth to think that sociology has "outgrown" the need for typologies. In fact, new ideas, theories, and sociological areas of research continually require new typologies. Even researchers in older, more mature sociological areas that have based their theory and research on inadequate typologies may find that the foundations of their field are crumbling, requiring new attempts to provide sound typological reinforcements.

In addition to the constant need for typological renewal and rejuvenation, some sociologists find

that attempts to move past types to sophisticated statistical analyses of ratio variables are confronted with a bewildering array of obstacles. Contemporary sociological statisticians who wish to rely on ratio variables are faced with a classic paradox. On the one hand, their regression models assume (or even demand) at least interval, or ideally ratio, variables. On the other hand, sociological theory is dependent on empirically important concepts, many of which are found to be essentially nominal or ordinal in their measurement levels. These include central ascribed or achieved statuses such as gender, race, religion, geographic region, nationality, occupation, and political affiliation.

Other important variables, such as income, education, and age, are more suitable for sophisticated statistical models. However, even these variables often are utilized theoretically in a limited ordinal form (young–old, high income–low income, etc.). Thus, there may be an empirical disjuncture between the type of variable needed for regression analysis (or other modern statistical techniques) and the type required by empirical sociological theory. Theory needs concepts such as race, gender, and religion, and these concepts are more suited for typological analysis than for regression analysis.

This suggests two areas of future research. One is to modify regression models to accommodate categorical variables, and this has been done (Aldrich and Nelson 1984). However, such accommodation may be costly, as it is unclear whether modified models operate efficiently or significantly underestimate the degree of explained variance. The second avenue is to rely more heavily on typological analysis. Although this may not seem as “sophisticated,” it may prove more compatible with theory and thus facilitate theoretical development more than statistical models do.

TYPOLOGIES IN THE AGE OF STATISTICS

If one has to choose between a sophisticated statistical analysis with variables that are not central to sociological theory and a typological analysis that accommodates theoretically important variables, it is foolish to rule out the latter in the name of scientific progress. Such progress would be false if the use of sophisticated techniques proved theo-

retically vacuous. This would be a classic case of the statistical tale wagging the theoretical dog. A wiser course is to recognize the complementarity between typologies and statistics. Statistics need not be viewed as necessarily or inevitably supplanting typologies; instead, each can be used when it proves valuable.

The conclusion to this point is that sociological progress has not rendered typological analysis obsolete by emphasizing statistical techniques such as multiple regression analysis. Thus, it may prove useful to look further at the epistemological foundations of contemporary sociology to see what the role of typologies is in an era when statistical analysis dominates. Consider the gap between the language of theory construction and the language of statistical data analysis. Imagine that a sociologist is interested in the type concept of “underachiever” and defines it as a person who has the ability to achieve at a higher level than is actualized.

When one substructures this type, it is clear that it is formed from two dimensions: (1) individual ability and (2) individual achievement. The sociologist can then theorize that an affluent childhood results in a particular type of personality. Individuals with that personality feel no pressing psychological need to achieve at a high level, since their needs continue to be met. This is an intriguing and ideographically rich sociological hypothesis. It involves images of a living person who has a particular type of childhood that leads to a particular type of adulthood. Thus, an earlier type concept (“the rich kid”) evolves into a later type concept (“the underachiever”). Conversely, one could hypothesize that the type concept of “impoverished youth” leads to the subsequent adult concept of “overachiever.”

The most direct way to test the hypothesis that the rich kid evolves into the adult underachiever is to identify a group of rich kids, follow them until adulthood, and then measure their subsequent achievement rates over a period of time. However, this is both tedious and time-consuming and is not the typical approach in social science. The most common approach is to gather cross-sectional survey data and then conduct a statistical analysis on the data. It is simple to select the two salient variables of parental wealth and adult achievement. Suppose one finds a negative correlation between parental wealth and adult achievement.

Since a negative correlation of achievement with wealth is not synonymous with the type concept of underachievement, the data analysis is not adequate to test the hypothesis.

Even if the statistical analysis were sufficient to test the hypothesis, a mere correlation value (e.g., $r = .43$) is very sterile and is isolated from both sociological reality and the richness of sociological theory. It fails to convey the richness of the type-concept description. While the type referent for the type concept of “underachiever” is the holistic, living human individual, the referents for the statistical analysis are the variables of wealth and achievement, which seem artificially separated from the sociological reality the theory refers to and the type concept manages to capture.

The unfortunate aspect of this for sociological development is that it leaves theory construction and statistical analysis as two juxtaposed but separate entities with a clear disjuncture between them. This disjuncture results from the fact that theorizing is largely a conceptual undertaking. It involves both deductive and inductive reasoning, and its language is the holistic language of the individual actor. The prime theoretical referent is the object, not the variable. This object is usually the human individual but can be an alternative object, such as a group, city, or country. In any event, the primary focus is on the object, with variables receiving a secondary focus. However, even if variables have the primary focus, the focus remains on both object and the variables.

In statistics using R-analysis such as multiple regression, the epistemological focus is quite different. Here objects such as persons enter the analysis only as data carriers in the sample. As soon as the R-matrix of correlations among variables is established, it suffices for the remainder of the analysis. The result is that the individuals virtually disappear from the picture except in those rare instances in sociology where Q-correlations are used.

Thus, theory and statistical analysis remain two separate paradigms within sociology rather than two aspects of the same research process. This obviously hinders scientific progress sociology and stands in stark contrast to the physical sciences, where theory and method are not separated processes but are well integrated, enabling much swifter progress.

INTEGRATING TYPES AND TAXA

One way to bridge the dichotomy between theory and statistical method is to link qualitative type concepts with the empirical clusters derived quantitatively through methods of numerical taxonomy. Following the lead of Bailey (1994), these are called taxa. As was noted above, types are generally conceptual, monothetic, and based on underlying R-dimensions (although the cell entries are empirical objects). In contrast, taxa tend to be empirical, polythetic, and Q-analytic (based on individuals). While the differences may seem to mimic the differences between theory and statistics discussed above, both types and taxa can be seen primarily as mirror images of each other and thus as having structural similarities that allow a bridge to be built from one to the other.

Since much theorizing is done in terms of types, a needed first step is to move from the realm of type concepts to the realm of empirical data analysis. While this traditionally is accomplished by turning from theory to statistical analysis, an alternative is to link conceptually formed types with statistically derived taxa.

The first task is to move from the conceptual to the empirical. As outlined in Bailey (1994, p. 66), this is rather straightforward and merely involves the identification of empirical cases for each conceptual cell. An example would be to locate an actual ethnographic type such as “bundle stiff” (Spradley and McCurdy, 1972). The empirical cases found for each cell in a typology (such as Figure 1) are equivalent to the taxa formed through cluster analysis. The second task in bridging the gap between types and taxa is converting from monothetic to polythetic. As was discussed above, this can be achieved in various ways, such as Lazarfeld’s (1937) process of pragmatic reduction. The third task is to connect the R-analysis of types with the Q-analysis of taxa. The easiest way to accomplish this is to use R-analysis for clustering.

In the other direction—from taxa to types—all the tasks are reversed and involve going from empirical to conceptual, from polythetic to monothetic, and from Q-analysis to R-analysis. Going from empirical to conceptual entails finding a concept to represent the statistically constructed group. For example, if the cluster analysis yields an empirical cluster composed primarily of people who scored very high on an exam, one

could formulate the type concept of "high achievers" to represent it.

The second task involves going from polythetic to monothetic. Technically speaking, this entails changing a heterogeneous empirical grouping to a homogeneous grouping and cannot be accomplished empirically except somewhat artificially. For example, Lockhart and Hartman (1963) constructed monothetic clusters by discarding all the characters that varied within the group. This is compensated for by the prior step, in which the conceptual type concept monothetically represents the empirical polythetic taxa. The third task is to achieve R-analytic clustering by using R-correlations rather than Q-correlations in the cluster analysis.

CONCLUSION

A well-constructed typology can bring order out of chaos. It can transform the overwhelming complexity of an apparently eclectic congeries of numerous apparently diverse cases into a well-ordered set of a few homogeneous types clearly situated in a property space of a few important dimensions. A sound typology forms a firm foundation and provides direction for both theorizing and empirical research. No other tool has as much power to simplify life for a sociologist.

The task for the future is the further elaboration of this crucial nexus between the qualitative and statistical approaches. This requires effort from sociologists with both theoretical and statistical talents. McKinney (1966, p. 49) recognizes the "complementary relationship of quantitative and typological procedures" and advocates "the emergence of a number of social scientists who are procedurally competent in both typology and statistical techniques." Costner (1972, p. xi) also recognizes the basic unity of the qualitative and quantitative approaches to typology construction.

For further information on typologies, see Capecchi (1966), Sokal and Sneath, (1963), Sneath and Sokal (1973), Bailey (1973, 1974, 1983, 1989, 1993, 1994), Hudson et al. (1982), Aldenderfer and Blashfield (1984), and Kreps (1989).

URBAN SOCIOLOGY

Urban sociology studies human groups in a territorial frame of reference. In this field, social organization is the major focus of inquiry, with an emphasis on the interplay between social and spatial organization and the ways in which changes in spatial organization affect social and psychological well being. A wide variety of interests are tied together by a common curiosity about the changing dynamics, determinants, and consequences of urban society's most characteristic form of settlement: the city.

Scholars recognized early that urbanization is accompanied by dramatic structural, cognitive, and behavioral changes. Classic sociologists (Durkheim, Weber, Toinnes, Marx) delineated the differences in institutional forms that seemed to accompany the dual processes of urbanization and industrialization as rural-agrarian societies were transformed into urban-industrial societies (see Table 1).

Several key questions that guide contemporary research are derived from this tradition: How are human communities organized? What forces produce revolutionary transformations in human settlement patterns? What organizational forms accompany these transformations? What differ-

ences do urban living make, and why do those differences exist? What consequences does the increasing size of human concentrations have for human beings, their social worlds, and their environment?

Students of the urban scene have long been interested in the emergence of cities (Childe 1950), how cities grow and change (Weber 1899), and unique ways of life associated with city living (Wirth 1938). These classic treatments have historical value for understanding the nature of pre-twentieth-century cities, their determinants, and their human consequences, but comparative analysis of contemporary urbanization processes leads Berry (1981, p. xv) to conclude that "what is apparent is an accelerating change in the nature of change itself, speedily rendering not-yet-conventional wisdom inappropriate at best."

Urban sociologists use several different approaches to the notion of community to capture changes in how individual urbanites are tied together into meaningful social groups and how those groups are tied to other social groups in the broader territory they occupy. An interactional community is indicated by networks of routine, face-to-face primary interaction among the members of a group. This is most evident among close friends and in families, tribes, and closely knit locality groups. An ecological community is delimited by routine patterns of activity that its members engage in to meet the basic requirements of daily life. It corresponds with the territory over which the group ranges in performing necessary activities such as work, sleep, shopping, education,

Classic Contrasts Between Urban and Rural Societies

Institution	Urban-Industrial	Rural-Agrarian
Agreements	Contractual	Personal
Authority	Bureaucratic	Paternalistic
Communication	Secondary	Primary
Integrative mechanism	Specialization	Common experience
Normative standards	Universalistic	Particularistic
Normative structure	Anomic	Integrated
Problem solution	Rational	Traditional
Production	Manufacturing	Agriculture
Social control	Restitutive	Repressive
Social relations	Segmentalized	All encompassing
Socialization	Formal	Informal
Stratification	Achieved status	Ascribed status
Values	Money and power	Family
World views	Secular	Sacred

Table 1

and recreation. Compositional communities are clusters of people who share common social characteristics. People of similar race, social status, or family characteristics, for example, form a compositional community. A symbolic community is defined by a commonality of beliefs and attitudes among its members. Its members view themselves as belonging to the group and are committed to it.

Research on the general issue of how these forms of organization change as cities grow has spawned a voluminous literature. An ecological perspective and a sociocultural perspective guide two major research traditions. Ecological studies focus on the role of economic competition in shaping the urban environment. Ecological and compositional communities are analyzed in an attempt to describe and generalize about urban forms and the processes of urban growth (Hawley 1981).

Sociocultural studies emphasize the importance of cultural, psychological, and other social dimensions of urban life. These studies focus on the interactional and symbolic communities that characterize the urban setting (Wellman and Leighton 1979; Suttles 1972).

Early theoretical work suggested that the most evident consequence of the increasing size, density, and heterogeneity of human settlements was a breakdown of social ties, a decline in the family, alienation, an erosion of moral codes, and social disorganization (Wirth 1938). Later empirical research has clearly shown that in general, urbanites

are integrated into meaningful social groups (Fischer 1984).

The sociocultural tradition suggests that cultural values derive from socialization into a variety of subcultures and are relatively undisturbed by changes in ecological processes. Different subcultures select, are forced into, or unwittingly drift into different areas that come to exhibit the characteristics of a particular subculture (Gans 1962). Fischer (1975) combines the ecological and subcultural perspectives by suggesting that size, density, and heterogeneity are important but that they produce integrated subcultures rather than fostering alienation and community disorganization. Size provides the critical masses necessary for viable unconventional subcultures to form. With increased variability in the subcultural mix in urban areas, subcultures become more intensified as they defend their ways of life against the broad array of others in the environment. The more subcultures, the more diffusion of cultural elements, and the greater the likelihood of new subcultures emerging, creating the ever-changing mosaic of unconventional subcultures that most distinguishes large places from small ones.

Empirical approaches to urban organization vary according to the unit of analysis and what is being observed. Patterns of activity (e.g., commuting, retail sales, crime) and characteristics of people (e.g., age, race, income, household composition) most commonly are derived from government reports for units of analysis as small as city blocks and as large as metropolitan areas. These types of

data are used to develop general principles of organization and change in urban systems. General questions range from how certain activities and characteristics come to be organized in particular ways in space to why certain locales exhibit particular characteristics and activities. Territorial frameworks for the analysis of urban systems include neighborhoods, community areas, cities, urban areas, metropolitan regions, nations, and the world.

Observations of networks of interaction (e.g., visiting patterns, helping networks) and symbolic meanings of people (e.g., alienation, values, worldviews) are less systematically available because social surveys are more appropriate for obtaining this kind of information. Consequently, less is known about these dimensions of community than is desirable.

It is clear that territoriality has waned as an integrative force and that new forms of extralocal community have emerged. High mobility, an expanded scale of organization, and an increased range and volume of communication flow coalesce to alter the forms of social groups and their organization in space (Greer 1962). With modern communication and transportation technology, as exists in the United States today, space becomes less of an organizing principle and new forms of territorial organization emerge that reflect the power of large-scale corporate organization and the federal government in shaping urban social and spatial organization (Gottdiener 1985).

Hawley's (1950, 1981) ecological approach to the study of urban communities serves as the major paradigm in contemporary research. This approach views social organization as developing in response to basic problems of existence that all populations face in adapting to their environments. The urban community is conceptualized as the complex system of interdependence that develops as a population collectively adapts to an environment, using whatever technology is available. Population, environment, technology, and social organization interact to produce various forms of human communities at different times and in different places (Table 2). Population is conceptualized as an organized group of humans that function routinely as a unit; the environment is defined as everything that is external to the population, including other organized social groups.

Technological advances allow people to expand and redefine the nature of the relevant environment and therefore influence the forms of community organization that populations develop (Duncan 1973).

In the last half of the twentieth century, there were revolutionary transformations in the size and nature of human settlements and the nature of the interrelationships among them (Table 3). The global population "explosion" created by an unprecedented rapid decline in human mortality in less developed regions of the world after 1950 provided the additional people necessary for this population "implosion:" the rapid increase in the size and number of human agglomerations of unprecedented size. Urban sociology attempts to understand the determinants and consequences of this transformation.

The urbanization process involves an expansion in the entire system of interrelationships by which a population maintains itself in its habitat (Hawley 1981, p. 12). The most evident consequences of the process and the most common measures of it are an increase in the number of people at points of population concentration, an increase in the number of points at which population is concentrated, or both (Eldridge 1956). Theories of urbanization attempt to understand how human settlement patterns change as technology expands the scale of social systems.

Because technological regimes, population growth mechanisms, and environmental contingencies change over time and vary in different regions of the world, variations in the pattern of distribution of human settlements generally can be understood by attending to these related processes. In the literature on urbanization, an interest in the organizational forms of systems of cities is complemented by an interest in how growth is accommodated in cities through changes in density gradients, the location of socially meaningful population subgroups, and patterns of urban activities. Although the expansion of cities has been the historical focus in describing the urbanization process, revolutionary developments in transportation, communication, and information technology in the last fifty years expanded the scale of urban systems and directed attention toward the broader system of the form of organization in which cities emerge and grow.

Comparative Urban Features of Major World Regions

Basic Feature	Nineteenth Century North America	Twentieth Century North America	Third World	Postwar Europe
Summary	Concentrated	Spread out	Constrained	Planned
Size	1–2 million	14 million	19 million	8 million
Density	High	Low	Medium	High
Timing	250 years long period	Emergent no pressure	Very rapid since 1950s	Very slow stationary
Scale	Regional and local	Inter-metro and global	Global and local	National and local
City system	Rank size regional	Daily urban national	Primate national	Rank size national
Occupations	Secondary manufacture	Tertiary services	Family and corporate	Diverse mixture
Spatial mix	Zone-sector core focus	Multinodal mosaic	Reverse zonal	Overlaid mixed use
Rural–urban differences	Great in all areas	Narrow and declining	Medium and growing	Narrow except work
Status mix	Diverse hierarchical	High overall poor pockets	Bifurcated high % poor	Medium compacted
Migration	Heavy rural-urban and foreign	Inter-metro and foreign	Heavy rural-urban circulation	Foreign skilled
Planning	Laissez-faire capitalism	Decentral, ineffective	Centralized, ineffective	Decentral, effective

Table 2

Much research on the urbanization process is descriptive in nature, with an emphasis on identifying and measuring patterns of change in demographic and social organization in a territorial frame of reference. Territorially circumscribed environments employed as units of analysis include administrative units (villages, cities, counties, states, nations), population concentrations (places, agglomerations, urbanized areas), and networks of interdependency (neighborhoods, metropolitan areas, daily urban systems, city systems, the earth).

The American urban system is suburbanizing and deconcentrating. One measure of suburbanization is the ratio of the rate of growth in the ring to that in the central city over a decade (Schnore 1959). While some Metropolitan Statistical Areas (MSAs) began suburbanizing in the late 1800s, the greatest rates for the majority of places occurred in the 1950s and 1960s. Widespread use of the automobile, inexpensive energy, the efficient production of materials for residential infrastructure,

and federal housing policy allowed metropolitan growth to be absorbed by sprawl instead of by increased congestion at the center.

As the scale of territorial organization increased, so did the physical distances between black and white, rich and poor, young and old, and other meaningful population subgroups. The Index of Dissimilarity measures the degree of segregation between two groups by computing the percentage of one group that would have to reside on a different city block for it to have the same proportional distribution across urban space as the group to which it is being compared (Taeuber and Taeuber 1965). Although there has been some decline in indices of dissimilarity between black and white Americans since the 1960s, partly as a result of increasing black suburbanization, the index for the fifteen most segregated MSAs in 1990 remained at or above 80, meaning that 80 percent or more of the blacks would have had to live on different city blocks to have the same distribution in space as whites; thus, a very high

degree of residential segregation remains. Although there is great social status diversity in central cities and increasing diversity in suburban rings, disadvantaged and minority populations are overrepresented in central cities, while the better educated and more affluent are overrepresented in suburban rings.

A related process—deconcentration—involves a shedding of urban activities at the center and is indicated by greater growth in employment and office space in the ring than in the central city. This process was under way by the mid-1970s and continued unabated through the 1980s. A surprising turn of events in the late 1970s was signaled by mounting evidence that nonmetropolitan counties were, for the first time since the Depression of the 1930s, growing more rapidly than were metropolitan counties (Lichter and Fuguitt 1982). This process has been referred to as “deurbanization” and “the nonmetropolitan turnaround.” It is unclear whether this trend represents an enlargement of the scale of metropolitan organization to encompass more remote counties or

whether new growth nodes are developing in nonmetropolitan areas.

The American urban system is undergoing major changes as a result of shifts from a manufacturing economy to a service economy, the aging of the population, and an expansion of organizational scale from regional and national to global decision making. Older industrial cities in the Northeast and Midwest lost population as the locus of economic activity shifted from heavy manufacturing to information and residentiary services. Cities in Florida, Arizona, California, and the Northwest have received growing numbers of retirees seeking environmental, recreational, and medical amenities that are not tied to economic production. Investment decisions regarding the location of office complexes, the factories of the future, are made more on the basis of the availability of an educated labor pool, favorable tax treatment, and the availability of amenities than on the basis of the access to raw materials that underpinned the urbanization process through the middle of the twentieth century.

The same shifts are reflected in the internal reorganization of American cities. The scale of local communities has expanded from the central business district-oriented city to the multinodal metropolis. Daily commuting patterns are shifting from radial trips between bedroom suburbs and workplaces in the central city to lateral trips among highly differentiated subareas throughout urban regions. Urban villages with affluent residences, high-end retail minimalls, and office complexes are emerging in nonmetropolitan counties beyond the reach of metropolitan political constraints, creating even greater segregation between the most and least affluent Americans

Deteriorating residential and warehousing districts adjacent to new downtown office complexes are being rehabilitated for residential use by childless professionals, or "gentry." The process of gentrification, or the invasion of lower-status deteriorating neighborhoods of absentee-owned rental housing by middle- to upper-status home or condominium owners, is driven by a desire for accessibility to nearby white-collar jobs and cultural amenities as well as by the relatively high costs of suburban housing, which have been pushed up by competing demand in these rapidly growing metropolitan areas. Although the number of people involved in gentrification is too small to have reversed the overall decline of central cities, the return of affluent middle-class residents has reduced segregation to some extent. Gentrification reclaims deteriorated neighborhoods, but it also results in the displacement of the poor, who have no place else to live at rents they can afford (Feagin and Parker 1990).

The extent to which dispersed population is involved in urban systems is quite variable. An estimated 90 percent of the American population now lives in a daily urban system (DUS). These units are constructed from counties that are allocated to economic centers on the basis of commuting patterns and economic interdependence. The residents of a DUS are closely tied together by efficient transportation and communication technology. Each DUS has a minimum population of 200,000 in its labor shed and constitutes "a multinode, multiconnective system [which] has replaced the core dominated metropolis as the basic urban unit" (Berry and Kasarda 1977, p. 304). Less than 4 percent of the American labor force is engaged in agricultural occupations. Even

the residents of remote rural areas are mostly "urban" in their activities and outlook.

In contrast, many residents of uncontrolled developments on the fringes of emerging megacities in less developed countries are practically isolated from the urban center and live much as they have for generations. Over a third of the people in the largest cities in India were born elsewhere, and the maintenance of rural ways of life in those cities is common because of a lack of urban employment, the persistence of village kinship ties, and seasonal circulatory migration to rural areas. Although India has three of the ten largest cities in the world, it remains decidedly rural, with 75 percent of the population residing in agriculturally oriented villages (Nagpaul 1988).

The pace and direction of the urbanization process are closely tied to technological advances. As industrialization proceeded in western Europe and the United States over a 300-year period, an urban system emerged that reflected the interplay between the development of city-centered heavy industry and requirements for energy and raw materials from regional hinterlands. The form of city systems that emerged has been described as rank-size. Cities in that type of system form a hierarchy of places from large to small in which the number of places of a given size decreases proportionally to the size of the place. Larger places are fewer in number, are more widely spaced, and offer more specialized goods and services than do smaller places (Christaller 1933).

City systems that emerged in less industrialized nations are primate in character. In a primate system, the largest cities absorb far more than their share of societal population growth. Sharp breaks exist in the size hierarchy of places, with one or two very large, several medium-sized, and many very small places. Rapid declines in mortality beginning in the 1950s, coupled with traditionally high fertility, created unprecedented rates of population growth. Primate city systems developed with an orientation toward the exportation of raw materials to the industrialized world rather than manufacturing and the development of local markets. As economic development proceeds, it occurs primarily in the large primate cities, with very low rates of economic growth in rural areas. Consequently, nearly all the excess of births over deaths

in the nation is absorbed by the large cities, which are more integrated into the emerging global urban system (Dogan and Kasarda 1988a).

Megacities of over 10 million population are a very recent phenomenon, and their number is increasing rapidly. Their emergence can be understood only in the context of a globally interdependent system of relationships. The territorial bounds of the relevant environment to which population collectively adapts have expanded from the immediate hinterland to the entire world in only half a century.

Convergence theory suggests that cities throughout the world will come to exhibit organizational forms increasingly similar to one another, converging on the North American pattern, as technology becomes more accessible globally (Young and Young 1962). Divergence theory suggests that increasingly divergent forms of urban organization are likely to emerge as a result of differences in the timing and pace of the urbanization process, differences in the positions of cities in the global system, and the increasing effectiveness of deliberate planning of the urbanization process by centralized governments holding differing values and therefore pursuing a variety of goals for the future (Berry 1981).

The importance of understanding this process is suggested by Hawley (1981, p. 13): "Urbanization is a transformation of society, the effects of which penetrate every sphere of personal and collective life. It affects the status of the individual and opportunities for advancement, it alters the types of social units in which people group themselves, and it sorts people into new and shifting patterns of stratification. The distribution of power is altered, normal social processes are reconstituted, and the rules and norms by which behavior is guided are redesigned."

LEE J. HAGGERTY

URBAN UNDERCLASS

No social science concept has generated more discussion and controversy in recent years than that of the urban underclass. Some argue that it is little more than a pithy and stigmatizing term for the poor people who have always existed in stratified societies (Gans 1990; Jencks 1989; Katz 1989; McGahey 1982). Others contend that the underclass is a distinct and recent phenomenon, reflecting extreme marginalization from mainstream economic institutions and aberrant behavior (drug abuse, violent crime, out-of-wedlock births), that reached catastrophic proportions in the inner cities by the early 1980s (Glasow 1980; Auletta 1982; Reischauer 1987; Nathan 1987; Wilson 1987, 1996). Among the multifaceted, subjective, and often ambiguous definitions of the urban underclass, most all include the notions of weak labor-force attachment and persistently low income (Jencks and Peterson 1991; Sjoquist 1990). Indeed, the first scholar who introduced the term "underclass" in literature characterized its members as an emergent substratum of the permanently unemployed, the unemployable and the underemployed (Myrdal 1962).

Widely differing interpretations of the causes of the presence of an underclass have been offered, ranging from Marxist to social Darwinist. The most influential contemporary analysis of the urban underclass is Wilson's (1996) *When Work*

Disappears. Building on his earlier treatise *The Truly Disadvantaged* (1987), Wilson links the origins and growth of the urban underclass to the structure of opportunities and constraints in American society. Its roots are hypothesized to lie in historical discrimination and the mass migration of African-Americans to northern cities in the first half of the twentieth century. Its more recent growth and experiences are posited to have resulted from industrial restructuring and geographic changes in metropolitan economies since the 1960s, in particular the economic transformation of major cities from centers of goods processing to centers of information processing and the relocation of blue-collar jobs to the suburbs. These changes led to sharp increases in joblessness among racially and economically segregated African-Americans who had neither the skills to participate in new urban growth industries nor the transportation or financial means to commute or relocate to the suburbs. Rapidly rising joblessness among inner-city African-Americans, together with selective outmigration of the nonpoor, in turn caused the high concentrations of poverty and related social problems that characterize the urban underclass (see also Kasarda 1985, 1989; Wilson 1991; Hughes, 1993).

Alternative views on the cause of the underclass appear in the works of Murray (1984), Mead (1988), and Magnet (1993). These conservative scholars view underclass behaviors as rational adaptations to the perverse incentives offered by government welfare programs that discourage work and a lack of personal responsibility among many for actions harmful to themselves and others. Abetted by well-intentioned but misguided public programs, joblessness and persistent poverty are seen more as the consequences of deviant behaviors than as the causes of those behaviors. For an elaboration of these competing views and a partial empirical assessment, see Kasarda and Ting (1996).

Measurement of the size of the underclass varies as much as explanations of its causes. A number of researchers have focused on individual-level indicators of persistent poverty, defined as those who are poor for spells from n to $n + x$ years (Levy 1977; Duncan et al. 1984; Bane and Ellwood 1986) and long-term Aid to Families with Dependent Children (AFDC) recipients (Gottschalk and Danziger 1987). In an empirical study, Levy (1977) estimated that approximately eleven million Ameri-

cans were persistently poor for at least five years. When the underclass was defined as those who were not need persistently poor for eight or more years, six million people were found in that category (Duncan et al. 1984). This represented approximately one-fifth of the thirty-two million Americans living in poor households in 1988 (Mincy et al. 1990).

Another measurement strategy focuses on the geographic concentration of the poor. Using the U.S. Bureau of the Census tract-level definitions of local poverty areas, Reischauer (1987) reported that among the population living in such poverty areas, the central cities housed over half in 1985, up from one-third in 1972. Jargowsky (1997) documented that along with the growth of poverty populations in metropolitan areas, the number of high poverty areas (defined as census tracts containing at least 40 percent poor people) more than doubled between 1970 and 1990. The number of African-Americans living in high-poverty areas, mostly segregated ghettos, climbed from 2.4 million to 4.2 million in that period, far outpacing other minority groups. By 1990, 34 percent of poor African-Americans in metropolitan areas resided in high-poverty census tracts (see also Kasarda 1993).

Massey and Denton (1993) present an analysis and simulations that lead them to conclude that concentrated poverty can be explained largely by two basic factors: the degree of spatial segregation of a racial group and the group's overall poverty rate. Their analysis and conclusion sparked heated debates over racial versus economic segregation explanations (Jargowsky 1997).

As was noted above, the concept of the underclass typically is considered to entail more than poverty. It also is posited to incorporate geographically concentrated behavioral characteristics that conflict with mainstream values: joblessness, out-of-wedlock births, welfare dependency, dropping out of school, drug abuse, and illicit activities.

While considerable debate continues to surround definitions and even the existence of the underclass, attempts have been made to measure its size by using aggregated "behavioral" indicators derived from census tract data. Ricketts and Sawhill (1988) measured the underclass as people living in neighborhoods whose residents in 1980 exhibited disproportionately high rates of school

dropout, joblessness, female-headed families, and welfare dependency. Using a composite definition in which tracts must fall at least one standard deviation above the national mean on all four characteristics, they found that approximately 2.5 million people lived in those tracts in 1980 and that those tracts were disproportionately located in major cities in the Northeast and Midwest. They reported that in underclass tracts, on average, 63 percent of the resident adults had less than a high school education, 60 percent of the families with children were headed by women, 56 percent of the adult men were not regularly employed, and 34 percent of the households received public assistance. Their research also revealed that although the total poverty population grew only 8 percent between 1970 and 1980, the number of people living in underclass areas grew 230 percent, from 752,000 to 2,484,000.

Mincy and Wiener (1993) and Kasarda (1993) updated Ricketts and Sawhill's analysis by using 1990 census tract data. Both found that the number and concentration of persons living in tracts with disproportionately high rates of problem attributes continued to rise in the 1980s, although not nearly as much as it did in the 1970s.

These location-based aggregate measures of underclass populations have been criticized on the grounds that aside from race, most urban census tracts are quite heterogeneous along economic and social dimensions. Jencks (1989; Jencks and Peterson 1991), for example, observes that with the exception of tracts made up of public housing projects, there is considerable diversity in residents' income and education levels, joblessness, and public assistance reciprocity in even the poorest urban neighborhoods. Conversely, considerable numbers of urban residents who are poor, jobless, and welfare-dependent live in census tracts where fewer than 20 percent of the families fall below the poverty line.

Nevertheless, while most scholars concur that behaviors linked to underclass definitions and measurements are found throughout society, it is the concentration of these behaviors in economically declining inner-city areas that is said to distinguish the underclass from previously impoverished urban subgroups. Geographic concentration is argued to magnify social problems and accelerate their spread to *nearby households* through social

contagion, peer pressure, and imitative behavior (Wilson 1987, 1996). The members of economically stable households selectively flee the neighborhood to avoid these problems. Left behind in increasingly isolated concentrations are those with the least to offer in terms of marketable skills, role models, and familial stability. The result is a spiral of negative social and economic outcomes for those neighborhoods and the households that remain.

Incorporating the effects of neighborhoods and social transmission processes means that the future research agenda on the urban underclass will be qualitative as well as quantitative in approach. Ethnographic studies of underclass neighborhoods, family structures, and individual behaviors will complement growing numbers of surveys on and sophisticated statistical analyses of the persistence and intergenerational transfer of urban poverty (see Anderson 1990, 1994; Furstenberg et al. 1999). Additionally more comparative studies will assess similarities to and differences from the American case in European, Latin American, and Asian cities. The root of this work stretches deep, building on classic culture of poverty (Lewis 1966) and social and economic marginalization theses (Clark 1965).

UTOPIAN ANALYSIS AND DESIGN

NOTE: Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.

"From the time of its first discovery, the island of King Utopus has been shrouded in ambiguity,

and no latter-day scholars should presume to dispel the fog, polluting utopia's natural environment with an excess of clarity and definition" (Manuel and Manuel 1979, p. 5).

But this ambiguity extends well beyond simple obscurity or murkiness; it reaches to unqualified contradiction. Many utopian visionaries have been denounced for their meticulous delineation of details as they constructed models of social worlds bearing no resemblance to existing, potential, or possible reality. Utopias, it would seem, suffer from the twin infirmities of ambiguity and excessive efforts to achieve clarity and definition. Our dictionaries tell us they are, on the one hand, ideally perfect places but, on the other hand, are simply impractical thought or theory. Utopians are customarily viewed as zealous but quixotic reformers. The books in which they describe their societies may be praised as fascinating, fanciful literature but not as scientific tomes.

It is quite possible as well as reasonable to view utopians as model builders. Models are quite different objects from what is being modeled and have properties not shared by their counterparts. "The aim of a model is precisely not to reproduce reality in all its complexity. It is, rather, to capture in a vivid, often formal way what is essential to understanding some aspect of its structure or behavior" (Weizenbaum 1976, pp. 149–150).

One occupational disability of model builders everywhere is a sort of pathological obsession with a single element, or at most a strictly circumscribed set of elements, of reality, along with an unwavering refusal to examine the larger milieu in which they are found.

In Sir Thomas More's *Utopia* (1653), a central value or societal goal is the concept of economic equality; but this does not include the notion of social equality. There exists in Utopia a large underclass of slaves who are assigned the more distasteful but necessary tasks of the society. This class is composed of war prisoners (More's society is not free of war), persons born into slavery (it is not free of slavery), condemned criminals from other countries who are purchased from foreign slave markets (crime has not been eliminated), and working-class foreigners (class distinctions persist) who volunteer for slavery in Utopia rather than suffer the unpleasant conditions in their home countries (ethnic and immigration difficulties con-

tinue to exist). All able-bodied persons in Utopia become part of its work force—slaves, male nonslaves, and even women! This is seen as an enormous augmentation of the work force. Within each household, however, male dominance prevails. Households are under the authority of the oldest free male. Women are specifically designated as “subordinate” to their husbands, as children are to their parents and younger people generally are to their elders. In Utopia, the applicability of equality is severely restricted.

In discussing utopias it is important to distinguish between analytic and design models. Analytic models purport to be summaries of existing empirical reality; design models are summaries or sketches of future, past, or alternative societies, social structures, or worlds.

Characteristically, utopian literature contains a critique of existing society along with a model of a different one. Frequently the design model incorporates a more or less indirect critique of an existing state of affairs. Plato's *Republic* (1941), the work that seems to have been the prototype of More's *Utopia*, was greatly influenced by the social conditions observed and experienced by Plato. He saw the Athens in which he lived as a very corrupt democracy and felt that in such a system politicians inevitably pandered to mobs. If the mob insisted upon venal demands, politicians found it necessary to agree with them or lose their own positions. Reform, he felt, was not possible in a corrupt society. In the *Republic* Socrates, voicing Plato's sentiments, concludes that “the multitude can never be philosophical. Accordingly, it is bound to disapprove of all who pursue wisdom; and so also, of course, are those individuals who associate with the mob and set their hearts on pleasing it” (1941, p. 201).

Interestingly, it has been suggested that Plato's hostility to democracy was, at least to some extent, shaped by his economic and social background. Members of his family were large landholders who, along with others in a similar position, saw the rise of commerce as a threat to their economic positions. Democratic government undermined their political preeminence, as did militant foreign policies. They had a great deal to lose through war because they were subject to heavy war taxes. Moreover, some had had their lands ravaged by Spartans during the Peloponnesian War; others

had retreated behind the walls of Athens. These conservative elements were not above attempting to subvert the democratic system (Klosko 1986, p. 10).

In any event, Plato's utopia is clearly elitist in nature. For a variety of reasons most utopian schemes seem to be controlled by elites of some sort. As one writer explains it:

They begin with the proposition that things are bad; things must become better, perhaps perfect here on earth; things will not improve by themselves; a plan must be developed and carried out; this implies the existence of an enlightened individual, or a few, who will think and act in a way that many by themselves cannot think and act. (Brinton 1965, p. 50)

For Plato, the elites were what he called philosophers. In a sense these were the theoreticians or model makers. The problem he saw was converting their models—their ideal worlds—into reality. Plato was very realistic about this matter of convertibility. He has Socrates ask, “Is it not in the nature of things that action should come less close to truth than thought?” (1941, p. 178). He is, however, concerned about trying to come as close as possible to having the real world correspond to the ideal one. The solution? To have philosophers become rulers or to have rulers become philosophers. In either case enormous, if not complete, power is to be held by a caste of elites.

In effect, social inequality is found even in the work of the triumvirate usually referred to as the “utopian socialists”: Claude Henri de Rouvroy de Saint Simon (1760–1825), Charles Fourier (1772–1837), and Robert Owen (1771–1858).

In his early work Saint Simon's elites were scientists, but later he tended to subordinate them or at least to keep them on a par with industrial chiefs. He evaded the problem of social equality by saying that each member of society would be paid in accordance with his or her “investment.” This referred to the contribution each made to the productive process. Since different people had different talents, these contributions would differ. Some people's contributions would be more important than others', and accordingly those people would be paid more. But although the rewards of different people would differ, there would not be wide discrepancies between the rewards of the

lowest- and highest-paid workers (Manuel and Manuel 1979, pp. 590–614).

Unlike Saint Simon, who never wrote a detailed description of a utopian society, Charles Fourier wrote thousands of pages of detailed descriptions of his “Phalanx,” including architectural specifications, work schedules and countless other details. The Phalanx was to be organized essentially as a shareholding corporation. Members were free to buy as many shares as they wished or could afford. Fourier stressed the fact that in his utopia there would be three social classes: the rich, the poor, and the middle. The condition of the poor would be enormously better than their condition in existing society, but the rich or upper class would be entitled to more lavish living quarters, more sumptuous food, and, in general, a more luxurious life-style than the others. During the last fifteen years or so of his life, most of Fourier’s efforts were devoted to the search for a wealthy person to subsidize a trial of his Phalanx (Beecher 1986).

Robert Owen insisted on what he regarded to be complete equality. Conceding that people were born with differing abilities, he contended that these abilities were provided by God and should not be the basis for differential rewards. Nevertheless, as a self-made man who became extremely successful and managed the most important cotton-spinning factory in Britain, he never seemed to lose the self-assurance that he knew best how to manage a community and that all members would understand the wisdom of his decisions. He has been characterized as a benevolent autocrat who acted somewhat like a military commander who has little direct contact with his troops (Cole 1969; Manuel and Manuel 1979, pp. 676–693).

In the United States, the most widely read utopian novel based on the assumption of absolute economic equality is undoubtedly Edward Bellamy’s *Looking Backward* (1887). Bellamy (1850–1898), influenced by the development of the large economic trusts in the United States, postulated that by the year 2000 only one enormous trust would remain: the United States government. He went to great pains to make it clear that his utopia was devoid of Marxist or other European influences. The principle of income or reward on which it was based was neither “From each according to his investment or product” nor the classic

“From each according to his ability, to each according to his need,” although it was much closer to the latter than to the former.

In Bellamy’s vision of the United States in the year 2000, each person received an equal share of the total national product. In effect, every inhabitant received a credit card showing his or her share of the product. The share could be spent in any manner. If too many individuals decided to buy a particular product, the price of that product would be raised. The point, however, is that people were entitled to a share of the national product *not* on the basis of their individual productivity but simply because they existed as human beings. In some telling passages Bellamy’s characters observe that members of families do not deny food or other needs to other family members because they have been unproductive. In effect, the entire country (and, presumably, ultimately the entire world) would resemble our more primitive notion of one family.

Bellamy’s work received widespread attention throughout the world. In England, William Morris (1834–1896) objected strenuously to the centralized control and bureaucratic form of organization in *Looking Backward*. Morris wrote his own utopian novel, *News from Nowhere* (1866). Unlike Bellamy’s utopia, which came into being through a process of evolution, a violent revolution has occurred in *Nowhere*. London has become a series of relatively small villages separated by flowers and wooded areas. There is no centralized government—no government at all—as we normally understand it. With the end of private property and domestic arrangements in which women are essentially the property of men, the underlying reasons for criminal behavior have been eliminated. Random acts of violence are regarded as transitory diseases and are dealt with by nurses and doctors rather than by jailers.

It has been argued that Morris was essentially an anarchist theorist, although Morris himself vigorously objected to such characterization of his work. It has been suggested that anarchism has two major forms: collectivist and individualist. Morris is seen as essentially a collectivist anarchist, although not an anarchosyndicalist—the form that stresses trade-union activity. He ridiculed conventional forms of individualism. Anarchism itself is defined as a social theory that advocates a commu-

nity-centered life with great amounts of personal liberty. It opposes coercion of its population (Sargent 1990, pp. 61–64).

Other commentators see *News from Nowhere* as an effort by Morris to present his arguments against anarchism (Holzman 1990, p. 99). It seems clear that his work does not fit neatly into any prefabricated ideological cubbyhole. Morris cherished aesthetic over intellectual values (he was an architect, artist, poet, designer, and craftsman). When one of his characters in *News from Nowhere* is asked how labor is rewarded, the reply is quite predictable: it is *not* rewarded. Work has become a pleasure—not a hardship. Each person does what he or she can do best; the quandary of extrinsic motivation has substantially disappeared.

Motivation, however, is the central concern in B. F. Skinner's *Walden Two* (1948). Burrhus Frederic Skinner (1904–1990) was a professional psychologist whose utopia was a product of his interest in behavioral engineering. His ideal community has been described as one of means rather than of ends—one in which technique has been elevated to utopian status (Kumar 1987, p. 349).

This is not completely accurate. It does capture the essence of how Skinner himself saw his utopia, but it omits direct consideration of the implicit values held by its designer.

Skinner himself was unquestionably a well-motivated, humanistic scientist, but he neglected his customary penetrating analysis when approaching the area of values held by the boss scientist. At one point in *Walden Two*, however, he does seem to have some insight into this difficulty. Frazier, the founder of the community, voices the unspoken criticism of one of the other characters by pointing to his own insensitivity to the effect he has on others, except when the effect is calculated; his lack of the personal warmth responsible in part for the success of the community; the ulterior and devious nature of his own motives. He then cries out, “But God *damn* it Burris . . . can't you see? *I'm-not-a-product-of-Walden-Two!*” (Skinner 1948, p. 233).

Economic and basic social equality exist in this community, but effective control is exercised through the built-in reinforcement techniques of its designer. When Frazier is challenged on this by one of the characters who observes that Frazier,

looking at the world from the middle of the twentieth century, assumes he knows the best course for humanity forever, Frazier essentially agrees. His defense is that the techniques of behavioral engineering currently exist (and presumably will continue to be used), but they are in the wrong hands—those of charlatans, salespeople, ward heelers, bullies, cheats, educators, priests, and others. Ultimately, Skinner's designer insists, human beings are never free—their behavior is determined by prior conditioning in the society in which they were raised. The belief in their own freedom is what allows human beings unwittingly to become conditioned by reinforcers in their existing environments.

Thus, in effect, *Walden Two* achieves its effects by changing the psychological characteristics of its inhabitants through environmental modification. Its final form is presumably an experimental question. The queries are simple enough and are stated explicitly at one point: What is the best behavior for the individual as far as the group is concerned? How can an individual be induced to behave in that way? The answer presumably can change over time, on the basis of experimental experience. The entire edifice would seem to depend upon the continuing moral superiority of the reinforcement designers over the charlatans they replace.

Quite a different sort of utopia has been proposed by the philosopher Robert Nozick, who outlines what he calls the framework for a utopia. In a word (or two), this framework is equivalent to what Nozick calls the minimal state (Nozick 1974, pp. 297–334). This is a state “limited to the narrow functions of protection against force, theft, fraud, enforcement of contracts, and so on . . . any more extensive state will violate persons' rights not to be forced to do certain things and is unjustified . . .” (Nozick 1974, p. ix).

Nozick is not concerned with modifying behavior or specifying social structures beyond this minimum state. He begins with the assumption that individual persons have certain rights that may never be violated by any other person or the state. These include the right *not* to be killed or attacked if you are not doing any harm; *not* to be coerced or imprisoned; *not* to be limited in the use of your property if that use does not violate the rights of others.

In arguing for a minimal state, Nozick, on the one hand, is arguing against anarchism (in which there is no state at all). On the other hand, he argues against all forms of the welfare state (in which some people with excessive wealth may be required to surrender some of their property to help others who are less fortunate) (Paul 1981).

As Nozick sees it, rights define a moral boundary around individual persons. The sanctity of this boundary takes priority over all other possible goals. Thus, it becomes readily understandable why he feels that nonvoluntary redistribution of income is morally indefensible:

It is an extraordinary but apparent consequence of this view that for a government to tax each of its able-bodied citizens five dollars a year to support cripples and orphans would violate the rights of the able-bodied and would be morally impermissible, whereas to refrain from taxation even if it meant allowing the cripples and orphans to starve to death would be the morally required governmental policy. (Scheffler 1981, p. 151)

Here again we see the clash of values that lie at the heart of utopian schemes and their critics. A serious and widely discussed effort to resolve these clashes was made late in the twentieth century by another social philosopher, John Rawls. *A Theory of Justice* (Rawls 1971) was not a utopian novel but a meticulously argued tome that has been compared with John Locke's *Second Treatise of Civil Government* and John Stuart Mill's *On Liberty*. The central question confronting his work has been expressed thus: "Is it possible to satisfy the legitimate 'leftist', 'socialist' critics of Western capitalism within a broadly liberal, capitalist and democratic framework?" (Goldman 1980, p. 431).

Unfortunately, Rawls has found himself increasingly caught between attacks from both the left and the right. The left feels he has not gone far enough in constraining property rights; the right feels he places too great an emphasis upon the value of equality, especially at the expense of the right to property (Goldman 1980, pp. 431–432).

A central point argued by Rawls is that there is no injustice if greater benefits are earned by a few, provided the situation of people not so fortunate is thereby improved (Rawls 1971, pp. 14–15).

As one commentator expressed it, for Rawls equality comes first. Goods are to be distributed equally unless it can be shown that an unequal distribution is to the advantage of the least advantaged. This would be a "just" distribution (Schaar 1980). One might add, parenthetically, that this justice would depend substantially upon the nature of the existing social and economic arrangements under which this inequality occurs. Would a different set of arrangements allow greater equality? For example, is capital available only through private sources? Would public sources serve similar ends with less inequality?

The central issue for utopian analysts from Plato through twentieth-century philosophers is how one constructs a "just" society. But there is no single definition of "just"; it all depends on what you consider to be important. Are you concerned exclusively with yourself? your immediate family? others in your community? in your country? in the world?

And so it is that utopian analysis and design ultimately begin with an implicit, if not explicit, value orientation. One school of thought begins with an overwhelming belief that elites of one sort or another must be favored in the new society. Elite status may be gained through existing wealth, birth, talent, skill, intelligence, or physical strength. Another school begins with what is, broadly speaking, the concept of equality. Here the implicit notion is not unlike Western ideas of the family: to each equally, irrespective of either productivity or need. Between these two polar positions lie a range of intermediate proposals that may provide greater amounts of compensation based upon some definition of need or elite status. In turn, compensation may or may not be linked directly to political or other forms of power.

Issues relating to the nation-state (its form, its powers, and even its very existence), ethnicity, and inequality became acute in the final decade of the twentieth century. Ethnic groups throughout the world grew militant in their demands for their own national entities. Many saw this as a path to a solution for their own problems of inequality. With the apparent easing, if not the elimination, of Cold War tensions between the Soviet Union and the United States, widespread controversies began relative to the shape of a "new world order." This posed unprecedented challenges to utopian thought.

To deal with these challenges, social scientists, as well as imaginative novelists and others, were confronted with the task of integrating value configurations, social structures, and psychological sets on levels that may well make all previous efforts at utopian analysis and design resemble the stumbling steps of a child just learning to walk.

ROBERT BOGUSLAW

V

VALIDITY

In the simplest sense, a measure is said to be valid to the degree that it measures what it is hypothesized to measure (Nunnally 1967, p. 75). More precisely, validity has been defined as the degree to which a score derived from a measurement procedure reflects a point on the underlying construct it is hypothesized to reflect (Bohrnstedt 1983). In the most recent *Standards for Educational and Psychological Testing* (American Psychological Association 1985), it is stated that validity “refers to the appropriateness, meaningfulness, and usefulness of the specific inferences made from . . . scores.” The emphasis is clear: Validity refers to the degree to which evidence supports the *inferences* drawn from a score rather than the scores or the instruments that produce the scores. Inferences drawn for a given measure with one population may be valid but may not be valid for other measures. As will be shown below, evidence for inferences about validity can be accumulated in a variety of ways. In spite of this variety, validity is a unitary concept. The varied types of inferential evidence relate to the validity of a particular measure under investigation.

Several important points related to validity should be noted:

1. Validity is a matter of degree rather than an all-or-none matter (Nunnally 1967, p. 75; Messick 1989).
2. Since the constructs of interest in sociology (normlessness, religiosity, economic conservatism, etc.) generally are not ame-

nable to direct observation, validity can be ascertained only indirectly.

3. Validation is a dynamic process; the evidence for or against the validity of the inferences that can be drawn from a measure may change with accumulating evidence. Validity in this sense is always a continuing and evolving matter rather than something that is fixed once and for all (Messick 1989).
4. Validity is the sine qua non of measurement; without it, measurement is meaningless.

In spite of the clear importance of validity in making defensible inferences about the reasonableness of theoretical formulations, the construct more often than not is given little more than lip service in sociological research. Measures are assumed to be valid because they “look valid,” not because they have been evaluated as a way to get statistical estimates of validity. In this article, the different meanings of validity are introduced and methods for estimating the various types of validity are discussed.

TYPES OF VALIDITY

The *Standards* produced jointly by the American Psychological Association, the American Educational Research Association, and the National Council on Measurement in Education distinguish between and among three types of evidence related to validity: (1) *criterion-related*, (2) *content*, and (3)

construct evidence (American Psychological Association 1985).

Criterion-Related Evidence for Validity. Criterion-related evidence for validity is assessed by the correlation between a measure and a criterion variable of interest. The criterion varies with the purpose of the researcher and/or the client for the research. Thus, in a study to determine the effect of early childhood education, a criterion of interest might be how well children perform on a standardized reading test at the end of the third grade. In a study for an industrial client, it might be the number of years it takes to reach a certain job level. The question that is always asked when one is accumulating evidence for criterion-related validity is: How accurately can the criterion be predicted from the scores on a measure? (American Psychological Association 1985).

Since the criterion variable may be one that exists in the present or one that a researcher may want to predict in the future, evidence for criterion-related validity is classified into two major types: predictive and concurrent.

Evidence for *predictive validity* is assessed by examining the future standing on a criterion variable as predicted from the present standing on a measure of interest. For example, if one constructs a measure of work orientation, evidence of its predictive validity for job performance might be ascertained by administering that measure to a group of new hires and correlating it with a criterion of success (supervisors' ratings, regular advances within the organization, etc.) at a later point in time. The evidence for the validity of a measure is not limited to a single criterion. There are as many validities as there are criterion variables to be predicted from that measure. The preceding example makes this clear. In addition, the example shows that the evidence for the validity of a measure varies depending on the time at which the criterion is assessed. Generally, the closer in time the measure and the criterion are assessed, the higher the validity, but this is not always true.

Evidence for *concurrent validity* is assessed by correlating a measure and a criterion of interest at the *same* point in time. A measure of the concurrent validity of a measure of religious belief, for example, is its correlation with concurrent attendance at religious services. Just as is the case for

predictive validity, there are as many concurrent validities as there are criteria to be explained; there is no single concurrent validity for a measure.

Concurrent validation also can be evaluated by correlating a measure of *X* with extant measures of *X*, for instance, correlating one measure of self-esteem with a second one. It is assumed that the two measures reflect the same underlying construct. Two measures may both be labeled self-esteem, but if one contains items that deal with one's social competence and the other contains items that deal with how one feels and evaluates oneself, it will not be surprising to find no more than a modest correlation between the two.

Evidence for validity based on concurrent studies may not square with evidence for validity based on predictive studies. For example, a measure of an attitude toward a political issue may correlate highly in August in terms of which political party one *believes* one will vote for in November but may correlate rather poorly with the *actual* vote in November.

Many of the constructs of interest to sociologists do not have criteria against which the validity of a measure can be ascertained easily. When they do, the criteria may be so poorly measured that the validity coefficients are badly attenuated by measurement error. For these reasons, sociological researchers have rarely computed criterion-related validities.

Content Validity. One can imagine a *domain of meaning* that a construct is intended to measure. *Content validity* provides evidence for the degree to which one has representatively sampled from that domain of meaning. (Bohrnstedt 1983). One also can think of a domain as having various facets (Guttman 1959), and just as one can use stratification to obtain a sample of persons, one can use stratification principles to improve the evidence for content validity.

While content validity has received close attention in the construction of achievement and proficiency measures psychology and educational psychology, it usually has been ignored by sociologists. Many sociological researchers have instead been satisfied to construct a few items on an ad hoc, one-shot basis in the apparent belief that they are measuring what they intended to measure. In

fact, the construction of good measures is a tedious, arduous, and time-consuming task.

Because domains of interest cannot be enumerated in the same way that a population of persons or objects can, the task of assuring the content validity of one's measures is less rigorous than one would hope. While an educational psychologist can sample four-, five-, or six-letter words in constructing a spelling test, no such clear criteria exist for a sociologist who engages in social measurement. However, some guidelines can be provided. First, the researcher should search the literature carefully to determine how various authors have used the concept that is to be measured. There are several excellent handbooks that summarize social measures in use, including Robinson and Shaver's *Measures of Social Psychological Attitudes* (1973); Robinson et al.'s *Measures of Political Attitudes* (1968); Robinson et al.'s *Measures of Occupational Attitudes and Occupational Characteristics* (1969); Shaw and Wright's *Scales for the Measurement of Attitudes* (1967); and Miller's *Handbook of Research Design and Social Measurement* (1977). These volumes not only contain lists of measures but provide existing data on the reliability and validity of those measures. However, since these books are out of date as soon as they go to press, researchers developing their own methods must do additional literature searches. Second, sociological researchers should rely on their own observations and insights and ask whether they yield additional facets to the construct under consideration.

Using these two approaches, one develops *sets* of items, one to capture each of the various facets or strata within the domain of meaning. There is no simple criterion by which one can judge whether a domain of meaning has been sampled properly. However, a few precautions can be taken to help ensure the representation of the various facets within the domain.

First, the domain can be stratified into its major facets. One first notes the most central meanings of the construct, making certain that the stratification is exhaustive, that is, that all major meaning facets are represented. If a facet appears to involve a complex of meanings, it should be subdivided further into substrata. *The more one refines the strata and substrata the easier it is to construct the items later and the more complete the coverage*

of meanings associated with the construct will be. Second, one should write several items or locate several extant indicators to reflect the meanings associated with each stratum and substratum. Third, after the items have been written, they should be tried out on very small samples composed of persons of the type the items will eventually be used with, using cognitive interviewing techniques, in which subjects are asked to "think aloud" as they respond to the items. This technique for the improvement of items, while quite new in survey research, is very useful for improving the validity of items (Sudman et al. 1995). For example, Levine et al. (1997) have shown how cognitive interviewing helped in the improvement of school staffing resources, as did Levine (1996) in describing the development of background questionnaires for use with the large-scale cognitive assessments. Fourth, after the items have been refined through the use of cognitive laboratory techniques, the newly developed items should be field-tested on a sample similar to that with which one intends to examine the main research questions. The field-test sample should be large enough to examine whether the items are operating as planned vis-à-vis the constructs they are putatively measuring, using multivariate tools such as confirmatory factor analysis (Joreskog 1969) and item response theory methods (Hambleton and Swaminathan 1985).

Finally, after the items are developed, the main study should employ a sampling design that takes into account the characteristics of the population about which generalizations are to be made (ethnicity, gender, region of country, etc.). The study also should be large enough to generate stable parameter estimates when one is using multivariate techniques such as multiple regression (Bohrnstedt and Knoke 1988) and structural equation techniques (Bollen 1989).

It can be argued that what the *Standards* call content validity is not a separate method for assessing validity. Instead, it is a set of procedures for sampling content domains that, if followed, can help provide evidence for *construct validity* (see the discussion of construct validity below). Messick (1989), in a similar stance, states that so-called content validity does not meet the definition of validity given above, since it does not deal directly with scores or their interpretation. This position can be better understood in the context of construct validity.

Construct Validity. The 1974 *Standards* state: “A construct is . . . a theoretical idea developed to explain and to organize some aspects of existing knowledge. . . It is a dimension understood or inferred from its network of interrelationships” (American Psychological Association 1985). The *Standards* further indicate that in developing evidence for construct validity,

the investigator begins by formulating hypotheses about the characteristics of those who have high scores on the [measure] in contrast to those who have low scores. Taken together, such hypotheses form at least a tentative theory about the nature of the construct the [measure] is believed to be measuring.

Such hypotheses or theoretical formulations lead to certain predictions about how people. . . will behave. . . in certain defined situations. If the investigator’s theory. . . is correct, most predictions should be confirmed. (p. 30)

The notion of a construct implies hypotheses of two types. First, it implies that items from one stratum within the domain of meaning correlate together because they all reflect the same underlying construct or “true” score. Second, whereas items from one domain may correlate with items from another domain, the implication is that they do so only because the constructs themselves are correlated. Furthermore, it is assumed that there are *hypotheses* about how measures of different domains correlate with one another. To repeat, construct validation involves two types of evidence. The first is evidence for *theoretical validity* (Lord and Novick 1968): an assessment of the relationship between items and an underlying, latent unobserved construct. The second involves evidence that the underlying latent variables correlate as hypothesized. If either or both sets of these hypotheses fail, evidence for construct validation is absent. If one can show evidence for theoretical validity but evidence about the interrelations among those constructs is missing, that suggests that one is not measuring the intended construct or that the theory is wrong or inadequate. The more unconfirmed hypotheses one has involving the constructs, the more one is likely to assume the former rather than the latter.

The discussion above makes clear the close relationship between construct validation and the-

ory validation. To be able to show construct validity assumes that the researcher has a clearly stated set of interrelated hypotheses between important theoretical constructs, which in turn can be measured by sets of indicators. Too often in sociology, one or both of these components are missing.

Campbell (1953, 1956) uses a *multitrait-multimethod matrix*, a useful tool for assessing the construct validity of a set of measures collected using differing methods. Thus, for example, one might collect data using multiple indicators of three constructs, say, prejudice, alienation, and anomie, using three different data collection methods: a face-to-face interview, a telephone interview, and a questionnaire. To the degree that different methods yield the same or a very similar result, the construct demonstrates what Campbell (1954) calls *convergent validity*. Campbell argues that in addition, the constructs must not correlate too highly with each other; that is, to use Campbell and Fiske’s (1959) term, they must also exhibit *discriminant validity*. Measures that meet both criteria provide evidence for construct validity.

VALIDITY GENERALIZATION

An important issue for work in educational and industrial settings is the degree to which the criterion-related evidence for validity obtained in one setting generalizes to other settings (American Psychological Association 1985). The point is that evidence for the validity of an instrument in one setting in no ways guarantees its validity in any other setting. By contrast, the more evidence there is of consistency of findings across settings that are maximally different, the stronger the evidence for *validity generalization* is.

Evidence for validity generalization generally is garnered in one of two ways. The usual way is simply to do a nonquantitative review of the relevant literature; then, on the basis of that review, a conclusion about the generalizability of the measure across a variety of settings is made. More recently, however, meta-analytic techniques (Hedges and Olkin 1985) have been employed to provide quantitative evidence for validity generalization.

Variables that may affect validity generalization include the particular criterion measure used, the sample to which the instrument is adminis-

tered, the time period during which the instrument was used, and the setting in which the assessment is done.

Differential predication. In using a measure in different demographic groups that differ in experience or that have received different treatments (e.g., different instructional programs), the possibility exists that the relationship between the criterion measure and the predictor will vary across groups. To the degree that this is true, a measure is said to display *differential prediction*.

Closely related is the notion of *predictive bias*. While there is some dispute about the best definition, the most commonly accepted definition states that predictive bias exists if different regression equations are needed for different groups and if predictions result in decisions for those groups that are different from the decisions that would be made based on a pooled groups regression analysis (American Psychological Association 1985). Perhaps the best example to differentiate the two concepts is drawn from examining the relationship between education and income. It has been shown that that relationship is stronger for whites than it is for blacks; that is, education differentially predicts income. If education were then used as a basis for selection into jobs at a given income level, education would be said to have a predictive bias against blacks because they would have to have a greater number of years of education to be selected for a given job level compared to whites.

Differential prediction should not be confused with *differential validity*, a term used in the context of job placement and classification. Differential validity refers to the ability of a measure or, more commonly, a battery of measures to differentially predict success or failure in one job compared to another. Thus, the armed services use the battery of subtests in the Armed Services Vocational Aptitude Battery (U.S. Government Printing Office 1989; McLaughlin et al. 1984) in making the initial assignment of enlistees to military occupational specialties.

MORE RECENT FORMULATIONS OF VALIDITY

More recent definitions of validity have been even broader than that used in the 1985 *Standards*.

Messick (1989) defines validity as an evaluative judgment about the degree to which “empirical and theoretical rationales support the *adequacy* and *appropriateness* of *inferences* and *actions* based on . . . scores or other modes of assessment” (p. 13). For Messick, validity is more than a statement of the existing empirical evidence linking a score to a latent construct; it is also a statement about the evidence for the appropriateness of using and interpreting the scores. While most measurement specialists separate the use of scores from their interpretation, Messick (1989) argues that the value implications and social consequences of testing are inextricably bound to the issue of validity:

[A] social consequence of testing, such as adverse impact against females in the use of a quantitative test, either stems from a source of test invalidity or a valid property of the construct assessed, or both. In the former case, this adverse consequence bears on the meaning of the test scores and, in the later case, on the meaning of the construct. In both cases, therefore, construct validity binds social consequences to the evidential basis of test interpretation and use.” (p. 21)

Whether the interpretation and social consequences of the uses of measures become widely adopted (i.e., are adopted in the next edition of the *Standards*) remains to be seen. Messick’s (1989) definition does reinforce, the idea that although there are many facets to and methods for garnering evidence for inferences about validity, it remains a unitary concept; evidence bears on inferences about a single measure or instrument.

GEORGE W. BOHRNSTEDT

VALUE-FREE ANALYSIS

See Epistemology; Positivism; Scientific Explanation.

VALUES THEORY AND RESEARCH

The study of values covers a broad multidisciplinary terrain. Different disciplines have pursued this topic with unique orientations to the concept of values. The classic conception of values in anthropology was introduced by Kluckhohn and Strodtbeck (1961). In this view, values answer basic existential questions, helping to provide meaning in people's lives. For example, Kluckhohn and Strodtbeck argue that Americans value individual effort and reward because of their fundamental belief in the inherent goodness of human nature and the capacity of individuals to obtain desired ends. Economists have considered values not in terms of the meaning they provide but as a quality of the objects used in social exchange (Stigler 1950). For economists, objects have value but people have preferences, and those preferences establish hierarchies of goods. It is the goods that have value, with those which are both scarce and highly desirable being the most highly valued.

Sociologists, particularly Parsons, have emphasized a different conception of values (see

Parsons and Shils 1951). In sociology, values are believed to help ease the conflict between individual and collective interests. Values serve an important function by enabling individuals to work together to realize collectively desirable goals. For example, while all the individual members of society may believe that public education is a good idea for themselves, their children, and/or the well-being of society in general, none of them is excited by the prospect of paying taxes to build schools and pay teachers. Even when people believe in the collective good, their private interest (keeping one's money for one's own use) conflicts with the necessities for keeping a society organized. Values such as being socially responsible, showing concern for others, and education encourage people to sidestep their own desires and commit themselves to the more difficult task of social cooperation. As Grube et al. (1994, p. 155) argue, "values play a particularly important role because they are cognitive representations of individual needs and desires, on the one hand, and of societal demands on the other."

Another way to understand the sociological conception of values is to examine when values become vital in social life. They do not matter much when everyone is in full agreement. For example, everyone values breathing over asphyxiation. Even though this value may be of life-and-death importance, it is not a particularly important object of social inquiry because no one disagrees about whether one should hold one's breath. The situation has been quite different with regard to abortion, affirmative action, the death penalty, same-sex marriage, environmental protection, and many other social issues that elicit conflicts in personal values. Values are important to understand when they conflict between individuals, groups, or whole societies. They provide a window through which one can view conflicts and variations within and between societies.

Although many formal definitions of values have been advanced by sociologists, one definition in particular captures the concept's core features well. Smith and Schwartz (1997, p. 80) observe five features:

1. Values are beliefs. But they are not objective, cold ideas. Rather, when values are activated, they become infused with feeling.

2. Values refer to desirable goals (e.g., equality) and to the modes of conduct that promote these goals (e.g., fairness, helpfulness).
3. Values transcend specific actions and situations. Obedience, for example, is relevant at work or in school, in sports or in business, with family, friends or strangers.
4. Values serve as standards to guide the selection or evaluation of behavior, people, and events.
5. Values are ordered by importance relative to one another. The ordered set of values forms a system of value priorities. Cultures and individuals can be characterized by their systems of value priorities.

Smith and Schwartz's conceptualization is consistent with the sociological view that values are abstract concepts, but not so abstract that they cannot motivate behavior. Hence, an important theme of values research has been to assess how well one can predict specific behavior by knowing something about a person's values. If someone claims to believe in protecting the environment, for example, how confidently can one assume that that person recycles, contributes to the Sierra Club, or supports proenvironmental legislation? Below, several empirical efforts to measure the link between values and behavior are discussed. However, some scholars are skeptical that such a link can be drawn (Hechter 1992, 1993).

The definition given above emphasizes the link between values and desired goals. In an earlier discussion, Schwartz (1992, p. 4) argued that values, when defined in this way, reflect three basic requirements of human existence: "needs of individuals as biological organisms, requisites of coordinated social interaction, and survival and welfare needs of groups." By understanding values, one can learn about the needs of both individuals and societies. Sociologists are especially concerned with how values facilitate action toward ends that enhance individual and collective outcomes or are perceived to do so by society's members. Research on values does not presuppose which values are best (social scientists are not preachers) but tries to discover what people believe in and how their beliefs motivate their behavior. A major part of the enterprise is concerned with strategies to measure

values: which ones people hold, how strongly they hold them, how their value priorities compare with those of others, how the value priorities of different groups or societies compare with one another.

Values research has a long and varied history in sociology. Important theoretical and empirical studies of values have been made by Parsons and Shils (1951), Kluckhohn (1951), Williams (1960), Allport et al. (1960), Scott (1965), Smith (1969), and Kohn (1969). Because the field is so broad, this article cannot cover all the ground but concentrates on recent empirical endeavors. Other reviews summarize the early studies in detail, such as Blake and Davis (1964), Williams (1968), Zavalloni (1980), Spates (1983), and Ball-Rokeach and Loges (1992).

Contemporary areas of research in values are not well integrated; each represents an active arena of social research that is empirically driven and theoretically informed. Below, will be summarized these areas, noting the unique contributions and insights of each one. The research reviewed here has been conducted by psychologists and political scientists as well as sociologists. However, all of it is premised on the sociological conceptual framework of values inherent in the definition given above.

THE ROKEACH TRADITION

The most influential researcher on values in the last three decades is Rokeach. The focus of his work has been the development of an instrument to measure values that he believes are universal and transsituational (see especially Rokeach 1973). That is, Rokeach has tried to develop an instrument that can be used to compare individual commitment to a set of values wherever the researchers live and whenever they complete a survey. This instrument has been widely used in the measurement of values (Mayton et al. 1994).

The Rokeach Value Survey is an instrument made up of thirty-six value items that are ranked by survey subjects. The items are divided into two sets. The first ones are termed "instrumental values" and refer to values that reflect modes of conduct, such as politeness, honesty, and obedience. The second set refers to "terminal values" that reflect desired end states, such as freedom, equality, peace, and salvation. Each set of eighteen

value items is ranked by subjects according to the items' importance as guiding principles in their lives. The purpose of the procedure is to force subjects to identify priorities among competing values. In this model, the values are assumed to be universal; therefore, to some extent, each value is supported by every subject. The question is how subjects adjudicate between value conflicts. For example, the instrumental value "broad-minded" may conflict with the value "obedience." How would a person who is trying to conform to the expectations of racist parents maintain a broad-minded commitment to diversity? By requiring that values be rank-ordered, the Rokeach Values Survey helps disclose a person's value priorities.

One of the distinct advantages of the Rokeach Value Survey is that it is a fairly simple instrument that can be used by researchers in a variety of settings. Thus, it was possible to see if the value priorities of Michigan college students were similar to those of other subsamples of Americans, allowing comparisons of those with different demographic characteristics, such as age, sex, race, religion, and education. For example, in a national sample, Rokeach found that men and women tended to prioritize "a world at peace," "family security," and "freedom; however, men strongly valued "a comfortable life" while women did not, and women strongly valued "salvation" while men did not. Value priorities have been shown to be linked to a variety of attitudes about contemporary social issues. For example, as would be predicted, concern for the welfare of blacks and the poor is stronger among those who value equality.

The Rokeach Value Survey has been used by numerous researchers to explore many facets of values, such as the relationship between values and behavior, the role of values in justifying attitudes, and the extent to which people remain committed to particular values over time. An important early study of values employing the Rokeach model was conducted by Feather (1975), who measured the values of Australian high school and college students as well as those of their parents. One central finding demonstrated the importance of a close fit between the person and the environment in which that person is situated: Students were happiest when their values were congruent with those articulated by the schools they attended or the subjects they studied. Another finding was that parents were consistently more conservative, em-

phasizing values such as national security, responsibility, and politeness, while their children were more likely to emphasize excitement and pleasure, equality and freedom, a world of beauty, friendship, and broad-mindedness. It also was found that student activists were distinctive in their emphasis on humanitarianism, nonmaterialism, and social and political goals.

The Rokeach model underscores the potential conflicts between individuals with different value priorities. Different positions on important social issues may be traced to differential commitments to particular values. For example, Kristiansen and Zanna (1994) report that supporters of abortion rights emphasize values such as freedom and a comfortable life, whereas opponents place a high priority on religious salvation. Moreover, as they defend their positions, each group will justify its position by referring to its own value priorities; this, of course, may not be very convincing to people who do not share them. This may be one reason why the abortion debate seems intractable. Individuals also may be ambivalent about particular social issues because of their pluralistic commitment to two or more values that conflict in the public policy domain. This is the essence of Tetlock's (1986) "value pluralism model of ideological reasoning." For example, liberals tend to weight equality and freedom fairly equally, causing them to feel ambivalently about affirmative action policies (Peterson 1994).

Rokeach and Rokeach (1980) argue that values are not simply hierarchically prioritized but that each is interrelated in a complex system of beliefs and attitudes. Thus, a belief system may be relatively enduring, but changes in one value may lead to changes in others and in the whole system. When are personal values likely to endure, and when are they likely to change? Rokeach argues that individuals try to maintain a consistent conception of themselves that reflects their morality and competence. When their actions or beliefs contradict this self-conception, they feel dissatisfied and change is likely to occur to bring their actions or beliefs into line. Grube et al. (1994) review a number of studies in which researchers attempted to uncover contradictions in subjects'

values with the prediction that this conflict would lead to value change. These works have been called "self-confrontation" studies; they have found a significant degree of value change as a result of the method, even over long periods. However, the method is much less effective at inducing specific behavioral changes.

The central claim of values researchers is consistent with a commonsense understanding of values. Values are important because they guide people's behavior. At times they may be an even stronger motivation than is self-interest. For example, fear of arrest may not be as good an explanation for one's choice not to shoplift as is the more straightforward commitment to the value of right conduct. However, this central claim has been the most controversial in values research. The robust finding that values directly affect behavior has never surfaced in values research. The link does not exist, or several links in a long chain of causes intervene between these two crucial variables. This ambiguity has led Hechter (1992), for example, to suggest that social scientists stop using the term "values." Kristiansen and Hotte (1996, p. 79) observed that "although values, attitudes, and behavior are related, these relations are often small . . . one wonders why people do not express attitudes and actions that are more strongly in line with their values." Many people also wonder whether current measures of values are adequate. The Rokeach Value Survey, for example, may not be sufficiently complete or its definitions of values may be too abstract or vague to predict behavior accurately.

Kristiansen and Hotte (1996) argue that values researchers must pay much closer attention to the intervening factors in the values-behavior relationship. For example, those factors may include the way in which individuals engage in moral reasoning. Making a behavioral choice requires the direct application of very general values. How is this done? What do people consider in trying to make such a decision? Do they rely on ideological commitments to moral principles? Do they take into consideration the immediate context or circumstances? How much are they influenced by social norms? These questions are likely to guide

research on the values-behavior connection in the future.

THE SCHWARTZ SCALE OF VALUES

A major evolution of the Rokeach Values Survey is found in the cross-cultural values research of Schwartz (see especially Schwartz 1992 and Smith and Schwartz 1997). Like Rokeach, Schwartz has focused on the measurement of values that are assumed to be universal. To that end, Schwartz has modified and expanded the Rokeach instrument. He also has proposed a new conceptual model that is based on the use of the new instrument in more than fifty countries around the world and more than 44,000 subjects (Smith and Schwartz 1997).

According to Schwartz (1992), values are arrayed along two general dimensions (Figure 1). In any culture, individual values fall along a dimension ranging from “self-enhancement” to “self-transcendence.” This dimension reflects the distinction between values oriented toward the pursuit of self-interest and values related to a concern for the welfare of others: “It arrays values in terms of the extent to which they motivate people to enhance their own personal interests (even at the expense of others) versus the extent to which they motivate people to transcend selfish concerns and promote the welfare of others, close and distant, and of nature” (1992, p. 43). The second dimension contrasts “openness to change” with “conservation”: “It arrays values in terms of the extent to which they motivate people to follow their own intellectual and emotional interests in unpredictable and uncertain directions versus to preserve the status quo and the certainty it provides in relationships with close others, institutions, and traditions” (1992, p. 43). This dimension indicates the degree to which individuals are motivated to engage in independent action and are willing to challenge themselves for both intellectual and emotional realization. Schwartz (1992, pp. 5–12) further postulates that within these two dimensions, there are ten motivational value types:

1. *Universalism*: “understanding, appreciation, tolerance, and protection for the welfare of all people and for nature”

Figure 1. Structural relations among ten motivational types of values

SOURCE: Schwartz (1997), p. 87.

2. *Benevolence*: “preservation and enhancement of the welfare of people with whom one is in frequent personal contact”
3. *Conformity*: “restraint of actions, inclinations, and impulses likely to upset or harm others and violate social expectations or norms”
4. *Tradition*: “respect, commitment, and acceptance of the customs and ideas that one’s culture or religion imposes on the individual”
5. *Security*: “safety, harmony, and stability of society, of relationships, and of self”
6. *Power*: “attainment of social status and prestige, and control or dominance over people and resources”
7. *Achievement*: “personal success through demonstrating competence according to social standards”
8. *Hedonism*: “pleasure or sensuous gratification for oneself”
9. *Stimulation*: “excitement, novelty, and challenge in life”

10. *Self-direction*: “independent thought and action—choosing, creating, exploring”

Like Rokeach, Schwartz conceptualizes these motivational types as being dynamically interrelated, with those closest together being conceptually linked and having the greatest influence on one another. This model was not developed deductively but was derived from an empirical project of data collection in which the Schwartz Scale of Values was used. This instrument, which includes fifty-six Rokeach-style values items, is completed by subjects who rate each item on a ten-point scale of personal importance. Unlike the Rokeach instrument, this scale does not require the respondents to rank-order the items. Through the use of a multidimensional scaling technique (smallest-space analysis), statistical correlations of individual items in a survey sample are mapped in a two-dimensional space. Thus, each item is plotted on a graph, and clusters of those items constitute the domains identified in Figure 1. The major finding of the Schwartz project is that this basic visual model reappears in culture after culture. The system of values is essentially the same worldwide, although the emphasis given to particular domains varies from place to place.

Schwartz’s dynamic model provides new insight into the values–behavior debate. Schwartz argues that the relationship of values to behavior (or any other variable) must be understood in the context of a multidimensional system. Voting for a particular political platform, for example, can be predicted on the basis of a person’s value priorities. Given the interrelatedness of values in Schwartz’s model, a person’s values form a system: For example, a person who strongly endorses universalism is unlikely to endorse its distal correlate power while moderately endorsing values that are in closer proximity. Schwartz (1996) has used data from these values systems to predict political behavior.

Schwartz’s research is especially important for distinguishing values at the individual and cultural levels. Individuals may differ in their values, but so too do cultures, with the members of one culture tending toward one set of priorities and the mem-

bers of another culture tending toward a different set. Cultural variation in values is of special interest to sociologists, while individual-level values are closer to the interests of social psychologists. Cultural values are important to sociologists because they reflect ways in which society balances conflicting concerns between individuals and groups and the dominant themes around which individuals are socialized. One issue is the provision of public goods; another is the extent to which individuals profess autonomy from the collectivity rather than identifying with it.

To obtain cultural-level values, Schwartz (1994) used the mean scores of values for each culture sample as the basis for plotting a new two-dimensional model. The data points thus are cultures rather than individual respondents. Among other findings, Schwartz discovered that east Asian nations emphasize hierarchy and conservatism, whereas west European nations emphasize egalitarianism and individual autonomy. Anglo nations, including the United States, fall between these extremes, emphasizing mastery and autonomy but also hierarchy; this may explain the greater tolerance for income inequality in countries such as the United States (Smith and Schwartz 1997).

Smith and Schwartz (1997) argue that values research should take two trajectories in the future. First, most studies now ask the respondents to report their own value priorities, whereas, especially for culture-level analyses, it would be useful to ask the respondents to report what they believe are the prevailing values of their culture. This may provide a better account of the normative milieu in which people evaluate their values and decisions. Second, most studies have examined the strength of individual commitment to particular values, but little research has dealt with the degree of value consensus in a culture. Because of the sociological concern about linking cultural values and the organization of societies, this is a crucial topic. One intriguing hypothesis is that socioeconomic development may enhance value consensus, while democratization may decrease it. These tendencies have broad implications for social stability and change in the future as countries pursue these goals.

INDIVIDUALISM AND COLLECTIVISM

In cross-cultural research on values, no concepts have been explored in as much detail as individualism and collectivism. Consistent with the underlying theme of values research that private and communal interests may conflict, individualism and collectivism speak directly to the various ways in which cultures have balanced these competing goals.

The concept of individualism as a cultural construct has received much empirical attention, particularly since the publication of Hofstede's (1980) study of 117,000 IBM employees worldwide. In that study, fifteen items related to employment goals were subdivided into related clusters by using factor analysis, one of which Hofstede labeled individualism, inspiring this line of research. Theory and measurement in individualism and collectivism are associated primarily with Triandis (see especially Triandis 1989, 1995 and a review by Kagitcibasi 1997). In this tradition, the individualistic cultures of the West are typically contrasted with the collectivistic cultures of the East and Latin America. For example, Kim et al. (1994, pp. 6-7) argue that an individualistic ethos encourages individuals to be "autonomous, self-directing, unique, assertive, and to value privacy and freedom of choice." In contrast, "interdependency, succor, nurturance, common fate, and compliance" characterize a collectivistic ethos.

Triandis (1989, p. 52) defines collectivism in terms of in-groups and out-groups: "Collectivism means greater emphasis on (a) the views, needs, and goals of the in-group rather than oneself; (b) social norms and duty defined by the in-group rather than behavior to get pleasure; (c) beliefs shared with the in-group rather than beliefs that distinguish self from in-group; and (d) great readiness to cooperate with in-group members." Collectivism is characterized by two major themes that are consistent with the values dimensions of Schwartz's theory. First, collectivism is defined by conservation values: conformity, tradition, and security. The Japanese proverb "The nail that sticks up gets hammered down" illustrates the demand for conformity in the collectivistic Japa-

nese society. Second, collectivism is characterized by self-transcendent values. Individuals demonstrate a great willingness to cooperate in the pursuit of collective benefits, sacrificing their self-interest to do so. In conflicts between individual and collective interests, collectivists will subsume their individual interests in favor of those of the in-group. However, collectivists are not universally self-transcendent. Cooperation and self-sacrifice extend only to the boundaries of the in-group.

Individualism and collectivism are cultural constructs that define the values of societies, not those of individuals. Triandis argues that individuals vary in their adoption of the cultural ethos. To distinguish individualistic cultures from individualistic individuals, he uses the terms "idiocentrism" for the individual-level correlates of individualism and "allocentrism" for the individual-level correlates of collectivism. An individualistic culture is defined by having a majority of idiocentrics. These individuals identify primarily with the values of individualism, but not in every situation. Thus, individualistic cultures have both idiocentrics and allocentrics, and idiocentrics are collectivistic on occasion.

Triandis has developed a fifty-item scale to measure the various elements of individualism and collectivism. In addition, he advocates a multimethod approach to their study. For example, Triandis et al. (1990) used several measures, including the Schwartz Scale of Values. One of the measures is the Twenty Statements Test (Kuhn and McPartland 1954), which asks respondents to finish twenty sentences that begin with the words "I am . . ." This test is used to measure the degree of social identification or the "social content of the self" by disclosing the number and ordinal position of group membership references to the self relative to the number and ordinal position of individual references to the self. For example, "I am white" refers to group membership, whereas "I am kind" refers to a character trait. Collectivists are predicted to identify more closely with groups than are individualists. In Triandis et al.'s study, less than one-fifth of a U.S. sample's responses were social, whereas more than half of a mainland Chinese sample's responses were social. Using

another measure, individualists and collectivists were distinguished by attitude scales measuring the perceived social distance between in-group members and out-group members. Collectivists perceived in-group members as being more homogeneous than did individualist and also perceived out-group members as being more different from in-group members than did individualists.

Among the numerous findings of studies of the values-behavior relationship, one theme is particularly apparent. Individualists tend to emphasize competition, self-interest, and “free riding,” whereas collectivists tend to emphasize cooperation, conflict avoidance, group harmony, and group enhancement. Thus, in balancing individual and collective needs, collectivists favor the group more readily than do individualists. Collectivists also have been shown to favor equality in distributive outcomes, whereas individualists favor equity (Kagitcibasi 1997). Because this adjudication between the self and the collective is central to values research, this theme is replayed across research programs. Below, a line of research—“social values”—that provides a unique methodology for understanding these values will be examined.

Sociological research on values has long considered the relationship between values and social progress. For example, Weber ([1905] 1958) argued that an important factor in the rise of capitalism was the emergence of the Protestant Ethic, which encouraged hard work and self-control as a means of salvation. Thus, individuals were guided less by economic necessities or external coercion than by religious commitment. In values research, establishing a causal relationship between cultural values and social arrangements and outcomes is an ongoing endeavor. Triandis (1989), for example, suggests that individualism has two important structural antecedents: economic independence and cultural complexity. Independence enables individuals to pursue their own interests without fearing the economic consequences of deviation from the group. Cultural complexity, such as ethnic diversity and occupational specialization, fosters divergent interests and perspectives within a culture, increasing individualistic orientations. Another strand in values research has examined the

issues of cultural values and economic development. This line of research, which was initiated by Inglehart, is summarized below.

Future research on individualistic and collectivistic values is likely to proceed along three lines. First, these concepts may become more closely integrated with Schwartz’s general theory of values. Schwartz (1990, 1994) makes a case for this, and researchers are beginning to use measures of individualism/collectivism concurrently with the Schwartz Scale of Values (Triandis et al. 1990). Second, the overarching concepts of individualism and collectivism are becoming increasingly refined as specific relationships between values and other variables are examined. Triandis (1995) proposes that individualism and collectivism be further distinguished by horizontal and vertical dimensions in which “horizontal” refers to egalitarian social commitments and “vertical” refers to social hierarchies. Vertical collectivism may characterize the value structure of rural India, vertical individualism may characterize the structure of the United States, horizontal collectivism may characterize an Israeli kibbutz, and horizontal individualism may characterize Sweden’s value structure (Singelis et al. 1995). Third, another refinement has been proposed by Kagitcibasi (1997), who argues that “relational” individualism/collectivism be distinguished from “normative” individualism/collectivism. The normative approach emphasizes cultural ideals, such as an individualistic culture’s prioritization of rights and a collectivistic culture’s stress on group harmony and loyalty. The relational approach emphasizes differing concepts of the self in individualism and collectivism. In individualistic cultures, the self is perceived to be autonomous, with clear boundaries drawn between the self and others. In collectivist cultures, the self is perceived as more interdependent, with greater self-identification with the group.

SOCIAL VALUES

The measurement of social values constitutes a unique approach in values research. More than any other approach, this one directly addresses the adjudication between individual and collective in-

terests. The basic issue in this research is how individuals prioritize allocations between themselves and anonymous others. How much are individuals willing to sacrifice their own interests for the good of the group?

Social values research is grounded in a larger paradigm of experimental gaming, the most famous example of which is the “prisoner’s dilemma.” Although game theory is quite complex, most experimental games have as a central theme the conflict between individual and collective outcomes. This is particularly true in “*n*-person” prisoner’s dilemma games and “commons” games, both of which are more generally called social dilemma games (for a general review of social dilemmas research, see Yamagishi 1994). The social values measure is a slight variation of these games, which always involve decisions that result in various payoffs to the self and others. These games are laboratory analogues of real-world situations in which values may play a significant role in behavioral choices. The example of supporting a tax levy for public education discussed at the beginning of the article constitutes a social dilemma because individual interests are in direct conflict with the common good. Another example is proenvironmental behavior such as not littering and recycling. The classic prisoner’s dilemma refers to a hypothetical situation involving the choice between exposing a coconspirator of a crime to obtain a lenient sentence and remaining loyal in spite of the greater personal risk in doing so.

In this research tradition, social values are measured through the administration of “decomposed games” to college students participating in social psychology experiments (Messick and McClintock 1968). Essentially, the subjects are presented with a series of payoffs that vary in consequence for both the self and a paired player. The subjects are asked to choose between two and sometimes three outcomes. For example, a subject may be asked which of the following outcomes would be preferable: receiving \$8 while the other person receives \$2 and receiving \$5 while the other person also receives \$5. The constellation of several choices with varying outcomes determines the subject’s social values. Primarily, the technique

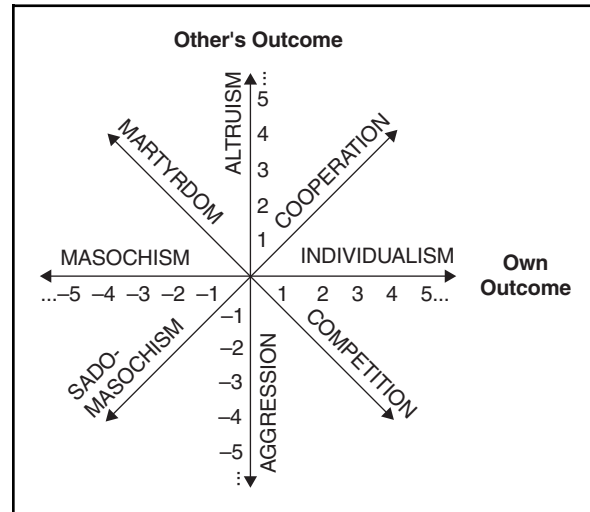

Figure 2. Vectors that define a subset of social values (Given a particular value orientation, an actor should select that combination of available own and others outcomes that has the greatest projection on the correspondent vector)

SOURCE: McClintock and Van Avermaet (1982), p. 49.

distinguishes between altruists, cooperators, individualists, and competitors, the most common classifications.

Each orientation is an indication of the preference that is given for the outcomes for both the self and the other. Subjects may attempt to maximize or minimize their own or others’ outcomes or may be indifferent to one or the other. Figure 2 displays the universe of social values in a two-dimensional representation of preferences for the self and the other. Altruists are defined by indifference to their own outcomes and a preference for maximizing others’ outcomes. Cooperators attempt to maximize both their own and others’ outcomes. Individualists maximize their own outcomes but are indifferent to those of others. Competitors are concerned with maximizing their own outcomes while minimizing others’ outcomes; that is, they attempt to maximize the difference between their own and others’ outcomes. Theoretically, other social values may exist, such as aggressors, who are indifferent to the self while minimizing others’ outcomes; sadomasochists, who minimize both self and others’ outcomes; masochists, who mini-

mize their own outcomes but are indifferent to others', and martyrs, who minimize their own outcomes while maximizing those of others. Except for occasional aggressors, these orientations have not been found empirically. Subjects who show no consistent pattern of choice are treated as unclassifiable.

Kuhlman and Marshello (1975) have shown that social values influence choices in prisoner's dilemma games, Liebrand (1986) and McClintock and Liebrand (1988) have demonstrated their influence in a variety of *n*-person games, and Kramer et al. (1986) have done the same thing in regard to a commons dilemma. In other words, values have been demonstrated to clearly affect behavioral choices in these laboratory situations.

Altruists and cooperators tend to cooperate, while individualists and competitors tend to defect (not cooperate). The essence of social values is the identification of individual differences regarding preferred outcomes in interdependent situations. One interpretation of social values is that "cooperators have internalized a value system in which satisfaction with interdependent relationships is directly proportional to the level of collective welfare they produce; competitors' rewards are directly proportional to how much more they receive than others; and individualists are relatively indifferent to others' outcomes, making them most similar to the traditionally conceived 'economic person'" (Kuhlman et al. 1986, p. 164).

Studies of social values have found that cooperators and noncooperators view social dilemmas differently. In general, decisions in social dilemmas are evaluated in terms of intelligence and morality. Players often are seen as making either "smart" or "good" decisions. Intelligence conforms to a player's social values. Cooperators tend to view cooperation as the intelligent choice, predicting that unintelligent others will defect. Noncooperators tend to view defection as the intelligent choice, predicting that unintelligent others will cooperate. This self-serving reversal does not occur with morality, however. Van Lange (1993) found that both cooperators and noncooperators view cooperation as moral. Both groups expect

more cooperation from highly moral others than from less moral others.

Although noncooperators see a link between morality and cooperation, they do not tend to view the social dilemma situation as being primarily moral. Cooperators are more likely to view cooperation as a moral act. Noncooperators frame the problem not in terms of morality but in terms of power: Cooperation is viewed as weak rather than moral. This is called the "might over morality hypothesis" (Liebrand et al. 1986). Viewing cooperation as both weak and unintelligent may provide the self-justification necessary for pursuing an egoistic goal ("Van Lange 1993). The might over morality hypothesis may overstate the case for noncooperators. Defectors have been found to assign more moral attributions to defection than do cooperators (Van Lange et al. 1990). The difference may be not only that cooperators view the dilemma as a moral situation more than defectors do but also that defectors may view their moral obligations differently. Both groups are likely to view self-enhancement as an important value.

Despite the fact that cooperators view social dilemmas as highly moral, their cooperation is not a matter of pure altruism. They are concerned with joint outcomes, with the self included. When they are exploited by noncooperators, they quickly defect (Kuhlman and Marshello 1975). In a study by Kuhlman et al. (1993), cooperators viewed cooperation as a partially self-interested act. That is, they recognized the self-beneficial outcomes of collective cooperation. By contrast, competitors and individualists did not do this. For cooperators and competitors, the difference may be explained by trust. Cooperators are high trusters, assuming that others will be cooperative. Competitors are low trusters, expecting others to defect as they themselves do (Kelley and Stahelski 1970). Competition therefore may be a result of a fear of exploitation or of losing in a competitive social arena. Individualists were found to be high trusters (expecting others to cooperate), unlike competitors. In this case, defection may be motivated more by greed than by fear.

Two studies suggest that social values discovered in the laboratory may have ecological validity,

that is, be relevant to real-world situations. Bem and Lord (1979) created a three-part strategy: First, they had experts list the personality characteristics of cooperators, competitors, and individualists. Second, they used decomposed games to measure the subjects' values. Third, they had the subjects' dormitory roommates describe the personality of the subjects. The personal descriptions of specific individuals correlated with both the personality templates created by the experts and subjects' social values as measured by the games. McClintock and Allison (1989) assessed the social values of subjects and, after several months, mailed them a request to donate their time to a charitable cause. Cooperators were more willing to donate time than were competitors and individualists.

Social values research describes differing motivational preferences and behaviors in social dilemmas. This line of research is fascinating because it has adopted the methodology (experimental games) of "rational choice" theorists, who argue that prosocial values always will be trumped by considerations of self-interest. Although the experimental paradigm is clearly artificial and perhaps contrived, it has fostered an accumulation of controlled evidence that supports the basic thesis of values research: Values are important determinants of behavioral choice.

INGLEHART'S POSTMODERN THESIS

Values research as it is described in this article has followed two distinct strands represented by several schools of theory and research. The first is the micro-level strand. Values research at the microlevel has focused on individual values: what they are, how they are measured, how they vary, and how they affect behavior. The various methodologies for measuring values, from Rokeach's value survey, to the Schwartz scale, to Messick and McClintock's decomposed games, represent this strand. The second strand operates at the macro level, the level of cultures or societies. In this strand, one question concerns the distinct cultural variations in values priorities, such as Triandis's individualism versus collectivism. Another question follows from

Weber's work drawing a link between cultural values (Protestantism) and socioeconomic change (the emergence of capitalism). The contemporary work of Inglehart is concerned with the association of values and economic development and with how changes in economic conditions are reflected in very different value priorities. Important works in this tradition include Inglehart (1990) and Abramson and Inglehart (1995). A good summary is found in Inglehart (1995).

The starting point for this line of research is Weber's ([1905] 1958) classic association between Protestantism and the rise of capitalism in the West. Protestant Europe created a new value system that replaced several dogmatic restraints on the development of medieval European society. Weber was principally interested in the shift from traditional authority, best represented by the church, to what he called "rational-legal" authority, which endorsed individual achievement over ascriptive status and the preeminence of the impersonal state as an arbiter of conflicts. Crucial to modernization was secularization, which was reflected in an emerging scientific worldview, and bureaucratization, which was reflected in the rise of organizations driven by attempts at efficiency and explicit goal setting.

Inglehart argues that modernization has followed a fairly straightforward trajectory with economic growth and security at its epicenter. Correlated with modernization has been a coherent set of values such as industriousness, equity, thrift, and security. However, the achievement of economic security in the last twenty-five years in many countries around the world is fostering a change in the dominant values paradigm. Inglehart suggests that people may be experiencing a turn toward postmodern values that emphasize individualistic concerns such as friendship, leisure, self-expression, and the desire for meaningful, not just wealth-creating, work. In key ways, postmodern values follow a path similar to that of modernization values, especially in regard to secularization and individuation. However, they branch in other directions on several points. In societies in which major proportions of the members are economically secure, individuals seek to fulfill postmaterialistic

aims such as environmental protection and relational satisfaction. Individuals reject large institutions, whether religious or state-based, focusing instead on more private concerns. They seek new outlets for self-expression and political participation, particularly through local activism.

Some evidence for the postmodern shift comes from Inglehart and Abramson's (1994) analyses of the Euro-Barometer Surveys, which have measured values at frequent intervals since 1970 in all the European Community nations. These surveys have shown a general increase in postmaterialistic values.

Other evidence regarding the postmodern thesis is drawn from the 1990–1991 World Values Survey, which included data from representative samples from forty-three countries and more than 56,000 respondents. Using multiple indicators for the identification of modern and postmodern values, Inglehart tabulated mean scores for each country for forty-seven values. Those scores were employed in a factor analysis that disclosed two important dimensions. The first dimension contrasts traditional authority with rational-legal authority, and the second contrasts values guided by scarcity conditions with those guided by postmodern or security conditions. The distribution of these values in a two-dimensional space is illustrated in Figure 3. These distributions of values also correspond to countries, and so they can be plotted in a two-dimensional space (Inglehart 1995). For example, Inglehart places the United States, Great Britain, and Canada as well as the Scandinavian countries in the postmodern end of this dimension. China, Russia, and Germany ranked highest in the rational-legal domain. Nigeria stood out in its emphasis on traditional authority, while India, South Africa, and Poland fell between an emphasis on traditional authority and an emphasis on scarcity values.

These data do not suggest that once a country achieves a certain level of economic security, a sweeping change in values follows. The process is gradual, with segments of the population shifting from generation to generation. Hence, even in "postmodern" societies, many, if not most, of the members are likely to emphasize "modernist" val-

ues (Kidd and Lee 1997). These data do not suggest that those who adopt postmodern values score higher on various indicators of subjective well-being (Inglehart 1995). What changes is not their level of happiness per se but the criteria by which they evaluate their happiness.

Two issues will continue to receive attention in this line of research. First, there has been some debate about the role of environmentalism as a postmodern value. Does it indicate postmodern commitments, suggesting that it will be valued only by economically secure societies, or is it a more inclusive phenomenon? For a discussion of this issue, see Kidd and Lee (1997) and Brechin and Kempton (1997) along with other articles in that issue of *Social Science Quarterly*. More generally, the postmodern thesis must be tested with cross-national time-series data to identify values changes over time. These data also will provide insight into questions of causality (Granato et al. 1996): Do values affect economic development, or vice versa?

CONCLUSION

Values research has been of interest to sociologists throughout the history of the discipline. Recently, the study of values has produced novel empirical research programs that carefully address core questions in this field of inquiry. Most fundamentally, values researchers ask what motivates behavior: Is it self-interest alone, self-interest and external coercion, or a combination of self-interest, coercion, and internalized values? A central issue in this line of questioning is the role of values in adjudicating conflicts between individual and collective pursuits.

Values researchers begin with the task of values measurement. What values do people hold? Which ones do they prioritize? How do values differ between members of society and between different cultures? Rokeach supplied the most common measure of values, and Schwartz expanded that measure. Messick and McClintock supplied a very different and innovative measure of social values within the paradigm of game theory research. Schwartz, Triandis, and Inglehart have

Figure 3. Variation in the values emphasized by different societies: traditional authority versus rational-legal authority and scarcity values versus postmodern values

SOURCE: Source: Inglehart (1995), p. 389.

made valuable contributions to the understanding of values cross-culturally. Of particular note is the apparent universality in the conceptual organization of values worldwide, while much variation in the cultural commitment to particular values has been observed.

Beyond measurement, values researchers have been concerned with the role of values in social

interaction. Do values motivate behavior? How are values related to other motivators of behavior? How do individuals increase or decrease their commitment to particular values? How do societies undergo values changes? How are conflicts between values adjudicated between individuals, between individuals and their communities, and between different cultures? Each of the research

traditions described in this article has made a contribution to an understanding of the complex values-behavior relationship. Rarely, however, has the question of values acquisition and retention been addressed. Given the enormous progress in cross-cultural values research, it is likely that this domain will garner a great deal of research attention in the next few years.

VIOLENCE

See Crime Rates; Criminology; Crowds and Riots; Family Violence; Sexual Violence and Exploitation; Terrorism.

VOLUNTARY ASSOCIATIONS

The 1990s saw renewed interest in and concerns about voluntary associations and their roles in society. On the international level, countries that had been part of the Soviet Union and its power bloc continued to form and experiment with what they called "informal groups," which had the essential characteristics of voluntary associations. That is, those groups were independent of control from outside sources, people were free to join or leave them, and members established their own objectives and goals and developed means that might achieve them. Among the most important developments arising from these informal groups was the emergence of political parties as part of the struggle to establish democratic governments.

ORIGIN OF THE IDEA OF VOLUNTARY ASSOCIATIONS

It is generally acknowledged that the origins of voluntary associations are in the writings of early Reformation leaders such as Martin Luther and John Calvin (Hooker 1997). Calvin taught that all believers should participate equally in church decisions. The way to accomplish this equality was to see the church as a free and voluntary association of members; at the same time, to become a member, an individual had to be approved by the congregation. An early expression of this democratic church model developed in New England towns, with the local Congregationalist church as the prototypical voluntary association.

When Alexis de Tocqueville based *Democracy in America* on his tour of the United States in the 1830s, he took particular note of the degree to which Americans formed groups to serve personal interests and solve problems from the mundane to the profound. Tocqueville (1956) was particularly impressed by New England small towns with their autonomous local church congregations, whose citizens gathered in "town meetings" and voted on projects, from building schools and roads to caring for the poor. Current American nostalgia for local control to preserve the moral order may owe much to the almost sacred aura given to the reading of Tocqueville's description of early American society.

CHARACTERISTICS AND OBJECTIVES OF VOLUNTARY ASSOCIATIONS

Research on voluntary associations was limited until recently, with most people accepting their importance to a free society and concentrating on questions of demographic characteristics and the contributions they made to local communities (Irwin et al. 1997).

One of the most consistent findings about voluntary associations (Cutler 1976) was that individuals with higher socioeconomic status (SES) were more likely to participate in voluntary associations. Age, race, and gender (while influenced strongly by SES) also were identified as important factors in membership, with middle-aged persons, whites, and males more likely to be members.

Gender differences in voluntary association membership have been studied in terms of rates of participation as well as differences in the types of organizations to which each sex belongs. Historically, women's participation rates in voluntary associations (McPherson and Smith-Lowin 1986) were lower than men's. Furthermore, the groups to which women belonged tended to be smaller, single-sex, and expressive rather than instrumental. Still, in the 1980s, Knoke (1986) reported that the gender gap was narrowing as more women entered the professional ranks.

Studies of the effect of race on voluntary association membership provided inconsistent findings. For example, Hyman and Wright (1971) documented a sharp increase in membership among blacks between 1955 and 1962 (sharper than that among whites). However, blacks continued to be less likely to belong to a voluntary association other than the local church congregation and its Bible study groups. Knoke (1986, p.4) summarized more recent research with the statement that "researchers generally found that blacks' participation rates fell below whites' but disagreed on whether the gap could be traced to black SES disadvantages."

Researchers interested in the way nonpolitical voluntary associations influence political participation have found that individuals who are members of such organizations are more likely to vote and participate in politics (Sigelman et al. 1985; Wolfinger and Rosenstone 1980; Milbrath and Goel 1977; Rogers et al. 1975).

Voluntary associations range in size from groups of four or five persons to those with hundreds of thousands of members worldwide; structures vary from very informal with little leadership and few norms or guiding rules to highly structured with formal leadership, codes of conduct, and elected and appointed offices. These differences reflect different goals and the ability to influence civic and political affairs.

Some associations, such as the American Medical Association, labor unions, and churches that are hierarchic in structure or practice infant baptism, may have some of the characteristics of voluntary associations, but they are not seen as such in the definition adopted here.

CURRENT RESEARCH

In the United States, Putnam (1996) developed the hypothesis that voluntary associations might well have run their course as he recounted the tale of "Bowling Alone," suggesting that the decline of voluntary associations was bringing with it a decline in the country's civic health. His hypothesis sparked renewed interest in voluntary associations and their place in American society.

While Putnam was suggesting the decline of voluntary associations, Wuthnow (1994) was reporting on the large and apparently growing number of Americans who were joining small groups that seemed to have the characteristics of voluntary associations. Wuthnow's national survey of American adults found that "exactly forty percent of the adult population of the United States claims to be involved in a small group that meets regularly and provides caring and support for those who participate in it" (1994, p. 45). Assuming that an American adult belonged only to one small group, Wuthnow estimated that at the time of his study, there were at least three million small groups active in the United States, with approximately one group for every eighty people, assuming group size averages of close to twenty-five. Drawing on a variety of sources, Wuthnow subdivided these small groups as follows:

Bible study and related religious groups:
1.7 million

Self-help groups: 500,000

Special-interest groups (political, sports,
book and/or discussion): 750,000
(1994, p.76)

These figures contrast sharply with earlier attempts to estimate the number of voluntary associations active in American society. Rose (1967) estimated that there were over 100,000 such associations in the United States, and Hyman and Wright (1971) reported that 57 percent of the American adult population did *not* belong to a voluntary association. However, local and regional studies found higher participation rates. For example, Babchuk and Booth's Nebraska study (1969) found that 80 percent of the adult population belonged to at least one voluntary association. More recently, Knoke observed that "perhaps one third of U.S. adults belong to no formal voluntary organizations and only a third hold membership

in more than one (not including churches)” (1986, p. 3). Excluding churches may help account for much of the discrepancy in the figures provided by various scholars.

The highest figure provided for membership in voluntary associations among adult Americans came from the 1990–1991 World Values survey. Galston and Levine (1997, p. 2) reported that that survey showed that “82 percent of Americans belonged to at least one voluntary association, a rate exceeded only by Iceland, Sweden and the Netherlands.” This survey was carried out as Wuthnow was doing his study of small groups and Putnam was bemoaning the decline of at least some kinds of voluntary associations.

Evidence of concerns about growth and decline in voluntary associations can be found in events such as the agreement between Lions Clubs International and the Junior Chamber International (JCs) to form a global partnership to boost membership and encourage lifelong service to the community. Lions International (1998) reported 1.4 million members representing 43,700 clubs in 185 countries, while the Junior Chamber reported 322,000 members in 9,000 chapters in 123 nations. The members of JCs typically have been in the under-40 age bracket; the intent of the new collaboration is to have them join Lions Clubs as they move up the age ladder. Both groups would be encouraged to work more closely together in community service. In this way, they hope to stem the age creep that has brought stagnation and decline to many voluntary associations.

Skocpol and her colleagues in the Harvard Civic Engagement Project have begun to document the local, state, and national linkages of voluntary associations, in the process challenging the assumption that the strength of American civic life ever lay in the local focus of voluntary associations. In her historical overview, Skocpol (1997) identified events such as the Revolutionary War and the subsequent electoral politics, along with the development of an extraordinarily extensive and efficient national postal system, as key factors encouraging the activities of thousands of local and extralocal voluntary associations. Major growth spurts occurred between 1820 and 1840, from after the Civil War to the end of the century, and in the 1930s. These growth spurts seem to be related

to the great issues of the time: slavery and its moral dilemmas, industrialization, and economic crisis.

The Harvard group has so far tracked detailed life histories of some fifty-five voluntary associations that have enrolled 1 percent or more of American adults at some point in their history. Four-fifths of these associations still exist, with most of them paralleling the three-tiered government structure with local, state, and national branches. Although many groups have come and gone at the local level, a more balanced historical view sees voluntary associations as vital links between local and national civil life. The social historian Alexander Hoffman was cited as stating that “local institutions and organizations may best be understood as branch offices and local chapters . . . the building blocks of a ‘nation of joiners.’ . . . Americans enlisted in local church groups, fraternal lodges, clubs, and other organizations that belonged to nationwide networks” (Skocpol 1997, p. 3).

There is evidence of a decline in some types of voluntary associations even as new small groups emerge. For example, Skocpol (1996) noted that since the 1960s, the Christian Coalition has been one of the few cases of local to national federations growing, while some, such as the Lions, Rotary, and the Junior Chamber, have found themselves with an aging population and in a process of slow decline or even death. Thus, the new alliance between the Lions and the Junior Chambers mentioned above may be seen as an effort at revitalization.

Current research about voluntary associations has revealed a decline of same-sex organizations, growing numbers of college-educated and professional women members, and the replacement of family-oriented by professional associations. As Skocpol put it, “the best educated people are still participating in more groups overall, but not in the same groups as their less well-educated fellow citizens” (1997, p. 5).

At least in the short run, the educational gap, which is reflected in the occupational and income gaps, seems more of a threat to the well-being of civil society than does the so-called loss of the local group. Indeed, Wuthnow’s data, supported by recent research on small faith communities in the U.S. Catholic Church (D’Antonio 1997), suggests the opposite: Small associations are alive and booming at the local level, with more than a little sup-

port from national organizations that provide regional gatherings, bring together diverse racial and ethnic groups, and provide a wide range of literature that urges outreach as a part of their mission. Their members may be spending more time working in soup kitchens and other service activities. Meanwhile, other small groups are supporting local teenage sports clubs rather than participating in union-style bowling leagues.

Among Wuthnow's findings was that social support in these small groups tends to focus on the individual; the groups themselves revealed tendencies to see political and social issues in a conservative vein. Outreach seldom got beyond the soup kitchen state of concern for others.

To the extent that these new groups cut across class, gender, and age lines, they may be fulfilling the hope expressed by Skocpol (1997, p. 5) that Americans will find new ways to work together, "not just on 'helping the poor' but 'doing with' rather than 'doing for' if we want to revitalize the best traditions of American voluntarism."

NEW DIRECTIONS

Among the new directions in voluntary association activity is the development of an interdisciplinary relationship between social work and veterinary medicine. Built on the premise that "democracies are based on the value of the worth and dignity of each person, and the empowering of persons to take action in their own lives" (Granger and Granger 1998), Colorado State University has established a Human-Animal Bond Center (HABIC). Its goal is to provide animal-assisted therapy and activities in partnership with community health, mental health, education, and human service programs. The founders of this program extend the respect for humans to animals and to the environment as a crucial element in the survival of a democratic society. The essential factor in their vision is the linkage of voluntary associations with formal groups such as social work agencies and veterinary medicine societies.

At the international level, scholars in Finland are going beyond studying the functional role of voluntary associations in the stability and growth of democratic societies. They propose that "from the point of view of social constructionism voluntary associations can be seen as forums for the

production and transmitting of social meanings. This is an intersubjective process which may yield objectivated and taken-for-granted meanings. If internalized, these meanings become the source of personal identity and goal-formation of the association. Thus voluntary associations can be seen not only as part of the western culture heritage but also as cultures in themselves" (Raivio and Heikkala 1998, p. 1).

CONCLUSION

Voluntary associations generally are seen as central ingredients of a pluralist democratic society. Millions of Americans belong to hundreds of thousands of these associations, as do growing numbers of people worldwide. Among the more important research findings has been the multifaceted nature of voluntary associations' growth and impact: Some associations have remained strictly local; some have grown from local to state, national, and international levels; and not a few have grown from the top down, such as the American Legion and the PTA. Their influence on local, state, and national governments has led to much important legislation, such as the GI Bill fostered by the American Legion.

A review of the literature and current research challenges the nostalgic view that what is needed to restore vitality to American democracy is a return to localism and a shrinking national government. Instead, these findings suggest that the current trend toward the growth of a variety of types of voluntary associations, within and across national boundaries and working with rather than apart from governments, is the best formula for the revitalization of American political democracy. The limited evidence from other societies suggests that that same formula applies to all societies seeking to model Western democracies.

WILLIAM V. D'ANTONIO

VOTING BEHAVIOR

In addition to sociologists, scholars from many different fields, including history, political science, psychology, and geography, have studied elections and voting behavior. In current American sociology, however, these topics are largely neglected. Major advances have been made in related disciplines, yet as of one of the pioneers, the sociologist Rice (1928, p. p.vii) stated: "The phenomena of politics are functions of group life. The study of group life per se is a task of sociology." In general terms, despite variations in emphasis between different approaches, the sociological study of voting behavior is concerned with the way individuals obtain, select, and process information related to the political arena; the various forces that shape this process; the relevance individuals attribute to the political sphere; and how they decide to participate in or refrain from specific political actions. Elections provide a convenient focus, a point where the often elusive and latent processing of political information manifests behavioral correlates such as voting or abstaining and supporting one candidate or the other. In contrast, forecasting election returns is not a primary goal of the sociological study of voting behavior, although the general public, parties, and politicians are interested mostly in this aspect. Much applied research served these immediate needs and interests in the past and continues to do so. Still, in the field of voting behavior, pure (academic) and applied research peacefully coexist; cross-fertilization rather than mutual irreverence characterizes their relationship.

The study of voting behavior began in the late eighteenth century (Jensen 1969), although most of the very early work does not meet strict schol-

arly standards. In the course of its development as an academic discipline, two different strands that are still discernible have emerged. The first strand—*aggregate data analysis*—is characterized by the use of actual election returns compiled for geopolitical units such as wards, districts, and counties. Those returns are compared with census data, providing a sociodemographic profile of those areal units. Starting in the late nineteenth century, there developed a school of quantitative historiography that made extensive use of maps representing voting and/or census information by using different shades and colors (Frederick Jackson Turner in the United States and André Siegfried in France). The mere visual inspection and somewhat subjective interpretation of those maps by the Turner school were supplemented and then replaced by more vigorous statistical techniques, in particular correlation analysis, inspired by the sociologist Franklin Giddins at Columbia. One of Giddins's students, Rice (1928), demonstrated the utility of quantitative methods in politics. At the University of Chicago, interdisciplinary cooperation in the social sciences produced some of the most outstanding work of that time (e.g., Gosnell 1930). The advent of modern survey research in the 1930s and 1940s, however, obscured the aggregate approach for quite some time.

The second strand in the study of voting behavior—*analysis of survey data*—also had some early forerunners. Polling individuals about their voting intentions (“straw polls”) or past voting decisions started in the late nineteenth century. In one of the most extensive efforts, more than a quarter million returns from twelve midwestern states were tabulated by a Chicago newspaper for the 1896 presidential contest between McKinley and Bryant. In the 1920s, straw polls conducted by newspapers and other periodicals were quite common and popular. Their reputation was ruined, though, by the failure of the *Literary Digest* poll to foresee the landslide victory of Franklin D. Roosevelt in the 1936 election. By that time, however, pioneers of modern public opinion research such as George Gallup, Archibald Crossley, and Elmo Roper had started to use more rigorous sampling methods as well as trained interviewers to ensure a proper representation of all strata of the electorate (Gallup [1944] 1948).

Interest in voting and political behavior and concern with mass communication, marketing

strategies, and the public's attitude toward World War II stimulated the rapid development of modern survey research from about the mid-1930s through the 1940s and the establishment of survey research centers in both the academic and commercial sectors (Converse 1986). These centers include the Survey Research Center/Institute for Social Research (ISR) at the University of Michigan and the National Opinion Research Center (NORC) at the University of Chicago on the academic side and Gallup's American Institute of Public Opinion on the commercial side, to name just a few early organizations that are still leaders in the field.

Modern voting research based on the survey method typically uses small but randomly selected samples of about 1,000 (rarely more than 2,000) eligible voters. Information is collected through the use of standardized questionnaires that are administered by trained interviewers in person or increasingly over the telephone. Advances in modern communication technology such as the Internet are likely to change the face of scholarly survey research even more drastically in the very near future. “Standardized” means that a question's wording is predetermined by the researcher and that the interviewer is supposed to read questions exactly as stated and in the prearranged order. For the most part, the response alternatives also are predetermined (“closed questions”); sometimes, for select questions, verbatim answers are recorded (“open questions”) and subsequently sorted into a categorical scheme. In contrast to aggregate-level analysis and the use of official election returns, survey-based research on voting behavior relies on self-reports by individual citizens. Thus, it is subject to bias and distortion resulting from question wording, dishonest answers, memory failure, and unstable attitudes even if the sample is properly drawn. Its major advantage is the unequivocal linkage of demographic traits (e.g., age, sex, ethnicity, and social class) and political attitudes and behavior on the level of the individual.

AGGREGATE DATA ANALYSIS

The use of aggregate data in studying voting behavior poses formidable methodological problems, yet it is the only approach available to study voting behavior before the mid-1930s. For example, the Germans voted Hitler into power in genuinely

democratic elections in the late 1920s and early 1930s. The voting behavior of Germans in the Weimar Republic has been subject to much debate and controversy in political sociology. The earlier consensus that Hitler's support came predominantly from the lower middle classes was challenged by later studies (e.g., Childers 1983; Falter 1991) that contended that his support had a much wider base cutting across all social groups.

Findings based on aggregate data analysis often depend heavily on seemingly technical details of preparing the database and the choice of specific statistical techniques. As a rule, findings are more reliable if the geopolitical units are small. However, even if the greatest care is exercised, there is always the danger of an "ecological fallacy." To use a contemporary example, if the vote for a white candidate increases with a rising percentage of white voters across voting districts, it is plausible to assume that people have voted along racial lines, yet this need not be the case. Perhaps ethnic minorities in predominantly white districts are more likely to vote for a white candidate than they are elsewhere. Therefore, they, not the white voters, may be responsible for the increased share of the white candidate.

A solution to the ecological inference problem has been proclaimed (King 1997), but despite some progress, that claim appears to be overstated. In spite of all the remaining shortcomings, though, aggregate data analysis is an indispensable tool for tracing patterns of voting behavior over time in a sociohistorical analysis (e.g., Silbey et al. 1978) or analyzing contemporary voting behavior when sufficiently detailed and reliable survey data are not available. Particularly for local or regional studies, there may not be sufficient funds to conduct appropriate surveys or the research interest may develop only after the elections have taken place.

SURVEY-BASED VOTING RESEARCH

The Columbia School. Four landmark studies connected with the presidential elections of 1940, 1948, 1952, and 1956 mark the establishment of scholarly survey-based research on voting behavior (Rossi 1959). In essence, those studies provided the core concepts and models used in contemporary voting research. Reviewing those studies provides an introduction to present-day theories of voting behavior in U.S. presidential elections,

while congressional elections typically follow a very simple pattern: Incumbents are rarely defeated.

The first two studies were conducted by Lazarsfeld and his associates at Columbia University. Their main intention was to "relate preceding attitudes, expectations, personal contacts, group affiliations and similar data to the final decision" (Berelson et al. 1954, p.viii) and trace changes of opinion over the course of a campaign. Emphasizing the particular set of political and social conditions and its importance for this process, the Columbia group restricted its studies to one community (Erie County, Ohio, in 1940 and Elmira, New York, in 1948) and interviewed the same respondents repeatedly: up to seven times in 1940 and four times in 1948. Repeated interviews, or a "panel design," became a standard feature of more sophisticated voting studies, while the major studies to come abandoned the focus on one community in favor of nationwide representation.

Several major findings emerged from the Erie County study (Lazarsfeld et al. [1944] 1968). First, people tend to vote as they always have, in fact as their families have. In the Michigan school of voting behavior (see below), this attitude stability was conceptualized as "party identification," a stable inclination toward a particular party that for the most part develops during adolescence and early adulthood.

Second, attitudes are formed and reinforced by individuals' membership in social groups such as their social class, ethnic group, and religious group and by the associations they belong to. More concretely, the research team found that people of lower social status, people in urban areas, and Catholics tended to be Democrats while people of higher social class, people in rural areas, and Protestants were more likely to be Republicans. Subsequently, the alliance of particular segments of the population with specific parties was amply documented despite modifications in its particular form. More so than in the United States, voting behavior in the major European democracies (notably Britain and West Germany) could be explained largely by the links between social groups and particular parties (Lipset and Rokkan 1967), although those links have been weakening.

Third, change does occur, and people under cross-pressures are the most likely to change. A cross-pressure occurs when the set of different

group memberships provides conflicting stimuli. For example, in 1940, Protestant blue-collar workers experienced a pull toward the Republicans on the basis of their religious affiliation and a pull toward the Democrats because of their class position. In the United States today, the impact of religious affiliation is more complicated, but the general notion of cross-pressure remains important.

Fourth, Lazarsfeld and colleagues developed the concept of a “two-step flow of information.” According to this concept, most people are not directly persuaded by the mass media even if they are susceptible to change. Instead, they tend to follow opinion leaders, who are the informal leaders in the various social networks (family, friends, associates at the workplace) in which individuals are involved. These leaders pay close attention to the media; they disseminate and validate media messages. With the ever-increasing impact of mass media (television and more recently the Internet) over the last fifty years, this result of the 1940 study may not reflect the situation today. Unfortunately, it is very difficult to prove media effects conclusively, and the cumulative empirical evidence has not been able to settle a long-standing controversy about the extent of media effects.

The 1948 Elmira study was designed to test further and if necessary modify the findings of the earlier study and integrate the results into the body of existing knowledge (see Berelson et al. 1954, pp. 327–347, for a comparative synopsis of several major studies). As a matter of fact, its main contribution lies in the refinement of several aspects that were not covered sufficiently in the Erie County study. However, the Elmira study still failed to show systematically the links between the efforts of the various institutions in the community and the decisions of the voters. The focus on those links was the key rationale for limiting these studies to one community, a feature that invites doubt whether the findings can be generalized to all American voters.

The Michigan School. The sociological approach of the Columbia school was subsequently overshadowed by the social psychological model of the Michigan school that came to dominate survey-based voting research for many years. After a smaller study in 1948 (Campbell and Kahn 1952), the Michigan team, led by Campbell, conducted major studies in 1952 and 1956 (Campbell et al.

1954; Campbell et al. 1960). In contrast to Lazarsfeld and associates, their studies used national samples, thus expanding the geographic coverage, but only two interviews, one shortly before and one shortly after the elections. In addition, the Michigan group introduced far-reaching changes in the conceptualization of the voting process. On the basis of its national study of 1948, those researchers felt that social group memberships have little direct impact on the voting decision. Instead, they focused on “the psychological variables which intervene between the external events of the voter’s world and his ultimate behavior” (Campbell et al. 1954, pp. 85–86). In particular, they considered three concepts: party identification, issue orientation, and candidate orientation. *Party identification* refers to the sense of personal attachment an individual feels toward a party irrespective of formal membership or direct involvement in that party’s activities. It is thought of as a stable attitude that develops early in life. In contrast, both issue orientation and candidate orientation depend on the context of a particular election. *Issue orientation* refers to individuals’ involvement in issues they perceive as being affected by the outcome of an election. For example, if individuals are concerned about the economy and feel that it makes a difference whether the country has a Democratic or a Republican president, this will have an impact on their voting decisions. Similarly, *candidate orientation* refers to individuals’ interest in the personality of the candidates and to a possible preference that derives from the personal traits of the candidates. For example, Ronald Reagan portrayed himself as a firm and determined leader but also as a caring and understanding father. In that way, he was able to attract many voters otherwise attached to the Democrats.

The Michigan model posits a “funnel of causality.” The social factors emphasized by the Columbia school are not dismissed outright but are viewed as being at the mouth of the funnel, having an indirect effect only through the three central psychological variables, particularly party identification. Party identification in turn affects issue orientation and candidate orientation as well as having a direct effect on the voting decision. The simplicity of this model is both its strength and its weakness. It clearly marks the shift of emphasis to psychological processes of individual perception and evaluation, but it does not explicitly address

the social and political context. However, in *The American Voter* (Campbell et al. 1960), the Michigan group presents a much more comprehensive analysis of the 1956 elections, addressing topics such as the role of group membership, social class, and the political system without, however, explicitly expanding the basic model.

Additional concepts that have been used widely in subsequent research include the concept of a *normal vote* and the typology of elections as *maintaining*, *deviating*, or *realigning* (Campbell et al. 1966) and an assessment of mass belief systems (Converse 1964). The concept of a normal vote follows directly from the basic model: If all voters follow their long-standing inclinations (vote according to party identification), they produce a normal vote. Comparing actual election returns with the (hypothetical) normal vote allows one to assess the impact of contemporaneous, mostly short-term factors. In a maintaining election, the party with the larger number of partisans wins, but its vote share may be somewhat different from its normal share as a result of short-term factors. If short-term factors lead to the defeat of that party, the elections are considered deviating. Realigning elections mark a major shift in basic allegiances. Such shifts are rare and typically are not accomplished in a single election. In the 1930s, the American electorate shifted toward the Democrats as a consequence of economic depression and Roosevelt's New Deal, which promised a way out. However, given their long-term nature, processes of dealignment and realignment are difficult to determine in strict empirical terms (Dalton et al. 1984; Lawrence 1996).

With respect to the nature of mass belief systems, Converse's (1964) article triggered a long-lasting debate that has been settled. Converse asserted that the vast majority of the American people have little interest in politics, that their opinions on issues lack consistency and stability over time, and that those opinions are mostly "non-attitudes." Consequently, a large portion of the electorate does not vote at all; if those people do vote, their vote is based mostly on partisanship and/or a candidate's personality, not on an independent and careful evaluation of the issues.

Critique of *The American Voter* and subsequent refinements. Like other landmark empirical studies, *The American Voter* was not exempt

from sometimes radical critiques that can be grouped into three categories: challenges to the allegedly derogatory image of the American electorate and its implications for the democratic process, assertions that the findings are valid only for the 1950s, and a methodological critique of operationalization, measurement, and model specification. Most of the methodological critique is too technical to be discussed in this article (see, Asher 1983).

One of the earliest and most vocal critics was Key (1966). Using a reanalysis of Gallup data from 1936 to 1960, he developed a typology of "standpatters," "switchers," and "new voters" and asserted that the global outcome of those elections followed a rational pattern derived from an appraisal of past government performance. Hence, as a whole, the electorate acts responsibly despite the fact "that many individual voters act in odd ways indeed" (Key 1966, p. 7).

The most comprehensive effort to review American voting behavior over time, a critique of the second type, was presented by Nie et al. (1976), based on the series of Michigan election studies from 1952 to 1972. Still working within the framework of the Michigan model, those authors found significant changes in the relative importance of its three central factors: a steady decrease in the level of party identification, particularly among younger groups, and a much stronger relative weight of issue orientation and candidate orientation. In a turbulent period of internal strife and social change (civil rights, the Vietnam War, Watergate), the electorate became more aware of issues and much more critical of parties and the established political process. Nie et al. (1976) found a decomposition of the traditional support bases for both Democrats and Republicans, all adding up to an "'individuation' of American political life" (p. 347).

Still largely following the path of the Michigan school, much research in the 1980s was directed toward issue voting, which reflects a continuing decline in stable party attachments through political socialization and/or group memberships. In particular, the impact of economic conditions on electoral outcomes was investigated both in the United States and in other major Western democracies (Eulau and Lewis-Beck 1985; Lewis-Beck 1988; Norpoth et al. 1991). The findings were

diverse, contingent on the specification of the research question and the national context, yet one general pattern emerged and was confirmed beyond the United States in many national elections in the 1990s: Political actors perceived as better able to handle economic matters than their competitors have a significant advantage, and perceived economic competence is strongly related to an individual's voting decision.

Fiorina's (1981) concept of *retrospective voting* can be seen as a bridge between the classic Michigan model and the newer directions that have emerged in the last two decades. Fiorina posits that both party identification and issue orientation are largely dependent on the evaluation of past government performance. Party identification thus represents a sort of running tally of past experience. It is still a long-term influence, but it is subject to gradual change and is based more on cognition than on affection.

More Recent Approaches. With some simplification, one can discern three major directions in voting research in the last fifteen to twenty years, each anchored in a different discipline: Rooted in economic theory, rational choice models have been applied to voting (as well as to many other forms of social behavior); drawing on more general psychological theories, the subfield of political psychology studies in a comprehensive way how the individual perceives and processes political information, with voting being only one specific aspect; and the focus on reference groups on both the macro level such as class or religion (an important strand in European research on voting) and the micro level (social networks) has reemphasized the sociological perspective.

Rational choice models see the voter as carefully evaluating the pros and cons of each party or candidate, assessing its utility (consumer models as in Himmelweit et al. 1985) and proximity to the voter's own position (spatial models as in Enelow and Hinich 1984, 1990; directional models as in Rabinowitz and MacDonald 1989), and then voting for the closest or most useful party and/or candidate. It is doubtful, however, whether such models adequately portray the actual process of reaching a voting decision except among the small segment of highly informed and highly motivated citizens. The rational choice approach has been criticized more generally as conceptually inadequate

for the analysis of mass political behavior (e.g., Green and Shapiro 1994). Other criticism has come from within the rational choice camp, leading, for example, to an "expressive model of voting" (Brennan and Lomasky 1993) that shifts the focus away from the instrumental aspect of voting but maintains the conceptual and terminological framework.

The literature in political psychology is too extensive to be discussed in detail here; overviews are provided by Lau and Sears (1986), Sniderman et al. (1991), and Mutz et al. (1996), among others. However, the contribution of this approach to the discussion of two long-standing controversial topics must be mentioned explicitly: media effects and political belief systems. In regard to media effects, a number of studies using more refined concepts (agenda setting, framing, priming) have suggested a more direct and stronger impact of media than previously had been assumed (see Kinder 1998; Zaller 1996), but a generally accepted model of how the mass media influence the political process has not emerged. In regard to political belief systems or the lack thereof, the notion of a politically uninformed or ignorant and irrational electorate has strong implications for normative theories of democracy and, on a practically level, campaign strategists. There continues to be strong and largely undisputed empirical evidence that many Americans have rather limited factual knowledge of specific bills and policies, the makeup of political institutions, and even their elected representatives. However, it is controversial whether that lack of specific knowledge matters and whether voters are nevertheless able to make "correct" or "reasonable" choices on the basis of more implicit forms of information processing (Delli Carpini and Keeter 1996, Lau and Redlawsk 1997). In both areas, political psychology has not settled the controversy, but it has provided enhanced conceptualizations to guide more productive empirical analyses.

In regard to sociological perspectives, community studies (as in the Columbia school) have attempted to assess the impact of the local context on the decision making of the individual. Context information is gathered by using block-level census data or tracing and interviewing members of the social network of the primary respondents (Huckfeldt 1986; Huckfeldt and Sprague 1995).

On the macro level, the social cleavage approach, long dominant in European voting research (see below), has gained some attention in the United States (see Brooks and Manza 1997).

Voting Behavior in Other National Contexts.

The Michigan school of voting behavior has continued to have a major impact on the emergence of survey-based voting research in other Western democracies (see Beyme and Kaase 1978; Butler and Stokes 1976; Heath et al. 1985; Rose 1974) and electoral research today (e.g., Kaase and Klingemann 1998). A strict replication of the basic model, however, has rarely been feasible because of considerable differences in political systems, party organizations, and electoral rules. In particular, attempts to devise valid measures of the key concept of party identification have produced mixed results at best (e.g., Budge et al. 1976).

Despite considerable variation across European democracies and within specific countries, political parties articulate specific programmatic positions derived from basic ideological beliefs that bind all party members, and parliamentary votes typically follow party lines. Political parties, then, dominate the political contest, and most major parties have their roots in social cleavages relating to class, religion, region, or ethnicity. Consequently, such social group memberships have been powerful determinants of voting behavior (Lipset and Rokkan 1967). Much of the European debate in the last twenty years, however, has focused on evolving changes in the electorate that result in more volatile voters. First, the impact of social (class) origin on the individual life course in general (educational attainment, occupational opportunities, marriage and family, etc.) has declined, leading to a more idiosyncratic definition of self-interest and as a consequence a less predetermined voting pattern. Second, a growing disenchantment with established political parties and politicians in general has weakened the once highly internalized norm of political participation through voting and increased the propensity to vote for new and often extremist parties as a token of protest. Thus, the once stable alliances between parties and certain segments in the electorate along social cleavages have weakened (Crewe and Denver 1985; Franklin et al. 1991; Miller et al. 1990), though there is no consensus whether "class voting" has ended (e.g., Manza et al. 1995).

The emergence of new democracies after the demise of the Communist bloc in eastern Europe in the late 1980s and the continuing process of European integration, including the creation of European Union as a single political and not just economic entity, have created new challenges and opportunities for voting research in Europe. With the introduction of a common currency in 1999, a continuing reduction of national sovereignty, and a generally strengthened position of the European Parliament in exercising control over the executive branch (European Commission), European elections will lose their stigma as second-order elections. Studies of European elections in 1974, 1979, and 1994 suffered from limited funding and broke no new conceptual ground. However, they did establish the fact that national rather than pan-European issues dominated voting choices (Schmitt and Mannheim 1990; Van der Eijk and Franklin 1996). This is likely to change, but it is too early to tell the role these elections will play in the further process of European unification and whether voting behavior in those elections will follow patterns different from those in national elections.

The methodological problems of the European election studies in achieving functional equivalence of the instruments (questions) and ensuring uniform quality standards in sampling and interviewing are even more formidable in the new eastern European democracies. Apart from the technical aspects of conducting valid and reliable surveys, there may be inherent limits to exporting the survey method (Bulmer 1998). Rather than relying solely on survey data and taking them at face value, analysts must employ a more comprehensive approach that integrates quantitative and qualitative research, such as the one used by White et al. (1997) in their study of Russian voters. In the absence of a stable party structure and stable political institutions more generally and with the relative novelty of voting in free elections, it is unrealistic to expect the Michigan model or any other "reductionist" model to provide an adequate description of voting behavior in eastern Europe.

Beyond Europe, it is doubtful whether the concept of voting is functionally equivalent to voting in the United States or western Europe because of systemic differences and traditions. For example, even if one accepts the premise that Japan is a pluralist democracy (Richardson 1997),

an intricate net of mutual obligations governs much social behavior, including voting, and for many years relevant electoral competition occurred only within one dominant party. Still, the Michigan model has guided much Western research on Japanese voting behavior (Flanagan et al. 1991).

OUTLOOK

Compared to the United States, research on voting behavior in western Europe has been tied more closely to the study of mass political behavior in general, satisfaction with democracy, the parties, the politicians, and, the stability of the political system despite a continuing orientation toward the Michigan model and its variants. What European research has to offer are not better micro models of voting behavior but detailed trend analyses of cross-national comparative data that put voting into a broader context of political behavior (e.g., Klingemann and Fuchs 1995). As a result of the systemic differences within Europe and the methodological limitations of the database, no unified theory of voting behavior has emerged. For each individual (national) election, there is a plausible explanation, at least in retrospect, drawing on well-recognized factors such as perceived economic competence and leadership image, but the relative weight of each factor varies from one election to the next. As information and communication behavior is undergoing drastic changes as a result of technological advances (Internet) and the ever-increasing presence of the media, it will become even more difficult to determine the relative weight of each factor in a voter's choice. The Columbia studies dealt with voters in a relatively contained world in which the amount of information and the number of transmission channels were limited; voters in the twenty-first century will be faced with an overload of information and will be as closely connected to the political world (or its competing representations) as they want to be. At best, more knowledgeable voters will be able to make better informed choices; at worst, more perplexed voters will succumb to the most skillful public relations managers. Somehow voters will have to reduce this complexity, and turning to social groups for guidance is a likely strategy. While it will be important to continue to study the processes of cognition and information processing, the real key to voters' "rationality" may lie in their social relations. More than ever, the study of vot-

ing behavior will have to build bridges between the various disciplines and incorporate the sociological perspective.

W

WAR

The ubiquity and importance of war have made analyses of its causes a central concern of scholars for over two millennia. Many of the fundamental questions about the causes of war were raised by Thucydides in the fifth century B.C., but the vast amount of work on the topic since that time has produced ongoing debates instead of generally accepted answers. Studies of war can be divided into three broad categories (reviews of the literature using similar frameworks are provided by Waltz 1959; Bueno de Mesquita 1980; and Levy 1989). The first type takes the system as whole as the unit of analysis and focuses on how characteristics of the interstate system affect the frequency of war. States are the unit of analysis in the second type, which explores the relationships among the political, economic, and cultural features of particular states and the propensity of states to initiate wars. The third type analyzes war as an outcome of choices resulting from small group decision making.

Some debates focus on characteristics of the interstate system that are thought to increase or decrease the chance of war. Are wars more likely during a period of economic prosperity or one of economic contraction? Which is more likely to maintain peace, a balance of power in the international system or a situation in which one state is hegemonic? Has the increasing power of transnational organizations such as the United Nations changed the likelihood of war in the contemporary world?

Social scientists also disagree about the effects of political and economic factors within a state on

the possibility of war. Does a capitalist economy make a state more or less likely to initiate wars? Do democratic states start wars less often than autocracies do? Is increasing nationalism likely to cause more wars? Is the ethnic composition within and between states an important determinant of war?

There is also no consensus on which model of individual decision making is most appropriate for the study of war. Is the decision to go to war based on a rational calculation of economic costs and benefits, or is it an irrational outcome of distortion in decision making in small groups and bureaucracies? Are wars based on nationalist, ethnic, or religious conflicts generated more by emotions or values than by rational choices?

THE INTERSTATE SYSTEM AND WAR

Most studies of war that use the interstate system as the unit of analysis begin with assumptions from the “realist” paradigm. States are seen as unitary actors in realist theories, and their actions are explained in terms of the structural characteristics of the system. The most important feature of the interstate system is that it is anarchic. Unlike politics within states, relations between states take place in a Hobbesian state of nature. Since an anarchic system is one in which all states constantly face actual or potential threats, their main goal is security. Security can be achieved in such a system only by maintaining power. In realist theories, the distribution of power in the interstate system is the main determinant of the frequency of war.

Although all realist theories agree on the importance of power distribution in determining war, they disagree about which types of power distributions make war more likely. Balance-of-power theories (Morgenthau 1967) suggest that an equal distribution of power in the system facilitates peace and that an unequal distribution leads to war. They argue that parity deters all states from aggression and that an unequal power distribution generally will result in the strong using force against the weak. When one state begins to gain a preponderance of power, a coalition of weaker states will form to maintain their security by blocking the further expansion of the powerful state. The coalitions that formed against Louis XIV, Napoleon, and Hitler seem to fit this pattern.

Hegemonic stability theory (Gilpin 1981) suggests exactly the opposite: that unequal power in the system produces peace while parity results in war. When one state has hegemony in the world system, it has both the incentive and the means to maintain order. It is not necessary for the most powerful state to fight wars, since its objectives can be achieved in less costly ways, and it is not rational for other states to challenge a state with overwhelming power. Gilpin notes that the periods of British and U.S. hegemony were relatively peaceful and that World Wars I and II occurred during intervening periods in which power was distributed more equally. Since balance-of-power and hegemonic stability theories seem to explain some but not all of the cases, what is needed is a theory specifying the conditions under which either parity or hegemony leads to war.

Balance-of-power and hegemonic stability arguments are not applicable to all wars, only those between great powers. A third attempt to explain great-power war is power transition theory (Organski 1968). This theory suggests that differential rates of economic growth create situations in which rising states rapidly catch up with the hegemonic state in the system and that this change in relative power leads to war. Organski argues that the rising state will initiate a war to displace the hegemonic state. This final part of the argument is questionable, since it seems at least as plausible that the hegemonic state will initiate the war against the rising challenger to keep the small advantage it still has (Levy 1989, p. 253).

Debates about power transitions and hegemonic stability are of much more than theoretical interest in the contemporary world. Although the demise of the Soviet Union has left the United States as an unchallenged military hegemon, American economic superiority is being challenged by the European Union (EU) and emerging Asian states (Japan in the short run, perhaps China in the long run). If power transition and hegemonic stability theories are correct, this shift of economic power could lead to great-power wars in the near future. If the main challenge is from the EU (the most likely scenario), it will be interesting to see if the cultural heritage of cooperation between the United States and most of Europe will be sufficient to prevent the great-power war that some theories predict.

Another ongoing debate about systemic causes of war concerns the effects of long cycles of economic expansion and contraction. Some scholars argue that economic contraction increases the chance of war, since the increased scarcity of resources leads to more conflict. Others have suggested the opposite: Major wars are more common in periods of economic expansion because only then do states have the resources necessary to fight. Goldstein's (1988) research suggests that economic expansion tends to increase the severity of great-power wars but that economic cycles have no effect on the frequency of war.

Two important changes in the last fifty years may make many systemic theories of war obsolete (or at least require major revisions). The first is technology. Throughout history, technological changes have determined the general nature of warfare. By far the most significant recent development has been the availability of nuclear weapons. Since the use of these weapons would result in "mutually assured destruction," they may have made war much less likely by making it irrational for both parties. Of course, the broadening proliferation of nuclear weapons raises serious problems, as does their existence in currently unstable states such as the Russian federation. A second technological change that may alter the nature of war is increasing dependence on computers. Although computers have increased the accuracy and precision of many types of military technology, they also leave the countries using them vulnerable to new kinds of attacks by "hackers" who could not only disarm military operations but

bring whole economies to a halt by disrupting the computer systems necessary for their operation.

The second significant change in the last half of the twentieth century has been the development and increasing power of transnational organizations such as the United Nations. Most theories of war begin with the assumption that the interstate system is anarchic, but this is no longer valid. If the military power of the United Nations continues to grow, that organization could become more and more effective at preventing wars and suppressing them quickly when they start. Of course, it remains to be seen whether powerful existing states will cede more power to such institutions.

Theoretical debates about the systemic causes of war have not been resolved, in part because the results of empirical research have been inconclusive. To take one example, equality of power in the interstate system decreased the number of wars in the nineteenth century and increased the number in the twentieth century. Proponents of each theory can point to specific cases that seem to fit its predictions, but they must admit that there are many cases it cannot explain. At least part of the problem is that systemic theories have not incorporated causal factors at lower levels of analysis, such as the internal economic and political characteristics of states. Since the effects of system-level factors on war are not direct but always are mediated by the internal political economy of states and the decisions made by individual leaders, complete theories of the causes of war must include these factors as well.

CAPITALISM, DEMOCRACY, AND WAR

One of the longest and most heated debates about the causes of war concerns the effects of capitalism. Beginning with Adam Smith, liberal economists have argued that capitalism promotes peace. Marxists, by contrast, suggest that capitalism leads to frequent imperialist wars.

Liberal economic theories point to the wealth generated by laissez-faire capitalist economies, the interdependence produced by trade, and the death and destruction of assets caused by war. Since capitalism has increased both the benefits of peace (by increasing productivity and trade) and the costs of war (by producing new and better instru-

ments of destruction), it is no longer rational for states to wage war. The long period of relative peace that followed the triumph of capitalism in the nineteenth century and the two world wars that came after the rise of protectionist barriers to free trade often are cited in support of liberal economic theories, but those facts can be explained by hegemonic stability theorists as a consequence of the rise and decline of British hegemony.

In contrast to the sanguine views of capitalism presented by liberal economic theories, Marxists argue that economic problems inherent in advanced capitalist economies create incentives for war. First, the high productivity of industrial capitalism and a limited home market resulting from the poverty of the working class result in chronic "underconsumption" (Hobson [1902] 1954). Capitalists thus seek imperial expansion to control new markets for their goods. Second, Lenin ([1917] 1939) argued that capitalists fight imperialist wars to gain access to more raw materials and find more profitable outlets for their capital. These pressures lead first to wars between powerful capitalist states and weaker peripheral states and then to wars between great powers over which of them will get to exploit the periphery.

In contrast to the stress on the political causes (power and security) of war in most theories, the Marxist theory of imperialism has the virtue of drawing attention to economic causes. However, there are several problems with the economic causes posited in theories of imperialism. Like most Marxist arguments about politics, theories of imperialism assume that states are controlled directly or indirectly by dominant economic classes and thus that state policies reflect dominant class interests. Since states are often free of dominant class control and since many groups other than capitalists often influence state policies, it is simplistic to view war as a reflection of the interests of capitalists. Moreover, in light of the arguments made by liberal economists, it is far from clear that capitalists prefer war to other means of expanding markets and increasing profits.

With the increasing globalization of economies and the transition of more states to capitalist economies, the debates about the effects of capitalism, trade, and imperialism on war have become increasingly significant. If Adam Smith is right, the future is likely to be more peaceful than

the past, but if Marxist theorists are right, there will be an unprecedented increase in economically based warfare.

The form of government in a country also may determine how often that country initiates wars. Kant ([1795] 1949) argued that democratic states (with constitutions and separation of powers) initiate wars less often than do autocratic states. This conclusion follows from an analysis of who pays the costs of war and who gets the benefits. Since citizens are required to pay for war with high taxes and their lives, they will rarely support war initiation. Rulers of states, by contrast, have much to gain from war and can pass on most of the costs to their subjects. Therefore, when decisions about war are made only by rulers (in autocracies), war will be frequent, and when citizens have more control of the decision (in democracies), peace generally will be the result.

Empirical research indicates that democratic states are less likely than are nondemocratic states to initiate wars, but the relationship is not strong (Levy 1989, p. 270). Perhaps one reason for the weakness of the relationship is that the assumption that citizens will oppose war initiation is not always correct. Many historical examples indicate that in at least some conditions citizens will support war even though it is not in their economic interest to do so. Nationalism, religion, ethnicity, and other cultural factors often are cited as important causes of particular wars in journalistic and historical accounts, but there still is no general theory of the conditions in which these factors modify or even override economic interests. Many classical sociological arguments suggested that these "premodern" and "irrational" sources of war would decline over time, but the late twentieth century has demonstrated the opposite. Nationalist and ethnic wars have become more common and intense. This raises the general issue of the factors affecting the choices individuals make about war initiation: Can these factors be modeled as rational maximization of interests, or is the process more complex?

DECISION MAKING AND WAR

Although the assumptions may be only implicit or undeveloped, all theories of war must contain some assumptions about individual decision making. However, few theories of war focus on the individual level of analysis. One notable exception

is the rational-choice theory of war developed and tested by Bueno de Mesquita (1981).

Bueno de Mesquita begins by assuming that the decision to initiate war is made by a single dominant ruler who is a rational expected-utility maximizer. Utilities are defined in terms of state policies. Rulers fight wars to affect the policies of other states, essentially to make other states' policies more similar to their interests. Rulers calculate the costs and benefits of initiating war and the probability of victory. War is initiated only when rulers expect a net gain from it.

This parsimonious set of assumptions has been used to generate several counterintuitive propositions. For example, common sense might suggest that states would fight their enemies and not their allies, but Bueno de Mesquita argues that war will be more common between allies than between enemies. Wars between allies are caused by actual or anticipated policy changes that threaten the existing relationship. The interventions of the United States in Latin America and of the Soviet Union in eastern Europe after World War II illustrate the process. Other counterintuitive propositions suggest that under some conditions a state may rationally choose to attack the stronger of two allied states instead of the weaker, and under some conditions it is rational for a state with no allies to initiate a war against a stronger state with allies (if the distance between the two is great, the weaker state will be unable to aid the stronger). Although these propositions and others derived from the theory have received strong empirical support, many have argued that the basic rational-choice assumptions of the theory are unrealistic and have rejected Bueno de Mesquita's work on those grounds.

Other analyses of the decision to initiate war focus on how the social features of the decision-making process lead to deviations from rational choice. Allison (1971) notes that all political decisions are made within organizations and that this setting often influences the content of decisions. He argues that standard operating procedures and repertoires tend to limit the flexibility of decision makers and make it difficult to respond adequately to novel situations. Janis (1972) focuses on the small groups within political organizations (such as executives and their cabinet advisers) that actually make decisions about war. He suggests

that the cohesiveness of these small groups often leads to a striving for unanimity that prevents a full debate about options and produces a premature consensus. Other scholars have discussed common misperceptions that distort decisions about war, such as the tendency to underestimate the capabilities of one's enemies and overestimate one's own. In spite of these promising studies, work on deviations from rational choice is just beginning, and there still is no general theoretical model of the decision to initiate war.

CONCLUSION

The failure to develop a convincing general theory of the causes of war has convinced some scholars that no such theory is possible, that all one can do is describe the causes of particular wars. This pessimistic conclusion is premature. The existing literature on the causes of war provides several fragments of a general theory, many of which have some empirical support. The goal of theory and research on war in the future will be to combine aspects of arguments at all three levels of analysis to create a general theory of the causes of war.

WHITE-COLLAR CRIME

In his 1939 presidential address at the annual meeting of the American Sociological Society, Edward H. Sutherland used, with great effect, the term "white-collar crime." In an interesting introduction to his discussion of Sutherland, Green (1990) noted that in 1901, 1907, and 1935, respectively, Charles Henderson, Edward Alsworth Ross, and Albert Morris had "anticipated" the ideas Sutherland had presented, after conducting much research, in 1939. Sutherland depicted a white-collar criminal as any person of high socioeconomic status who commits a legal violation in the course of his or her occupation (Green 1990). Later he defined white-collar crime as criminal acts committed by persons in the middle or upper socioeconomic groups in connection with their occupations (Sutherland 1949). Since that time, the concept has undergone some modification and "has gained widespread popularity among the public" but "remains ambiguous and controversial in criminology" (Vold and Bernard 1986). More specifically, some definitions have deleted the class of the offender as a consideration.

Edelhertz (1970) defines white-collar crime as an “illegal act or series of illegal acts committed by nonphysical means and by concealment or guile, to obtain money or property, to avoid payment or loss of money or property, or to obtain business or personal advantage.”

Others have attempted to refine the definition by differentiating between occupational and corporate contexts (Clinard and Quinney 1973; Clinard and Yeager 1980), clarifying the difference between and among government, corporate, organizational, and occupational crimes (Coleman 1994; Green 1990; Punch 1996) and avoiding the use of the term “crime” by substituting “law violations” that involve the violator’s position of power (Biderman and Reiss, 1980). Tappan (1947) said that white-collar crimes are not “crimes” if they are not included in legal definitions.

While various writers measure the extent of white-collar crimes in terms of the number of “violations” (Clinard and Yeager 1980) or the extent of harm done to the public, business, or the environment (Punch 1996), others focus on dollar costs. Reiman (1995) modified the cost estimates of white-collar crimes by the U.S. Chamber of Commerce (1974) and made those figures applicable to 1991. Among his categories were consumer fraud, credit card and check fraud, embezzlement and pilferage, insurance fraud, receiving stolen property, and securities theft and fraud. His total amounted to \$197.76 billion for 1991. Reiman noted that those figures compared favorably with Clinard’s estimate of \$200 billion for one year (1990) and with a similar figure reported in *U.S. News and World Report* (1985). Reiman notes that his own estimate, is on the conservative side but that it is “almost 6000 times the total amount taken in all bank-robberies in the US in 1991 and more than eleven times the total amount stolen in all thefts reported in the FBI Uniform Crime Reports for that year” (1995, p.111). Reiman’s figures apparently do not include any of the vast amounts of money lost in the savings and loan scandal. These issues are elaborated on below.

Green (1990) states that Sutherland’s three main objectives were to show that: (1) white-collar crime is real criminality because it is law-violative behavior (Sutherland asserted that civil lawsuits resulting in decisions against persons or corporations should be considered convictions and are

proof of violations of law), (2) poor people are not the only ones who commit crime, and (3) his theory of differential association constituted an approach that could explain a general process characteristic of all criminality.

Sutherland held that typical crime “statistics” picturing the criminal population as made up largely of lower-class, economically underprivileged people give a false impression of noncriminality on the part of the upper classes, including respected and highly placed business and political persons (Sutherland 1949). His white-collar criminality included some of the following: misinterpretation of the financial statements of corporations, manipulation of the stock exchange, bribery of public officials to obtain desirable contracts, misrepresentation in advertising and salesmanship, embezzlement and misuse of trust funds, dishonest bankruptcies, and price-fixing. He quoted the Chicago gangster Al Capone calling such practices “legitimate rackets” (Sutherland 1949) to differentiate them from the more violent rackets of the underworld.

Sutherland held that white-collar criminals are relatively immune because of the class bias of the courts and the power of their class to influence the administration of the law. As a result of this class bias, the crimes of the “respectable” upper class generally are handled differently than are the crimes of the lower class. To compensate for this class bias, Sutherland argued that official conviction statistics must be supplemented by evidence of criminal violations from other sources, such as hearings before regulatory commissions, civil suits for damages, administrative hearings, and various other procedures outside criminal court prosecutions (Vold and Bernard, 1986).

Coleman (1994) says that because “Sutherland’s work focused almost exclusively on business crimes and especially violations of federal economic regulations” and because he failed “to devote more attention to violent white-collar crimes,” a debate sprang up about whether white-collar crime is really crime. Since business offenses were handled as civil or administrative matters, Sutherland’s detractors suggested that white-collar criminals were not “real” criminals. Coleman states, “Had the argument focused on flammable clothes that burned helpless children,” Sutherland would have been in a stronger position. Still, Coleman

suggests, Sutherland would have encountered resistance. When he made his address in 1939, crime was seen as something that happened primarily among immigrants and poor people. The idea that business leaders should be considered criminals had an un-American sound to it. Moreover, corporate executives were not likely to support such ideas. Coleman holds, however, that Sutherland won the first round of this debate with the scholars who criticized him.

Tappan was one of the first to criticize Sutherland's position. Tappan, who was trained as both a lawyer and a sociologist, asserted that crime, if legally defined, was an appropriate topic of study for sociologists (1947). Accordingly, he felt that actions that were not against the law were not crimes and that persons who had not been convicted of criminal charges were not criminals. Sutherland, following Sellin (1951), held that Tappan's criterion of legal conviction was too far removed from the offense, which may go undetected, unprosecuted, and/or unconvicted (Green 1990). Burgess (1950) agreed with Tappan that Sutherland erred in failing to distinguish between civil and criminal law. However, Vold and Bernard (1986) suggest that a scientifically adequate theory of crime must explain all behaviors that have the same essential characteristics, whether or not the behavior has been defined as a crime by criminal justice agencies. Sutherland initiated his attempt to develop such a theory with his theory of differential association, which he felt could explain both lower-class and white-collar crime.

Biderman and Reiss (1980) considered white-collar crime to consist of "violations of law, to which penalties are attached, and that involve the use of a violator's position of significant power, influence, or trust in the legitimate economic or political institutional order for the purpose of illegal gain, or to commit an illegal act for personal or organizational gain." Coleman (1994) defines white-collar crime as a "violation of the law committed by a person or group of persons in the course of their otherwise respected and legitimate occupational or financial activity." Green (1990) points out that the terms "respectable" and "significant power or influence" employed in these definitions do not represent an improvement of Sutherland's definition because they are relative terms. Because of such problems, Green seems to suggest that pinpointing the white-collar criminal

(person) is considerably more problematic than delineating white-collar crime. He agrees with Sutherland that white-collar crime is inexorably limited to occupational opportunity.

In their analysis of corporate violations, Clinard and Yeager (1980) say that while corporate crime is white-collar crime, occupational crime is a different type of white-collar crime. Building on earlier work by Clinard and Quinney (1973), they suggest that "occupational crime is committed largely by individuals or by small groups of individuals in connection with their occupations." They include under this type "businessmen, politicians, labor union leaders, lawyers, doctors, pharmacists, and employees who embezzle money from their employees or steal merchandise and tools. Occupational crimes encompass income tax evasion; manipulation in the sale of used cars and other products; fraudulent repairs of automobiles, television sets, and appliances; embezzlement; check-kiting; and violations in the sale of securities" (1980, p. 18).

Clinard and Yeager, in agreement with Sutherland's opinion of what constitutes law violation, say that "a corporate crime is any act committed by corporations that is punished by the state, regardless of whether it is punished under administrative, civil, or criminal law" (1980, p. 16). They also state that Sutherland conducted the first research in this area and that his book *White Collar Crime* (1949) should have had the title of their book: *Corporate Crime*.

Green has extended the work of Clinard and Quinney and Clinard and Yeager and that of others in *Occupational Crime* (1990). He claims that corporate crime almost always occurs within the course of one's occupation, and thus the term "occupational crime" encompasses corporate offenses. To Green, occupational crime refers to any act punishable by law that is committed through an opportunity created in the course of an occupation that is legal. Green goes on to say that the criterion of a legal occupation is necessary, since otherwise the term could include all crimes. A legal occupation, he indicates, is one that does not in itself violate any laws. Thus, the term would exclude persons with occupations that are illegal to begin with, such as bank robbers and professional con men. He lists four types of occupational crime: (1) crimes for the benefit of an employing

organization, (2) crimes by officials through their state-based authority, (3) crimes by professionals in their capacity as professionals, and (4) crimes by individuals as individuals.

Coleman (1994) has noted both the tendency to redefine the concept of white-collar crime to include any nonviolent crime based on concealment or guile (Webster 1980) and the tendency to impose new terms such as "occupational crime," "corporate crime" (discussed above), "elite deviance," "corporate deviance," and "organizational crime" (not to be confused with "organized crime"). Coleman states that "the whole point behind most criminologists' concern with white collar crime is to give the same kind of attention to the crimes of the powerful and privileged that is given to common offenders." He states that the term "white-collar crime" best serves this purpose or goal and is too useful a conceptual tool to be thrown out: "Because it clearly identifies a specific problem of great concern to people around the world, 'white collar crime' has become one of the most popular phrases ever to come out of sociological research" (Coleman 1994, p. 5).

Coleman (1994) clearly acknowledges that some of the criticisms of Sutherland's original definition are valid; for example, (1) responsibility for some white-collar offenses is attributable to groups, and (2) many white-collar offenses are committed by persons from the middle levels of the status hierarchy. Coleman (1994) states that in a major respect, however, Sutherland's views seem relevant. One of the central issues in early debates about the definition of white-collar crime was whether the term should include violations of civil as well as criminal law. As the study of white-collar crime has developed over the last fifty years, many criminologists have sided with Sutherland's view that it should include both civil and criminal violations (Wheeler 1976; Schragger and Short 1978; Braithewaite 1979; Clinard and Yeager 1980; Hagar and Parker 1985).

Following the lines of other students, Coleman states that a typology of white-collar crimes is needed (1994, p. 10). He suggests that while a humanistic perspective might focus on the consequences of white-collar crimes for victims (property losses versus physical injury), a more useful typology might center on differences between offenders. Thus, he suggests a dichotomy between occupational crimes (consisting of offenses by in-

dividuals, whether employee or employer) and organizational crimes, which include both corporate and government crimes.

Poveda (1994, p. 70) asserts with some justification that the design of a typology depends on the theoretical biases of the researcher. He says that scholars need to be aware of the diversity of white-collar crime in considering explanations. Poveda suggests that there are two traditions, both of which can be traced to the initial Sutherland-Tappan debate. One school, the Sutherland school, focuses on the offender as the defining characteristic of white-collar crime. The other school emphasizes the offense as the central criterion of white-collar crime (Poveda 1994, p. 39). Both traditions are alive and well.

TRENDS IN RESEARCH: CORPORATE, OCCUPATIONAL, AND ORGANIZATIONAL CASES

Punch, Reiman, Clinard and Yeager, Green, and Coleman are unanimous that interest in white-collar crime emerged or gathered speed after the Watergate scandal in the 1970s. It does seem that while there was early excitement over Sutherland's initial 1939 address, interest quickly waned. In the late 1940s, interest in social order seemed to predominate. Clinard and Yeager (1980) reviewed the events of the 1960s and 1970s, describing the occasional corporate conspiracies and environmental abuses that came to the public's attention. They noted how the short and suspended sentences given to Watergate offenders contrasted "sharply with the 10-, 20-, 50-, and even 150-year sentences given to burglars and robbers." Reiman, beginning with the first edition *The Rich Get Richer and the Poor Get Prison* (1979), has been a consistent critic of the different ways in which justice has been meted out to the poor and the well to do.

Clinard and Yeager (1980), in what Punch (1996) calls the piece of research that is closest to Sutherland's legacy, conducted the first large-scale comprehensive investigation of the law violations of major firms since Sutherland's pioneering work. Sutherland (1949) conducted his study on seventy of the two-hundred largest U.S. nonfinancial corporations. The study of Clinard and Yeager (1980) involved a systematic analysis of federal administrative, civil, and criminal actions initiated or com-

pleted by twenty-five federal agencies against the 477 largest publicly owned manufacturing (Fortune 500) corporations and 105 of the largest wholesale, retail, and service corporations in the United States in the period 1975–1976. Thus, they had a total sample of 582 corporations. Clinard and Yeager found the following:

A total of 1,553 federal cases were begun against all 582 corporations during 1975 and 1976 or an average of 2.7 federal cases of violation each. Of the 582 corporations, 350 (60.1 percent) had at least one federal action brought against them, and for those firms that had at least one actions brought against them, the average was 4.4 cases. (1980, p. 113)

Six main types of violations were reported by Clinard and Yeager (1980): administrative, environmental, financial, labor, manufacturing, and unfair trade practices. Their evidence shows that “often decisions on malpractice were taken at the highest corporate levels, that records were destroyed or ingeniously doctored by executives and their accountants and that the outcomes of these decisions can have serious economic, financial, political, personal, and even physical consequences” (Punch 1996, p. 52).

Punch (1996) focused on selected cases, mainly from other countries, that bear on his hypothesis that business is criminogenic, i.e., it justifies or tolerates illegal behavior. This parallels Clarke’s (1990) contention that crime and misconduct are endemic to business and that the key to understanding them lies in recognizing the structure that the business environment gives to misconduct both in terms of opportunities and in terms of how misconduct is managed. Punch states that his underlying purpose is to use his cases to “unmask the underlying logic of business and the submerged social world of the manager” (1991, p. 213). Punch states, however, that he is not asserting that most companies are guilty of criminal behavior. Indeed, he says that “there are companies which explicitly set out to conform to the law; they maintain a record of no transgressions” (p. 214). In short, Punch focuses on companies that engage in corporate deviance.

If after reviewing the works of Clinard and Yeager (1980) and Sutherland (1949), a student of crime still is inclined to conclude that the term “white-collar crime” refers to harmless or small

mistakes in judgment rather than to harmful, selfish, profit-oriented motives followed by an intentional cover-up of brutal consequences, Punch sets the record straight. One of the most chilling of his cases is the Three Mile Island nuclear accident in Pennsylvania in March 1979. A series of incidents involved (1) a leaking seal, (2) leading to feedwater pumps that failed to come into operation and remove heat from the core (3) because of blocked pipes stemming from (4) valves having been left in the wrong position after routine maintenance some days earlier and (5) that could not be seen because the control switch indicator was obscured. Through further accidents, mounting tension, and delays, danger increased and a complete meltdown loomed. Then, “almost by coincidence, and perhaps because of a new shift supervisor checking the PORV [pilot-operated relief valve], the stuck relief valve was discovered. More as an act of desperation than understanding. . . the valve was shut” (p. 126). Punch then quotes Perrow (1984, p. 29):

It was fortunate that it occurred when it did; incredible damage had been done with substantial parts of the core melting, but had it remained open for another thirty minutes or so, and HPI [high-pressure injector] remained throttled back, there would have been a complete meltdown, with the fissioning material threatening to breach containment.

What Punch (1996) describes in his recounting of this case and others includes the following:

1. Earlier warnings by an efficient inspector about the inherent dangers in nuclear plant procedures had been brushed aside; the inspector then had been subjected to strong informal control in an attempt to deflect his message.
2. Profitability (based on the productivity of privately run industry) was the top priority, and this is a problem in most corporations.
3. Management responds to crises such as the one described (by Perrow, Punch, and others) by keeping things running.
4. Regulatory agencies tend to compromise rather than enforce the rules governing safety; indeed, they appear to “have a dual function both to regulate and promote an industry” (p. 255).

Among his conclusions, Punch writes:

When cleared of radioactive debris, Unit Two will remain in quarantine for thirty years until it is dismantled as planned along with Unit One, which will then have reached the end of its working life. Until 2020, then, Unit Two at Three Mile Island in the middle of the Susquehanna River will remain a silent sentinel to a disturbing case of incompetence, dishonesty, complacency, and cover-up. (pp. 134–135).

This conclusion is disturbingly similar to that made earlier by Clinard and Yeager (1980) as they noted the evasion of responsibility by many of the corporate managers in their study and the unethical climates that disregarded the public's welfare (p. 299). Punch (1996) found a similar criminal climate in cases that involved Thalidomide and its effects on pregnancy, originating in Germany; the Guinness affair in England involving illegal financial dealings; the Italian affair involving business, politics, organized crime, and the Vatican Bank; a case in the Netherlands involving deviance in a shipbuilding conglomerate; and the savings and loan scandal in the United States.

The savings and loan scandal, covering the period 1987–1992, represents one of the greatest fraud cases in the twentieth century (Mayer 1990; Pizzo et al. 1989; Thio 1998). Thio stated that this fraud cost taxpayers \$1.4 trillion. Coleman (1994) explained that the rise in interest rates in the 1980s created serious economic problems for many savings and loan associations (thrifts) as their inventories of low-interest fixed-rate mortgage loans became increasingly unprofitable. The thrifts had been restricted until then by government regulations and were losing money. Punch (1996) suggests that the election of Ronald Reagan to the presidency accelerated an ideology of deregulation that held that business should be freed from undue rules and restrictions and that market forces should be given free rein to enhance competition. Deregulation of the industry did take place, and this meant that interest rates were not rigid, financing could be offered with no down payment, and loans could be given for consumer and commercial purposes. Those developments opened up opportunities for unscrupulous businesspersons who moved in and exploited the thrifts for devious purposes. Deregulation not only loosened con-

trols but “raised the limit of federal protection on deposits to \$100,000; brokers could make commissions on them, investors received higher interest rates and the S&L attracted new funds while enjoying a federal safety net” (Punch 1996, p. 16). As quoted by Punch (1996), the Federal Home Loan Bank-Board reported the following to Congress in 1988:

Individuals in a position of trust in the institution or closely affiliated with it have, in general terms, breached their fiduciary duties; traded on inside information; usurped opportunities for profits; engaged in self-dealing; or otherwise used the institution for personal advantage. Specific examples of insider abuse include loans to insiders in excess of that allowed by regulation; high-risk speculative ventures; payment of exorbitant dividends at times when the institution is at or near insolvency; payment from institutions' funds for personal vacations, automobiles, clothing, and art; payment of unwarranted commissions and fees to companies owned by a shareholder; payment of “consulting fees” to insiders or their companies; use of insiders' companies for association business; and putting friends and relatives on the payroll of the institutions. (U.S. General Accounting Office 1989, p. 22).

Calavita and Pontell (1990) categorized these fraudulent practices as “unlawful risk-taking,” “looting,” and “covering-up.” Their work indicates that this type of corporate crime was unlike that reported by writers such as Clinard and Yeager (1980), which was designed to enhance corporate profits; rather, the savings and loan affair revealed premeditated looting for personal gain. They called this kind of crime “a hybrid of organizational and occupational crime”; this was crime by the corporation against the corporation, encouraged by the state, and with the taxpayer as the ultimate victim (Calavita and Pontell 1991).

Those studies of corporate, organizational, and occupational crimes appear to follow Sutherland's initial focus and concerns and to establish what might be called a Sutherland school of white-collar crime. Other researchers besides those mentioned earlier have made valuable contributions to this growing field, including Geis (1968), Braithewaite (1984), and Vaughn (1983).

OFFENDERS AND OFFENSES

The focus on offenses has been referred to by Poveda (1994) as a second school of thought that follows Tappan's tradition and is distinct from Sutherland's tradition with its emphasis on the offender. Social class, of course, has always been at the center of this debate in terms of its relationship to white-collar crime. While Sutherland emphasized that many violations were committed by respectable persons in the course of their occupations, Tappan argued for the recognition of the law in defining crime. Poveda states that

the law of course specifies which acts are to be criminalized regardless of who commits them. In this view the defining characteristic of white-collar crime is the offense rather than the offender. The problem of defining white-collar crime from this perspective becomes one of deciding which subset of crimes is "white collar." By separating white-collar crime from the characteristics of the offender, white-collar crime in the legal tradition ceases to be linked to any particular social class. (1994, p. 40)

Edelhertz (1970) objected to Sutherland's assertion that white-collar crimes must occur in the course of the offender's occupation. He argued that that definition excludes offenses such as income tax evasion, receiving illegal Social Security payments, and other similar offenses, that he considered white-collar crime. Edelhertz's work suggests that the class of the offender need not be central to the concept of white-collar crime but that the offense should be the central consideration. In this respect, he reflected Tappan's stance. According to Poveda (1994), criminologists who focus on the offense have come to dominate views among workers in the justice system and have become more numerous among criminologists since Edelhertz modified Sutherland's definition in the 1970s.

Shapiro (1990) also suggests that the analysis of white-collar crime must shift from a focus on the offender to focus on the offense, particularly when violations of trust situations and norms are involved. She argues that the leniency shown to white-collar criminals accused of securities fraud has resulted from the social organization of their offenses and the problems of social control they posed rather than from class biases involving higher status.

It is relevant, then, to ask whether the laws on white-collar crime are applicable to corporations as well as to individuals. After reviewing the historical development of laws creating various white-collar crimes (embezzlement and theft, unfair competition, bribery and corruption, endangerment of consumers and workers, and environmental degradation), Coleman (1994) explained that the laws involving criminal intent have been extended to include corporations, stating that "it is now common for corporations to be charged with criminal violations of the regulatory statutes as well as more serious offenses" (p 125). As will be seen below, conviction and punishment are different matters.

CONVICTIONS AND SENTENCING

In the 1980s, Wheeler directed a series of studies at Yale University that focused on both offenders and offenses as well as on a comparison of white-collar and conventional crimes. Wheeler et al. (1982, 1988) focused on eight white-collar offenses in the federal system, which they clustered into three types organized by complexity: (1) the most organized: antitrust and securities fraud, (2) intermediate: mail fraud, false claims, credit fraud, and bribery, (3) the least organized: tax fraud and bank embezzlement. Their studies included only convicted offenses, not violations of civil or administrative regulations. They found that white-collar criminals are better educated, older, and more likely to be white and well off financially compared with conventional criminals. They also found that female white-collar offenders are more similar to conventional criminals than to their male counterparts. In an analysis of the Yale data, Daly (1989) found substantial differences between male and female white-collar offenders. Daly raised questions about whether the term "white collar" should be applied to women since they seldom committed offenses as part of a group, made less money from their crimes, and were less educated. Box (1983) suggested that female workers had fewer criminal opportunities than men. In another important tangent to their findings, Weisbund et al. (1991) argued that much white-collar crime is engaged in by middle-class individuals, revealing an unexpected source of inequality in the Justice Department.

In the area of sentencing, Wheeler and colleagues (1982) found that higher-status defendants

charged with white-collar crimes were more likely to receive jail sentences than were lower-status defendants. In explanation, they suggested that because most cases against high-status defendants were never prosecuted, the few cases that were prosecuted were compelling. They also noted that the research was conducted shortly after the Watergate scandals, when judges were more attentive to misdeeds attributed to greed. In another study of sentencing and status, Hagar and Parker (1985), in an analysis of data on persons charged with criminal and noncriminal acts, observed differential sentencing of employers, managers, and workers. They found that compared with workers, managers were more likely and employers were less likely to be charged under the criminal code. Employers were instead more likely to be charged with Securities Act violations that carried less stigma and a shorter sentence. They noted that employers are in positions of power that allow them to be distanced from criminal events and obscure their involvement. Finally, they stated that Sutherland noted an "obfuscation as to responsibility" that accompanies corporate positions of power. Thus, employers face securities charges rather than criminal charges that require a demonstration of malice.

The Clinard and Yeager study (1980) did not include street criminals. The authors note that there is more leniency for corporate than for other white-collar offenders. In their study, it was found that only 4 percent of sanctions handed out for corporate violations involved criminal cases against individual executives. Of the fifty-six convicted executives in large corporations, 62.5 percent received probation, 21.4 percent had their sentences suspended, and 28.6 percent were incarcerated (p. 287). Among the latter defendants, two received six-month sentences and the remaining fourteen received sentences averaging only nine days (1980).

Relevant here are criticisms of legislation designed to control crime. Geis (1996) points out that legislation dealing with "three strikes" has given a "base on balls" to white-collar offenders and indicates an underlying class, ethnic, and racial bias that seeks to define criminals as "others" rather than confronting the more costly crimes of community leaders and the corporate world.

After reviewing a number of studies of sentencing, including studies by Shapiro, Wheeler and colleagues, Clinard and Yeager, Hagar and

Parker, and Mann, Coleman concludes that "the evidence leaves little doubt that white collar offenders get off much easier than street offenders who commit crimes of similar severity" (1994, p. 157). He notes, however, that "there is some evidence that the punishment for white-collar offenses has been slowly increasing in recent years" (p. 157). Coleman still maintains that while there is increasing severity of punishment, such prosecutors remain rare. He says that "Leo Barrile [1991] concluded that only 16 cases of corporate homicide have [ever] been charged, only 9 of those made it to trial, and in only three cases were corporate agents sentenced to prison" (p. 157).

IMPLICATIONS FOR RESEARCH AND THEORY

Poveda (1994) notes that "in spite of the recent work on white collar offenses, our knowledge of white-collar crime is much more circumscribed than that of conventional crime and draws more heavily upon official crime statistics" (p. 79). He says that Wheeler and associates concluded that the vast majority of white-collar offenders are nonelite offenders who look like average Americans. Wheeler and colleagues argued that Sutherland's definition was narrowly focused on the upper class and ignored the middle group of offenders. Poveda suggests that "it is time to consider alternate approaches to gaining knowledge about white-collar crime, approaches that circumvent the official statistics." (1994, p. 79) because of the need to gather more information about crimes in large organizations. Poveda states that "large organizations have the power and resources to control public information about themselves to a much greater extent than other kinds of offenders" (1994, p. 79). He asserts that researchers will have to penetrate the curtain of secrecy that may enclose illegal behavior.

Poveda proposes that there is a need to study accidents and scandals. He cites the suggestions of Molotch and Lester (1974), who showed how routine news events are managed by political actors in society: corporations, labor unions, the president, members of Congress, and so on. These actors define issues for the public construct the news. Only accidents and scandals "penetrate this constructed reality of the news by catching these

major actors off guard. While accidents are unplanned, scandals involve planned events but they must typically be disclosed by an inside informer to an organization because they involve sensitive information (Poveda 1994, p. 80). Poveda suggests that these events often reveal the incidence of white-collar crime. He says that the *Challenger* disaster was an “‘accident’ that led to disclosures of questionable judgment by the National Aeronautics and Space Administration and the Morton Thiokol Corporation” (p. 81). Punch (1996) has undertaken research that focused on accidents and scandals. This research involved case studies of the savings and loan scandal, the Three-Mile Island nuclear accident, and many others. Braithwaite has written about the drug companies and their record of fraud in testing, price-fixing, and the provision of perks for medical practitioners (Braithwaite 1984).

It is important to note that research in Britain by Clarke and in Britain, Holland, and the United States by Punch and others suggests that corporate, organizational, and occupational crime in the industrial world have more common elements than differences. Moreover, cybercrime, relying heavily on the Internet, has increased greatly according to a report by the British Broadcasting Corporation. Fraud employing stolen credit cards and stolen identities would appear to have worldwide similarities as a result of the growing use of the World Wide Web.

Punch has noted that researchers are increasingly targeting accidents, disasters, and scandals in the business world. He has not noticed any slackening of the calculative nature of business, as evidenced in the transfer of technology and manufacturing to developing nations. Noting the existence of, if not an increase in, the number of shrewd players on the world scene and the growth of unregulated markets, Punch expects fresh scandals not only in the United States but in eastern Europe and the Far East (1996, pp. 268, 269). There is, then, growing agreement that a focus on accidents, disasters, and scandals will provide a growing database on white-collar crime and its various types and that such a database will lead to the development of a more adequate theory of white-collar crime. This would seem to be a prerequisite for the development of an adequate system of deterrence of white-collar crime.

There seems to be agreement that criminologists are some distance away from developing an adequate theory of white-collar crime. Wheeler and associates, Yeager and associates, Poveda, Braithwaite, Coleman, and others have contributed to concept development and theory building in this field. Thus, Reed and Yeager (1996) have emphasized the need to assess how notions of self-interest become merged with corporate interests and the conditions under which these socially constructed interests lead to socially harmful outcomes. Wheeler (1992) has addressed a similar concern with motivational and situational processes that drive individuals to risk involvement in white-collar crime. Coleman also asserts that the related theoretical problems of motivation and opportunity must be understood. He considers the neutralization of ethical standards by which white-collar criminals justify their pursuit of success, the secrecy that shields corporate actions, and the opportunities provided by the legal and judicial systems essential links in the development of an understanding of this type of crime.

Braithwaite (1984) also draws on the structure of opportunity in attempting to understand organizational crime but is perhaps best known for his concept of reintegrative shaming. In his approach, he utilizes control theory, specifying the processes by which corporate offenders are encouraged to strengthen their stake in conformity. He asserts that the other kind of shaming—stigmatization—has the effect of reinforcing offenders in their criminality.

There is an apparent need for a continued focus on occupational and corporate deviance and on individual and organizational offenders in the field of white-collar crime. Interest has been growing in the field, and there is reason to believe that academic researchers, government agencies, and legislatures must communicate with one another more if progress is to be made in the important matter of constructing better deterrents to white-collar crime. However, as suggested by Punch and others, investigators must search more closely for the dark, irrational side of organizations—incompetence, neglect, ambition, greed, power—as well as for motives and structures that allow managers to practice deviance against the organization. It is clear that while many researchers argue for a focus on the organization and others emphasize the need to study individual offenders, there is a grow-

ing acceptance of the need to explore all avenues that lead to white-collar crime. Indeed, there seems to be a clamor among researchers that not only must motivation and opportunity be studied but that the subcultures that facilitate immoral behavioral structures should be analyzed to understand white-collar or any other type of crime.

JAMES E. TEELE

WIDOWHOOD

Marriages that do not end in divorce eventually dissolve through the death of a spouse. The stress of bereavement derives largely from the disorganization caused by the loss of the deceased from the social support system of the survivor. The death of a marital partner requires the development of alternative patterns of behavior so that the survivor can maintain satisfactory relations with the family, the kin group, and the community and sustain his or her personal equilibrium. Families exhibit considerable diversity in their attempts to accomplish these transitions. The difficult and sometimes devastating transition to widowhood or widowerhood necessitates a reintegration of roles suitable to a new status. If children are present, parental death precipitates a reorganization of the family as a social system. Roles and status positions must be shifted, values reoriented, and personal and family time restructured. The potential for role strains and interpersonal conflicts becomes evident as relationships are lost, added, or redefined (Pitcher and Larson 1989). Loneliness becomes a major problem. In many modern societies, this adaptive process proceeds

with few or no guidelines because the widowed person tends to be "roleless," lacking clear norms or prescriptions for behavior (Hiltz 1979).

WIDOWHOOD ACROSS CULTURES

Human behaviors generally are guided by the dominant prescriptions and proscriptions embedded in particular societies, and this is reflected in wide cross-cultural variations among those who have lost a spouse through death (Lopata 1996). For example, the situation of Hindu widows in India has undergone numerous changes, ranging from extremely harsh treatment in the past to slow but steady improvement in the modern era. The custom of *suttee*—the wife's self-immolation on her husband's funeral pyre—has long been outlawed but periodically reappears, especially in rural areas. Even today, widows in that highly patriarchal, patrilineal, and patrilocal society experience isolation and a loss of status. Their remarriage rate is very low. Widows often face a difficult life that is influenced by vestiges of patriarchal and religious dogma and exacerbated by economic problems that force them to become dependent on sons, in-laws, and others. Widowers, by contrast, are encouraged to remarry soon and add progeny to the patriarchal line. Israel is another place where the society and religion are strongly patriarchal and women lose status in widowhood. Jewish mourning rituals "tend to isolate the widow and tie her to the past rather than providing means of creating a new life" (Lopata 1996). Moreover, women who lose husbands through civilian causes of death encounter greater difficulties than do those whose husbands are killed in the military. War widows and their families receive preferential treatment through government policies that give them special recognition, numerous benefits, and many more alternatives for improving their status and prestige than is possible in more traditional societies. Remarriage, for example, is a much more acceptable alternative for women in Israel than it is in India.

All societies are undergoing various degrees of transition. Korea is a society whose transitional problems are dramatically reflected in the situation of widows. Earlier in Korean history, widowhood resulted in a loss of status and remarriage generally was prohibited. Husbands tended to be much older than their wives and to have a higher

mortality rate, and a large number were killed in wars. Moreover, widowers remarried, whereas most widows remained single. All these factors contributed to a widening ratio of widows to widowers over the years. Under the impact of modernization, including increased urbanization and industrialization, Korean society is being transformed, and with it the conditions surrounding the status of widowhood. This transformation includes a shift from authoritarian societal and familial systems in a primarily rural environment toward systems based on more equalitarian norms. Widows began to move to the cities, and this had advantages and disadvantages. On the one hand, they could accompany their sons and take advantage of urban services and the possibility of new friendships. On the other hand, the move removed them from their extended families and neighborhood friends and the communal supports in their rural villages. Living with a son in the city often strained the daughter-in-law relationship. In addition, being distanced from the relatively stable and integrated life of their villages and lacking friendship networks in their new environment often left them vulnerable to loneliness, especially in the case of the elderly widowed. Presumably, succeeding generations with greater personal resources will encounter fewer adaptational requirements.

While survivors face certain common problems and role strains both within and outside the immediate family, it is difficult to specify a normative course of adjustment. This is the case because the widowed are a heterogeneous group characterized by wide differences in social and psychological characteristics. It also is due to the fact that spousal loss evokes a panorama of emotional and behavioral responses from the survivors, depending on factors such as the timing and circumstances of the spouse's death. For example, a wife whose husband was killed in a military battle will respond differently than she would if he had committed suicide or suffered a long terminal illness. Many other antecedent conditions, such as the quality of the marital relationship, affect the bereavement reactions and coping strategies of survivors.

THE DEMOGRAPHICS OF WIDOWHOOD

Census data for the United States show that at the end of the 1990s there were more than 13.5 mil-

lion widowed persons, 85 percent of whom were women. However, people in the widowed category may leave it through remarriage. Hence, the number of people who have ever experienced spousal loss is much greater than is indicated by these data.

For some decades, the widowed female has outnumbered her male counterpart by an ever widening margin. Three factors account for this: (1) Mortality among females is lower than it is among males, and therefore, greater numbers of women survive to advanced years, (2) wives are typically younger than their husbands and consequently have a greater probability of outliving them, and (3) among the widowed, remarriage rates are significantly lower for women than for men. Other factors that contribute to the preponderance of widows include war, depressions, and disease pandemics.

For several reasons, widowhood has become largely a problem of aged women. Each year in the United States, deaths of spouses create nearly a million new widows and widowers. Among people 65 years of age or over, roughly half the women compared with about 14 percent of the men are widowed. (U.S. Bureau of the Census 1997). Advances in medical technology and the pervasiveness health programs have extended life expectancy. The probability of mortality before middle age has decreased, and for the most part widowhood has been postponed to the later stages of the life cycle. Gains in longevity have been more rapid for women than for men. Thus, the growing proportion of elderly females accents their higher rates of widowhood. About one-fourth of all married women will become widows by age 65, and one-half of the remaining women will be widowed by age 75. During that age span, only one-fifth of men will lose their wives. It is projected that the ratio of widows to widowers will increase dramatically from nearly six to one currently to ten to one over the next quarter century.

Because the large majority of the widowed are women, most studies have concentrated on them, while the social consequences for men who lose their spouses has remained a comparatively unexplored area since Berardo (1970) called attention to this gap three decades ago. Widowers, although fewer in number, face many of the same adjustments that confront their female counterparts. At the same time, there is ambiguous evidence that

suggests that widowers have greater vulnerability compared to their female counterparts, while other studies present the situation of widows as more problematic. This disagreement in findings results in part from the failure of many studies to control for the confounding influences of factors such as age, social class, income, health, and retirement.

RESEARCH FINDINGS ON WIDOWHOOD

In making the transition from marriage to widowedhood, the bereaved often are confronted with a variety of personal and familial problems and are not always successful in adapting to those circumstances. This is reflected in the findings that compared with married persons, the widowed consistently have higher rates of mortality, mental disorders, and suicide (Balkwell 1981; Smith et al. 1988). While there is a consensus that bereavement is stressful, research on its effects on physical health has yielded inconsistent results. The evidence shows that the widowed experience poorer health than do the married, but the reasons for this difference are unclear.

Because widowhood is most likely to occur in the elderly, research has focused on that population. However, there is some evidence that the transition to widowhood varies by developmental stage. Older widows adapt more readily because losing a spouse at an advanced age is more the norm, making acceptance of the loss easier than it is for those who are young when widowed. Grieving over the death of a husband or wife at older ages can be exacerbated if additional significant others also die, requiring multiple grieving. This can cause *bereavement overload*, which makes it difficult for the survivor to complete the grief work and bring closure to the bereavement process (Berardo 1988). There is a consensus that the distress associated with conjugal bereavement diminishes over time. Grief becomes less intense as the years pass, but this is not a simple, linear process. The emotional and psychological traumas of grief and mourning may recur sporadically long after a spouse has died.

Gender differences in adaptation to widowhood have been widely debated. The evidence suggests a somewhat greater vulnerability for widowers (Stroebe and Stroebe 1983). Men are less likely to have same-sex widowed friends, are more likely to be older and less healthy, have fewer

family and social ties, and experience greater difficulty in becoming proficient in domestic roles (Berardo 1968, 1970). Higher mortality and suicide rates also suggest greater distress among widowers.

Continuous widowhood has been associated with a loss of income and an increased risk of poverty. Two-fifths of widows fall into poverty at some time during the five years after the death of their husbands. Female survivors, for example, have dramatically higher proportions in poverty than do their divorced counterparts, although both groups experience economic risk resulting from the ending of their marriages that may impede their and their families' adjustment to a new lifestyle (Morgan 1989). There is some evidence that widowers also suffer a decline in economic well-being, although to a lesser degree than do their female counterparts (Zick and Smith 1988). Poor adjustment to widowhood thus may be related to a lack of finances. Elderly individuals often have below-average incomes before the death of a spouse. They may be unwilling or unable to seek employment and are likely to face discrimination in the labor market (Morgan 1989). The younger widowed are more likely to have lost a spouse suddenly and therefore may be unprepared to cope with a lower financial status.

Life insurance has become a principal defense against the insecurity and risk of widowhood in urban industrial society with its nuclear family system. It is a concrete form of security that may help a bereaved family avoid an embarrassing dependence on relatives and the state in the case of an untimely death. However, the amount of insurance obtained is often insufficient to meet the needs of the survivors. Even in instances in which adequate assets have been accumulated, many surviving wives are not prepared to handle the economic responsibilities brought about by a husband's death (Nye and Berardo 1973). Presumably, in the future, a better educated and occupationally experienced population of widows, especially those who were involved in a more equalitarian marital relationship of shared responsibilities, will be better able to cope with their new single status.

Widowhood often leads to changes in living arrangements. Reduced income may force surviving spouses to seek more affordable housing. They also may choose to relocate for other reasons, such

as future financial and health concerns, a desire to divest themselves of possessions, and a desire to be near relatives or friends (Hartwigsen 1987). Most often, survivors living alone are women, usually elderly widows. Isolation and lack of social support can lead to deterioration in their physical and mental well-being. Compared with elderly couples, they are much more likely to live in poverty and less likely to receive medical care when it is needed (Kasper 1988).

WIDOWHOOD AND DIVORCE

Similarities and Differences. Early epidemiological analyses suggested that more deleterious effects were associated with separation and divorce than with widowhood. However, later surveys found higher levels of physical and psychological distress among the widowed than among the divorced. (Kitson et al. 1989). These contradictory findings have not been reconciled. However, for many decades, researchers also have perceived a number of similarities in adjustment between the two groups. For both, there are accompanying disruptions in lifestyle related to changes in income, social interactions, definitions of self, lost emotional attachment, and general psychological well-being. For example, similarities in adjustment have been noted with respect to mode of death or cause of divorce, including the amount of prior warning or preparation a person has before either event, the degree of responsibility felt, and the cause of the event. The more unexpected the loss is, the more responsibility one feels for the loss and wonders whether he or she could have prevented it or helped the spouse and the more difficult the adjustment is.

Another similarity is that whether a spouse is lost through divorce or widowhood, the length of time for adjustment shows considerable variability. The degree of emotional attachment affects the degree of anxiety and depression associated with the loss of a partner, and in both cases the attachment declines as time passes. Emotional attachment is a normal outcome of the tendency for people to form strong affectional bonds to significant others and is not pathological. However, the accumulative changes that occur with the loss of a partner make those who are divorced or widowed more vulnerable to psychological and physical illness, suicide, accidents, and death. While

most partners return to their former level of functioning within a couple of years after the loss of a spouse, some never recover and continue to have poor levels of functioning.

There are also specific factors that make adjustment in widowhood or divorce more difficult, including age, gender, race, and socioeconomic status. Adjustment to the loss of a spouse in either case appears to be more difficult for younger women. Some analysts argue that age is a confounding factor because younger women are more studied as divorcees and older women more studied as widows and because divorce is more common among the young and widowhood more common among the old. The latter factor means that one's adjustment is somewhat dependent on those who have gone before and can help socialize a person to the new role. However, more recent research suggests that younger women still face more adjustment problems (Kitson et al. 1989; Gove and Shin 1989). Analyses suggest that the young and the old bereaved differ in both the intensity of grief and patterns of grief reactions, especially with respect to adverse health and psychological outcomes within the first two years after the demise of a husband (Sanders 1988). It appears that younger widows experience a different adjustment than do older widows, in part because they have fewer cohort friends who are also widows.

Younger survivors are developmentally "out of sync" with their cohorts, and this exacerbates their sense of loneliness and need for companionship (Levinson 1997). Their expectations may be different because they have more years ahead and more potentially eligible marital partners in the future than do older widows. Blacks appear to have an easier time adjusting to the loss of a spouse through divorce than do whites, and black females, who may receive more familial support than whites do, appear to adjust more easily than do white females. Finally, income and financial security play a major role in adjustment: Those near poverty have the most difficult time coping with the loss of a spouse. Female survivors have more problems coping with the loss of income than do their male counterparts, often because their incomes are tied to health insurance, retirement, and other benefits that accompanied the husband's occupation. Men have more difficulty than do women handling the household chores

that were often the responsibility of their wives. Future male cohorts may have less difficulty with this because of changes in the socialization of male children and the rising age at first marriage, and the fact that young men have to cope with household responsibilities on their own before marriage.

WIDOWHOOD AND REMARRIAGE

The probability of remarriage is significantly lower for widows than for widowers, especially at the older ages. It appears that while a large majority of older widows remain attracted to and interested in men in terms of companionship, for a variety of reasons only a small minority report a favorable attitude toward remarriage (Talbot 1998). Some may feel they are committing psychological bigamy and therefore reject remarriage as an option (DiGiulio 1989). There is also a tendency to idealize the former partner, a process known as sanctification (Lopata 1979). This makes it difficult for widows to find a new partner who can compare favorably with the idealized image of the deceased (Berardo 1982). Widows also remarry less frequently than do widowers because of the lack of eligible men and the existence of cultural norms that degrade the sexuality of older women and discourage them from selecting younger mates. Many women manage to develop and value a new and independent identity after being widowed, leading them to be less interested in reentering the marriage market.

There are other barriers to remarriage for the widowed. Dependent children limit the opportunities of their widowed parents to meet potential mates or develop relationships with them. Older children may oppose remarriage out of concern for their inheritance. Widowed persons who cared for a dependent spouse through a lengthy terminal illness may be unwilling to risk bearing that burden again.

WIDOWHOOD AND MORTALITY

The increased risk of mortality for widowed persons has been widely reported. Men are at a greater risk than women after bereavement. The causes of these differences are unknown. Marital selection theory posits that healthy widowers remarry quickly, leaving a less healthy subset that experiences premature mortality. Other factors, such as common

infection, shared environment, and lack of adequate daily care, also may influence the higher mortality rates of the widowed.

Studies of whether anticipatory grief or forewarning of the pending death of a spouse contributes to adjustment to bereavement have yielded conflicting results (Roach and Kitson 1989). Some suggest that anticipation is important because it allows the survivor to begin the process of role redefinition before the death, whereas unanticipated death produces more severe grief reactions. Survivors who have experienced unexpected deaths of their spouses report more somatic problems and longer adjustment periods than do those who anticipated the loss. Anticipatory role rehearsal does not consistently produce smoother or more positive adjustment among the bereaved. It appears that the coping strategies employed by survivors vary with the timing and mode of death, which in turn influence the bereavement outcome.

SOCIAL SUPPORT AND REINTEGRATION

It has been suggested that social support plays an important role in the bereavement outcome and acts as a buffer for stressful life events, but the research is somewhat inconclusive, partly as a result of difficulties identifying those support efforts which produce positive outcomes and those which do not and the fact that support needs change over time. Nevertheless, there is evidence that the extent to which members of the social network provide various types of support to the bereaved is important in the pattern of recovery and adaptation (Vachon and Stanley 1988). Available confidants and access to self-help groups to assist with emotional management can help counter loneliness and promote a survivor's reintegration into society. The social resources of finances and education have been found to be particularly influential in countering the stresses associated with the death of a spouse. Community programs that provide education, counseling, and financial services can facilitate the efforts of the widowed and their families to restructure their lives.

For many older widows, a substantial period of future living alone remains: on average, another fourteen years or more. Borrowing from occupational career models, some researchers have suggested that adopting a "career of widowhood" orientation may facilitate the recovery and well-

being of these survivors: "That is, for most persons, widowhood need not be considered the end of productive life, but rather the beginning of a major segment of the life course, and one that should be pursued vigorously in order for it to be successful and fulfilling" (Hansson and Remondet 1988). In this perspective, the widowed are encouraged to seek control over their existence by actively construing their own life courses. The assumption is that they will adapt better if they plan for where they want to be at different potential stages during the entire course of widowhood. This plan might include the following phases: "a time for emotional recovery; a time for taking stock, reestablishing or restructuring support relationships, and formulating personal directions for the future; a time for discovering a comfortable and satisfying independent lifestyle, and for determining an approach to maintaining economic, psychological, and social functioning; perhaps a time for personal growth and change; and a time for reasoned consideration of one's last years and assertion of a degree of control over the arrangements surrounding one's own decline and death."

There is considerable heterogeneity among the survivor population and thus in their ability to implement a successful "career in widowhood." They differ, for example, in *relational competence*, that is, characteristics that help them acquire, develop, and maintain personal relationships that are essential for social support (Hansson and Remondet 1988). Establishing a new and satisfying autonomous identity after the loss of a spouse is never easy. The probability of achieving that goal can, however, be enhanced through counseling strategies designed for individual circumstances and programs that help survivors avoid desolation coupled with meaningful social and familial support systems.

FELIX M. BERARDO
DONNA H. BERARDO

WORK AND OCCUPATIONS

Work is the defining activity in people's lives. In most of the world, it is a matter of survival, but work also places people in stratification systems, shapes their physical and emotional well-being, and influences their chances for social mobility. Although the term "work" generally is used to denote the exertion of effort toward some end, economically it refers to activities oriented toward producing goods and services for one's own use or for pay. The conception of work as a means of generating income underlies most sociological scholarship on work and most of the available statistics. Unpaid productive work, including that done in the home (indeed, homemaking is the largest occupation in the United States) and volunteer work, tends to be invisible. This article focuses primarily on paid work.

EVOLUTION OF WORK

Although contemporary work differs dramatically from work in the past, the evolution of the organization of production and people's attitudes toward work have important legacies for workers today. For much of human history, work and home lives were integrated: Most work was done at or near the home, and people consumed the products of their labor. The predecessors of the modern labor force were nonagricultural workers, in-

cluding servants and skilled artisans who made and sold products. The development of industrial work supplemented human effort with machines, introduced a division of labor that assigned specialized tasks to different workers, and ushered in a wage economy. In Europe, industrial work began as cottage industry, in which middlemen brought unfinished goods to cottagers—often women and children—who manufactured products. However, the exploitation of energy sources that could fuel large machines, the growing number of displaced peasants forced to sell their labor, and the expansion of markets for industrial goods made it more economical to shift industrial work to factories. The ensuing Industrial Revolution in the West laid the foundation for modern work and created the modern labor force. Some workers in developing countries continue to do agricultural or other subsistence work; others work in industrialized sectors, although seldom with the protections advanced industrial countries afford their workers.

THE LABOR FORCE

In developed societies, the labor force—people who are employed or are seeking paid work—includes most adults. In Western industrialized nations, it ranged in the middle 1990s from less than half the adults in Ireland, Italy, and several Middle Eastern and north African countries to around 80 percent in Denmark, Cambodia, China, Iceland, Rwanda, Slovenia, and Burundi (United Nations 1999).

The composition of the labor force is in a continual flux. Although women and children were well represented in the earliest labor force in Western countries, as industrial labor replaced agricultural work, wage workers became increasingly male. However, as the growth of jobs labeled “women’s work” has drawn increasing numbers of women into the labor force worldwide, the labor force has become more sex-balanced. Women’s participation in the formal labor force varies cross-nationally, however. In the 1990s, according to the United Nations, women’s share of the labor force ranged from one in nine (Iran) to one in four workers (Turkey) in the Middle East and in north African countries. In Latin American countries, three to four in ten workers were female; as were 38 (Indonesia) to 48 percent (Cambodia) in southeast Asia, 38 (South Africa) to 50 percent (Burundi)

in sub-Saharan Africa, and 38 (Italy, Spain, Japan) to 48 percent (Norway, Denmark, Sweden) in the advanced industrial countries.

In the United States, more than 46 percent of the labor force was female in 1998. Just as the U.S. labor force has become more diverse in gender, it has become more diverse in its racial and ethnic composition. As the “baby bust” cohorts replace the baby boom cohorts, the U.S. labor force is aging. Smaller cohorts of young workers will lead employers to turn to other labor sources, such as immigrants, to fill low-wage, entry-level jobs.

Although child labor has all but disappeared in advanced industrial nations, children are a significant presence in the labor force in many developing countries. According to the International Labour Organization (ILO) (1996, number 16), in the mid-1990s, three to four of every ten sub-Saharan African children between ages 10 and 14 worked to help support themselves and their families. In some Asian countries, more than three children in ten are in the labor force (Bangladesh, Bhutan, East Timor, Nepal), and in several Latin American countries, at least one child in four works for pay (Bolivia, Brazil, Dominican Republic, Guatemala, Haiti, and Nicaragua). Child labor in Third World countries is partly a product of a global economy that makes impoverished children particularly attractive to Western-based multinational corporations in their worldwide search for cheap and docile workers.

Extent of paid work. The amount of time people spend at paid work has changed through the centuries. In the early decades of industrialization, adults and children often worked fourteen-hour days, six days a week. After labor organizations won maximum-hours laws and overtime pay, the average workweek shrank for European and American workers, although in some countries hours are increasing for some workers. In 1997, Japan’s workers logged more hours of work than did those in other countries for which records are available, averaging 1,990 hours annually, with U.S. workers second at 1,904 hours. Germany’s and Denmark’s workers average the fewest hours of paid work per year: 1,573 and 1,665, respectively (ILO 1998, number 25, p. 31). Declines in work hours mask a division in the extent of paid work, with growing numbers either putting in very long workweeks or working part-time. In many

industrialized countries, the proportion of workers employed part-time has doubled since the 1970s; indeed, the growth in part-time jobs almost entirely accounts for the growth of total employment in industrialized countries (ILO 1996, number 17, p. 28). This growth reflects both demand-side and supply-side forces. Teenagers and women with children disproportionately opt for part-time jobs to leave time for school or unpaid family work, and employers structure some jobs as part-time to avoid paying fringe benefits. The increased number of jobs structured as part-time has caused growth in the number of persons who work part-time involuntarily.

Unemployment and underemployment.

Throughout history, people seeking adequately paid employment usually have outnumbered jobs, leaving some would-be workers unemployed or underemployed. According to the ILO (1998, number 27, p. 6), one-third of the world's workers are underemployed (850 million persons) or unemployed (150 million persons), and unemployment is in the double digits in several countries, including Botswana, Spain, Finland, Puerto Rico, Barbados, and Poland (United Nations 1999). Globalization contributes to unemployment as multinational companies draw people in developing countries into the labor force and then put them out of work when they close plants in pursuit of cheaper labor (Dickinson 1997). In 1996, unemployment in the industrialized countries ranged from 4 percent in Norway to over 11 percent in Germany, with intermediate levels in Sweden, the United Kingdom, and the United States. (At the end of 1998, U.S. unemployment had fallen to 4.3 percent, although the rates for racial and ethnic minorities and youth were much higher.) In general, official statistics in industrialized countries underestimate unemployment by excluding "discouraged workers" who have stopped looking because they cannot find jobs for which they qualify.

Preparing for jobs. Workers' education and training affect the jobs they obtain. Schools teach vocational skills (including literacy and numeracy), inculcate traits that employers value (e.g., punctuality, ability to deal with bureaucracies), and provide credentials that signal the ability to acquire new skills. Vocational education provides skills and certification. In Germany, for example, vocational training is a major source of workers' skills. In the United States, in contrast, many workers—

especially those in traditionally male blue-collar jobs—acquire most of their skills on the job, whereas professionals and clerical workers acquire their skills largely before beginning employment. Jobs in advanced industrial societies—especially high-technology jobs—tend to require both more and different kinds of skills, such as precision and flexibility, as well as formal knowledge (Hodson and Parker 1988). In postindustrial societies, knowledge and technical expertise have become increasingly important for good jobs. As a growing number of jobs require at least some college, workers without a high school diploma face difficulties finding jobs that pay well and provide advancement opportunities. Moreover, workers displaced from production jobs need new skills for reemployment, and so refraining has become increasingly important.

Job outcomes. The processes that allocate workers to occupations, employers, and jobs are important because those elements strongly affect workers' earnings. Although thousands of distinct labor markets serve different locales and occupations, to understand the job-allocation process, it is necessary to distinguish primary markets that fill jobs characterized by high wages, pleasant working conditions, the chance to acquire skills, job security, and opportunities to advance from secondary markets that fill low-paid, dead-end, low-security jobs. Firms in the primary sector fill non-entry-level jobs through internal labor markets that provide employees with "ladders" that connect their jobs to related jobs higher in the organization. The failure of secondary-market jobs to provide job ladders that reward seniority, along with low pay and poor working conditions, encourage turnover (Gordon 1972). Both statistical discrimination and prejudice disproportionately relegate certain workers—the young, inexperienced, and poorly educated; racial and ethnic minorities; immigrants; and women—to jobs filled through secondary labor markets.

WORK STRUCTURES

In classifying the paid work people do, social scientists refer to industries, occupations, establishments, and jobs. An industry is a branch of economic activity that produces specific goods or services. An establishment is a place where employees report for work, such as a firm or plant. An

occupation refers to a collection of jobs involving similar activities across establishments, whereas a job is a set of similar work activities performed at a specific establishment. In 1990, the U.S. Census Bureau distinguished 503 “detailed” occupations (for example, funeral director, meter reader, x-ray technician) that it grouped into six broad categories: managerial and professional specialties; technical, sales, and administrative-support occupations; service occupations; precision production, craft, and repair occupations; operators, fabricators, and laborers; and farming, forestry, and fishing occupations. The steady growth in the number of occupations since the Industrial Revolution reflects the increasing division of labor in complex societies. This elaboration of the division of labor is more visible at the job level. The U.S. Department of Labor’s *Dictionary of Occupational Titles* lists several thousand job titles, and the approximately 130 million employed Americans hold about a million different jobs.

Occupational structure. The distribution of workers across occupations in a society provides a snapshot of that society’s occupational structure. Comparing societies’ occupational and industrial structures at different times or across nations reveals a lot about their economic and technological development and the job opportunities available to their members. For example, in 1870, agriculture employed half of all American workers; in the 1990s, it provided jobs for about 2 percent. The effects of changing occupational and industrial structures—driven largely by the disappearance of smokestack industries and the explosion of service jobs in the United States—are expressed in the sharp decline in a worker’s chances of getting a unionized skilled production job. Hit hardest by the dwindling number of these jobs are the white men who once monopolized them. In contrast, the growing number of management jobs in the United States created a record number of managerial positions in the 1990s. This growth has helped to integrate managerial jobs by sex and race.

Job segregation by sex and race. One of the most enduring features of paid work is the differential distribution of male and female and white and minority workers across lines of work and places of employment, with minorities and white women concentrated in the less desirable jobs (Carrington and Troske 1998a, 1998b). In 1990, among all gainfully employed women in the United

States, 28 percent were concentrated in just 5 of the 503 detailed occupational categories—secretary, bookkeeper, manager, clerk, and registered nurse—and over half worked in just 19 of the 503 occupations distinguished by the Census Bureau. Men, in contrast, are spread more evenly across occupations: The top five—manager/administrator, production supervisor, truck driver, sales supervisor, and wholesale sales representative—accounted for 19 percent of all employed men. However, within-occupation sex segregation (many jobs share a single occupational title) means that job segregation is considerably more pervasive than is occupational segregation.

In every country, the sexes are segregated into different jobs, although the extent of occupational sex segregation varies sharply across nations: It is highest in Middle Eastern and African nations and lowest in Asian/Pacific nations (Anker 1998). In advanced industrial nations, it correlates positively with women’s labor force participation, paid maternity leave, and the size of the wage gap (Rosenfeld and Kalleberg 1990). Levels of sex segregation in European countries reflect both postindustrial economic structures that concentrate women in sales and service jobs and adherence to norms of gender equality. Independent of these forces, customarily male production jobs remain outside the reach of most women, and women continue to dominate clerical occupations (Charles 1998).

The last thirty years has witnessed worldwide declines in occupational sex segregation (Anker 1998). Integration occurs primarily through women’s entry into customarily male occupations rather than the reverse. Falling levels of occupational sex segregation can mask ongoing job-level segregation (Reskin and Roos 1990). Training workers for nontraditional jobs and enforcing antidiscrimination laws and affirmative-action regulations appear to be the most effective remedies for reducing sex segregation.

Occupations and jobs also are segregated by race. For example, before World War II, American blacks were concentrated in farming, service, and unskilled-labor jobs in the secondary sector of the economy, such as domestic worker, porter, and orderly. War-induced labor shortages opened the door to a wider range of jobs for blacks, and antidiscrimination regulations (especially Title VII of 1964 Civil Rights Act) further expanded blacks’

opportunities. As a result, racial segregation across occupations has declined sharply in the United States since 1940, especially among women. There is little systematic cross-national research on job segregation or job discrimination by race, although scattered studies document both around the world. For example, Moroccans are excluded from semi-skilled jobs in the Netherlands, West Indians face discrimination in Canada, and Vietnamese and the aboriginal populations encounter it in Australia (ILO 1995, number 12, pp. 29–30).

Workers' experience and preferences influence where they work and what they do, but at least as important are the operation of labor markets—the mechanisms that match workers to jobs and set wages—and employers' preferences and personnel practices. Sociologists have documented the importance of personal networks for workers' employment outcomes (e.g., Fernandez and Weinberg 1997). Employers favor the use of social networks to recruit workers because of their efficiency, low cost, and ability to provide information unavailable through formal sources. However, because people's acquaintances tend to be of the same sex and race, recruiting through employees' networks effectively excludes sex- and race-atypical workers.

Layoffs and Displacement. U.S. data for the 1980s and 1990s indicate that trends in job displacement rates roughly parallel those for unemployment. Between 1993 and 1995, 12 to 15 percent of workers lost a job because their companies closed, their jobs were cut, or work was slack. Depending on economic conditions, between 25 and 40 percent of displaced workers remain jobless one to three years later, and reemployed workers typically earn less than they did in their previous jobs (Economic Report of the President 1999).

REWARDS FOR EMPLOYMENT

People seek jobs that maximize extrinsic rewards—income, prestige, the chance for promotion, and job security (Jencks et al. 1988)—as well as intrinsic rewards—satisfaction and autonomy. Earnings are the primary incentive for most workers. However, pay differs sharply across individuals and social groups. Substantial racial, sex, and ethnic inequality in pay characterize all industrial societies, although their extent depends on whether

countries permit unequal pay for equal work and the degree to which workers are segregated into unequally paying jobs on the basis of sex, race, or ethnicity. In the United States, the 1963 Equal Pay Act that outlawed wage discrimination by race, national origin, and sex and declining occupational segregation by race have reduced the racial gap in earnings among men and almost eliminated it among women. The disparity in earnings between the sexes has declined more slowly because of the resilience of sex segregation. Hence, in 1998, women employed full-time year-round earned 74 percent of the annual earnings of their male counterparts. The wage gap varies across nations (and across occupations and industries within countries). In the first half of the 1990s, pay inequality was lowest in Australia, Egypt, Kenya, Jordan, and New Zealand, where women averaged about 80 percent of what men earned, compared to a low of just 60 percent in Korea (ILO 1997, number 22). Factors that can reduce the wage gap among full-time workers include equalizing the sexes' educational attainment and labor-market experience, creating sex-integrated jobs, and implementing pay systems that compensate workers for the worth of a job without regard to its sex composition.

Occupational prestige. Social standing is conferred on persons partly on the basis of their jobs. In fact, social scientists have treated the distinction between blue-collar and white-collar jobs as a rough proxy for workers' social status. However, to capture the effects of one's type of work on one's social status, more sophisticated ways to measure occupational prestige are needed. The most commonly used is the Duncan Socioeconomic Index (SEI) (Duncan 1961), which assigns a score to each occupation on the basis of its incumbents' average educational and income levels. The occupational status hierarchy is quite stable over time and across cultures (Treiman 1977). Within societies, the occupational standing of workers is highly stratified. In the United States, for example, most workers have occupations with relatively low SEI scores.

Intrinsic rewards: job satisfaction. In advanced industrialized countries, many workers see a job as a place to find fulfillment, self-expression, and satisfaction. Workers in routine jobs try to imbue them with challenge or meaning, in part by creating a workplace culture. These adaptations contribute to the high levels of satisfaction Americans report with their jobs. Nonetheless, not all jobs are

satisfying, and not all workers are satisfied. On the assumption that dissatisfied workers are less productive, employers in the United States and other advanced industrialized countries have devised strategies such as workplace democracy, job-enrichment programs, and “quality circles” to enhance job satisfaction. According to Lincoln and Kalleberg (1990), however, Japanese and German workers, who show the lowest levels of satisfaction, are among the world’s most productive.

WORK AND FAMILY

In expanding the factory system, the Industrial Revolution separated work and family, creating a division of labor that mandated domestic work for women and market work for men. Although women increasingly hold paid jobs, paid employment has not exempted them from primary responsibility for domestic work. Role overload and its concomitant stresses are risks for all workers, but especially for employed mothers, who accounted for 70 percent of married mothers and 60 percent of single mothers in the United States in 1996. Women have adapted by working part-time, sacrificing leisure time, renegotiating the domestic division of labor in their families, cutting out some domestic tasks, and purchasing more services. (The trend toward purchasing more services has fueled the growth of service jobs in fast-food chains, child care, and cleaning services and thus has increased the demand for low-wage workers.) What employed parents want most is flexible scheduling (Glass and Estes 1997), although organizational pressure prevents some from taking advantage of it when it is available (Hochschild 1997).

Just as paid work competes with workers’ domestic obligations, the demands of family life interfere with workers’ ability to devote themselves entirely to their jobs. Thus, employers have two incentives to reduce work–family conflicts: reducing absenteeism and turnover and increasing workers’ productivity and organizational commitment (Glass and Estes 1997). Many employers in advanced industrial societies have provided some of their employees with assistance with child care. The governments of most advanced industrialized countries have mandated programs such as parental leave, state-run nurseries, and guaranteed benefits for part-time workers. Among the 152 member nations of the ILO, only two advanced industrial

countries provide no paid maternity leave: New Zealand and the United States (ILO 1998, number 24, pp. 18–19). Employers’ increasing reliance on female workers and politicians’ desire for women’s support should bring more family-friendly policies and practices in the twenty-first century.

TRENDS IN WORK

Control of work. As Marx recognized, whenever different actors control the tools of production and perform work, control over the work process is potentially a matter of contention. Employers have relied on a variety of tactics to control the labor process: paternalism, close supervision, embedding control into the technology of work, deskilling work, and bureaucratic procedures such as career ladders (Edwards 1979). Workers have resisted more or less effectively through collective action, including attempts to create a monopoly of their skills or the supply of labor. At the end of the twentieth century, several factors had given employers the upper hand in the struggle for control, including the decline of labor unions in Western industrialized societies (ILO 1997, number 22, p. 7), the disappearance of lifetime job protection in formerly communist societies, an increasing technological capacity to monitor workers electronically, access to a global “reserve labor army,” and the use of nonstandard employment relationships (see below).

Technological change. The history of work is a chronicle of technological innovation and its transformation of the production of goods and services. Employers invest in technology to increase productivity, contain labor costs, and control how work is done. According to some observers (e.g., Braverman 1974), employers seek technical advances in order to reduce workers’ control over the labor process and employ less skilled and thus cheaper labor. Some analysts see technological change as a threat to skilled jobs; others see technology as creating more of those jobs. The development of microelectronic technology has brought this debate to the fore.

Innovations in microprocessor technology have permitted advances in information processing and robotics that are revolutionizing the production of goods and services. Robots work around the clock, perform hazardous tasks, and have low operating costs. Although technical advances enhance jobs,

they also subject workers to technological control (an estimated 80 percent of U.S. workers are electronically monitored, for example [ILO 1998, no. 24, p. 25]) and, by improving productivity, lead to job losses. In industrialized nations, for example, microelectronic technology has eliminated some unskilled jobs and facilitated work transfers that shift tasks from paid workers to consumers such as banking transactions. By making it possible to export jobs to cheaper labor markets, technology has reallocated jobs from the workers who once performed them to lower-paid workers in other parts of the world. Although technological change has created jobs, it has eliminated more job—particularly less-skilled ones—than it has created and has eroded skills in middle- to low-skill jobs such as clerical work (Hodson and Parker 1988). Its creation of new highly skilled jobs has contributed to the economic polarization of workers and spurred the migration of well-educated workers from developing to advanced industrial countries (Hodson 1997).

The globalization of work. Although segments of the economy such as service work are organized locally, production work increasingly is organized in a global assembly line (Dickinson 1997). For jobs in which technology preempts skill, multinational corporations' worldwide pursuit of low-wage docile labor and microelectronic technology and cheap transportation reduce the friction associated with moving production around the globe. As a result, there has been a steady exportation of jobs from industrialized countries to the Pacific Rim, Latin America, and the Caribbean, where labor is cheap and tractable and labor laws are lenient. This redistribution of manufacturing jobs from advanced industrial nations to developing nations—fueled by the growth of multinational corporations—has given birth to an international division of labor in which the United States and other advanced industrial nations have become postindustrial societies that specialize in producing services rather than goods, while workers in less developed countries manufacture products, often under unsafe conditions. For example, between 1980 and 1993, semi-industrialized and industrialized countries in the Americas and Europe lost 30 to 70 percent of their jobs in the textile and footwear industries, while African and Asian countries have experienced astronomical job growth in those industries (ILO 1996, vol. number 18). Be-

tween 1970 and 1990, the number of textile and footwear jobs doubled, tripled, or more in Korea, Indonesia, Sri Lanka, Bangladesh, and Malaysia where production workers earn from one-fifth to one-half as much as do their counterparts in advanced industrial countries. Meanwhile job growth in developing countries leads to the disproportionate employment of teenagers and young adult women, who work for lower pay than do adult men.

Just as jobs move in search of cheaper workers, workers move in search of better-paying jobs. Often, however, the outcome of this migration is low-skilled, low-paid employment in domestic or service work. However, skilled technical and professional jobs also draw workers in global migration streams. In the mid-1990s, according to the ILO (1995, number 13), 70 million immigrants—most from the Third World—resided in countries other than their nations of birth. The globalization of competition among employers has made workers on different continents into competitors for jobs, held down wages, and militated against campaigns to improve working conditions in Third World establishments while eroding job security in First World production facilities (Hodson and Parker 1988; Dickinson 1997).

The externalization of work and the erosion of jobs. By the middle of the twentieth century, the normative employment relationship between employers and workers had become standardized in many industrialized societies. This standard employment arrangement typically involves the exchange of labor by a worker for a fixed rate of pay (hourly wages or a weekly, monthly, or annual salary) from an employer, with the labor performed on a preset schedule—usually full-time—at the employer's place of business, under the employer's control, and often with the shared expectation of continued employment. However, to cut costs and enhance flexibility, employers are increasingly "externalizing" work in terms of physical location administrative control and the duration of employment (Pfeffer and Baron 1988).

This externalization is seen in the increasing number of persons working for pay at home and the growth of nonstandard employment relationships (Barker and Christensen 1998). Neither home-work nor nonstandard employment relations are new. Only after unions won the right to bargain collectively and statutory rights protecting work-

ers did homework and nonstandard employment relations give way to standard employment relationship in advanced industrialized countries. In the 1990s, however, the trend seemed to have reversed. In 1995, for example, eight million Americans, at least two million Europeans, six million Filipinos, and one million Japanese worked for pay at home. Millions of these homeworkers telecommute (ILO 1998, number 27, p. 23). Many workers, especially women, opt for homework as a way to earn wages while supervising their children (Jurik 1998). However, part of the price of this flexibility is a lack of protection by health and safety regulations or maximum-hours rules, and these workers are outside the reach of organizing efforts. In addition, whether homework involves children is difficult to monitor even in countries strongly opposed to child labor (ILO 1995).

Work is externalized in a second way: Firms contract with individuals for specific duties (independent contractors) or with intermediary organizations that employ workers rather than directly employing all the persons who do work for them. Although contracting has long been common for some forms of work (e.g., agricultural labor), employers around the world are increasingly contracting out jobs formerly done by their own employees in everything from construction and manufacturing to human resources and security. Worldwide, more than one in four service workers are contract laborers. By outsourcing these functions to contract workers or independent contractors, employers avoid the obligation to provide long-term employment and short-circuit protective labor laws that apply to employees. Other nonstandard employment relationships include temporary work and part-time work, both of which disproportionately employ women, members of racial and ethnic minorities, and young workers.

The growth of nonstandard employment relationships has led some observers to predict an end to work organized through standard employment relations or the bifurcation of employment relations, with firms hiring core workers who enjoy the benefits of standard employment and creating explicitly temporary connections with peripheral workers who lack benefits and job security (Smith 1997; Leicht 1998). According to the U.S. Bureau of Labor Statistics, the proportion of U.S. workers in nonstandard work is slowly increasing (Barker

and Christensen 1998). In summary, employment relations must be seen as falling on a continuum from long-term attachments under bureaucratic control to weak connections of uncertain duration (Pfeiser and Baron 1988). Most research on work and occupations in industrial societies has dealt with the former end of the continuum. Technological change and globalization are shifting jobs—even in industrial countries—toward the latter end.

BARBARA F. RESKIN

WORK ORIENTATION

The sociology of work emerged as a specialty area in the 1980s, when the American Sociological Association prepared a compendium of course syllabi for the area and a number of textbooks appeared. The name of this sociological subfield is new, but the general area is not. The sociology of work represents an integration of two long-standing specialties: industrial sociology and occupations/professions. It also draws from industrial and organizational psychologists and sociologists' attempts to integrate stratification and organization literatures to better understand the employment relationship.

The study of the employment relationship encompasses a multitude of topics ranging from how the individual is initially matched to a job to all that happens on the job (being paid, becoming satisfied or dissatisfied, forming cliques, etc.) and to turnover (quitting or being dismissed). Considered important to these topics are the orientations employees have toward their work, the topic of this article.

Definitions of work abound, but most include the following features. First, although groups or collectivities may be viewed as actors involved in work (e.g., work groups, task groups, teams, or committees), the focus of attention, and therefore the unit of analysis, is usually the individual. Second, the individual is involved in physical or mental activity. Third, this activity usually involves some form of payment, but pay is not necessary for an activity to be considered work. This allows people involved in housekeeping activities to be included, along with family members who labor to support a family enterprise and volunteer helpers. Fourth, the activity involves the production or creation of something. Fifth, this usually is a good or service. Sixth, this good or service is valued by the individual or others and thus usually is consumed by either or both. Work thus is defined as the mental or physical activity of an individual directed toward the production of goods or services that are valued by that individual or others.

"Orientation to work," unfortunately, is a term without a clear or precise meaning. Generally, it is used to refer to two broad areas: (1) motivation to work and (2) responses to work. The first area covers why people work and for some time has

occupied the attention of industrial and organizational psychologists, who analyze need hierarchies, self-actualization, and intrinsic and extrinsic motivations. The second area has more often attracted the attention of sociologists. It takes the activity of work as given and addresses the ways in which individuals react to it. Job satisfaction and commitment have been given the most attention when sociologists study reactions to work.

This article is organized around work motivation and responses to work, but it places those topics the context of the social organization of the workplace. With only a few exceptions, work occurs in a social setting that has been called a “contested terrain” by Edwards (1979). Sociologists want to go beyond strictly individualistic portrayals of human behavior and are especially interested in understanding how this social setting, the workplace, affects an individual’s work orientation. The explanations of this influence, often referred to as social control arguments, are discussed here. Finally, gender differences in work orientations need to be addressed. However, because the concept of alienation is related to job dissatisfaction and has been so prevalent in sociological accounts of work, it is considered first.

ALIENATION

Sociologists continue to draw from Marx in referring to an alienated individual as being separated or estranged from certain aspects of work that give meaning and significance to that work and to life as a whole. For Marx, these aspects of work are control over the product, control over the work process, creative activity, and social relations with others. Clearly, a negative side of work is portrayed when alienation is the concept of interest.

A survey of journals and sociology of work texts over the past several decades suggests that sociologists have lost interest in this concept. For example, indexes for 1980s texts (e.g., Kalleberg and Berg 1987) do not include the term “alienation,” and the Price and Mueller (1986) handbook on the measurement of major organization concepts does not devote a chapter to alienation. Even in 1990s texts and anthologies (e.g., Hodson and Sullivan 1995; Wharton 1998), alienation is given only limited attention.

This does not mean that interest in alienation is dead. Three things have happened. First, interest has shifted to conceptualizing and measuring positively worded concepts such as like job satisfaction. Second, scholars have moved away from the picture of capitalist work settings universally producing alienated workers and gone on to formulate a picture of multidimensional work settings and multimotivated employees who respond to work in varying ways. Third, out of this more pluralistic image of work, several concepts—for example, work motivation, self-actualization, job satisfaction and commitment—have emerged in an attempt to bring more precision to descriptions of how individuals are oriented to their work. Thus, alienation has been absorbed into several other concepts.

A particular line of research has implications for understanding alienation: Following more a Marxian picture of work, it has been assumed that the more formal and bureaucratic the workplace is, the more alienated (dissatisfied) the workers are. This assumption has been challenged with the argument that formal rules and regulations actually increase satisfaction in the workplace because they provide guidelines that apply to all and thus protect workers from arbitrary and unfair treatment. Although workers may not like the rules, the authority system is perceived as legitimate because all workers are treated according to the same formal rules. Research supports this more positive portrayal of formal rules and regulations.

WORK MOTIVATION

Historically, sociologists have flirted with psychological concepts such as work motivation and work involvement and have disagreed about the relevance of those concepts to the study of social phenomena. For example, among the authors of the sociology of work textbooks in the past two decades, only Hall (1986) gives critical attention to the theoretical and empirical literature on the topic. Any treatment of work orientation must include this material, however, because most current literature is an offshoot of or a reaction to those theories.

Work motivation is the internal force that activates people to do the work associated with their jobs. Two theoretical traditions have been dominant. First, need theories argue that individu-

als are motivated by internal needs that usually develop early in life and often are not consciously recognized. Maslow (1954) identified a hierarchy of needs and claimed that higher-order needs (goals) cannot be met until lower-order needs are met sequentially. This hierarchy begins at the bottom with basic physiological needs and ends at the top with self-actualization. Others have modified Maslow's hierarchy into a continuum with fewer levels and with the idea that lower-order needs may reemerge at later stages as unmet. Herzberg (1966) was more interested in job satisfaction and argued that individuals are motivated by two types of factors: "Motivators" are the more intrinsic features of work, such as responsibility, advancement, and achievement, whereas "hygiene" factors characterize the workplace and include pay, job security, and working conditions. When motivators are present, employees are satisfied, but if they are absent, employees are not. When the hygiene factors are present, employees are neither dissatisfied nor satisfied, but when they are absent, employees are dissatisfied. McClelland (1961) argued that certain socialization environments produce a need for achievement and that individuals socialized in that manner strive for excellence in whatever they undertake. Management scholars were especially interested in this theory since it suggested who should be hired or promoted. Finally, McGregor (1960) argued that assumptions about human nature and motivation have resulted in two approaches to organizational design. Theory X is based on the assumption that individuals are basically lazy and are motivated primarily by extrinsic rewards such as pay. Theory Y assumes that humans act responsibly and contribute their skills and talents when their intrinsic needs, such as self-actualization, are met. This distinction is not unlike the classic dichotomy between functionalist and Marxian portrayals of society and human nature.

Overall, these need theories have lost favor. The empirical support is weak, the use in applied settings has proved difficult because of problems associated with measuring need levels and attempting to alter personality patterns that have developed in childhood, and the significance of the environment has been neglected.

The second dominant perspective—expectancy theory—comes from organizational and industrial psychologists. It bypasses the issue of needs

and emphasizes cognitive and rational processes. The underlying assumption is that motivations to work vary substantially from one individual to the next and are mutable across time and space (Vroom 1964; Lawler 1973). Motivations reflect the interplay of effort, expectations about outcomes, and the importance or value given to those outcomes. Put another way, a person's motivation to behave in a particular way is a function of the expected results and how valuable those results are to that person. Until recently, this theory has been dominant in studying work motivation in industrial and organizational psychology.

Sociologists are generally aware of these motivation theories and, like psychologists, now give less attention to need theories. However, unlike psychologists, they have not been overly interested in the theories per se of work motivation. In fact, psychologists have led the way in developing theories of motivation, and sociologists usually are a generation behind in adopting or rejecting those theories. For example, Smither (1988) mentions equity, behavioral, and goal-setting theories as receiving much attention in the psychological work motivation literature. Although equity theory has been explored for some time experimentally by sociologists, there is no evidence that sociologists have adopted in significant way any of these "newer" approaches to work motivation. What sociologists do in practice matches the expectancy model more closely. The picture is one in which "the fit" of an individual's characteristics and expectations with the actual work conditions forms the basis for whether that individual is motivated.

What sociologists have emphasized instead of motivation theory is socialization to work, that is, how individuals learn their work roles. This is not surprising given the long-standing interest of both sociologists and social psychologists in socialization processes. One stream of thought in this area concerns socialization into professional roles, where a popular strategy is to examine career stages. Another approach is represented by the work of Kohn and Schooler (1982), who not only argue for the intergenerational class-based transmission of work values but also propound and demonstrate reciprocal effects: An individual's work orientations (e.g., self-direction) are affected by job conditions, but those orientations also affect the kinds of jobs with which the individual is associated.

RESPONSE TO WORK: JOB SATISFACTION

Although the wording of definitions for “job satisfaction” has varied dramatically across disciplines and scholars, there is a near consensus on what the concept is. Smith et al. (1969) succinctly define it as the degree to which individuals like their jobs. The common element across definitions like this is the idea of the individual positively responding emotionally or affectively to the job.

The major issues in the study of job satisfaction are (1) What produces job satisfaction? (2) What are the consequences of differing levels of job satisfaction? and (3) Is it a global or unitary concept, or should facets (dimensions) of it be investigated?

Two dominant arguments exist regarding the determinants of job satisfaction. The first is that an individual’s job satisfaction is determined by the dispositions or “personality” traits that an employee brings to the workplace. In simple terms, individuals vary along a continuum from a negative to a positive orientation. These dispositions are reflected in a person’s responses to work conditions as well as to aspects of life such as family satisfaction and more general life satisfaction. The second argument is considered more “sociological” and emphasizes the importance of the work conditions an employee experiences. This approach is closer to a Marxian perspective in that it is the structural conditions of the workplace that make work rewarding or not rewarding; any individual dispositional differences that exist wane in importance in the face of these structural features.

Although sociologists give lip service to the disposition argument, the literature unequivocally documents a stronger interest in identifying the features of work that affect job satisfaction. Within this perspective, however, there is considerable disagreement about which features of work are important. One major debate concerns whether extrinsic (e.g., pay and fringe benefits) or intrinsic (e.g., self-actualization and task variety) features of work are more important. Following a needs framework or arguments from neoclassical economics about economic rationality leads one to argue that the extrinsic features must exist before the intrinsic features become important. In contrast, an expectancy argument would state that any of these features can be important and that it is the fit of what is found in the workplace with what the

individual expects and values that is crucial in determining the satisfaction level. A popular argument that has an expectancy logic associated with it comes from the justice literature. A theme common to all distributive justice theories is that an individual compares his or her actual reward with what is believed to be just or fair. Individuals expect a just reward and are dissatisfied if a reward is unjust. Another frequently used general perspective for understanding the effect of work conditions on job satisfaction is social exchange theory, which also relies on an expectancy logic. As developed initially by Homans (1958) in the study of small groups and extended to the study of organizations by Blau (1964), exchange theory argues that individuals enter social relations in anticipation of rewards or benefits in exchange for their inputs and/or investments in the relationship. Simply put, workers are satisfied with their jobs if the rewards they value and expect are given to them in exchange for their work effort and performance.

It is impossible to summarize here the thousands of studies conducted on the determinants of job satisfaction. Instead, a list of variables that have been found to have some relationship with job satisfaction is provided (the sign indicates the direction of the relationship with regard to satisfaction): variety (+), pay (+), autonomy (+), instrumental communication (+), role conflict (-), role overload (-), work group cohesion (+), work involvement (+), distributive justice (+), promotional opportunities (+), supervisory support (+), task significance (+), and external job opportunities (-). Spector (1997) provides a more complete account of the determinants and correlates of job satisfaction.

The debate over which work conditions affect job satisfaction continues to direct the research of sociologists, but a more interesting question involves the disposition versus situation debate. Sociologists devote much effort to cataloging and operationalizing the objective structural features of work, and little attention is given to identifying and measuring the dispositional traits of individuals. Evidence, however, continues to mount that individuals exhibit basic dispositional traits (e.g., negative and positive affectivity) that are relatively stable throughout their lifetimes and over different employment situations (Watson and Clark 1984). This research strongly suggests that work-

ers with positive dispositions usually are more satisfied with their jobs regardless of the work conditions, while those with negative dispositions seem not to be satisfied with anything.

Another issue concerns the consequences of job satisfaction. Two outcomes have received the most attention, primarily because of their practical significance to any business enterprise: job performance and withdrawal behavior, which includes absenteeism and voluntary turnover. The satisfaction–performance argument is of long-standing interest and thus has generated considerable empirical data. The hypothesis is that satisfaction is positively and causally related to productivity, and support is provided by meta-analyses showing a positive correlation of .25. In short, satisfied workers perform better, but the relationship is not a strong one. The weakness of this relationship could be due to the difficulties associated with measuring job performance, however.

With regard to the satisfaction–withdrawal relationship, the hypothesis is that the most satisfied employees will be the least often absent and the least likely to quit voluntarily. The meta-analyses for the satisfaction–absenteeism relationship suggest that the relationship is between $-.10$ and $-.15$, which is weak at best. The findings for the satisfaction–turnover relationship are stronger (meta-analysis correlation of $-.25$), but the conclusion is that job satisfaction serves more of a mediating function. That is, the structural features of work (e.g., promotional opportunities) and employee characteristics (e.g., education) directly affect job satisfaction (and commitment), which in turn affects turnover.

The final issue here is whether job satisfaction is a unitary concept or is a complex of many facets or dimensions. Since a fairly large number of work features are known to affect job satisfaction, it is logical to expect that individuals can be satisfied with some of these but not others. The data support this logic. In particular, there is evidence that for almost any distinct feature of the work situation—pay, autonomy, variety, work group cohesion, feedback—satisfaction scales can be developed that divide into distinct (but related) factors along these dimensions. This poses not only a theoretical problem but also a scale construction problem. As a simple example, a person may be satisfied with the pay but not satisfied with feed-

back about job performance. Combining scores for these two factors will show the person to be neither satisfied nor dissatisfied for the composite scale. In such situations, the rule of thumb is that scales developed to measure various satisfaction dimensions should not be combined. However, global job satisfaction scales—those which ask more generally about liking one's job—can be used to represent a person's general affective reaction to a job. Sociologists more often use these global scales and assume that work is experienced and responded to globally.

The facet approach clearly becomes more important in applied research. If an employer wishes to alter the work setting to increase job satisfaction, a global scale will be only somewhat helpful; a scale that captures satisfaction with pay, routinization, communication, and the like, will provide the information necessary to implement specific structural changes. Numerous established measures of job satisfaction, both global and facet-based, exist (see Cook et al. 1981; Price and Mueller 1986; Spector 1997).

RESPONSE TO WORK: WORK COMMITMENT

Although some concepts, such as Dubin's (1956) central life interest and Lodahl and Kejner's (1965) job involvement, go back more than three decades, most of the interest in work commitment has emerged fairly recently, to a large extent during a time when interest in job satisfaction has been diminishing. If employee commitment is defined as the level of attachment to some component or aspect of work, the door is opened to a large number of types of commitment. The most common strategy adopted for understanding various types of commitment is to differentiate between the components and the foci of commitment.

There are numerous potential foci of commitment, with those receiving the most attention being commitment to work, the career, the organization, the job, and the union. It is organizational commitment, however, that has received the most theoretical and empirical attention (Mueller et al. 1992). Considerable interest exists in how workers form and manage their commitments to multiple foci (Hunt and Morgan 1994; Lawler 1992; Wallace 1995). For example, if a worker is strongly committed to his or her career, will this translate

into a similarly strong commitment to his or her employer (organization)? Although some suggest that commitment is a zero-sum phenomenon by which commitment to an employer must decline if commitment to one's career increases, research consistently shows that most commitments to multiple foci are positively related.

Three components of commitment have received the most attention (Meyer and Allen 1997): affective commitment, continuance commitment, and normative commitment. *Affective* commitment refers to a worker's emotional attachment to an organization. Organizational and industrial psychologists are given credit for initiating interest in this concept. They argue that commitment intervenes between various features of work and individual characteristics and the outcomes of absenteeism and voluntary turnover. Sociologists (e.g., Lincoln and Kalleberg 1990) tend to see the structural conditions of work as the ultimate causes of affective commitment. The evidence generally is consistent with the claims from both disciplines (Hom and Griffeth 1995; Mueller and Price 1990). *Continuance* commitment treats a person's degree of attachment as a function of the costs associated with leaving an organization. In practice, it has been operationalized as the employee's stated intention to stay (or leave). This form of organizational commitment can be traced back to Becker's (1960) side-bet theory. Individuals are portrayed as making investments (e.g., seniority, a pension fund, coworkers as friends) when they are employed in a particular organization. These side bets accumulate with tenure and thus become costs associated with taking employment elsewhere. An employee will discontinue employment only when the rewards associated with another job outweigh the accumulated side bets associated with the current one. Although the evidence for the reasoning behind this theory has not been supported, research has consistently shown a relatively strong negative relationship (meta-analysis correlation of $-.50$) between intent to stay and voluntary turnover. Much of the literature identifies intentions to stay or leave as intervening between affective commitment and turnover. *Normative* commitment refers to the felt obligation to stay with an employer. Remaining attached to an organization is what one should do even if one is not emotionally attached or has only a limited investment.

Without question, affective organizational commitment has dominated the scholarly interest of those who study organizational commitment. It is strongly positively related to job satisfaction and negatively related to absenteeism and turnover. These relationships indicate the importance of studying and understanding employee commitment not only to address the practical issues confronting human resource managers but also to address classical sociological concerns about the "glue" that holds social groups together.

SOCIAL CONTROL IN THE WORKPLACE

This article began with a description of the workplace as a contested terrain, a social setting in which employer and employee struggle for control. The image that comes from most economists is that monetary rewards are what motivate both employers and employees: Employers want to maximize profits, and workers want high pay for their work. The implication of this for workers is that they will be satisfied and committed if their pay is high, and if it is not, they can quit to take another job. This argument and causal linkage have been challenged both empirically and theoretically in sociology. There are three issues here. First, as was alluded to above, pay is only one of many factors that affect satisfaction and commitment. Second, employers, not workers, historically have had the upper hand in controlling the workplace and establishing the employment relationship. Third, job satisfaction and commitment can and are manipulated by employers to increase productivity and retain employees. There have been several different historical accounts of how this employer control occurs (e.g., Clawson 1980; Edwards 1979; Jacoby 1985; Vallas 1993), but two basic models dominate the literature. They can be differentiated by whether the social control is direct or indirect and by the importance given to worker satisfaction and commitment in the control process.

The historically dominant model of the workplace portrays direct control of workers by the employer. Direct supervisory monitoring, "machine control," and strictly defined divisions of labor are used to control the behavior of employees. In such instances, job satisfaction and organizational commitment may emerge to increase performance, but they are viewed as secondary to the direct control that is essential to maximizing work-

ers' productivity. The other model relies much less on direct supervision and control by the production process and instead argues that high-performance employees are controlled *indirectly* by manipulating work structures that in turn produce satisfied and committed workers. It is the satisfied and committed workers, then, who will be the most productive. Lincoln and Kalleberg (1990) argue for this model (called the "corporatist" model) in their study of U.S. and Japanese workers. Concretely, they find that organizational structures that facilitate participation, integration, individual mobility, and legitimacy result in more satisfied and committed employees. This sociological interest in workplace control has practical implications. The same dichotomy is recognized in human resource management (HRM), where the direct strategy is called the control strategy and the indirect strategy is called the commitment strategy (Arther 1994). Similarly, in education, concern with low achievement scores among U.S. students has resulted in a debate over the organizational design of schools (Rowan 1990). The more direct approach, also called the control strategy, is based on an elaborate system of bureaucratic controls for regulating classroom teaching and standardizing student learning opportunities and outcomes. The more indirect approach, also called the commitment strategy, rejects bureaucratic controls and standards and argues instead for innovative working arrangements that support teachers' decision making and increase their involvement in the tasks of teaching. The claim for the second approach is that satisfied and committed teachers are critical to improving student performance. Without question, then, worker satisfaction and commitment still constitute a major component in the critical debates about social control in the workplace, worker productivity, and societal outcomes such as student achievement.

GENDER DIFFERENCES

Associated with the increase in sociological interest in gender inequalities over the last three decades has been an increased concern with whether the work orientations of women and men are different. Two questions have received considerable attention. One concerns whether women and men have different work values, and the other refers to what is called the gender job satisfaction paradox.

Research consistently has shown that women are just as satisfied (and often more satisfied) with their jobs as their male counterparts are. This is viewed as a paradox because women's jobs are on the average "worse" jobs with lower pay, less autonomy, and fewer advancement opportunities. Several arguments have been offered to account for this paradox (Phelan 1994; Mueller and Wallace 1996). Justice-related arguments center on (1) women accepting their lower rewards because of their lower inputs, (2) women being socialized to accept the idea that lower rewards are all they are entitled to, and (3) women being satisfied because they are comparing their rewards to those of other women, who also receive less. The consensus seems to be that the "other women as referent" explanation best explains the paradox. The major competing explanation is that women and men value different aspects of work. This leads directly to the question of gender differences in work values.

Probably the most popular explanation for the gender satisfaction paradox is that men value extrinsic rewards (e.g., pay, benefits, and authority) more than women do, while women value intrinsic rewards (e.g., social support) more than men do. As a consequence, women are not less satisfied when they receive less pay and are promoted less often than are men. Research findings strongly reject this argument, however. Women and men hold essentially the same workplace values (Hodson 1989; Phelan 1994; Mueller and Wallace 1996; Rowe and Snizek 1995; Ross and Mirowski 1995).

These similar workplace values do not mean, however, that men have the same degree of work-family conflict as do women. Research shows that this conflict is greater for women (Glass and Estes 1997). This finding only adds to the paradox: If women have worse jobs and experience more work-family conflict, why are they so satisfied with their jobs?

THE FUTURE

The last two decades in the United States have witnessed considerable change in the workplace. Organizations have downsized, hired more temporary (contingent) workers, and outsourced production tasks to become more flexible in competing in an increasingly global marketplace. In addition, the income gap between the top and

bottom segments of society has grown, labor union membership has declined to an all-time low, and although unemployment continues to be low, job expansion has occurred mainly in the service sector, where many jobs do not have advancement potential. All this suggests that in the future workers can expect to move from employer to employer more often. Also, workers can expect to find that their employers are less concerned with whether employees are satisfied and less interested in gaining a long-term commitment from them. As a consequence, occupational or career commitment may become a more important motivating factor for workers than is organizational commitment or job satisfaction. Without doubt, this changing landscape for the employment relationship will keep sociologists interested in studying and understanding work values, job satisfaction, and commitment.

CHARLES W. MUELLER

WORLD RELIGIONS

Religious life throughout the world, regardless of the specific tradition, exhibits both personal-psychological and communal-social aspects. Of course, persons within the diverse religious traditions of the world perceive the spiritual dimension of their faith as transcending both the individual psychological and emotional as well as the corporate and social aspects of their faith's expressions. Nonetheless, two major academic strands of religious studies over the last century have focused primarily on either the psychological (e.g., James

1961; Freud 1928; Jung 1938) or the social (e.g., Weber 1963; Durkheim 1965; Wach 1958) dimensions of religion. An Oglala Lakota's ("Sioux" in Algonquian) vision reveals these two interactive aspects of religion.

The Plains Indians in America were noted for their vision quests, and periods of fasting and life-cycle rituals often were associated with those quests. However, the vision of Black Elk, a Lakota shaman, occurred spontaneously when he was 9 years old and was stricken by fever and other physical maladies (Neidardt 1972, pp. 17-39). His vision began with two men dressed in traditional garb but shaped like slanting arrows coming from the sky to get him. As a little cloud descended around him, the young Black Elk rose into the sky and disappeared into a large cloud bank. He saw an expansive white plain across which he was led by a beautiful bay horse. As he looked in the four directions, he saw twelve black horses in the West, twelve white horses in the North, twelve sorrel horses in the East, and twelve buckskin horses in the South. After the arrival of Black Elk, the horses formed into lines and formations to lead him to the "Grandfathers." As this heavenly equine parade proceeded, horses appeared everywhere, dancing and frolicking and changing into all types of animals, such as buffalo, deer, and wild birds. Ahead lay a large teepee.

As Black Elk entered the rainbow door of the teepee, he saw six old men sitting in a row. As he stood before the seated figures, he was struck by the fact that the old men reminded him of the ancient hills and stars. The oldest spoke, saying, "Your grandfathers all over the world are having a council, and they have called you here to teach you." Black Elk later remarked of the speaker, "His voice was very kind but I shook all over with fear now, for I knew that these were not old men but the Powers of the World and the first was the Power of the West; the second, of the North; the third, of the East; the fourth, of the South; the fifth, of the Sky; the sixth, of the Earth."

The spokesman of the elders gave Black Elk six sacred objects. First, he received a wooden cup full of water, symbolizing the water of the sky that has the power to make things green and alive. Second, he was given a bow that had within it the power to destroy. Third, he was given a sacred name, "Eagle Wing Stretches," which he was to embody in his role as shaman (healer and diviner)

for his tribe. Fourth, he was given an herb of power that would allow him to cleanse and heal those who were sick in body or spirit. Fifth, he was given the sacred pipe, which had as its purposes a strengthening of the collective might of the Lakota tribe and a healing of the divisions among the Lakota, to allow them to live in peace and harmony. Finally, Black Elk received a bright red stick that was the “center of the nation’s circle” or hoop. This stick symbolized a sacred focusing of the Lakota nation and linked the Lakota to their ancestors as well as to those who would follow them.

Black Elk’s vision ended with a flight into a foreboding future in which the Lakota would encounter white-skinned “bluecoats” who would threaten the sacred hoop of the Lakota nation. Many years later, as Black Elk reflected on his vision, he realized that even in the devastating upheaval caused by the wars between his nation and the “bluecoats,” his people had been given the sacred objects and rituals that would allow them to rise above mundane exigencies and to heal the nation and restore the hoop in times of trouble.

The vision of Black Elk makes it clear that what sometimes appear to be perfunctory religious rituals, fantastic myths, or arcane ethical injunctions often have their roots in a deep sense of the contact between human beings and that which they have experienced as a divine power. This article emphasizes the social aspects of world religions, but it is important to keep in mind that the religious experiences codified in the social institutions of the world’s religions are not fully captured by psychological or sociological explanations alone. There has been a tendency in the academic study of religion to interpret religious experiences and behavior by reducing them to psychological or social causes or antecedents. For example, Sigmund Freud (1928) reduces religious experiences to unconscious projections of human needs that he likens to infantile fantasies that rational humans should grow beyond. A contemporary of Freud, Emile Durkheim (1965, p. 466), has a tendency to reduce religions to their social functions: “If religion has given birth to all that is essential in society, it is because the idea of society is the soul of religion.”

While the pioneering work of Max Weber and Durkheim laid the groundwork for much of contemporary social analysis of religion, comparative

sociologists of religion such as Joachim Wach (1958) have tempered earlier tendencies toward sociological reductionism. Wach sought to understand the nature of religion by examining traditions throughout the world and noting the primary elements they shared. He identified religious experience as the basic and formative element in the rise of religious traditions around the world and then investigated the expression of this experience in thought, action, and community.

Wach said that there is a symbiotic relationship between religion and society. On the one hand, religion influences the form and character of social organizations or relations in the family, clan, or nation as well as develops new social institutions such as the Christian church, the Buddhist *sangha*, and the “Lakota nation.” On the other hand, social factors shape religious experience, expression, and institutions. For example, in Black Elk’s vision, the role of the warrior in Lakota society is expressed through the two men who come to escort Black Elk into the sky, and in his later mystical venture into the future, Black Elk as Lakota shaman (*wichash wakan* is one who converses with and transmits the Lakota’s ultimate spiritual power, or *Wakan*) becomes the ultimate warrior who battles a “blue man” (perhaps representing personified evil or the dreaded “bluecoats”). Lakota social conventions that name the natural directions as four (North, South, East, West) are modified by Black Elk’s vision to include Sky and Earth, making six vision directions that influence the number of elders Black Elk encounters in the heavenly teepee and the number of sacred objects he is given. Here the shaman’s vision modifies social conventions even as it creates a social subconvention for other visionaries who also name the directions as six. The objects are conventional implements of Black Elk’s culture that are empowered to serve symbolically as multivocal conveyors of sacred knowledge and wisdom. Finally, Black Elk’s vision can be viewed sociologically as confirming the corporate sacredness (the sacred hoop) of the nation of the Lakota. For example, a Lakota’s vision was powerful and meaningful only to the extent that the tribe accepted it. In this sense one can understand why Durkheim would say that religion, in this case the Lakota’s, is society writ large in the sky.

However, for Wach and for scholars, such as Niman Smart (1969), who follow his lead, the

forms and expressions of religious life are best understood as emanating from religious experience. Smart identifies six dimensions that all religions share: (1) ritual, (2) mythological, (3) doctrinal, (4) ethical, (5) social, and (6) experiential. The author of this article has provided an interpretative framework for understanding the necessary interdependence of these six elements of religious traditions in *Two Sacred Worlds: Experience and Structure in the World's Religions* (Shinn 1977). These dimensions of the religious life form the structure of this analysis of the social aspect of world religions.

RELIGIOUS EXPERIENCE

Building on the insights of William James and Rudolph Otto (1946), more recent scholars such as Wach, Smart, and Mircea Eliade (1959) seek the origin of religion in the religious experience of a founder or religious community. These scholars assert that genuinely religious experiences include an awareness or an immediate experience of an ultimate reality or sacred power, whether a theistic divinity as in the case of the God(s) of Judaism, Christianity, and Islam or a nontheistic transcendental reality as in the case of the Buddhists' Nirvana or the Hindus' Brahman/Atman. James suggests that transcendental or mystical experiences are immediate apprehensions of the divine that are marked by ineffability, a noetic quality, transiency, and passivity. From one perspective, ineffability can be understood as the inability of language to relay the emotional and cognitive content of a peak religious experience; it also may be described as a failure of language to capture the divine subject of such an experience, that is, the ultimate reality itself. Nonetheless, religious experiences inevitably are understood as providing new states of knowledge that cannot be grasped fully by the discursive intellect. This noetic dimension of religious experience often is described as the revelation of new knowledge (i.e., illumination) that is provided by religious experiences. In fact, it is precisely an awareness of an encounter with a sacred reality in religious experiences that differentiates these experiences from nonreligious peak experiences (e.g., an aesthetic peak experience of a piece of music). Religious experiences also tend to be marked by brevity (i.e., transiency) and the passivity of the person having the experience. While aesthetic, political, and erotic peak experiences may be characterized by ineffability,

transiency, and passivity, only religious experiences bring with them a consciousness of an encounter with a "holy other" sacred reality.

Whether a founding religious experience is immediate and direct, such as the Buddha's nontheistic enlightenment experience of Nirvana, or cumulative and indirect, as was the lengthy exodus journey of the Hebrews, religious experiences are, in Wach's terms, "the most powerful, comprehensive, shattering, and profound experience" of which human beings are capable (1958, p. 35). Wach concludes that a necessary criterion of genuine religious experience "is that it issues in action. It involves imperative; it is the most powerful source of motivation and action" (1958, p. 36). Consequently, religious experiences may be viewed as the wellspring of religion both in the formation of a new religious tradition and in the origin of the faith of the later generations.

Even if one accepts the primacy of religious experience, it is important to note that founding religious experiences are deeply immersed in the social and cultural realities of their time and place. For example, whether immediate and direct or cumulative and indirect, religious experiences inevitably are expressed in the language and concepts of the persons and culture in which they arose. Black Elk's vision of *Wakan* in the form of the six Grandfathers clearly reflects the Lakotas' social and political structure as well as their idealized notions of nation and nature. The Thunder Beings and Grandfathers who are the personifications of *Wakan Tanka* ("Great Power") obviously arise from the natural, linguistic, and social environments of the Lakota. So does the conception of *Wakan* itself as a pervasive power that permeates animal and human life as well as that of nature. A contemporary Lakota has said, "All life is *Wakan*." So also is everything which exhibits power whether in action, as in the winds and drifting clouds, or in passive endurance, as the boulder by the wayside.

Religious experiences occur to persons who have already been socialized. The most obvious social tool is the language used to express even the most profound religious experiences. The ineffable nature of religious experiences requires the use of metaphors or extensions of everyday language, as in the case of Black Elk, and to some extent, the experience itself is shaped by the language in which it is expressed.

Divine names usually are borrowed from the social and linguistic environment of the founder or founding community. For example, the exodus experience of the Hebrew people was interpreted by them as a liberating religious experience fostered by the God of Abraham, Isaac, and Jacob. This God, whose name is given in the Book of Exodus as Yahweh (“I am who I am”), is also called El Elyon (“God most high”), El Shaddai (“God of the mountain”), and Elohim (usually translated as “God”). Moses probably borrowed the name “Yahweh” from the Midianites. El Elyon was the high god of Salem (later called Jerusalem) and was worshiped by King Melchizedek. It also is known that the Canaanite high god of the same period was named El and appears in different cultic sites throughout the ancient Near East. Although it is clear that the Hebraic religious texts understand Yahweh and El quite differently than do their known local counterparts, the Hebrew high god embraced the local deity nomenclatures while modifying their meanings.

In a similar fashion, the divinity of the man Jesus is acknowledged in early Christian texts through references to earlier Jewish apocalyptic language and expectations. In the Jewish apocalyptic literature (e.g., I Enoch), the “Son of Man” appears as a righteous judge who will come to earth to signal the beginning of the heavenly kingdom and God’s rule. As an eternal savior, the Son of Man will come to save the righteous followers of God and destroy all those who ignore him. In those linguistic borrowings, however, significant modifications of the original conceptions are made to adjust the titles and expectations to the man Jesus as perceived by his followers. For example, Jesus comes as the Son of Man not primarily as a stern and vengeful judge but as a savior who is himself the sacrifice. This linguistic and conceptual transformation reflects the dependence of language on experience as much as it reveals the social and linguistic dimensions of religious experience.

Similar examples of borrowed—and transformed—god names abound in religious literature and history throughout the world. In Saudi Arabia in the sixth century, Mohammed elevated a local polytheistic Meccan god, Allah, to the status of an international deity. In tenth-century Indian Puranic literature, devotees of the god Vishnu promote his *avatar*, called Krishna, to a supreme

theistic position as the god above all gods. Although the *Bhagavata Purana* recounts the *lilas*, or play, of Krishna as though the author were describing historic figure, it is clear to textual scholars that there are two essentially distinct and dynamic story traditions arise from the Brahminical Krishna of *Bhagavad Gita* fame and from the indigenous cowherd Gopala Krishna associated with the western Indian Abhira tribes.

Although devotees of either Allah or Krishna now perceive their divinity and his name as having been “from the beginning,” there is little doubt that the local social and linguistic environments provided both content and context for the names of the divinities in these two traditions. Perhaps the most radical example of theistic amalgamation is that of the Indian goddess Kali. Described in medieval Indian texts as being synonymous with literally dozens of local and regional goddess names and traditions, Kali is a latecomer to the Indian theistic scene as one who is given the primary attributes of many gods and goddesses. The mythological tale of the birth of Kali reveals an amalgamation process that gave birth to this great goddess now worshiped by millions in India as the “Supreme Mother.” Finally, the concept and expressions of the nontheistic Nirvana experienced by the Buddha were fundamentally shaped by the notion of reincarnation or rebirth and other metaphysical assumptions common to most religious traditions in India in the fifth century B.C.

These examples show that while religious experience of the sacred may be the initiating point of the world’s religious traditions or an individual’s faith, that experience is given shape and substance by the linguistic and social context out of which it arises. It is also true, however, that life-altering religious experiences such as those described above shape the language and traditions through which they are expressed. This symbiotic relationship occurs in the other dimensions of religious life that are shared by the world’s religions.

MYTH AND RITUAL

Formative religious experiences contain within them impulses to expression (myth) and re-creation (ritual) that later become routinized and then institutionalized. Core myths and rituals, therefore, attempt to convey and re-create the experi-

ence of the founder or religious community. Both myths and rituals rely on symbols whose content must be shared in order for them to have meaning for the religious group that uses them. Symbols have not only shared cognitive meanings but also common emotional significance and value. That is, symbols do not simply convey intellectual understanding but also engender an emotive response. Furthermore, religious symbols are integrative and transforming agents in that they point to realities that have been encountered but are hidden from everyday vision and experience. Paul Ricoeur (1972) says that symbols yield their meaning in enigma, not through literal or direct translation. Symbols, therefore, suggest rather than explicate; they provide “opaque glimpses” of reality rather than definitive pictures. Understood in this fashion, the journey from symbol to myth is a short one for Ricoeur, who takes myth to be a narrative form of the symbol. Put simply, myths are narratives or stories of the sacred and of human encounters with it.

As stories of sacred powers or beings, myths fall into two basic categories: expressive and reflective. Expressive myths are sacred narratives that attempt to relate the founding or codifying religious experiences of a religious tradition, while reflective mythic narratives are composed subsequently to integrate the sacred experience into everyday life. For example, Black Elk’s “re-telling” of his vision experience becomes an expressive myth or sacred narrative for the Oglala Lakota to which they refer again and again in reflective stories of the Thunderbeings or the Grandfathers, wherein the Lakota attempt to extend the lessons of this experience to later problems they encounter. Nearly every extant religious tradition tells and retells its sacred narrative of the founder’s or founders’ encounter with the sacred reality. Black Elk’s vision becomes such a story for the Oglala Lakota.

The story of the exodus of the Hebrews is recounted as a symbolic and founding narrative of God’s liberation for Jewish people of all times. The stories of the life, death, and resurrection of Jesus form the core myths of Christians when one understands a myth to mean “sacred narrative” rather than “untrue story.” Likewise, the story of the Buddha’s arduous meditative journey culminating in the attainment of Nirvana inspires religious thought and behavior throughout all Buddhist

lands even today. Similarly, Muhammad’s auditory experience of Allah on Mount Hira, which resulted in his recording of the Qur’an, constitutes the sacred history of millions of Muslims on all the continents. Finally, even though scholars are confident in their judgment that the life of Krishna as told in the tenth-century *Bhagavata Purana* is really an anthology of stories borrowed from earlier Krishna traditions, these *lilas*, or “playful episodes,” told as a single life of Krishna have inspired religious experiences, poetry, and rituals that still enliven the lives of millions of Hindus throughout the world. From even this selective set of examples of founding myths, it is clear how deeply they drink from the social, linguistic, and institutional wellsprings of their time and place.

The generative function of core myths is shared by certain rituals that attempt to “represent” in a spatial and physical context the core experience of a religious tradition. From one perspective, core rituals are those that emerge from sacred narratives or myths as their active component. From a second perspective, core rituals represent repetitive, institutionalized behavior and clearly are immersed in the social sphere of religious life. For example, the Christian narrative that relates the Last Supper of Jesus as a sacramental event (e.g., Mark 14:12–26) is physically presented in the early Christian love feast that becomes the Lord’s Supper (Eucharistic ritual or Mass) of later Christian churches.

The work of Victor Turner (1969) in a traditional African religious context provides a vocabulary for the religious and social transactions that take place in core myths and rituals. Turner describes three phases in ritual reenactments that attempt to (1) separate or detach the participant from everyday consciousness and social position, (2) provide a moment of *liminality* and *communitas* of shared experience with participants in rituals, and then (3) reintegrate ritual participants back into everyday life with its social roles and structure. *Liminality* is the neutral psychological and social state of transition between one’s former social roles and consciousness and the new status one assumes beyond the ritual. *Communitas* for Turner is a mode of social relationship that is marked by an egalitarianism that is uncommon in the stratified roles and relationships of the everyday world. Consequently, Turner would argue

that religious rituals may provide an in-between, or liminal, moment of social and psychological experience that religious devotees often assert includes an encounter with their sacred power or reality.

The Passover narrative in the Book of Exodus provides a good example of a core myth that is later enacted, in this case in a Passover meal. In its literal meaning, the Passover myth refers to the tenth plague, when the angel of death killed Egyptian firstborn children while sparing the Hebrew children just before the exodus journey. In its symbolic sense, the Passover story that is “re-presented” in the Passover sacrificial meal symbolizes Yahweh’s power of liberation. To the extent that the story of the exodus reveals the beginning of Yahweh’s covenantal relationship to the Hebrew people, the Passover ritual attempts to re-create or revivify that relationship.

Beyond the community’s social embodiment of the sacred story of Israel’s encounter with Yahweh in a festive and communal sacrificial ritual of the Passover, the social aspects of both the myth and the ritual are evident. Sacrifices were the common mode of worship for the pre-Mosaic tribal religions as well as for the contemporary cults in Moses’ day. It is very likely that the Passover ritual described in Exodus 12 derives from a combination of a nomadic animal sacrifice and an agricultural feast of unleavened cakes, both of which predate the exodus event. While the Hebrews’ experience of Yahweh in the exodus journey reshapes both the story and the ritual as a liberation event, both the Hebrew myth and the ritual have antecedents in the social and religious world of which they were a part.

Similarly, the baptism and Eucharist rituals in the Christian faith are core rituals that stem from the religious narratives that gave birth to them. Likewise, traditional nontheistic Theravada forms of Buddhist meditation appear to stem directly from the Buddha’s spiritual struggle and release but draw on Jain and Hindu forms that predate them. Among the Oglala Lakota, the horse dance ritual was taught by Black Elk to his tribe in a fashion that replicated as closely as possible the vision he received. Therefore, the six old Grandfathers, the horses representing the four cardinal directions, and the various sacred implements he

was given all become central elements of the horse dance ritual.

In Islam, the Hajj is one of the five pillars of faith that is incumbent on all Muslims to honor and embody. The Hajj is a pilgrimage that reenacts the spiritual journey of Muhammad with periods of fasting, prayer, and meditation that culminate with ritual circumambulations of the Ka’ba, the black stone in the central mosque of Mecca that is the seat of Allah’s throne. In the Hindu devotional traditions, it is common for dramatic performances, stylized ritual dance forms such as Bharata Natyam, and temple dramatic readings to convey episodes of the encounter of devotees with the divine. Consequently, theatrical dramatic productions of the *lilas*, or playful pastimes, of the cowherd god Krishna are enjoyed by villagers throughout India not simply as theatrical events but as representations of Krishna’s delightful divine play. The daily ritual reenactment that occurs before the shrines of Krishna, Kali, and other Indian divinities is called *puja* and is a ritual ceremony that probably emanates from the stylized honorific behavior one accords to a royal guest. Here the social precursors to religious ritual are evident, even though they are transformed by the religious narrative and ritual context into which they are placed.

Scholars across a variety of disciplines and perspectives have asserted the interconnection of myth, ritual, and the religious community. Perhaps the most clear summary of this relationship is given by Bronislaw Malinowski, who says, “An intimate connection exists between the word, the mythos, the sacred tales of a tribe, on the one hand and their ritual acts, their moral deeds, their social organization, and even their practical activities on the other” (1954, p. 96). Malinowski indicates that while core myths and rituals may have their origin in founding religious experiences, they also serve as social “warrants” for the primary beliefs of the society out of which they arise and which they help shape. From this perspective, myths and rituals serve primarily as vehicles that legitimate social institutions. Core myths and rituals appear to be charged with the difficult task of representing and re-creating founding religious experiences. They also reflect and embrace their social and cultural contexts. Furthermore, not all myths and rituals serve this primary and essentialist function; certain myths, rituals, and religious behaviors diverge

considerably from the impetus the core narrative seems to suggest.

ETHICS

Malinowski and Wach make clear that ethics arise partly as a result of religious experience but also participate fully in social processes. While religious experiences may give rise to immediate expression (core myths) and reenactments (core rituals), they also give impetus to new attitudes and intentions, which are reflected in norms for behavior. In the Christian context, such behavior is claimed to be the mark of a “reborn” person whose conduct manifests the tangible effects of an experience of God. Conversely, the ethical norms and traditions that arise within a religious institution may reflect as much the mores of the surrounding culture and society as they do the experience upon which the institution was founded. Social factors such as language, family roles, and social customs play a role in the process of the externalization of the religious life in ethical laws. James says simply that behavior is the empirical criterion for determining the quality and validity of a religious experience. The distinction he makes between the person who has a religious experience and the person who undergoes a religious conversion is the distinction between having a highly charged peak experience and living a new life born of that experience.

It appears that all religious traditions evidence an interdependent and necessary relationship of conduct to experience so that what is experienced as an ecstatic encounter with the divine is expressed as a new and integrated mode of living. The committed ethical life of a devotee, then, is ideally understood as an active extension of religious experience expressed through communal or shared norms. While an immediate religious experience may provide a core religious impulse (e.g., to love God and one’s neighbor in the Christian context or to fear Allah in the Muslim context), that impetus becomes manifest in the concrete situations of social behavior. For example, the nontheistic enlightenment experience of the Buddha resulted in a sense of detachment from the world that was linked to enduring traditions of *metta* and *karuna* (love and compassion) and resulted in “detached compassion” as the complex ethical norm the Buddha modeled for his disciples.

The most obvious intrusion of social norms and processes into the religious life occurs in moral decision making. The natural and social worlds in which people live provide challenges and problems that require an ethical response. Consequently, life in the world poses many situations not anticipated in the religious texts and routinized ethical norms of religious traditions. As a result, over time, ethical systems often come to reflect the surrounding secular culture and social norms as much as they do the basic religious impulse from which they are supposed to derive their direction. This process is mediated during the life of the founder whose authority and behavior provides a model for action. In subsequent generations, however, individuals and institutions such as the Pope, the Buddhist *sangha* (community of elders), and the Lakota tribal council often determine the ethical norms of a community. When ethical statements and positions stray too far from their initial impulses, they are in danger of mirroring the society they intend to make sacred. Put simply, while ethical impulses may originate in religious experiences, the ethical laws, norms, and traditions that are constituted in scriptures and institutional pronouncements often distort the moral imperative by including rationalizations that conform to social, not religious, expectations.

An example of the difference between ethical impulse and moral law can be found in the Hebrew notion of a covenantal relationship with God. Moses and the exodus tribes experienced a compassionate, mighty, jealous, and demanding God. The laws of the early Hebrews, therefore, were viewed not only as commandments arising from a stern leader or group of legalistic lawmakers but also as expressions of an appreciative and liberating relationship with God. The Sinai story of the transmission of the Ten Commandments is intended to reveal the Hebrews’ ethical relationship with Yahweh. It was on that holy mountain that the covenant between Yahweh and his people was given concrete expression. However, this relationship was marked by infidelity on the part of Yahweh’s people. Therefore, for many of them, the codes of conduct contained in the Ten Commandments and the Levitical Code were experienced as the oppressive laws of a judgmental God.

Jesus summarized the essence of ethical behavior in a twofold commandment to love God and love one’s neighbor that was enjoined on all

who would count themselves as disciples of God. However, the teachings of Jesus and the commandment of love have led over the centuries to disputes about whether Christians should engage in war, permit abortions, treat homosexuals as equals, and allow divorces. Institutionalized Christian churches in their many forms have decreed what proper ethical conduct is with regard to such issues, and those norms vary and even contradict each other within and across Christian religious traditions. This is the difference between the imperative to love God and love one's "neighbor" and ethical laws that must express divine love in complex and rapidly changing social contexts and situations. Seemingly universal laws such as "Do not kill" mean something quite different to a Lakota warrior who may kill (and sometimes scalp) his enemy (but not a fellow tribesman) than they do to a Muslim who is encouraged to kill an infidel who defames Allah or to a Buddhist who is enjoined not to kill *any* living being.

Even among seemingly similar traditions, such as the Hindu devotional sects, ethical norms can vary immensely. In the Kali goddess tradition, animal sacrifice is still commonly practiced as a way of returning to the goddess the life-giving force she has bestowed on her creation. Some devotees of Kali have interpreted her mythological destruction of demons as a model for their own behaviors and have followed suit as thieves and murderers in the Indian Thuggi tradition. By contrast, Kali devotees such as Rahmakrishnan understand Kali to be a transcendent "ocean of bliss" who engenders peacefulness and nonviolence in her disciples.

What is true of all these religious traditions around the world is that persons usually are taught what constitutes proper or ethical behavior, and in that context, ethics are learned conceptions born of the social process and its experiences. Consequently, ethical norms and their expression often reflect the social environment in which religious traditions arise. A clear expression of this fact is found in the Hindu religious tradition's embrace of the caste system that sacralizes a socially elitist and patriarchal social system that predates Hinduism. Caste distinctions that are sacralized in the mythical and theological texts of the Hindu tradition serve as warrants for social roles and norms that undergird not only the Hindu traditions but also those of the Buddhists and Jains in India.

THEOLOGY AND DOCTRINES

Just as religious experience may result in the formation of a religious movement that tells the founding story of contact with a sacred power (core myth), tries to re-create that experience for the beginning and subsequent communities (core rituals), and impels new believers to act in accordance with this vision or revelation (ethical impulse leading to institutionalized ethics), so it is that even very early in a religious tradition's history questions and criticisms arise that must be answered. Religious reflection takes a variety of forms that touch the total corporate life of a religious community. Sacred scriptures often encompass expressive myths that relate in narrative form the founder's or founders' contact with the sacred core rituals in outline or in full, ethical injunctions and moral codes, and reflective myths, doctrines, and explications that attempt to answer believers' questions and unbelievers' skepticism. Almost inevitably, members of a religious community are provoked from without and within to explain how their sacred reality is related to the origin of the community and perhaps even to the origin of the world. Consequently, reflective myths that represent second-level or posterior reflection are incorporated to explain those beginnings.

Three distinct but interrelated purposes and functions of reflective myths are to (1) explain origins, (2) rationalize aspects of core beliefs, and (3) provide an apologetic defense of the faith to disbelieving insiders or outsiders. A good example of reflective theologizing is the development of the biography of the Buddha. The oldest Pali texts essentially begin the life of the Buddha with his disillusionment with the world at age 29, when he was already a husband and a father. The early texts indicate that his name was Siddhartha and that his father, Suddhodana, ruled a small district in the north Indian republic of the Sakyas. This early story indicates that Siddhartha was married at the age of 16 or 17, had a son, and then became disillusioned with the human suffering he saw around him and renounced the world to seek spiritual liberation while leaving his family behind.

Approximately five hundred years after the death of the Buddha, two separate "biographies" were written that contained accumulated legends not only about the miraculous birth of the Buddha but also about the great renunciation. The birth

story describes the descent of the Buddha from the heavens as a white elephant who miraculously enters his mother's side and is born nine months later as a fully functioning adultlike child. These biographies describe the Buddha's physical features (captured in religious images and icons) as including the lengthened ears of an aristocrat, a smoothly shaped conical bump on the top of the head indicating his intelligence, and other marks that foretell his later enlightenment.

These latter-day scriptures recount his renunciation of the world in a full-blown, theologized story of encounters with an ill man, a decrepit old man, a dead man, and a religious ascetic. The story of the Buddha's four visions provides a fuller explication of the reasons for his renunciation. Both the birth story confirming the Buddha's sacred origins and the story of the four visions of the Buddha (a rationalization of his renunciation) represent reflective myths that fill in biographical gaps in earlier stories of his life in light of his later enlightened status.

Parallels to the biographical history of the Buddha can be found in the scriptural stories of the miraculous births of Jesus, Mahavira (founder of the Jains), Krishna, Kali, and Muhammad, among others. A similar genre of reflective myths can be found in the creation stories that often are added dozens of years or even centuries after the founding experience. Good examples of this process are the Hebrew creation stories told in Genesis 1 and Genesis 2. God's creation in seven days is the youngest creation story (the priestly story of the seventh century B.C. that is told in Genesis 1:1–2:4a) and is placed at the beginning of the book of Genesis. It is likely that the Akkadian myth of Tiamat served as a model for this story of the creation of the world out of a watery chaos.

The older Yahwist creation story, found in Genesis 2:4b ff., is set in a desert environment instead of a primeval ocean and very likely goes back to the tenth century B.C. A decidedly more anthropomorphic story, the Yahwist Garden of Eden story, was added at least three to four hundred years after the exodus experience. Neither the priestly story nor the Yahwist story received its present form until the sixth or seventh century B.C., when both were called upon to explicate the creative power of their Hebrew God set against the Canaanites' theology of nature's seasonal birth,

death, and rebirth that the Hebrews encountered in Palestine. For the Palestinian farmer, Canaanite or Israelite, the question was, "Is it Yahweh or Baal to whom one should offer sacrifices and give allegiance if one's crops are to prosper?" The two Genesis creation stories explain not only who is responsible for the origin of life on earth but also how one can explain human illness, suffering, and death in the context of the God who led the Hebrews out of Egypt. In Africa and India, the numerous and sometimes contradictory creation stories one finds in a single religious tradition reveal less about the illogical nature of some reflective myths than they do about the human need to have questions of birth, death, suffering, social relationships, and the founding of the tribe placed in the context of a tradition's ultimate reality.

When religious traditions develop full-fledged social institutions, it is common for sacred texts and other interpretative theological texts to explain the necessity of those religious organizations and their officials. Whether it is the early church fathers' explanations of the seat of Peter on which the Pope sits in the Roman Catholic tradition or a Lakota visionary myth that explains the role of the shaman in the community, reflective myths and theologies develop as intellectual and institutional rationalizations for the extension of the founding experiences and tradition into all aspects of life and society. Religious councils, theological traditions, sectarian disputes, and doctrinal formulas all arise as socialized institutions that attempt to explicate, defend, and provide an apology for a religious faith firmly embedded in the personal and social lives of its adherents. For example, Islamic theology extends the influence of the Qur'anic faith into the economic, political, and social lives of the Muslim people. Likewise, from birth and family relationships through wars and death, the Lakota's life was experienced within the sacred hoop.

The extension of religious faith into all aspects of life is justified in scriptures and doctrinal tracts by the reflective process of mythmaking and theologizing. Peter Berger (1969) calls such activity the construction of a *nomos*. A theological *nomos* is essentially a socially constructed worldview that attempts to order all of human experience in the context of a sacred reality, whether theistic (e.g., Krishna or Allah) or nontheistic (e.g., Nirvana). Such theological reflection is determined to a

great extent by the social and human circumstances that give rise to the questions that must be answered as well as the language and social conventions through which the reflections are expressed. However, Wach reminds us that the prophetic function of religious traditions often shapes the social environment to a religious vision and not simply vice versa. Puritan society in colonial America is an example of religious faith shaping social mores and institutions.

INSTITUTIONS

Religious institutions arise as the fullest and most obvious social expression of a religious faith. They are equally the home for the core myths and rituals to be enacted and the loci of the religious communities whose individual and collective needs must be met. Religious institutions vary from formal collectivities such as the Christian church, the Muslim mosque, the Hindu temple, and the Buddhist *sangha* to their extended representations in festivals and ceremonial events such as weddings and funerals. It is within the social institution that *communitas* understood as a spiritual leveling of religious adherents exists alongside a religious community in which social differentiation and hierarchies usually persist. Religious institutions are usually the most deeply embedded social aspect of religion, since it is their task to control the external conduct of their members through rites, rituals, and ethical norms while providing an economic and political power base through which they can compete with other social institutions. Simply put, religious institutions are to a great extent socially constructed realities that provide for the habituation and rationalization of religious thought and behavior.

James (1961) viewed the church, synagogue, or other religious organization as a “secondhand” extension of the religious life. In terms of institutional leadership, Abraham Maslow (1970) distinguishes between “prophets” (i.e., those who found the religion) and “legalists” (those who regulate, systematize, and organize religious behavior in institutional forms). Even from this brief discussion of the interrelationships of the primary aspects of the religious life, one can see why Michael Novak says, “Institutions are the normal, natural expression of the human spirit. But that spirit is self-transcending. It is never satisfied with its own

finite expressions” (1971, p. 156). According to Novak, the basic conflict is between the human spirit and all institutions.

No religious institution has escaped criticism of its creeds, dogmas, ethics, and authoritative pronouncements from those within the tradition who insist that the essential faith demands revisions of the institution’s expressions of that faith. These criticisms give rise not only to reform movements but also to schisms and new sects that emerge as a result of the clash between the received faith in its textual and social forms and the religious experiences and impulses of a reformer or critic within the organization. Martin Luther was a reformer whose critique of his received Roman Catholic heritage was both personal and theological. Similarly, the numerous Buddhist sects that arose in the first hundred years after the death of the Buddha gained their impetus from quarrels over doctrine, lifestyle, and interpretations of the essential nature of the faith. The Sunni and Shi’a (also called Shi’ite) branches of Islam have dozens of contemporary expressions that emanate from a fundamental split in the tradition that occurred shortly after the death of Muhammad and focused on the source of authority for future proclamations in Islam. Typical of other religious traditions, Islam gave early birth to a pietistic mystical tradition, known as Sufism, which has consistently criticized both major theological branches of that religion for their legalistic and worldly focus to the detriment of the nourishment of the spiritual life. The Kabbala is a similar type of mystical reform tradition within Judaism. From one perspective, sectarian and schismatic movements are attempts to recapture the original experience and spirit of a religious tradition in response to institutionalized forms of worship and expression that appear devoid of the core spirit that gave birth to them. Nonetheless, in those cases where the new movement or sect survives its charismatic beginning, it necessarily develops the same institutional forms (religious community, rituals, ethics, etc.) that it rejected in its predecessor and that are experienced by some faithful later generations as too distant from its spiritual foundation and in need of reform. This pattern of dissatisfaction with institutional codifications of religious experience, a time of spiritual innovation or reform, and then institutionalization of the reform is one that continues in all the major religious traditions in the world,

producing new sects or, in rare cases, altogether new religious traditions.

NEW RELIGIOUS MOVEMENTS

The attempt to reform a traditional religion in a given cultural setting sometimes has produced a new religious movement (NRM) that threatens the established norms and values of the host society, not just the established religious institution. Often an NRM emanates from an established religion as a reform or even extension of that tradition. An example is early Christianity, which some Jewish and non-Jewish converts saw as fulfilling Jewish prophecy and others regarded as a dangerous and heretical sect that threatened both the Jewish and the Roman institutions of Jesus' time. When the connection with the established tradition is more tenuous, the new revelation and resulting behavior distance themselves almost immediately from traditional institutional forms. For example, Joseph Smith's discovery of lost tablets of scripture not only "completed" the Christian revelation and scriptures but essentially replaced them. Smith's Mormonism promoted theological (e.g., preeminence of the Book of Mormon), ethical (e.g., polygamy), and other views and practices that were at odds not only with traditional Christian norms and institutions but also with those of American society. Such NRMs often generate considerable opposition from both religious and political authorities who perceive a threat to their worldview and the norms that come from that *nomos*. In the first century after the death of Jesus, his followers were martyred by Roman authorities who considered them members of an NRM outside the protection of law afforded Jews in the Roman Empire. Likewise, by the end of the nineteenth century in America, the Mormons not only were attacked by their Christian neighbors as heretical "cult" but were for a time denied the legal right to hold property and to marry.

Approximately one hundred years after groups such as the Mormons, the Seventh-Day Adventists, and the Theosophical Society were considered "cults" to be suppressed, a new wave of NRMs (also called "cults") flooded America. Some of those NRMs were essentially splinter groups of Christians (e.g., Jesus movements) whose evangelical fervor and communitarian lifestyle set them

apart from more established Christian churches. Other NRMs, such as Scientology, were the imaginative offspring of idiosyncratic founders such as L. Ron Hubbard, a science fiction writer who promised "total freedom" to all who would practice his strict regimen of psychological and spiritual "clearing." Still other NRMs were imports from Asia with gurus such as Maharishi Mahesh Yogi (Transcendental Meditation) and Guru Maharaj Ji (Divine Light Mission) who taught their own particular Hindu meditational paths to enlightenment. One NRM, the Unification Church of Sung Mung Moon, was essentially a syncretistic blend of Christian missionary and Korean folk religious traditions. The Reverend Moon claims to have had a special revelation on Easter Sunday in 1936, when Jesus appeared to him and asked that Moon complete the messiah's work. Moon's revelation led to a new scripture called *The Divine Principle*, new rituals, and a worldwide mission to unify all Christian and world faiths.

Finally, some of the NRMs of the 1960s in America were not "new" at all but instead were traditional faiths of other cultures seeking converts in an American mission field. One such NRM was the International Society for Krishna Consciousness (ISKCON), more commonly called the Hare Krishnas. While lumped together with other NRMs, the Hare Krishnas practice what is more properly understood as a traditional form of devotional (*bhakti*) Hinduism centering on the god Krishna. This devotional Hindu faith was brought to America in 1965 by the Hindu sage A. C. Bhaktivedanta Prabhupada. Prabhupada was an *acharya*, or spiritual teacher, whose lineage traces back to the Krishna reformer Chaitanya in the sixteenth century and whose own guru asked him to bring the Hare Krishna faith to English-speaking people. While adapting his teachings to a foreign culture as all missionaries must, Prabhupada taught the same Indian scriptures (e.g., *Bhagavata Purana*), rituals (e.g., worship before Krishna images and chanting Krishna's name), religious dress (e.g., saffron robes), and ethics (e.g., vegetarianism and ritual cleanliness) that had been taught by Indian masters for centuries. While the Krishna faith originated over 2,000 years ago, part of what made this religion seem so new and different to American youths and religious institutions was its evangelical missionary and ecstatic devotional elements (e.g., public chanting and dancing), which

were innovations of Chaitinya's reform nearly 400 years ago (see Shinn 1987a).

Whatever the origin or character of NRMs, they represent external challenges to established religions in much the same way that sectarian reforms represent internal challenges. From the point of view of formative religious experiences, NRMs offer alternative spiritual paths to religious seekers who do not find spiritual satisfaction in their natal or traditional religious institutions (Ellwood 1973; Richardson 1985; Shinn 1993). The host society's response to NRMs often reveals the extent to which that society's secular or religious institutions satisfy the needs of its populace (Robbins and Anthony 1981; Barker 1982; Wilson 1981). When religious institutions have stagnated or strayed from their spiritual source, challenges and alternatives arise from within. Likewise, evangelical and missionary ventures from religions around the world take whatever opportunity they are given to provide alternative paths to spiritual fulfillment.

INTERSECTION OF WORLD RELIGIONS

One tendency of insitutionalized religious traditions is to seek to become world religions. The impetus to spread a religion throughout the world sometimes comes from the exclusivistic theological claims that assert the superiority of one faith over another (e.g., Christianity and Islam). Some religious traditions actively seek less to convert others than to assimilate other religions into their own theology and practice (e.g., Hinduism). Still others spread to other lands and cultures after being forced out of their homelands (e.g., Judaism and Buddhism). The broad reach of world religions has resulted in multifaith societies such as India (e.g., Hinduism, Islam, Sikhism, and Jainism), China (e.g., Confucianism, Buddhism, and Taoism), and the United States (e.g., Christianity, Judaism, and Islam), where different religions have coexisted for centuries. What can one expect of the interaction of world religions as rapid communications and travel bring people and their religious faiths face to face in ever greater numbers in the twenty-first century?

First, it should be expected that wherever religious institutions are interwoven with political and cultural institutions, resistance to or rejection of other world faiths will occur. This tendency will be exacerbated in areas where religious funda-

mentalism is the dominant voice. Islamic states such as Pakistan, Iran, and Afghanistan reveal how religious institutions are interwoven with political institutions in ways that suppress tolerance of other faiths. Adding tribal or ethnic loyalties to the mix only increases the difficulty of achieving interreligious tolerance and harmony. The Catholics and Protestants in Northern Ireland, the Bosnian Muslims and Serbian Christians in Bosnia-Herzegovina and the Tamil Hindus and Singhalese Buddhists in Sri Lanka all represent inseparable blends of political, ethnic, and religious exclusivity. Therefore, one mode of interaction of world religions will be intolerance of and sometimes violence toward other faiths created to a great extent by the socialization of religious institutions by the nationalistic and ethnic norms of the people and cultures they intend to save.

Second, in areas where religions have coexisted for a long time, it is common for accommodations and even assimilation to occur that reflect the common home. For example, Hinduism, Buddhism, and Islam have coexisted for more than nine hundred years in India, and in spite of their sometimes violent interactions, remarkable innovations have occurred. Leaders from the Muslim King Akbar to the Hindu sage Gandhi have sought to bring about mutual respect among the religions of India and all the world. Likewise, devotional Hinduism historically has often bridged religious divides by inviting people of all faiths and castes to join in its worship. In the case of Sikhism, Guru Nanck blended devotional Hindu traditions with certain Islamic tenets to form a syncretistic new faith in the sixteenth century. A similar phenomenon occurred in Iran, where Zoroastrian and Islamic roots gave rise in the nineteenth century to the Baha'i faith, which incorporates the scriptures and symbols of all the major world religions into a new syncretistic religion. While the birth of such new syncretistic world religions is rare, what does occur often—and probably will increase—is the adoption of ideas (e.g., reincarnation and impersonal divinity) and practices (e.g., vegetarianism and meditation) from one faith by persons of another faith.

Third, some religious individuals and institutions will continue to seek dialogue with and understanding of persons of other faiths while maintaining their own religious ideas and practices. For example, Mahatma Gandhi was deeply influenced

by the Christian and Muslim scriptures and near the end of his life sought peace between Hindus and Muslims when few others could rise above communal loyalties. Still, when shot by an assassin, Gandhi uttered the name of his Hindu family divinity, Rama. Gandhi appreciated the teachings and practices of other world religions but died a Hindu. In a similar fashion, the Buddhist Sarvodaya Movement in Sri Lanka borrows liberally from Gandhi's ideas and disciples even as it embeds its work in Buddhist ideas and practices. So too the Reverend Dr. Martin Luther King, Jr., learned the rudiments of nonviolent action from Gandhi's teachings while situating them within his Christian theology and faith. Thus, even when certain ideas are transferred from one faith to another out of respectful dialogue and interaction, it is common for one's native tradition to remain at the core of one's thought and action.

On a more formal level, there have been many attempts at interfaith dialogue in which the formulation of a common theology (i.e., "perennial philosophy") or practice for all religions has been sought (see Shinn 1987b). The Christian Trappist monk Thomas Merton spent many of the last years of his life reading about and having a dialogue with persons of other faiths. He was accidentally killed in Bangkok, Thailand, during an interfaith conference with Christian, Buddhist, and other monks from Asia. Most efforts at interfaith dialogue arise when individuals seek to understand their own faith better and to transcend the institutional reflections of a limited time and place. Both formal and informal dialogues are certain to increase as "the global village" becomes a reality and world religions become increasingly familiar in all lands.

CONCLUSION

Clifford Geertz argues that each world religion is essentially "(1) a system of symbols which acts (2) to establish powerful, pervasive, and long-lasting moods and motivation in men by (3) formulating conceptions of a general order of existence and (4) clothing these conceptions with such an aura of factuality that (5) the moods and motivations seem uniquely realistic" (1968, p. 1). This socio-anthropological definition of religion embraces in a clear and simple fashion most of the interpretation of underlying relationships that this article has described. Any religion, whether established or new,

is a system of symbols that simultaneously attempts to express and reveal dimensions of sacred experience beyond that of the everyday by using socially conditioned language and conceptions. Likewise, the general order of existence (*nomos*) that is formulated in the myths, rituals, and ethical norms of a religious tradition emerges from the social consciousness, communal norms, and shared conceptions of the community which give rise to those elements. Finally, what Berger calls "legitimation" and Geertz calls "factuality" represent nothing other than broad-based social acceptance of certain religious beliefs. Consequently, from their inception in religious experience to their full social expression in concrete institutions, religious traditions involve an interplay between personal and social forces. No aspect—experiential, mythical, ritual, ethical, doctrinal, or institutional—of any of the world's religious traditions escapes some social conditioning, and no culture or society is left unchallenged by its religious expressions and lifestyles.
