Well over a billion people are deprived of basic consumption needs. Of the 4.4 billion people in developing countries, nearly three-fifths lack basic sanitation. Almost a third have no access to clean water. A quarter do not have adequate housing. A fifth of children do not attend school to grade 5. About a fifth do not have enough dietary energy and protein. Micronutrient deficiencies are even more widespread. Worldwide, 2 billion people are anaemic, including 55 million in industrial countries. In developing countries only a privileged minority has motorized transport, telecommunications and modern energy. Inequalities in consumption are stark. Globally, the 20% of the world's people in the highest-income countries account for 86% of total private consumption expenditures—the poorest 20% a minuscule 1.3%. More specifically, the richest fifth:

- *Consume 45% of all meat and fish, the poorest fifth 5%.*
- *Consume 58% of total energy, the poorest fifth less than 4%.*
- *Have 74% of all telephone lines, the poorest fifth 1.5%.*
- *Consume 84% of all paper, the poorest fifth 1.1%.*
- *Own 87% of the world's vehicle fleet, the poorest fifth less than 1%.*

Although annual GNP growth rates were higher overall in LDCs (4.1 percent) than MDCs (2.2 percent) between 1980 and 1995 (UNDP 1998, p. 210), the *least* developed of these LDCs did not fare so well. Not only were their GNP growth rates (2.1 percent) lower than those of MDCs, they were also significantly below their 1970–1995 average annual population growth rate (2.6 percent) (UNDP 1998, p. 209), which means that these countries are actually falling behind in what little progress they have made (Estes 1988). For example, of the 50 countries that comprise sub-Saharan Africa

(Cunningham 1998), two-thirds have been evaluated as “least developed,” that is, targeted for priority international development assistance by the Nations Nations (UNDP 1998, p. 226). Consequently, some experts have openly questioned whether these countries will ever reach the level of industrialization and quality of life now enjoyed in the capitalist countries of the North (South Commission 1990, p. 19).

DEVELOPMENT GOALS: A VIEW FROM THE SOUTH

World War II marked the end of one era and the beginning of another. Among the more notable turning points following the war were the establishment of the United Nations (and its subsequent Universal Declaration of Human Rights), the onset of the Cold War between East and West, the emergence of many new independent states following the end of colonial rule, and the sudden realization that the income and development gaps between MDCs and LDCs were growing at a precipitous rate. In turn, these events sparked the generation of theories on international development (see, for example, *Modernization Theory*, *Convergence Theories*, *Dependency Theory*, *Global Systems Analysis*), the creation of organizations such as the International Monetary Fund (IMF) and the World Bank to design an open and stable global monetary system and to establish development and investment programs (IMF 1985), and the formation of various world commissions to address issues of global development (e.g., Brandt Report 1980; Pearson Report 1969; World Commission on Environment and Development 1987).

These activities were initiated largely in MDCs by Northern-based scholars and practitioners. Although there have been several prominent writers from the South who have viewed relations between MDCs and LDCs from a Southern perspective, (Cardoso and Faletto [1969] 1979; Said 1993; Sen 1990, 1992); it was not until 1990 that delegates from the South expressed their concerns in a representative and comprehensive manner. The South Commission (1990), initially formed in 1987, was comprised of twenty-eight members from twenty-six LDCs located on all continents of the South. Chaired by Julius K. Nyerere, former president of Tanzania, the South Commission “has its origins in a recognition within the South that developing

Human Development Index (HDI) by Level of Industrialization (1995)

HDI Measures	Industrial Countries ¹ (N = 50)	Developing Countries (N = 124)	Least Developed Countries ² (N = 43)	World (N = 174)
Life expectancy at birth (years)	74.2	62.2	51.2	63.6
Adult literacy rate (%)	98.6	70.4	49.2	77.6
Combined 1st; 2nd; and 3rd-level gross enrolment ratio (%)	82.8	57.5	36.4	61.6
Real GDP per capita (purchasing power parity US\$)	16,337	3,068	1,008	5,990
Human Development Index	0.91	0.54	0.34	0.77

countries have many problems and much experience in common, but that no one in the South was responsible for looking at these things in a comprehensive manner, or at the lessons about appropriate development strategies which could be drawn from them” (Nyerere 1990, p. v). Consequently, *The Challenge to the South* (South Commission 1990) is an attempt to articulate from a Southern perspective what needs to be done “to help the peoples and governments of the South to be more effective in overcoming their numerous problems, in achieving their ambition of developing their countries in freedom, and in improving the lives and living conditions of their peoples” (Nyerere 1990, p. vi).

As part of its initial mandate, the South Commission (1990) first defined its development goals:

Development is a process of self-reliant growth, achieved through the participation of the people acting in their own interests as they see them, and under their own control. Its first objective must be to end poverty, provide productive employment, and satisfy the basic needs of all the people, any surplus being fairly shared. This implies that basic goods and services such as food and shelter, basic education and health facilities, and clean water must be available to all. In addition, development presupposes a democratic structure of government, together with its supporting individual freedoms of speech, organization,

and publication, as well as a system of justice which protects all the people from actions inconsistent with just laws that are known and publicly accepted. (p. 13–14)

To achieve these development goals, the South Commission (1990) identified three interrelated task areas:

1. *National self-reliance.* Individual countries of the South must realize their own unique potential through united and sustained efforts on the part of *all* people working toward clearly defined interim and long-term objectives. However, because there are external factors (e.g., the current structure of the global economy) that impede progress, solidarity among nations of the South is crucial.
2. *South–South cooperation.* “By joint endeavours to use to the maximum their different resources of expertise, capital, or markets, all would be able to address their separate and differing needs more effectively, thereby widening their development options . . . By exploiting these openings for co-operation, the South as a group can also become stronger in its negotiations with the North” (p. 16).
3. *An organized South for meaningful North–South negotiations.* In their relations with the North, the South must “establish common priorities in keeping with the

development interests of all,” “share technical and negotiating expertise,” and “hold constructive South–South discussions in advance of negotiations” (p. 21). Also, the South should actively support the growing initiative to establish international regulatory frameworks for the enforcement of global economic relations (including finance and trade) that are in the best interests of *all* nations and *all* peoples.

From this brief review of the report of the South Commission, it is possible to identify several key features of sustained development, *as perceived by those affected*:

- The South must play an active role in its own self-reliant development,
- Democratic grassroots participation is essential,
- Cooperation must occur at several levels (e.g., community, nation, and region),
- International regulatory codes must be renegotiated between North and South.

Although it is too soon to assess what results the recommendations of the South Commission will achieve, there are indications that some progress is being made. For example, President James Wolfensohn of the World Bank proposed a *Challenge of Inclusion* (1997) during a recent annual meeting of the Bank. Wolfensohn’s “challenge” is similar to the objectives of the South Commission: “Our goal must be to reduce . . . disparities across and within countries, to bring more and more people into the economic mainstream, to promote equitable access to the benefits of development regardless of nationality, race, or gender” (p. 6). Moreover, the key elements of his challenge also resemble those offered by the South Commission:

- First and foremost, the governments and the people of developing countries must be in the driver’s seat—exercising choice and setting their own objectives for themselves . . .
- Second, our partnership must be inclusive—involving bilaterals and multilaterals, the United Nations, the European Union, regional organizations, the World Trade

Organization, labor organizations, NGOs [nongovernmental organizations], foundations, and the private sector . . .

- Third, we should offer our assistance to all countries in need. But we must be selective in how we use our resources. There is no escaping the hard fact: More people will be lifted out of poverty if we concentrate our assistance on countries with good policies than if we allocate it irrespective of the policies pursued . . .
- Finally, all of us in the development community must look at our strategies anew (Wolfensohn 1997, pp. 9–11).

Whether *The Challenge to the South* and *The Challenge of Inclusion* represent realistic steps toward meaningful North–South dialogue, cooperation, and beneficial action remains to be seen. However, if we do not tear down the many institutionalized structures of exclusion that are currently in place, all of us may eventually lose.

A NEW TECHNOLOGICAL REVOLUTION

Another set of challenges confronting LDCs is the new information and communications technology (ICT) revolution. Beginning in the late 1960s with breakthroughs in microelectronics and fiber-optic transmission (Diebold 1990; Gilder 1989), the ICT revolution is still very much in its genesis and is limited primarily to the developed countries (Hedley 1998). In 1994, just five G-7 nations (the United States, Japan, Germany, France, and United Kingdom) accounted for 80 percent of the information technology market, and American and Japanese corporations dominate the industry (Organization for Economic Co-Operation and Development [OECD] 1996, pp. 7, 37). Table 3 presents the stark facts of information communication by both traditional and modern means. Particularly with regard to telephones and personal computers, essential ingredients for electronic communication, the less developed, low- and middle-income countries are barely represented. In sub-Saharan African countries, for example, 51 percent of all telephones are located in the largest cities (7 percent in MDCs), and the average waiting time for a telephone connection is 15.2 years (Aggor 1998, p. 9). Inadequate infrastructure, low purchasing power, lack

Information Communication by National Level of Income

Means of Information Communication	High-Income Countries	Middle-Income Countries	Low-Income Countries	World
Daily newspapers per 1,000 people (1994)	303	62	12	98
Television sets/1,000 (1996)	611	252	47	211
Telephone main lines/1,000 (1996)	540	78	11	133
Mobile telephones/1,000 (1996)	131	8	0	28
Fax machines/1,000 (1995)	33.7	1.5	0.2	6.3
Personal computers/1,000 (1996)	224	2	..	50
Internet hosts/10,000 (July 1997)	203.5	2.4	0.1	34.8

Table 3

of technological skills, and poor competition and regulation mean that particularly in the least developed countries, it will take years to realize much benefit from the ICT revolution (World Bank 1999, pp. 62–64). By some measures, the knowledge and information gap between MDCs and LDCs is larger than the income gap.

Various development scenarios have been proposed in anticipation of the impact of a full-scale ICT revolution (Hedley 1999; Howkins and Valantin 1997). The basic question addressed is whether this revolution will “help level the international playing field in terms of opportunities for social and economic development” or whether it will “lead to increasing disparities in incomes and information access” (Baranshamaje et al. 1995). In order to address this question, a high-powered workshop comprised of twenty-seven experts in technology and development from five MDCs and eight LDCs was convened in 1996 (Howkins and Valantin 1997). Sponsored by the U.N. Commission on Science and Technology for Development and the Canadian-based International Development Research Centre, the delegates attempted to establish the parameters of worldwide ICT development. Four possibilities emerged, based on the inclusivity and openness of the global community and the proactive or reactive responses of individual countries (Howkins and Valantin):

1. *The march of follies*. “The global community is exclusive and fragmented,” and “most developing countries respond only partially and reactively to acquisition and use of ICTs.” In this scenario, the global rift between MDCs and LDCs widens.

2. *Cargo cult*. “The global community is inclusive and supportive,” but “most developing countries respond only partially and reactively to the acquisition and use of ICTs.” This scenario results in cultural imperialism in which a few transnational corporations dominate the ICT industry. Developing countries have little input.
3. *Netblobs*. “The global system is exclusive and fragmented”; however “developing countries take an active approach to the acquisition and use of ICTs and develop a complete set of policies.” This scenario produces regional groups or blocs based on shared cultures, religions, and languages. “At the end of the scenario period, the blocs have achieved much. They have created information societies and economies that reflect their own histories, traditions, cultures, and ways of doing business. But their insistence on their own regional laws, regulations, and trading principles creates centripetal forces that lead to a highly unstable situation.”
4. *Networld*. “The global community is inclusive and supportive,” and “developing countries have a complete and proactive set of policies toward the acquisition and use of ICTs.” This is a global village scenario in which corporations from developed countries operate out of “enlightened self-interest as they seek ways of working with companies and institutions in the developing world . . . Their awareness is matched by a realization in

developing countries that they should work with global corporations to create their own national information society and economy.”

The workshop delegates did not attempt to predict which of these four development scenarios was most probable. Rather, based on their two sets of parameters, they indicated the various possibilities, what would be required to reach each, and some of the development consequences that would likely flow from them. In other words, if the global community is not inclusive and supportive, and if developing countries do not develop a complete and proactive set of policies toward the acquisition and use of ICTs, then we may expect various consequences that are inimical to comprehensive and sustained development worldwide. As Herbert Simon (1987, p. 11) has observed:

Technological revolutions are not something that “happen” to us. We make them, and we make them for better or for worse. Our task is not to peer into the future to see what computers will bring us, but to shape the future we want to have—a future that will create new possibilities for human learning, including, perhaps most important of all, new possibilities for learning to understand ourselves.

Thus, if we wish to take up *The Challenge of Inclusion*, there are certain courses of action to follow. If we do not take up this challenge, then, according to the founding editor of *Scientific American*, the very survival of our species is at stake (Piel 1992).

R. ALAN HEDLEY

INFANT AND CHILD MORTALITY

Mortality affects the volume of a population. Deaths are not equally distributed among all groups; rather many unique patterns have been identified. For example, the probability of dying is high among both extremes of a population's age structure—the very young and the very old. As a general pattern, the death rate is relatively high at age zero, reaches a minimum in the range from ages ten to fifteen, and then begins to increase gradually with increasing age. This increase becomes marked after age forty-five or fifty (Coale 1965).

Infant and child mortality are important because the largest mortality risk differentials between a society with high mortality and one with low mortality are always found within infancy and childhood. Because infant and child mortality are often related to general levels of health and living conditions, they are often thought of as measures by which nations can gauge their current level of socioeconomic development and societal cohesiveness. Comparisons can then be made with past mortality estimates, along with those of neighboring nations, allowing a country to make projections concerning its future development and public policy programs. Assuming this general precept, researchers investigate historical mortality trends in an attempt to isolate general patterns of infant and child mortality. The goal is to provide information for policy makers, raise standards of living for residents of a nation, thereby reducing early childhood mortality.

MEASURES AND DATA SOURCES

The *infant mortality rate* (IMR) is defined by demographers as the probability that a newborn infant will die before it reaches its first birthday. This probability is generally computed by calculating the ratio of the number of infant deaths under one year of age in a given year per number of births in that given base year. This approach is termed a *period* IMR because it only utilizes data from one year to arrive at its estimate. This method is not entirely accurate in that it 1) utilizes infant deaths of those born in the preceding year and 2) misses those infant deaths that occur in the following year. If the number of births and deaths does not change drastically from year to year, then this method results in a close approximation of an infant's probability of survival to age one (Shryock and Siegel 1976).

A more accurate measure of infant mortality is a ratio that involves the use of infant birth and death data for two years. In this instance, a researcher is able to calculate more precisely the true probability of infant death by identifying all infant births in the base year of interest and linking them to their respective infants' deaths at less than one year of age in *both* the base year and the following year. This method is referred to as the *cohort* IMR for a given year and population. Infant mortality

rates are expressed in terms of infant deaths per 1,000 live births (Shryock and Siegel 1976).

In order to capture different causes that are known to affect the timing of infant deaths within the first year of life, researchers often decompose infant mortality into various components. *Neonatal mortality* usually refers to deaths of infants under 28 days of age, whereas *postneonatal mortality* involves the deaths of infants aged 28 to 364 days. Due to the large proportion of pregnancies that result in fetal deaths, and the existing similarity between the causes of death for fetuses and for neonates, other complementary measures have been constructed. *Fetal mortality* refers to fetal deaths at a gestational age greater than 28 weeks, and *perinatal mortality* is defined as fetal mortality plus infant deaths at less than 7 days of age. All corresponding rates are constructed in much the same manner as the IMR, including the use of either the period or cohort method of estimation. For both the fetal and perinatal mortality rates, researchers usually include the number of fetal or perinatal deaths (whichever may be the rate of interest) within the denominator of the rate along with the number of births for the population of interest (Shryock and Siegel 1976).

Conventionally, the number of deaths that occur among children aged one to four is a general measure of *child mortality*. In some cases, though, the child mortality rate may include the IMR (in which case it takes into account all deaths under five years of age). As a rule, most researchers interested in child mortality separate out infant mortality in order to arrive at a clearer picture of the specific causes of death that affect children who survive infancy. Child mortality rates are generally calculated by dividing the number of deaths of children aged one to four by the total number of children aged one to four in the population and multiplying by a 1,000 (Shryock and Siegel 1976).

The most common source of data on infant and child mortality in more developed countries (MDCs) is national vital statistics registries, which were established in some countries as early as the beginning of the eighteenth century (e.g., Sweden). Researchers are able to access detailed birth and death records for both infants and children and analyze their trends and patterns. Throughout the world, the most stable data on infant and child mortality have come from those countries

with established vital registration programs. For those MDCs that do not have adequate systems of vital registration and for the majority of less developed countries (LDCs) that do not have a vital statistics system in place, other techniques exist for estimating infant and child mortality (Palloni 1981). In most of these countries, population censuses and surveys of a sample of the total population are utilized to indirectly estimate mortality rates and trends (Hill 1991). Techniques developed in the late 1960s and early 1970s have been refined and improved upon in a variety of ways (United Nations 1990). Most techniques involve the use of birth histories collected from women in the population.

EPIDEMIOLOGIC TRANSITION AND INFANT AND CHILD MORTALITY

Early research on infant mortality revealed an array of factors that presumably led to infant mortality declines in certain countries, specifically certain Western European MDCs. The experiences of these nations are the basis for a set of general hypotheses regarding the decline of infant mortality. These nations serve as test cases because of the nature of the available data and the familiarity of researchers with them. Ideas have been developed concerning the relationship among certain economic, social, and technological developments and the reduction of adult, childhood, and infant mortality. Epidemiologic transition theory, as elucidated by Omran (1971, 1977), gives researchers a theoretical framework for understanding these processes as they have occurred throughout different time periods and within different nations. This theory outlines several stages that specific nations have moved through on their way to their current mortality patterns. Many have used this theory to investigate current infant mortality levels among various countries and within specific ones (Frenk et al. 1989; Pampel and Pillai 1986).

In applying the precepts of epidemiologic transition theory to the case of infant mortality, researchers have used diverse historical sources. Epidemiologic transition theory outlines three stages through which various Western European nations moved through as they advanced toward a higher state of economic and technological development. The first two stages, termed the Era of Pestilence and Famine and the Era of Receding

Pandemics, characterize most of human existence. Within these eras, infant and child mortality were relatively high and primarily due to the prevalence of infectious disease. In the third stage, the Age of Degenerative and Man-Made Diseases, infectious diseases receded and came under medical control. Infant and child mortality fell accordingly. Other causes of death now became important, and interest in them rose. In this sense, infectious infant mortality is currently associated with countries that are less developed and populations within countries that live at disadvantaged socioeconomic levels (Omran 1971, 1977).

To better understand changes in infant mortality according to epidemiologic transition theory, researchers must be able to access data that detail the cause of infant mortality death. But as has been noted, very few countries possess the data repositories, either current and past, to adequately examine infant mortality declines and their component causes. The use of neonatal and postneonatal IMRs were one way of moving forward with these types of studies without having the necessary data for detailed analyses. Neonatal and postneonatal mortality became associated with cause-of-death groupings according to general preconceived notions of etiologic mechanisms.

Bourgeois-Pichat (1951) presumed that infectious infant mortality was primarily due to environmental factors that were wholly amenable without medical intervention. This category was termed “exogenous” infant mortality (e.g., infectious, parasitic, and respiratory diseases), while “endogenous” infant mortality was defined as those causes of infant death that were primarily due to natal and antenatal factors (e.g., congenital malformations, prematurity). Neonatal mortality became a proxy for endogenous causes of death while postneonatal mortality was associated with exogenous mortality. All that was now minimally required to continue analyses of infant mortality transitions was information on the timing of infant death (Bogue 1969; Bouvier and Van der Tak 1976). Although these conceptual distinctions probably held true throughout most of human history, debates exist as to the current validity of these conceptualizations and the continued value of their use. The introduction of neonatal technologies and other factors in MDCs have led to further discussion and reconceptualization (Sowards 1997).

INFANT AND CHILD MORTALITY THROUGH HISTORY

Among historians such different academic spheres as demography, sociology of the family, and public health, there is an interesting debate concerning the timing and factors that have led to a decline in infant and childhood mortality. There are some interpretative similarities that may offer us a foundation with which to begin this discussion.

Historically, the size of the human population remained fairly constant until the first half of the eighteenth century. One hypothesis states that until then, although periods of low mortality were common, a population was still vulnerable to famines and epidemics, thus rendering population size stable. Before the Neolithic period (c. 9500 b.c.), it is estimated that infants had a 50 percent chance of surviving to adulthood (Stockwell and Groat 1984). It is thought that the first real decline in infant and child mortality came after the Neolithic revolution, when agriculture and animal domestication became more common, despite the increased spread of infectious diseases among now clustered and sedentary populations (Creighton-Zollar 1993). Within the framework of demographic transition theory, the staggering growth of the human population registered during the last 250 years is mainly explained by a combination of significant decrements in mortality and constant fertility rates (Kitagawa 1977; Stolnitz 1955).

Interestingly, some historians have found a link between the decline in infant mortality and the greater significance of children within the family organization. In the second half of the twentieth century, a discussion about the history of the family properly began with Philippe Ariès's *L'Enfant en la Vie Familiale sous L'Ancient Régime* (Van de Walle and Van de Walle 1990). Ariès suggests that the recognition of childhood as an independent stage of the life cycle occurred first during the sixteenth and seventeenth centuries. Other family historians have argued that infant mortality was so high that parents preferred not to “invest too much emotional capital in such ephemeral beings” (quoted by Van de Walle and Van de Walle 1990, p. 151).

For these authors, the British aristocracy's movement toward the increased domesticity of women redefined the role of the mother within

the domestic economy. British aristocratic mothers now spent an increasing significant proportion of their time with their infants and children, forming strong parent-child bonds, which had previously been weak. These mothers were the first social group to conceive of a child as a treasure above and beyond the small utilitarian value children may have previously possessed (Van de Walle and Van de Walle 1990).

These authors suggest that from the seventeenth through the nineteenth centuries, the interest in children became increasingly mother-centered. Feelings of empowerment over the health and well-being of infants and children rose to such a level that women began demanding that the medical community and government pay more attention to children. Children thus passed from a "private" realm of familial responsibility to a "public" one, with the community now expressing a vested interest in improving the health and well-being of children. These historical changes in the power structure of the family may have operated in conjunction with various other social and economic factors that led to the decreasing rate of infant and child mortality among Western developed countries (Van de Walle and Van de Walle 1990).

TWENTIETH-CENTURY MORTALITY TRENDS IN DEVELOPED COUNTRIES

Developed and developing countries are comprised of different population histories worthy of individual historical analysis, even though the only available and reliable documents that allow the reconstruction of demographic transitions are found in Europe. For some local Western European populations, studies have revealed that mortality levels decreased slightly between 1840 and 1860, but several scholars agree that the radical decline of mortality among the MDCs took place during the period 1880-1910 or even up to 1930 (Kitigawa 1977; Preston 1992; Stolnitz 1956). Although it is generally believed that this decrease in mortality levels was primarily due to a reduction of deaths during childhood, the causes of that change are still nonetheless a matter of controversy.

Epidemiologic transition theory's main argument is that the socioeconomic development achieved by those countries was fundamental in the reduction of mortality (Omran 1971). From

this perspective, socioeconomic factors such as improved health and hygienic habits, diet and standards of living, were the main determinants of the transition from high to low mortality in Western nations. The sanitary revolution played an auxiliary role within this process of transition. Some other scholars suggest that although the improvement of economic conditions in Western nations was important, but this was more a permissive element than a precipitating factor. For them, the introduction of hygienic measures that helped to control communicable diseases was the leading cause of the decreased mortality rate (Preston 1992; Preston and Haines 1991; Spiegelman 1956; Stolnitz 1956).

According to Stolnitz (1956), in the mid-1800s reliable estimates for France and England show that real per capita income was rising rapidly but declines in mortality were still rather negligible. On the contrary, when mortality declined clearly after 1870, the West had already experienced a diverse set of economic circumstances. For instance, in France and Sweden the decrease in mortality appears to have occurred at a time when economic growth was slower than in earlier decades, while in Great Britain standards of living may have been slightly declining. Simultaneously, great changes occurred in the field of bacteriology, including the discoveries of Pasteur, and the large-scale public health programs were implemented. At the end of the nineteenth century in England, the main reason for the reduction in mortality levels was due to the lower prevalence of diseases resulting from these health innovations.

A study of the importance of different causes of death during the transition to a lower mortality rate shows interesting findings (Preston and Nelson 1974). Among 165 local populations (from 43 countries around the world) from the period 1861-1964, approximately 60 percent of the total decline in death rates was attributed to declining mortality from infectious diseases—25 percent due to influenza, pneumonia, and bronchitis; 10 percent due to respiratory tuberculosis; 10 percent due to diarrheal diseases; 15 percent due to other infectious and parasitic diseases; another 20 percent was attributed to a decrease in vascular diseases.

Many Western countries experienced a steady decline in mortality rates after 1930. Spiegelman (1956) suggests that during the period 1930-1950,

these nations were experiencing a reduction in mortality at all stages of life. According to the author, from 1946 to 1954 most countries of Western Europe achieved a reduction of up to 33 percent in their IMRs. In Table 1 we reconstruct infant mortality trends for some selected countries during a period of forty-five years. In 1948, Sweden already had a relatively low IMR (23.2 per 1,000); by 1993 it had decreased to 4.8

Japan is a striking case. Japan, Australia, and New Zealand are included in Table 1 among the developed countries following the suggestion of the World Bank (1983), although they do not share the historical experience and culture of the Western countries included in the same group. The reduction of infant mortality has been explained by specific health measures first taken during the U.S. occupation after World War II and continued later by the Japanese government. During the 1930s, life expectancy at birth (life expectancy at birth represents the average number of years to be lived for a newborn, given a specific pattern of mortality in a country in a given moment) in Japan was similar to that in Western countries at the end of the nineteenth century. However, between 1948–1950 and 1951–1953, the increase in life expectation was about 5.5 years at age 0, 4 to 5 years at age 15, and 2 years at age 45. This was far and away the greatest average annual increase in demographic history (Stolnitz 1956). Table 1 shows a Japanese decrease in infant mortality from 61.7 per 1,000 in 1948 to 30.4 in 1960. This accelerated decrease continued to 13.1, 7.4, and 4.3 in 1970, 1980 and 1993, respectively, giving Japan the lowest IMR in the world.

In the United States, child mortality had been declining in the two decades before 1900 for the total population, although the decline was greater among whites than among blacks. It is difficult to estimate the magnitude of this differential because of data problems (Preston and Haines 1991). Preston and Haines find that between 1899 and 1900, 88 percent of deaths among those under age 15 were children aged 0 to 4 and 59 percent of these were infant deaths. Regarding the three main causes of infant mortality, 25 percent of deaths were due to gastrointestinal diseases, 20 percent to respiratory diseases (e.g., influenza, pneumonia, and bronchitis), and 27 percent to malformations and a wide array of causes, such as premature birth, debility and atrophy, inanition, and

hydrocephalus. The main causes of child mortality (deaths below age five) were basically the same, but with a slightly different distribution: 21 percent were due to gastrointestinal diseases, 23 percent respiratory diseases, and 20 percent to malformations.

In comparing eighteen developed countries, Pampel and Pillai (1986) found the United States to have a relatively high IMR despite its leading economic position. Indeed, the United States has the highest IMR among developed countries. Table 1 shows that in 1948 the American IMR was half that of Japan. By 1993, however, that ratio had reversed; for every Japanese infant death there were 2 in the United States. Although this 2:1 does not exist between the United States and other developed countries, most of the countries shown in the table had higher IMR rates than the United States before World War II and have achieved significant declines since that time.

To briefly highlight some other developed countries, we take Spain as an example. According to Spiegelman (1956), acute infectious diseases were not totally under control there before World War II. This country began the forty-five-year period covered in Table 1 with an IMR of 70 in 1948. Infant mortality has continually decreased, reaching 6.7 in 1993.

Another case that may be worthy of highlighting is that of Germany, which is included in the group of Western countries because of its reunification and the general adoption of a market economy. Interestingly, in 1948 the Democratic Republic (East Germany) had a considerably higher IMR than the Federal Republic (West Germany), 94.0 versus 70.1. East Germany's rate was slightly higher in 1960, but in 1970 the trend reversed. In later years, both countries experienced equal rates. In 1993, unified Germany's IMR was 5.8, the third lowest of this selected group of developed countries.

TWENTIETH-CENTURY MORTALITY TRENDS IN EASTERN EUROPE

It is difficult to obtain comparable data for Eastern Europe; Table 1 shows only a few examples. In Romania in 1948 the IMR was particularly high. From 1948 to 1960 the IMR was almost halved, decreasing from 142.7 to 75.7. That pace of decrease could not be sustained, and in 1993 it

INFANT AND CHILD MORTALITY

Infant Mortality Rates for some Selected Countries and Years

	<i>Infant Mortality Rate</i>				
	1948	1960	1970	1980	1993

Table 1

SOURCE: United Nations (1979, 1982, 1987, and 1996).

NOTE: *Data from 1983.

reached 23.3, the highest IMR among the Eastern European countries shown.

In the cases of Poland and Yugoslavia, both countries had a high IMR in the immediate postwar period (110.7 and 102.1, respectively). Despite its lower starting level, Yugoslavia consistently experienced higher rates thereafter: 87.7 in 1960, 55.5 in 1970, 32.8 in 1980, and 21.9 in 1993, whereas in Poland such rates have been 56.1, 33.2, 21.2, and 16.2 for the same years.

In 1948, Czechoslovakia had the lowest IMR among the Eastern bloc countries shown in Table 1, but it was still higher than that of Western countries. The decrease observed from 1948 to 1960 is very significant: from 83.5 to 23.5 in twelve years. This pace decelerated but continued to decline. By 1993, it had achieved an IMR similar to that of the United States: 8.5 deaths 1,000/live births.

TWENTIETH-CENTURY MORTALITY TRENDS IN DEVELOPING COUNTRIES

In the developing countries of Latin America, Asia, and Africa, reduction in mortality levels began around the beginning of the twentieth century. Scholars have found only fragmented information to reconstruct the demographic history of such countries. They can affirm, however, that the pace of declining mortality was slow until 1940 and accelerated after World War II (Kitagawa 1977; Meslé and Vallin 1996; Preston and Nelson 1974). According to Stolnitz (1956), the decline in mortality in developing countries during the postwar period, which was highly accelerated, has no parallels in the Western experience. The common explanation, found in numerous studies (Arriaga 1970; Kitigawa 1977; Preston 1976; Stolnitz 1956), is that access to medical innovations coming from developed countries and the implementation of specific programs of disease control were the main cause of the mortality reduction, especially in infant mortality.

Since the changes in those regions have not been uniform, currently there is a convergence of the mortality patterns in developing countries, whereas in the developed areas there is a marked divergence (Meslé and Vallin 1996). Indeed, trends

of mortality just described for developed countries show variations, but among developing countries such heterogeneity is even greater. It would be impossible in this space to describe the mosaic of infant mortality experiences in developing countries; however, we can point out some major tendencies and outstanding cases during the forty-five years period covered by Table 1.

In order to understand the scope of differences among developing countries, it is important to consider a general characteristic of populations with high mortality: The younger the age, the larger the absolute change in mortality rates (Arriaga 1970). At the beginning of this transition toward a low mortality pattern, drastic changes are observed in infant and child mortality among different populations. For many developing countries, infant and child mortality trends throughout history cannot be known because there are no available data. Although this issue will be discussed below, usually the more socioeconomically disadvantaged countries are the ones for whom the data are lacking.

Latin America. During the 1930s Latin America had a high mortality pattern. For instance, a newborn baby had less than a 50 percent chance of living to the age of thirty; consequently, no country had a life expectancy more than forty years at birth (Arriaga 1970). The main decline was registered between 1940 and 1960. The largest decline could be found during the 1940s; there was a slower pace of decrease in the 1950s (Arriaga 1989; Camposortega Cruz 1989a).

Brazil and Mexico are the two most highly populated countries in Latin America, and they experienced similar processes of industrialization up until the 1970s. Brazil had a military government and Mexico did not; however, both have high economic inequality, possibly Brazil the more so. Unfortunately there are no data available for Brazil prior to the 1980s, but Table 1 shows that its IMR was higher than that of Mexico in both 1983 and 1993. Mexico's IMR decreased by 25 percent between 1948 and 1960; it continued to decline even in the midst of a drastic economic recession that began in the 1980s. By 1993, the persistently high rate had been reduced to 34.0 infant deaths per 1,000 live-births; the Brazilian IMR was 47.0 in that year.

Argentina provides an example of early industrialization as well as early demographic transition in the region. During the immediate postwar period, this country had an IMR similar to those of several Western countries (69.5 in 1948); considering this fact, the rate in 1993 (22.9) was relatively high, even higher than the IMR (22.0) of Venezuela, a country that had a rate 30 percent higher than Argentina in 1948.

El Salvador, Bolivia, and Peru, some of the poorest countries in the region, had high IMRs in 1948. For example, in El Salvador a tenth of all infants died in 1948, but this rate had decreased 25 percent by 1960 to 76.3 infant deaths per 1,000 live births. This pace of decline slowed in subsequent years, reaching 42.0 in 1980. However, by 1993 this indicator of general well-being had reversed, and the IMR had increased slightly to 44.0, perhaps because of severe economic conditions during the 1980s.

In Bolivia, if the data in Table 1 are correct, the decrease in infant mortality between 1948 and 1960 was spectacular: from 131.3 deaths to 74.3 deaths per 1,000 within twelve years. Information for the 1970s is unavailable. In 1983 the rate was again high (124.4), but ten years later it had dropped to 75.0. These significant shifts give rise to concerns about the quality of the data. In any case, the IMR in 1993 was higher than the Salvadorian rate and similar only to the Peruvian one.

Bolivia and Peru have the highest IMRs among the selected countries (75.0 and 74.9, respectively). In this region, such a rate might be surpassed only by Haiti, for which information is not available. Interestingly, Peru had a decrease in its IMR from 1948 (109.0) to 1970 (64.6). But in 1983 the IMR was even higher than it had been twenty years earlier: In 1983 it was 98.6, up from 92.1 in 1960. Although the IMR had decreased to 74.9 in 1993, Peru still has one of the highest rates of infant mortality in all of Latin America.

In contrast, Cuba and Costa Rica have the lowest and the second lowest IMRs, respectively. The public health systems in both countries have good reputations throughout the region. Costa Rica shows a steady decrease from 1948, when its IMR was 90.4. By 1970, it had declined 30 percent, reaching 61.5. Contradicting Arriaga (1989) and Camposortega Cruz (1989a), this country achieved a steeper decrease in infant mortality during the

1970s: In 1970 the rate was 61.5 and in 1980, 20.2, showing a decrease of 33 percent. In 1993, the Costa Rican IMR was 13.7.

The Cuban IMR was already the lowest in the region in 1948 (40.1) among those countries shown in Table 1. Up until 1970 there was only a small and unsteady decrease to (38.7). During the 1970s and afterward, the country achieved significant decreases: The rate reached 19.6 in 1980 and 9.4 in 1993. The decrease in infant mortality has been one of the main goals and achievements of the Cuban health system, despite the country's unfavorable economic situation. Cuba now has the lowest IMR in Latin America, being only slightly higher than that of Czechoslovakia and the United States.

Asia. Infant mortality rates in Asia are quite diverse. As regards of India, Jain and Visaira (1988) argue that even though several studies suggest that the infant mortality rate in 1920 was 240 per 1,000 live births, this might have been understated, and the IMR could have been between 200 and 225 during the 1940s. This finding is in contrast to the estimations of Arriaga (1989) and other researchers. Using different sources of information and techniques, Jain and Visaira construct a trend of infant mortality with higher rates than those shown in Table 1, with the rates coinciding only since the 1970s. Jain and Visaira (1988) and Arriaga (1989) found that as a result of implementing a specific program of hygiene among mothers, infant mortality did decline after 1970. Between that year and 1993, the IMR decreased from 122.0 to 74.0.

Although there is no complete direct information for China that allows us to construct a complete infant mortality trend since the postwar period, some estimations are provided in a study by Banister (1986). From the mid-1960s to 1977-1978, the author and her colleagues found a constant decrease in infant mortality (from 70 to 40 deaths), although the trend was later reversed. Their calculation for 1981-1982 was 61 deaths per 1,000 live births, which does not match the information from the United Nations: 39.3 in 1983 and 44.0 a decade later (Table 1). Banister and her team examined the possibility of measurement errors in order to discern whether the estimation was fatally biased and changed the direction of the trend. They confirmed that such was not the case

(Banister 1986). There may have been an over- or underestimation between both calculations, but either way, the direction of the tendency toward an increasing IMR seem to be correct.

According to Banister (1986), there are three reasons that may explain this inversion. First, in 1978 a general economic reform began and the availability of preventive and curative health services was somehow affected, which may have been detrimental to the survival of some infants. Second, at the same time China's severe family-planning reached rural couples. In 1981, 53 percent of all births corresponded to second and higher-order births; therefore, if mothers of these unauthorized babies lacked prenatal care, not surprisingly their infants would experience higher risk of early death. Additionally, the provision of medical care had been tilted intentionally toward the only child, which may have implied the deterioration of the health care available for children in multichild families. Third, a decrease in the proportion of breast-feeding combined with the use of contaminated water used to mix formula might have adversely affected infant survival. Although these researchers did not have precise information on the proportion of breast-feeding, based on fragmentary data that proportion seems to have decreased (in 1982 22 percent of the babies in urban areas and 60 percent in rural settlements were breast-fed). A possible fourth factor is infanticide, but the distribution of infant deaths by sex did not show a bias toward more female deaths (it is said that there exists in China a preference for male babies). Hence, if infanticide played an important role in increasing the IMR, Banister's evidence suggest either that the incidence of female infanticide is not statistically significant or that respondents reported neither the birth nor the death of female victims of infanticide.

Sri Lanka is a rare case of a developing country's retaining records from nearly the beginning of the twentieth century. Stolnitz (1956) refers to Sri Lanka (formerly Ceylon) as one example of rapidly declining infant mortality; more recently, Meegama (1986) offers an overview of mortality trends since the beginning of the twentieth century. According to this latter author, during the second half of the nineteenth century, the IMR started to decrease because of a reduction in the

number of famines and the control of cholera epidemics.

During 1911–1915, the IMR was 201 deaths per 1,000 live births, fifteen years later it had decreased to 175 deaths. In 1945, at the end of the World War II, the IMR was recorded at 140 infant deaths per 1,000 live births. Prior to the war, there was a decrease in the mortality rate for both sexes and all age groups in both endemic and nonendemic malarial zones. One of the main reasons for this decline was the expansion of maternity and child welfare services, which decreased both infant and maternal mortality (Meegama 1986). It might have been the combination of that preexisting decline and the introduction of a wider range of medical measures that caused a steady decrease in mortality after the war. As shown in Table 1, in 1948 Sri Lanka had an IMR of 92.1. This was halved by the beginning of the 1970s (45.1) and was again reduced to a third of the 1970 rate by 1993 (16.5).

South Korea and Singapore are two cases of recent industrialization and fast decline in mortality patterns. Information is not available to reconstruct the South Korean mortality history; however, what can be seen in Table 1 is a decrease of more than 50 percent from 1983 to 1993. In 1983 the country had an IMR of 29.7, which had declined to 12.3 ten years later.

Singapore is another impressive case of accelerated reduction in infant mortality. In 1948, it had a relatively low IMR among Asian countries (80.8), but its rate was greater than that of Japan. By 1960, the rate had been reduced by more than 50 percent, reaching 34.8. The trend continued, and by 1993 Singapore's IMR was 4.7, similar to the Swedish and very close to the Japanese rate.

Africa. Mortality in Africa is the highest of any major region in the world and historically has had the least reliable information, with certain exceptions. Through the application of special techniques, mortality trends have been reconstructed. The pattern of mortality in Africa is characteristic of populations with a high mortality schedule: It is dominated by mortality among children under five years of age, and infectious, parasitic, and respiratory diseases are the major causes of death. Concerning infant mortality in Africa, we examine some cases from this region displayed in Table 1.

Kenya lacks a usable vital registration system, but the application of indirect techniques has helped in reconstructing mortality trends there. In 1948, when the country began its transition toward lower mortality, it might have had an IMR of 184 per 1,000 live births, according to some estimates (Ewbank et al. 1986). In 1970 that rate had dropped to 81.2, but in the following decades the pace of change was considerably slower; in 1993 the rate was 71.0. For an African country, this is a low mortality pattern, but it is comparable to some Asian countries and to the poorest in Latin America.

Mauritius has a mortality pattern that is gradually approaching that of Western Europe (United Nations 1984). It has the lowest IMR of African countries shown in Table 1. In the period immediately after the World War II, Mauritius had an IMR of 186.2 deaths per 1,000 live births; this decreased 62 percent in twelve years to 70.9 in 1960. That steady rate of decrease was maintained, with the IMR falling to 19.9 by 1993.

The South African case presented some different data analysis challenges because prior to the 1980s information on mortality was not available for the country as a whole but rather by ethnic group, showing the effect of apartheid on vital statistics but also allowing us to see ethnic differentials in the levels of infant mortality. As shown in Table 1, the white population had always been better off than their fellow South Africans; the IMR of the black population held relatively constant until 1970 and the IMR of the Asian population was located between that of the white and black populaces. The ratio of deaths between ethnic groups illustrates social differences: In 1948 there were approximately 4 black infant deaths for each white one and 1.7 black infant deaths for each Asian one. The ratio for Asian to white deaths was approximately 2-to-1 for babies under the age of one year. In 1970 the gap between blacks and the other races widened: There were 6.1 black infant deaths for each white death, 3.6 black infant deaths for each Asian death, and 1.7 Asian infant deaths for each white infant death. By the 1980s the information from the *Demographic Yearbook* was no longer classified by ethnic group; it shows that the general IMR decreased between 1983 and 1993, from 83.3 to 53.0, but it does not show the ethnic differential during those years.

DIFFERENTIALS IN INFANT AND CHILD MORTALITY

Numerous studies have documented and examined various differences in infant and child mortality among different groups along various socioeconomic and ecological spectrums. For most of the earliest periods under investigation, ecological and geographic factors seemed to account for most of the observed differences in infant and child mortality rates (Preston and Haines 1991). Current research on this topic is guided by a theoretical framework put forth by Mosley and Chen (1984). Their original intent was to outline an analytical framework for studying child survival in developing countries, but many researchers have found this framework to be extremely suitable for studying infant and mortality differentials within various contexts.

Mosley and Chen (1984) propose that all socioeconomic determinants, or exogenous factors, of child mortality operate through a set of biological mechanisms that they call "proximate determinants" or "intermediate variables." That is, social and economic factors influence infant and child mortality through a set of biological factors that an infant is born with. Many studies have identified numerous variables and factors that influence both the biological viability of an infant at birth and the health and well-being of the infant *ex utero*, thereby increasing or decreasing the probability that an infant will die before its first birthday or that a child will die before its fifth. These social and economic factors range from individual-level characteristics to household- and community-level factors.

Research has identified three main infant birth outcomes that exert major influences on infant survival chances and through which many exogenous factors operate: infant birthweight, gestational age, and the interaction of the two, sometimes referred to as intrauterine growth retardation (IUGR). Infants weighing less than 2,500 grams at birth (low birthweight, LBW) and infants of short gestation (less than thirty-seven weeks' gestation=premature) have been consistently found to be at dramatically higher risk of infant mortality (Hummer et al. 1999). Interactions between these two outcomes have also been found to affect infant mortality rates significantly (Frisbie et al. 1996). These relationships hold for both MDCs and LDCs (UN 1984).

Of the set of proximate and exogenous determinants originally outlined by Mosley and Chen (1984), most have been identified as having significant effects on infant mortality. Smoking, alcohol, and illicit drug use have all been shown to adversely affect infant and child mortality (Chomitz et al. 1995; Petitti and Coleman 1990). Maternal weight gain has been found to be negatively correlated with infant mortality risk; that is, the more weight a woman gains during her pregnancy, the lower the infant mortality risk (Hummer et al. 1999). The birth order of the infant is associated with differential infant mortality risks, while shorter interpregnancy intervals are linked to higher mortality risks (Kallan 1993; Miller 1991). Male infants have always had higher mortality risks (Rumbaut and Weeks 1996). The role of prenatal care has been debated in recent times, but most researchers agree that adequate prenatal care produces beneficial effects for the health and well-being of mothers, infants, and ultimately young children (Fiscella 1995). The effect on infant mortality risk of maternal age had previously been thought to be constantly negative in direction, but more recent analyses indicate that many interaction effects may work specifically through maternal age, making the conceptual picture much more complex (Geronimus 1987).

Exogenous factors have also been investigated and analyzed. One factor that has captured the continued interest of researchers is the role that race and ethnicity play in explaining infant and child mortality differentials. In both MDCs and LDCs consisting of multiracial and/or multiethnic populations, racial and ethnic infant and child mortality differentials often exist. For example, in 1996 the black population in the United States experienced an IMR of 14.1 while the white population experienced an IMR of 6.1 (MacDorman and Atkinson 1998). In 1990, the indigenous population of Mexico experienced a higher risk of infant mortality 1.5 times higher than the nonindigenous population (Fernández-Ham 1993). Although the role that race and ethnicity may play in IMR differentials is complex, there is agreement that such differences are based on social, economic and historical inequalities (Cooper and David 1986; David 1990). In LDCs those historical inequalities are also related to place of residence, which in most of these countries imply a more disadvantaged position for rural populations (Camposortega Cruz 1989b).

More direct socioeconomic indicators are currently being tested to identify their effects on mortality risks. Increases in maternal education have consistently been shown to decrease both infant and child mortality risk at both the individual and national levels (Hummer et al. 1992; Pampel and Pillai 1986). Marital status has also been linked to differential infant mortality risks; unmarried mothers have a higher risk for infant mortality. This may reflect the fact that single mothers often must bear the costs of both child-rearing and day-to-day living expenses with limited assistance (Frisbie et al. 1997). Studies have also identified the important role that income plays in influencing infant and child mortality risk (Geronimus and Korenman 1988). Cramer (1995) finds evidence of this association even when controlling for a wide array of other sociodemographic risk factors. Many others have explored the effects of various public health assistance and intervention programs, either by governmental or nonprofit agencies. In both MDCs and LDCs, some evidence exists to support the creation and implementation of such intervention programs, such as the Women, Infants and Children (WIC) program in the United States and governmental health programs in Guatemala (Moss and Carver 1998; United Nations 1984). According to Frenk and associates (1989), in certain developed countries there may exist two populations divided by their differential infant and child mortality risk. These researchers point to existing differences between insured and uninsured populations in Mexico as an example of the divergent character of national infant mortality profiles in both high- and middle-income countries (Frenk et al. 1989).

With the development of new theoretical frameworks and statistical methodologies, infant and child mortality research has traveled down new paths. One interesting development has been analyses based upon characteristics of both the individual and the neighborhood or community in which individuals live. Determinants of infant and child mortality are hypothesized to emerge from conflation of personal, household, and neighborhood factors. Collins and David (1997) find that violent neighborhoods may adversely effect an expectant mother's pregnancy outcome, in spite of the measured personal characteristics of the mother. Guest (1998) finds that the neighborhood unemployment level has an important effect on

infant mortality beyond effects due to other socioeconomic indicators and race.

PROSPECTS

The search for solutions to reduce levels of infant and child mortality will require the joint participation of multiple actors: governments, international agencies, nongovernmental organizations, and individuals within the scientific and policy communities. Predicting future trends in infant and child mortality remains a rather difficult task given the complexity of this phenomenon. However, scientific knowledge gathered at both the aggregate and individual levels should make reduction of the significant gap between the developed and developing world possible. The multiple differences that exist in mortality patterns within groups in both developed and developing countries are illustrated by the current age structure of mortality. In 1990-1995, life expectancy at birth was 74.4 years in developed countries and 62.3 years in the less developed world. This indicator is consistent with the corresponding IMRs: 10 versus 70 infant deaths per 1,000 live births for MDCs and LDCs, respectively.

It is noteworthy that infant and child mortality rates fell so drastically in the twentieth century. But even so, there remains the need to determine the next course of action in order to combat the mortality differentials between less and more developed nations and among various socioeconomic groups within nations. Continued successes will depend on identifying problem areas and creating innovative solutions to these health, and ultimately, social problems.

SAMUEL ECHEVARRÍA

INFORMAL ECONOMY, THE

Informal economic activity can only be understood in relationship to its counterparts in the institutions of the formal economy, most notably in markets for labor, goods, and services. In most modern, industrial, capitalist societies, economic activity occurs in the form of exchanges of cash for labor, consumer goods, and services within well-regulated economic institutions located within the

formal economy. The labor market, in particular, provides the framework for regulating the exchange of work and wages between sellers and buyers of labor (workers and employers) under the auspices of a legal and regulatory environment enforced by the state. At the same time, it is also widely recognized that livelihood strategies may entail all manner of exchange outside these formal institutions and regulations. That is, exchanges may occur in the informal economy. Goods and services may be bartered, traded for nonmonetary compensation, or produced under conditions that flaunt health and safety regulations. Earned income may go unreported and untaxed. Individuals may self-provision, using their own resources to produce and consume household necessities even when they are readily available for purchase. Credit may be extended on the basis of kinship and trust. Numerous other types of unrecognized exchanges create value “under the table,” that is, in the informal economy.

In some societies the informal economy is the dominant mode of economic activity. It is especially prominent in developing countries where the majority of the population may engage in various types of economic exchanges outside any formal regulation, cash economy, or state supervision. Yet informal activity is not limited to developing nations. Increasingly, economists, sociologists, and others who study work and labor markets recognize that the informal economy is very much present in first world industrial and postindustrial economies. The *shadow*, *black*, *gray*, *underground*, *subterranean*, or *parallel economy* are among the common euphemisms for an informal economy that exists side by side with its more studied and theorized counterparts in developed as well as developing nations, first and third worlds, urban and rural communities, and everything in between.

DEVELOPMENT OF THE CONCEPT

History. The term *informal economy* has numerous uses and meanings and few precise definitions. Its original formulation is attributed to an anthropologist, Keith Hart, studying emerging urban labor markets in Africa for the International Labour Office (ILO) (Hart 1973). Hart distinguished between waged employment in large firms or government agencies and self-employment in his studies of the urban labor force, noting the wide

variety of small-scale entrepreneurial activities that were central to the livelihood strategies and economic life of residents of urban centers in Africa. Small traders, food vendors, and sellers of goods or services from shoe shines to haircuts are the familiar mainstays of urban economies. Subsequent use of the term by the ILO came to mean self-employment and small-scale family enterprise correlated with poverty, underemployment, and low productivity, particularly in poor, developing nations. This view was widely adopted by analysts and policy makers for whom the informal economy was a phenomenon of poverty and underdevelopment, with the implication that development of a modern economy decreases the need for and significance of informal activity. Ultimately, informal work should be absorbed into the regulated economy.

More recently, assumptions about the scope, location, and importance of informal work have come under scrutiny, since it has been recognized that informal work is neither unique to impoverished Third World countries nor necessarily diminishing in size or importance. Several developments in diverse areas of economic sociology, but all of them linked to global economic restructuring, have led to renewed interest in informal work and a growing understanding that it is both more widespread and less understood than previous accounts suggested. Studies of urban ethnic enclaves, patterns of employment for new immigrants, and the explosion of the global division of labor in "world cities" have generated interest in informal work. Similarly, there has been a corresponding interest in livelihood and income-generating strategies of both the urban and rural poor, and in wide-scale economic restructuring that sought increased flexibility in production processes and labor practices, as well as recognition of the persistence of noncash exchanges in communities of all sizes and locations. Additionally, periodic headline-grabbing media accounts of sweatshops, child and immigrant labor abuses, and other gross violations of labor law and workplace protections have fueled broad awareness of the persistence and pervasiveness of informal activity.

Definitions. Despite growing awareness of the ubiquity of the informal sector, a precise definition remains elusive, and numerous issues remain

unresolved. Typically, informal activity is defined by what it is not; that is, it is not formal, it is not regulated, and it is not counted in official statistics and national accounting schemes. Castells and Portes (1989) provide an influential definition using this approach: "The informal economy is . . . a process of income-generation characterized by one central feature: it is unregulated by the institutions of society, in a legal and social environment in which similar activities are regulated" (p. 12).

While broadly inclusive, this definition provides little guidance for distinguishing between different types of activities conducted under different circumstances. For example, should overtly criminal activities, such as drug dealing, be classified in the same way as work that is otherwise legal, such as flea market sales, except that is unreported and untaxed? Should both production and consumption processes be classified as part of the informal sector? In other words, are the goods that are produced in sweatshops comparable to those produced at home for private consumption? When do self-employment and the use of family labor become informal work? These questions illustrate both the diverse approaches found in the literature and the confusion that exists there.

Other analysts emphasize specific defining characteristics of the informal economy rather than focusing on what it is not. For example, Roberts (1994), while accepting the basic outline of the standard definition, argues that the key feature of informality is not the absence of regulation but instead the existence of a specific type of regulation that dominates the activity. Thus, the informal sector is marked by the dominance of regulation based on personal relations and networks embedded in family, community, friendship, or ethnicity rather than on regulation organized on formal, legal, or contractual bases. Similarly, Mingione (1991) suggests that income strategies organized around reciprocal networks, such as those found in family and household labor and relations, characterize the informal sector. These analysts emphasize the interpersonal networks that create obligations and responsibilities that permit exchanges that bypass formal institutions. This approach has found expression in the many studies of immigrant labor and ethnic enclave enterprise where kinship and co-ethnic personal ties are the means for conducting business.

A number of taxonomies and typologies have been proposed in an effort to codify characteristics of informal activity. Feige (1990) distinguishes between illegal, unreported, unrecorded, and informal categories of a more encompassing *underground economy*. While there is much overlap, these categories appear to represent a continuum ranging from those most thoroughly in violation of the law to those that merely forgo its protections. Castells and Portes (1989) clearly differentiate informal from illegal by separating processes of production and distribution from the product itself. Thus, a perfectly legitimate product or service may be produced informally in violation of the law. Cappechi (1989) cross-classifies three types of labor markets (nonmonetary, informal monetary, official) with the equivalent three markets for goods and services to derive a nine-cell typology. Informality in either labor or product markets creates five types of informality.

Still other analysts argue that, fundamentally, informality can only be understood on a case-specific basis. For example, Gaughan and Ferman (1987) contend "that the term *informal economy* will mean different things in advanced industrial nations from what it does in developing countries. . . . poor communities as opposed to middle-class communities, or in an urban as opposed to a rural setting" (p. 18). In keeping with this notion of the variability of forms of informal activity, Miller (1987) discusses informal economies in the plural rather than the singular.

Regardless of specific emphasis, virtually all analysts agree that informal economies, sectors, activities, and labor can only be understood vis-à-vis their relationship to their formal counterparts and in the context of their relationship to the state (Roberts 1994). There is no such thing as an informal economy in the absence of a formal economy. Portes (1994) even suggests that the extent of informal activity depends on the degree of state regulation, with greater informal development representing a response to an overly restrictive formal sector. Furthermore, while many analysts discuss informal activity as outcomes or in terms of structural elements that comprise a form of economic institution, there appears to be greater utility in conceptualizing it as a process that varies in time and space. Thus, the concepts of informality and informalization, in which economic activity is evaluated in terms of its degree of

adherence to state regulation and particular labor practices, permit an assessment of variation in levels and development of informal sectors and their shares of the larger economy.

Forms of Informal Activity. Empirical studies of informal activity identify a wide range of actual practices. Ultimately, what is included and what is excluded depends on the specific definition and the specific context for the activities, as discussed above. Nevertheless, certain broad categories are regularly found in the literature. They can be categorized in terms of what type of exchange relationship is involved and the specific kinds of goods and services transacted. Thus, goods and services can be exchanged for income that goes unreported in any official venue, as exemplified by the babysitter or maid who gets paid in cash that is not taxed or reported by either employer or employee. They may be bartered and exchanged directly for the same or other goods or services, as in the trade of child-care services or child care for firewood. They may be supplied and consumed to save money or to self-provision, as when members of a household raise a garden and preserve food for home consumption.

Specific goods, services, and activities vary from place to place. Urban dwellers are unlikely to raise livestock or cut wood for home consumption, but they are no less likely than their rural counterparts to engage in child care or household and auto repair (Tickamyer and Wood 1998). Sweatshops and street vendors are most likely to be found in large urban labor markets (Gaber 1994; Sassen-Koob 1989), but industrial subcontracting and home assembly operations are well documented in rural communities as well (Gringeri 1994).

One of the problems in specifying types of informal activity is distinguishing informal from related forms of work and exchange. At the margins it may be extremely difficult to draw this line. For example, where does engaging in an activity for recreation or personal satisfaction end and self-provisioning begin? Should the avid gardener whose vegetable consumption is a by-product of the hobby be classified as engaged in informal work? Where should volunteer work done for charitable purposes be classified? Informal labor overlaps with many other forms of waged and unwaged labor, including social and generational

reproduction, self-provisioning and subsistence activities, consumption work, and community service as well as simple commodity production, self-employment, and subcontracting.

SOCIAL, SPATIAL, AND TEMPORAL DIMENSIONS

The expanding literature demonstrates that informality is not limited to a particular time, place, type of economy, or population group. Nevertheless, clear themes that focus on specific groups and places emerge in the research literature. Some of it is empirically based; some is speculative and yet to be tested or verified regarding who participates, where, and under what circumstances; and some is contradictory or unfounded. The most common assumption is that informal labor involves categories of workers who are disadvantaged in some manner and, therefore, are shut out from the opportunities available in the formal sector. For example, informal workers have been identified as particularly prevalent among racial and ethnic minorities, immigrants, women, and children (Hoyman 1987; Portes et al. 1989; Sassen-Koob 1984). Other studies would add rural residents (Fitchen 1981; Jensen et al. 1995) and the urban poor (Edin and Lein 1998).

While there are many specific accounts and case studies to illustrate the importance and workings of informal labor and sectors among these specific populations and locations, there is little evidence at this time to suggest that informal work is any more prevalent in one group compared to another. Furthermore, it is not always clear from these accounts whether informality adheres to the group or to the type of jobs certain groups are more likely to hold. For example, women are sometimes identified as more likely to operate in the informal sector, as is work that is typically female, such as child care and domestic service. If it is the case that women are more likely to work informally, is it because of gender or because they hold gendered jobs?

Informalization is often assumed to be increasing in both developing and developed countries as a response to the social and economic restructuring that has transformed and linked core and peripheral economies in the last several decades. Globalization, the growth of transnational

capitalism, and increased international competition have led capital to seek more flexible production processes, to escape from state regulation and taxation, and to reduce labor costs. This puts pressure on labor–capital agreements, benefits available from the welfare state, and the general availability of employment that pays a living wage, has social benefits, and observes rules and regulations. The result is increased self-employment, subcontracting, and, presumably, informal employment as employers seek to cut the costs of doing business and employees are forced to find any means of subsistence. Yet here, too, there is little empirical confirmation of what are largely untested hypotheses. For example, it is not yet established whether informal activity is more prevalent among different class and income groups, whether it is in fact a substitute for formal work, or whether it serves as a supplement to increase or stretch income. Instead, there is a rich tradition of case studies of different regions, communities, and industries that are informative but case-specific, lacking both comparability or comprehensiveness. Thus, it is premature to conclude that informality is increasing or that it is especially prevalent in some groups or places compared to others.

RELATIONSHIP TO THE ETHNIC ECONOMY

While informal economic activity is not limited to a particular market segment or group, researchers have shown particular interest in those forms of informal activity that occur in ethnic economies. Part of the reason for this is that the extensive literature on the ethnic economy offers a unique view of informal work given by researchers whose main purpose is not to examine the informal economy per se but to study ethnic exchange relationships (rather than class relationships) in the secondary labor market. This research shows that ethnic economies provide opportunities for unique forms of informal activity not commonly found in other sectors. However, the importance that is placed on informalization in the ethnic economy literature should in no way imply that the two economies are always congruent, although some enclave economies are almost entirely informal (Stepick 1989).

Ethnic economies are labor markets characterized by sectoral specialization of industries owned

and operated by entrepreneurs from the same ethnic or immigrant group and their co-ethnic workers. While ethnic and informal economies are not synonymous, the prevalence of work outside the formal sector within ethnic economies suggests that conditions in these labor-market areas necessitate, or at least are particularly well suited for, informal economic activity.

The reasons for this vary. Since most workers in the ethnic economy are immigrants from developing countries or ethnic minorities that face discrimination in the formal labor market, they often provide a pool of available cheap labor for the informal market. That is, the labor supply is cheap as long as the work remains part of the informal economy, since the cost of labor rises when wages are regulated. Enterprising businessmen and women can make use of this inexpensive labor, keeping their costs low by hiring "off the books" or paying piece rates for contracted work that may or may not be reported by the worker as income.

Since ethnic economies are also marked by subcultural norms and preferences, informal activity may also allow for cultural variation in working conditions. In the case of Latin American immigrant women, for example, the myriad home working opportunities within the ethnic economy allow mothers to earn needed income while still tending to their children and other domestic tasks. In fact, there is evidence that some home-based industries emerged in response to the demands of experienced female laborers who wanted to earn extra income but expressed a cultural preference to stay at home (Fernandez-Kelly and Garcia 1989).

While the magnitude of informal economic activities within ethnic economies is not known, studies of the garment industry in New York and Los Angeles, a sector that is almost exclusively part of the informal economy, suggest that many of the workers in the industry are unregistered and working out of their homes (Fernandez-Kelly and Garcia 1989; Sassen-Koob 1989; Stepick 1989). This is also true of the home-based electronics production industry (Lozano 1989). Latin American immigrant women comprise the largest portion of this work force that engages in the unreported assembling of electronic components at home on a piece-rate basis. The informal economy may also be responsible for the viability of these industries.

While the garment industry faltered in the 1980s, textile businesses owned by immigrants who sub-contracted homeworkers thrived.

Ethnic enclaves are a special condition of the ethnic economy that arises when an ethnic economy is located in a geographically concentrated area. This geographic concentration can also give rise to unique opportunities within the informal sector. In enclaves such as Washington Heights in New York City, Chinatown in Los Angeles, and Little Havana in Miami, the demand for capital for entrepreneurial ventures has created possibilities for informal money-lending operations. These tend to take the form of either rotating credit associations, whereby residents contribute small sums of money that are pooled and then loaned at low interest rates to other residents, or personal loans from one wealthy entrepreneur to a potential small-business owner. These lending transactions occur outside of state and federal lending laws and are often made without any written agreement by the participants. Social pressure alone seems sufficient to guarantee repayment. This is consistent with Roberts's (1994) contention that interpersonal networks regulate the informal economy.

Ethnic enclaves also generate a heightened demand for goods typical of those widely available in an immigrant's home country. This demand for ethnically defined goods creates unique opportunities for informal work. Enterprising men and women often produce foodstuffs and other products for sale out of their homes. Some also find customers among other immigrants who agree to resell their products in their retail shops and *bodegas*. The informal production of goods insures that costs to both the retailer and the customer remain low, insuring future demand.

WAYS OF MEASURING AND STUDYING

This brief discussion of informal activity in ethnic economies illustrates only one variation in the form and scope of this phenomenon and underscores the importance of further research to gain a greater understanding of how informal economic processes impact individuals, households, and labor markets. As previously noted, recognition that informal economic activity is widespread in developed as well as developing, urban as well as rural,

contexts is just beginning to emerge. Consequently, what is known about the size of the informal economy, its participants, its determinants, and its relationship to the formal sector remains limited.

Most of what we currently know about informal work comes from ethnographic and field studies using in-depth interviews and other qualitative data-collection techniques. These provide a rich and varied collection of information about the nature and meaning of informal work in different regions. These regions include remote rural areas such as the Ozarks (Campbell et al. 1993), rural Pennsylvania (Jensen et al. 1995), and the Southwest (Roberts 1994). Other researchers have also looked at urban subpopulations, including Latin American immigrants in New York City (Sassen-Koob 1989) and in Miami (Stepick 1989). These studies offer an intensive look at the kinds of informal activities that occur, who does them and why, and when people engage in informal economic activities.

Case studies and other qualitative methodologies have provided a rich source of data on specific groups and locales, but their limited geographic scope means that there is little information on informal economic activity in larger populations and subpopulations, thus limiting our understanding of the prevalence of such activities across rural and urban places. Furthermore, there appear to be inconsistencies about the nature of informal work across areas, and case studies can only begin to explore these seeming differences. For example, studies of informalization in rural areas suggest that bartering and self-provisioning are both a means of supplementing a meager income and a normative way of life. On the other hand, urban studies depict informal work as an activity engaged in when the avenues to work in the formal labor market are blocked.

Attempts to quantify informal activity for use in policy making have been made by several national and international agencies, although the methods employed are often crude. Portes (1994) separates these strategies into categories based on the following approaches: (1) the labor market, (2) the very small enterprise, (3) macroeconomic discrepancies, and (4) household consumption.

The first three approaches rely on data taken from industry reports and measures of national

economic activity such as the gross domestic product. The labor-market approach entails assigning all labor as informal if it is reported as self-employment in areas not typically assumed to be high status or high paying. The very small enterprise (VSE) approach, like the labor-market approach, is also based on industry data. Instead of focusing on self-employment, however, VSE-based estimates are predicated on the notion that all businesses employing fewer than ten workers are engaging in informal activity. In the third approach, discrepancies in different measures of similar economic activity are attributed to the informal economy.

The household consumption approach was developed in 1987 in an effort to surpass the limitations involved in estimating informal activity based on reported, presumably formal, production activities. Estimates of informal economic activity, using this approach, are based on consumer reports of "the amounts spent . . . on goods and services acquired off the books or on the side" (Smith 1987). This method is unique in that it focuses on consumption; however, it is also limited in that it assumes that all products are consumed by individuals rather than firms.

In recognition of the inability to generalize to larger geographic areas based on ethnographic data, in acknowledgment of the limitation of the assumptions entailed in current estimation strategies, and in order to limit the costs entailed in labor-intensive qualitative methodologies, some researchers are turning to more direct survey methodology to examine informal economic processes. Recent studies using survey methodology include work by Jensen and colleagues (1995), Tickamyer and Wood (1998), and Tolbert and colleagues (1996). They note that in order to provide systematic, representative, and comparable data across different locales on who participates and how extensively, where and when participation occurs, and under what circumstances, different data are needed. The goal of these researchers is to provide the baseline data that will enable future researchers to determine if informal activity is increasing or decreasing over time and with changing economic conditions. They are also interested in exploring the relationship between informal work and other social processes, including the relationship to formal labor-market participation, to household, family, and community structures and processes, and to human and social capital formation.

These newer studies are significant because they demonstrate that collecting direct information on informal work using structured survey techniques is possible despite the elusive nature of such activities, their often semilegal status, and respondents' seeming lack of awareness of the extent of their participation in informal work. These studies also underscore the need for better, more extensive tests of survey methods both to determine optimal strategies for using survey methodology on this topic and to provide definitive answers to the many questions posed about informal labor.

CONCLUSIONS

While sociologists, economists, and other researchers continue to provide information on informal work, there are many issues that remain unaddressed. These issues include questions regarding the prevalence, importance, and nature of informal activities. Why do people participate in the informal economy? How important is it to their economic survival? Is it vital or is it more socially driven, carrying little expectation for immediate economic reward? What percent of households engage in informal work, and which members of the household are most likely to be the workers? What are the economic returns to participation? Do formal and informal work complement or substitute for each other? Do people turn to the informal economy as a last resort in times when formal work is curtailed, or are certain types of people likely to engage in both formal and informal labor? And, finally, how is the probability of informal work shaped by individual, household, and labor-market characteristics?

Future research will need to address these issues. Furthermore, more studies will be needed at the national and international level (including comparative research) in order fully to understand the importance of the informal economy in shaping the larger economy as a whole. In order to understand this, it is essential to understand where the informal economy fits vis-à-vis the formal economy and how it has evolved. Is the informal economy merely a pure market response to unwanted government interference in commerce, or is it merely a reflection of expected social relationships in a given place and time? Most likely, the informal economy arises from a combination of

factors including poverty and normative pressures to help neighbors and for self-provision. A purely formal economic focus, however, limits our understanding of the range of possibilities entailed in informal work and the impact that such work has on shaping interpersonal processes. Furthermore, by limiting our measures of economic growth, household and individual well-being, inequality, and production to official statistics of formal economic activity, we see only a fraction of the entire picture. This is particularly problematic when policies that attempt to address these issues are shaped from these fragmented images.

Since modern economic policy has been shaped almost exclusively by focusing on the formal economy, conventional definitions of employment, unemployment, poverty, and economic growth may be insufficient to explain the myriad of issues that emerge when informal work is added to the picture. As it has become increasingly recognized that informal economic activity is vital to many individuals and households in both developed and developing countries, the need for more research has become more pressing. By addressing many of the unanswered questions that remain about the informal economy, policy makers can begin to address the labor-market problems that may force workers into informal economic activity, to regulate those activities that exploit certain segments of the work force, and to understand the importance of both formal and informal work as a means of improving living standards.

INFORMATION SOCIETY

Increased reliance on activities directly associated with the production, distribution, and utilization of information has led to characterizing many advanced countries of the world as information societies. The term *information society* and related concepts, such as information age and knowledge economy, describe a social system greatly dependent on information technologies to produce and distribute all manner of goods and services. In contrast to the industrial society, which relied on internal combustion engines to augment the physical labor of humans, the information society relies on computer technologies to augment mental labor.

Trends in labor-force composition both define and measure the extent to which a nation can be described as an information society. Machlup

(1962) was perhaps the first to describe U.S. society in these terms. He estimated that nearly one-third of the labor force in 1958 worked in information industries such as communications, computers, education, and information services, which accounted for 29 percent of the gross national product (GNP). Using a slightly different methodology, Porat (1977) estimated that information activities had risen to just under half of the U.S. GNP by 1967.

A defining attribute of the information society is the search for improvements in productivity through substituting information for time, energy, labor, and physical materials. In practical terms, this means supplying workers with computerized workstations that are networked to other workstations through intranets as well as the Internet. It allows the use of software to reprogram equipment in distant locations, and it often eliminates the physical delivery of messages and even products. These changes are aimed at making organizational production, distribution, and management decisions more efficient. An early indicator of the extent to which industries sought productivity improvements through the use of information equipment is that whereas only 10 percent of all U.S. investments in durable equipment was spent on the purchase of computers and communications equipment in 1960, that investment increased to 40 percent in 1984 (U.S. Congress 1988) and is now much higher.

The concept of postindustrial society, developed most notably by Daniel Bell (1973), anticipated development of the information society. The term *post-industrial* described the decline of employment in manufacturing and an increase in service and professional employment noted by Machlup (1962) and Porat (1977). Knowledge and information were viewed by Bell as the strategic and transforming resources of postindustrial society, just as capital and labor were the strategic and transforming resources of industrial society.

Advances in the capabilities of information technologies to process large quantities of information quickly have been a crucial factor in the development of the information society. These technologies are of two types, computer power and transmission capability. Development of inexpensive silicon integrated circuits containing as many as a million transistors on a single chip had

already been achieved by the mid-1980s, making it possible to pack enormous information processing power into very little space. As a result, desktop microcomputers gained the processing power comparable to the largest mainframe computers of the previous decade. Computational power continued to increase by a factor of ten every five to seven years in the 1990s (Martin 1995). Improvements in microprocessor technology, coupled with developments in parallel processing, storage methods, input-output devices, and speech recognition and synthesis, have continued to increase dramatically the nature, scale, and speed of tasks that can be accomplished on computers. All this has happened while prices for computers declined in an equally dramatic way.

Corresponding advancements have occurred in photonics as a result of the development of laser technology and ultra-pure glass fiber. These developments resulted in the ability to transmit enormous quantities of information long distances on tiny optic fibers without amplification. By the mid-1980s, AT&T Laboratories had transmitted 420 million bits per second of information over 125 miles without amplification. Advancements of this nature, as well as the use of satellites, made it possible for computers located thousands or tens of thousands of miles apart to share large amounts of information nearly as quickly and effectively as would happen if they were located in the same building. Like the price for computing power, the price for transmitting large amounts of information from one place to another also has declined.

These changes in computational and transmission power have made possible new ways of interacting and doing business. Automatic teller machines located on one continent can dispense cash from a bank located on another continent. Cash registers and gasoline pumps are connected to a telecommunications system so that credit card balances can be checked before making a sale. By pressing numbers on a touch tone telephone and without talking to another human being, products can be purchased, library books can be renewed, newspaper delivery can be started or stopped, survey questionnaires can be answered, and money can be transferred from one account to another. These examples illustrate not only the substitution of information technology applications for

human labor, but also the creation of services that could not previously be provided.

However, these developments pale beside the huge capability being unleashed by development of the World Wide Web. Once a system for the exchange of simple text messages among scientists, it has now expanded to a required form of communication for many, if not most, businesses and professionals. It is estimated that as many as 160 million users are now connected to the Internet, of which nearly half are in the United States and Canada. The rapid growth in Internet use in the mid-1990s has led to increases in connections among geographically dispersed work groups and to new methods for the selling of goods and services.

Development of the information society happened neither suddenly nor without warning. According to Beniger (1986), its roots go back to a crisis of control evoked by the Industrial Revolution in the late 1800s. Industrialization speeded up material-processing systems. However, innovations in information processing and communications lagged behind innovations in the use of energy to increase productivity of manufacturing and transportation systems. Development of the telegraph, telephone, radio, television, modern printing presses, and postal delivery systems all represented innovations important to the resolution of the control crisis, which required replacement of the traditional bureaucratic means of control that had been depended on for centuries before.

However, an entirely new stage in the development of the information society has been realized through advances in microprocessing technology and the convergence of mass-media telecommunications and computers into a single infrastructure of social control (Beniger 1986). An important factor in this convergence was digitalization of all information, so that distinctions between types of information such as words, numbers, and pictures become blurred, as does communication between persons and machines on the one hand, and between machines on the other. Digitalization, therefore, allowed the transformation of information into a generalized medium for processing and exchange by the social system, much as common currency and exchange rates centuries ago did for the economic systems of the world. Combining

telephone, television, and computer into a single device represents an important likely and practical consequence of this convergence.

Quite different views exist about the possible effects of the development of a full-fledged information society (Lyon 1988). One view is that it will empower workers, providing direct access to opportunities unavailable to them in an industrial society except by high organizational position and proximity to centralized positions of power. In 1985, Harlan Cleveland described information as being fundamentally different from the resources for which it is being substituted; for example, it is not used up by the one who consumes it, hence making its use possible by others. It is also easily transportable from one point to another, a characteristic made strikingly clear by the rapid rise of the World Wide Web. Cleveland argued that the information society would force dramatic changes in longstanding hierarchical forms of social organization, terminating taken-for-granted hierarchies based on control, secrecy, ownership, early access, and geography. A similar view was provided by Masuda (1981), writing in a Japanese context, who envisioned the development of participatory democracies, the eradication of educational gaps between urban and rural areas, and the elimination of a centralized class-based society.

A more pessimistic view of the consequences of knowledge as the key source of productivity was offered by Castells (1989). Fundamentally, the new information infrastructure that connects virtually all points of the globe to all others allows for great flexibility in all aspects of production, consumption, distribution, and management. To take advantage of the efficiencies offered by full utilization of information technologies, organizations plan their operations around the dynamics of their information-generating units, not around a limited geographic space. Individual nations lose the ability to control corporations. Information technologies, therefore, become instrumental in the implementation of fundamental processes of capitalist restructuring. In contrast to the view offered by Cleveland, the stateless nature of the corporation is seen as contributing to an international hierarchical functional structure in which the historic division between intellectual and manual labor is taken to an extreme. The consequences

for social organization are to dissolve localities as functioning social systems and to supersede societies.

There can be no doubt that the use of information technologies is significantly changing the structures of advanced societies. Yet it would be a mistake to think of the use of information technologies as a cause only, and not a consequence, of changes in societal structures. Laws have evolved in the United States in an attempt to regulate rates that can be charged for cable television, how much can be charged by providers for telecommunications services to schools and libraries, and what levels of telephone transmission services must be provided to individual households as a part of universal service. The influence of people's values is also being exerted on the extent and means by which confidentiality of data records must be protected; it also is being exerted through state and local laws mandating the accessibility of computers to schoolchildren.

Our rapid evolution to an information society poses many important sociological questions about how our increased dependence upon information technologies influences social interaction and other aspects of human behavior. The ability to transmit work across national boundaries, even the high likelihood that information essential to the operation of a nation will be stored outside rather than within a country, raises important questions about what is essential for preserving national sovereignty. The ability to control operations at long distance encourages an even greater division of labor among nations. As a result, labor unions may become powerless in the face of the ability of corporations to move production activities across national boundaries (Lyon 1988). And, just as elements of national society have weakened in the face of globalization, a set of counterforces have been unleashed whereby identity-based social movements compete to fill the void of power and control (Castells 1997). It is important for sociologists to seek an answer to the question of how the increased reliance on information technologies affects the sovereignty of individual nations and related social movements.

The information age provides new challenges for nearly all areas of sociology. It influences how and from whom we learn, with lifelong distance education changing the once essential learning

triangle of professor, student, and classroom. New types of crime, such as creating and spreading computer viruses, have been elevated from curiosities to major threats to the functioning of organizations, society, and the world order. The impact on people's self-concepts may also be substantial. From preschool on, computers have become part of the sociological and psychological development of children, the potential effects of which have yet to be fully understood (Turkle 1984). This interaction with computers now extends via the Internet to others with computers, so that the core sociological concept of social interaction must make room for electronic, long distance interaction and its consequences. Many adults now spend far more of their lives in interchange with computers than with another technological development, the automobile, which also dramatically changed people's lives in the industrial society.

Information technologies also have the potential for breaking down boundaries of individual communities, making it possible for people to bypass forming traditional community ties, unless extraordinary efforts are made to maintain them (Allen and Dillman 1994). Thousands of new job titles are added to the occupational structure of countries, while other job titles disappear. Robert Reich, for example, describes the evolution of jobs into three broad types—routine work, in-person service workers, and symbolic analysts (1991). The latter are theorized to be the creators of "value" in the information age, replacing land, plants, and equipment as the most valued production resource. These anticipated changes, to the extent they occur, provide the basis for evolution of a new class structure in society, based more upon educational accomplishment than upon the ownership of material resources.

Some have argued that we are evolving into a world of the information-rich and information-poor, with computer access and skills forming the great divide (Castells 1997; Lyon 1988). Even though computers seem omnipresent in society, they are present in only a minority (about 40 percent) of U.S. households and only half of those households have e-mail or Web access (National Telecommunications Information Administration [NTIA] 1998). To the extent that computers with Web connections shift from an optional way of

accessing important information and purchasing good and services to a mandatory means of obtaining competitive prices, a case can be made that class differences will expand.

It's appropriate that Daniel Bell, besides being one of the earliest prognosticators of the information age, also has more recently described quite different ways in which it could evolve (1989). He points out that the telecommunications revolution makes possible an intense degree of centralization of power if the society decides to use it in that way. However, because of the multiplicity, diversity, and cheapness of the modes of communication, decentralization is also possible. One of the important challenges for sociology is to understand which of these visions will prevail and why.

INHERITANCE

NOTE: Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.

Statutory and common laws governing inheritance have a profound effect on the formation or dissolution of household structures and the patterns of inheritance transfers over generations. A society, for any political or social reason, can initiate and promulgate a law or civil code controlling inheritance; inevitably, new laws or codes cause drastic change in the structure and functions of family systems.

In order to understand the subject of inheritance, it will be necessary to define many terms. To *inherit* is by law to receive property, resources, or, often, status from an ancestor at her or his decease or to take by intestate succession or by will. *Intestate succession* is a transfer of resources according to legal procedures that control distribution of the resources when there is no will. A person is *intestate* when he or she has not made a will. In a *will*, usually a written document, a person (or *testator*) makes a deposition of his or her property, and the deposition takes effect, at least in modern societies, upon the testator's death. A will is changeable and revocable during the lifetime of a testator.

Takers are successors or beneficiaries. *Impartible inheritance* is a situation, established by statute,

in which the property and resources are indivisible and are given to one person (*devisee*); this type of inheritance is likely to occur within family households primarily in rural areas of most historic societies, especially in Eastern and Western Europe. *Partible inheritance*, dividing assets for conveyance to one's heirs, is linked to nuclear family households found in those locations where there is accelerated industrialization and urbanization.

Any system of inheritance promotes the continuity of family and societal structures over generations. The transfer of resources from the older to the younger generation helps maintain a family's position and power in the social order. Such transfers also provide stability to existing societal caste and class arrangements and ordinarily are enconced deeply in tradition and myth. It is more likely that inheritance systems function to perpetuate existing social structures than to change society's organizations and institutions.

INHERITANCE, LAWS, AND CHANGE

Those most affected by changes in laws are persons with little power in society. This is evident in eighteenth- and nineteenth-century European societies, in which the promulgation of laws and decrees drastically affected the structure and practices of rural families. For example, Gaunt (1983) indicates that in nineteenth-century central Europe, in a section that is now part of Czechoslovakia, the decree to conscript unmarried men for military duty caused parents of serf families to encourage early marriage of their children. As a consequence, the incidence of complex family households increased, and there were changes in the patterns of inheritance succession. During a labor shortage in eighteenth-century Poland, fiefdom rulers encouraged endogamous marriage and attempted to restrict their chattels from leaving their villages. The economy was based on household unit sharecropping. The peasants encouraged complex family households consisting of two or more conjugal units, while the Polish lords favored neolocal household residence (Kochanowicz 1983). The inheritance outcomes of these efforts to circumvent political, economic, and social measures, often repressive in intent, affected existent family structures, their forms, and inheritance patterns.

The possession of equities, property, possessions, resources, and land (especially in the case of European peasants) determined whether these would compose an impartible or partible inheritance. For example, an impartible inheritance pattern is most likely when land is the primary family asset. In addition, the transfer of authority over these rights depended upon the timing of "stepping down," a process deeply embedded in the cultural traditions of the society (Gaunt 1983; Plakans 1989). Stepping down usually occurred through a retirement contract, which was essentially a will that indicated the conditions of the transfer from parents to children. This *inter vivos* phenomenon, a conveyance of property and other equities while the individual was alive and engaged in stepping down, was "one made of preserving intergenerationally the match between family and the property that provides its livelihood" (Sorensen 1989, p. 199). Stepping down, or disengaging, usually occurred when the oldest son married or when the parents were near or at retirement age. Stepping down was invoked by law or tradition, and it resulted in variations in inheritance patterns and in the organization of the life course of various family members.

Sorensen (1989) provides a detailed retirement contract of his great-grandfather on his mother's side, a prosperous farm family in the western part of Jutland, Denmark. The transfer of this medium-sized farm, substantially undervalued, when Laurids Poulsen was fifty-six, was apparently to make certain that the property remained in the family to buttress its position in the society.

It is not explicitly stated in the Poulsen retirement agreement that the heir, Alfred, would care for his parents in their declining years. The contract's provisions enabled Laurids and his wife, Maren, to be independent. Yet in this situation and, as Sorensen (1989) indicates, in Scandinavia since before the Middle Ages, transferring property to a son implied the promise of care in old age. Thus, there existed two motivations for conveying property to a son, but the stronger proved to be the hope of maintaining the property in the family over generations.

In former ages, conveying property and its accompanying position, status, and power was the intent of inheritance patterns. The preservation and maintenance of the family unit was the goal.

Impartible inheritance expressed this intent of maintaining the family property and social position, but it created obvious winners and losers. The transfer of a family's property to a single heir meant that other family members could leave to seek opportunities elsewhere or remain with the family enterprise in a subservient position.

The possibilities for fuller expression of family members' abilities, where talent and skills and not family membership determined the individual's life course trajectory, would come at a later period. Partible inheritance reduced the requirement that family members subordinate their desires, interests, and expectations to those of the family unit. Changes in a society's demographics, such as fertility and mortality, and changes in the means of producing goods and services resulted in lessened need for impartible inheritance. Partible inheritance became identified with the modern period of Western civilization.

MODERN PERIOD

Rules for succession and rules for inheritance of property are related but distinct from one another. Inheritance of property usually follows lines of succession to social position. Codified systems of secular law governing inheritance and status succession emerge in complex societies and are sufficiently precise and uniform to meet the majority needs of the population (Radcliffe-Brown 1935).

For urbanites in complex societies such as those in Europe and the United States, the transfer of land, dwelling unit, tools, and equipment is less critical to the survival and maintenance of the family over generations than it is for the rural resident. Economic assets other than land and buildings—that is, personal mementos and possessions—become the content of such transfers.

Rural landholders of modest means were unable to effect a pattern of impartible inheritance. Increasing societal complexity nurtured corporate agriculture in preference to the family farm. The reduction in the number of family-owned farms, the increasing dependence of farm family members upon the larger, mostly urban society for jobs that are not located close to the farm dwelling, price supports, and payment for nonproduction have diminished the possibilities for maintaining

the family farm over generations. Partible inheritance has become the norm.

This shift to partible inheritance under new rules of succession meant that for the first time the claims of the surviving spouse outweighed those of the surviving kin of one's lineage, a reversal of the pattern found in eighteenth- and nineteenth-century Europe and in primitive societies (Benedict 1936; Hoebel 1966). Under U.S. state statutes governing intestacy the surviving spouse and children share in the estate. The spouse receives at least one-third, depending on the number of surviving children and the specifics of the state law governing inheritance. If there is no surviving spouse the children share and share alike. Where there is no surviving spouse or children the estate passes to grandchildren. In the absence of grandchildren the next to receive are grandparents, then siblings, then more distant relatives.

Where testacy exists the estate usually passes to the surviving spouse. This horizontal transfer in the generational line of succession is uniquely modern and represents an evolution from the Roman definition of inheritance as "succession to the entire legal position of a deceased man" (Maine 1963, p. 208). In Rome the heir functioned as a guardian or executor of the estate to perpetuate the honor and status of the deceased and family survivors and to keep intact and extend the estate's holdings. The stepwise shift from decedent to surviving spouse and subsequent vertical transfer of equities to children after the death of the surviving spouse resulted in a family system based more on individual relationships, feelings, perceptions, and interactions and less on tradition, primogeniture, and maintaining properties and estates.

The pattern of conveying all property to the spouse, to be discussed further in this article, is a practice seemingly not in consonance with the concept and exercise of testamentary freedom.

TESTAMENTARY FREEDOM

Testamentary freedom, the individual's right to will away property to persons outside the family or to distribute to a number of heirs and legatees related by blood, consanguinity, or adoption, is a fundamental Anglo-American concept of the U.S. inheritance system. The primogeniture system, which passed all property to a single heir and was

most suited for the wealthy, was replaced in eighteenth-century England by a new law of the land—testamentary freedom. This occurred at the time England disposed its feudal land tenure system. The 1789 French Revolution, in keeping with its ideology of justice, freedom, equality, and fraternity, and for more concrete social and political reasons, enacted laws requiring equal distribution of a deceased person's assets among surviving children. Colonial settlers in the United States undoubtedly inspired by and enamored of the changes in English and French societies, brought with them this notion of testamentary freedom as part of their intellectual and cultural heritage.

At first blush the practice of testamentary freedom would seem at least to contradict if not destroy the major intent of an inheritance system. According to Edmund Burke, "the power of perpetuating our property in families is one of the most valuable and interesting circumstances belonging to it, and that which tends the most to the perpetuation of society itself" (1910, p. 121). The major question is whether testamentary freedom as it is practiced negates what Burke suggests is a most critical process for generational and societal continuity.

Testamentary freedom, like justice or liberty, is a relative and not an absolute condition. In practice it accommodates to family continuity over generations; a multilineal descent system; a highly differentiated society where the majority of assets owned by individuals are moveable; and values that espouse rationality, choice, freedom, and democracy. The right of an individual to dispose of property according to her or his wishes is recognized if the individual disposes property in a responsible fashion—when one takes care of one's kin, thus maximizing the possibilities of family continuity and orderly social relationships among family members. Testamentary freedom is not exercised absolutely. It accommodates to the norms of responsibility. Empirical data support the idea that compromise occurs among the interests of the individual's family and state in the exercise of testamentary freedom (Sussman, Cates, and Smith 1970).

Courts, social norms, and societal economic patterns limit the expression of testamentary freedom. Courts use the soundness of mind principle

in determining if an individual acts in a responsible fashion. Knowing what one possesses, the nature of the business in which one is engaged, and the natural objects of one's bounty are the essential components of the legal definition of a sound mind. In practice, courts almost universally consider the well-being of the family in addition to considering whether an individual has knowledge of his or her assets and successors (Cates and Sussman 1982). Neglecting or abandoning the family is viewed as unnatural, and being unnatural is equated with being of unsound mind. The media abound with cases regarding will contests involving decedents' bequests to loved pets, charities, strangers, or acquaintances. Preventing a distant relative from taking from or receiving an adequate share of an estate may result in legal action. Sussman, Cates, and Smith (1970) report a case in which charities were the major beneficiaries. The sole surviving relative, a niece, contested the will and lost, but she received a large out-of-court settlement of \$150,000. Courts, plaintiffs, and defendants normally favor out-of-court settlements because of lower economic and psychic costs. In 1965, when this case occurred, a settlement of \$150,000 was judged to be ample compensation. The settlement was also an indication that the well-being of a distant family member had been considered.

Prevalent social norms foster concern for the well-being of surviving family members. Believing that families should take care of their own and that family members should not be pauperized, the state has more than a legal interest in seeing that testamentary freedom be exercised with regard for the well-being of the family.

PATTERNS OF GENERATIONAL DISTRIBUTIONS

Complex societies have developed systems of state-wide resource transfers that have replaced in part some of the functions of the family inheritance system. These large-scale transfer systems, based on the principle of serial service, are society's way of taking care of those deemed dependent, those unable to contribute to the gross national product through gainful employment. Preponderant numbers of the very young and the elderly receive support from such transfers. The preeminent philosophical notion is that the young adult and middle

age generations, individuals ages sixteen to sixty five, pay through their earnings for government-initiated entitlement and needs programs such as Social Security, Medicare, Medicaid, educational grants, welfare payments, and so forth, programs to maintain and enhance the lives of the less fortunate. These generations may participate in these programs somewhat grudgingly, but they do so with the knowledge that they were supported during their childhood and with the expectation of being supported by these same programs in their old age. This pattern of society-wide transfers is characteristic of serial service.

Such massive transfers have reduced the economic burden of families in caring for dependent members. In some instances these programs have diminished the need for family members to provide extensive and intensive social and emotional support (Kreps 1965). Social Security pensions and other vested retirement programs, in both the private and public sectors, provide sufficient income for an increasing number of retirees. Most of them will be able to live independently or with minimal support from their relatives during their later adult years. Being economically independent or quasi-independent in old age with little need to rely upon the family's financial resources is a radical shift from earlier periods, when older relatives depended on the determinations of the inheritance system.

The society-wide transfer system based on universal taxation has not completely replaced the family inheritance system. One can view the former as an impersonal, bureaucratized, and universal system enacted primarily by statute or charter and monitored by official regulations. Participants become part of a large formal system and once they qualify are treated in a uniform manner. The use of computers and identification numbers increases the impersonality of support systems.

The family inheritance system, on the other hand, is influenced but not controlled by large-scale economic transfers. It exists and functions within a set of norms that extoll interpersonal relationships, continuity of marriage and blood lines, symbolic meanings, feelings of filial piety, nurturance, support, care, distributive justice, and reciprocity.

These institutional systems and programs that mutually support families probably condition the

bases upon which individual inheritance dispositions are made. Sussman, Cares, and Smith (1970) indicate that as a consequence of the growth of society-wide transfer programs,

Inheritance transfers may be less a consequence of acts of sexual reciprocity, based upon what specific individuals of one generation in a family do for others of another generation, but more a function of serial service. Serial service (a concept elaborated by William Moore, 1967) involves an expected generational transfer that occurs in the normal course of events. It is expected that parents have to help their young children, and middle aged children may be called upon to give care or arrange for care of an aged and often ailing parent. This is within the cycle of life, and services of this kind are expected and are not based upon reciprocal acts. Whatever parents have in the way of worldly possessions will in due course be passed on to lineal descendants. (p. 10)

Since the 1970s there has been a strong movement to reduce, or at best not increase, taxation to support benefit systems that assure society-wide economic transfers across generational lines. Those who support a reduction in such transfers strongly believe that the society has reached its absorptive capacity to pay increasingly higher costs for retirement and a variety of services to dependent family members. The cutback in government programs coupled with the exhortation that the government "should get off the back of family members" and the reglorification of the myth that families in ancient times cared for their own have resulted in increasing burdens for families in the care of their elderly and dependent members. This shift away from society to family responsibility for family members suggests a new look at family economic transfers and the role such inheritance plays in intergenerational relationships and in the solution of long-term care of aged and other dependent members.

INHERITANCE ISSUES FOR THE 1990S

Believing they do not want to be a burden to their children, older adults with economic resources and few relatives for whom to function as primary caregivers when needed are spending their inheritance on travel and other leisure activities and for

total medical and physical care as they move from independent to dependent living. A likely result is the diminishing of available funds to heirs and legatees and increased importance of family heirlooms. These gifts express the meaning and significance of the relationships between family members prior to the death of the testator.

The increasing unavailability of relatives, especially children, to care for aged family members will result in the assignment of heirs and legatees who are not related by blood or marriage. These are friends and service providers who supply social support, care, and nurturance and are "like family." Elders in the latter part of this century and well into the twenty-first, that is, members of the World War II baby boom generation, will be searching for a relative or someone to care for them in their declining years. Their drastically low reproduction rates and the consequences of the gender revolution begun in the 1960s will result in the availability of a severely limited number of immediate family members or distant relatives able or willing to provide care. Elderly people will turn to persons not related by blood or marriage—members of the individual's wider family (Marciano 1988). Wider family members are not a certain age, nor must they conform to traditional social norms; they are not related by blood or marriage. Bondings express deep friendship and voluntary informal contracted obligations and expectations. Wider family members today are on call and respond to requests for assistance immediately. They act and feel that they are at home in each other's household.

The consequence is an increasing incidence in the naming of such persons in wills and the probability that courts in the future will uphold their right to share the estate even in the case of intestacy. The courts may rule that traditional patterns of distribution to surviving family beneficiaries be modified to include those who provided care and nurturance to the deceased. The basis for such action is the notion of distributive justice, which invokes fairness. Those who have voluntarily provided services, intimacy, friendship, and care should be recognized and even rewarded. They have fulfilled the role of filial responsibility.

The dark side of this pattern is the exploitative friend, surrogate, or service provider who manipulates the care receiver and takes over the estate

through an *inter vivos* transfer or by a rewriting of the will. This sorcery, coupled with an increasing number of will contests, will keep attorneys in good financial stead and courts very busy for a long time.

Distributive justice, a just and fair distribution of resources as perceived by a testator or promulgated by the laws of intestacy, will be characteristic of transfers to family and kin as well as wider family members in the coming decades. A component of distributive justice is equality (Piaget 1932), a standard that is invoked by statutes governing intestacy. Equality is determined by the degree of relationship of the deceased to the survivor. Thus, upon the death of a parent intestate, equal shares are given to surviving children. If a spouse survives, she or he usually receives one-third of the estate, and the remaining two-thirds are distributed to surviving children.

Equity is another component of distributive justice. It implies a just and fair condition. It is not the same as equality. It is the "distribution of rewards and costs between persons" (Homans 1961, p. 74). Equity is the component most suited to arrangements for payment of rewards for incurred costs. Hence, both family and nonfamily members can expect rewards in property inheritance in relation to the costs incurred in caregiving and related activities. Such exchanges will become normative and generally accepted. Reciprocity is to be recognized and rewarded.

Portending the future, testators will increasingly enter into contracts with either family or nonfamily (wider) members, setting forth conditions and expectations of needed supports and caregiving (Hanks and Sussman 1990). Such contracts, seemingly as legal as any other contract, are likely to be challenged in the courts by those who stand to inherit under the laws of descent and succession. The rootedness of these contracts in distributive justice, with its fairness and equity principles, suggests that their validity will be sustained.

Contracts can involve *inter vivos* transfers or declarations in a will. For example, a middle-aged testator can give resources to a young relative or member of a wider family with a pay-back arrangement of care and service when needed by the benefactor. A will provision can readily be made.

The exact instrument that will enhance its legality needs to be developed in consultation with attorneys. Such contracts, similar to prenuptial agreements, drawn with both parties of sound mind, should be legal. These contracts will have provisions for modification and cancelation, like any other contract. The major point is that such contracts can reduce the concerns of an aging population regarding their life-style in very old age and diminish their total dependence upon institutional forms of care. The "inheritance contract" fosters independence and utilization of one's resources in meeting health and social needs. Caretaking as a family enterprise can reduce potentially the outlay of public monies currently expended for health and social service programs. This reduction in the economic burden of government is not tantamount to the elimination of current universal support programs. At best the inheritance contract helps provide meaningful relationships, establishes a procedure for planning and expending one's resources, and encourages individuals to rely less upon governmental institutions.

Openness in discussing wills is a new departure from the past and leads to forthrightness in discussing other family matters. Hanks (1989) reports in her sample of 111 corporate family members that 88 percent discussed their wills and 60 percent their funeral arrangements. Such openness with relatives can reduce future will contests and result in conversations and negotiations regarding foreseeable generational transfers and caregiving arrangements. The symbolic meaning attached to the passing on of jewelry, paintings, furniture, books, and other household items has been given very little attention (Sussman, Cates, and Smith 1970). Allocations of these items demonstrated to the recipients the kind of emotional and affective relationship they had with the deceased. More individuals experienced pain and depression from not receiving a promised or expected heirloom than from receiving a lesser share of property or equities. Strong feelings are aroused because of the memories connected with these heirlooms, and the deceased cannot be asked regarding her or his feelings and emotions toward the heir. Openness in discussing wills and related matters can reduce misunderstandings and misinterpretations regarding the meaning attached to the transfer of heirlooms and the trauma of not knowing.

In the 1990s and future decades inheritance will continue its patterns of transfer and distribution of properties and equities over generations. It will be a different system from that found in rural areas in historic or current time. It will continue to be insignificant in the generational transfer of status and power except for the wealthy classes. Things that will distinguish inheritance in the future from that of the past is the emergence of the inheritance contract; openness in discussing will contents with potential beneficiaries; greater inclusion of distant family relatives in wills; increased number of will contests; and increased incidence in the number of older adults who spend money on leisure activities or on their own health care rather than contribute it to their children's inheritance.

INTELLECTUALS

NOTE: Although the following article has not been revised for this edition of the *Encyclopedia*, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.

Modern societies face a growing dilemma posed by the fact that key institutions and their elites are increasingly dependent upon intellectuals, particularly those in universities, research institutes, and the cultural apparatus generally. Yet, the leaders in these same social units are among the major critics of the way in which the society operates, sometimes calling into question the legitimacy of the social order and its political structure. A ruling

elite, even one that is conservative and anti-intellectual, cannot respond to such challenges by crushing the intellectuals, unless it is willing to incur the punitive costs which such suppression entails. As the Polish “revisionist” philosopher Leszek Kolakowski (1968, p. 179) wrote while still a member of the Communist party, “the spiritual domination of any ruling class over the people . . . depends on its bonds with the intelligentsia . . . ; for the less one is capable of ruling by intellectual means, the more one must resort to the instruments of force.” Decades earlier, the classically liberal (*laissez-faire*) economist and sociologist Joseph Schumpeter (1962, p. 150) argued that under capitalism the dominant economic class must protect the intellectuals, “however strongly disapproving” they are of them, because they cannot suppress intellectual criticism without initiating a process of repression which will undermine their own freedom.

The word *intellectual* is fraught with ambiguities. The meanings attached to it are diverse (Lipset and Dobson 1972, pp. 137–140). In the loosest sense in which the word is used in common parlance today, intellectuals may be said to be all those who are considered proficient in and are actively engaged in the creation, distribution, and application of culture. Edward Shils (1968, p. 179) has suggested a comprehensive definition: “Intellectuals are the aggregate of persons in any society who employ in their communication and expression, with relative higher frequency than most other members of their society, symbols of general scope and abstract reference, concerning man, society, nature and the cosmos.” For analytic purposes, however, it is desirable to distinguish between several types. It is particularly useful to emphasize the much smaller category of “creative intellectuals,” whose principal focus is on innovation, the elaboration of knowledge, art, and symbolic formulations generally. Included in this group are scholars, scientists, philosophers, artists, authors, some editors, and some journalists, as distinguished from the more marginally intellectual groups who distribute culture, such as most teachers, clerics, journalists, engineers, free professionals, and performers in the arts, as well as those who apply knowledge in the course of their work, such as practicing physicians, lawyers, and engineers. To differentiate them from the intellectuals, they may be categorized as the *intelligentsia*.

The creative intellectuals are the most dynamic group within the broad stratum: Because they are innovative, they are at the forefront in the development of culture. The intelligentsia are dependent upon them for the ideational resources they use in their work. Much of the analytic literature dealing with intellectuals has emphasized their seemingly inherent tendency to criticize existing institutions from the vantage point of general conceptions of the desirable, ideal conceptions which are thought to be universally applicable. Thus, Joseph Schumpeter (1950, p. 147) stressed that “one of the touches that distinguish [intellectuals] . . . from other people . . . is the critical attitude.” Raymond Aron (1962, p. 210) argued that “the tendency to criticize the established order is, so to speak, the occupational disease of the intellectuals.” Richard Hofstadter (1963, p. 38) noted: “The modern idea of the intellectual as constituting a class, as a separate social force, even the term *intellectual* itself, is identified with the idea of political and moral protest.” Lewis Coser (1970, p. viii) in defining the term stated: “Intellectuals are men who never seem satisfied with things as they are. . . . They question the truth of the moment in higher and wider truth.”

These concerns are iterated by the fact that “intelligentsia” and “intellectuals,” the two words most commonly used to describe those in occupations requiring trained or imaginative intelligence, were used first in the context of describing those engaged in oppositional activities. “Intelligentsia,” first began to be used widely in Russia in the 1860s, referring to the opposition to the system by the educated strata. It was generally defined as “a ‘class’ held together by the bond of ‘consciousness,’ ‘critical thought,’ or ‘moral passion.’” (Malia 1961 p. 5) “Intellectual” as a noun first secured wide usage in France during the infamous Dreyfus case in 1898. A protest against Dreyfus’s unjust imprisonment (after a biased court-martial), signed by a variety of writers and professors, was published as the “Manifesto of the Intellectuals.” The anti-Dreyfusards then tried to satirize their opponents as the self-proclaimed “intellectuals” (Bodin 1962, pp. 6–9; Hofstadter 1963, pp. 38–39). The term was picked up in the United States in the context of characterizing opponents to World War I.

The American intellectual also has been seen as a source of unrest. Many have called attention to this phenomenon, seeing it as a continuing one in

American history (May 1963; Hayek 1949, pp. 417–433). Richard Hofstadter (1965, pp. 111–112) described their stance of alienation as “historical and traditional,” and pointed out that “even the genteel, established intellectuals of the mid-nineteenth century were in effect patrician rebels against the increasing industrialization and the philistinism of the country. So that it has been the tradition of American intellectuals of all kinds and stamps to find themselves at odds with American society: this, I think, to a degree that is unusual elsewhere.” A century ago, Whitelaw Reid (1873, pp. 613–614), the editor of the *New York Tribune*, pointed to the role of the American “Scholar in Politics” as a foe of the “established,” and a leader of the “radicals.”

The reader should not get the impression that intellectual and student involvement in protest is confined to left-wing or progressive movements. This is not true, as witnessed, for example, by the intellectuals and students who constituted a core segment of activist support for the Fascist party of Mussolini, and of the National Socialist party of Hitler, before they took power, as well as among fascist and assorted anti-Semitic right-wing extreme groups in France and various countries in Eastern Europe up to World War II (Hamilton 1971; Röpke 1960, pp. 346–347). In Eastern Europe and the Soviet Union, intellectuals have been in the forefront of the struggles against Communist regimes, behavior that is perceived as left, i.e. opposition to statism, authoritarianism, and severe stratification.

In the United States, although scattered groups of right-wing intellectuals have emerged at times, the record seems to validate Richard Hofstadter’s (1963, p. 39) generalization that for almost all of this century the political weight of American intellectuals has been on the progressive, liberal, and leftist side. Quantitative data derived from attitude surveys, the earliest dating back to before World War I, plus assorted other reports of the political orientations of the American professoriate, down to the present, strongly indicate that American intellectuals have consistently leaned in this direction (Lipset and Dobson 1972, pp. 211–289; Lipset 1991). This bias, to a considerable extent, reflects the absence or weakness of a legitimate national conservative tradition in America. National identity and national ideology are linked to a value system that emphasizes egalitarianism and populism, stemming from an elaboration of

principles enunciated in the Declaration of Independence. Thus, when American intellectuals point up the gap between the real and the ideal, whether the latter is represented by what was in a bygone Jeffersonian laissez-faire era (a utopia of equal yeoman farmers) or what it should be (a classless participatory future), they challenge the system for not fulfilling the ideals implicit in the American Creed.

Still, the argument is frequently made that inherent in the structural changes since World War II, which have been described as leading to a “postindustrial society,” has been a growing interdependence between political authority and intellectualdom, which should have reduced the critical stance. Modern developed socioeconomic systems are highly dependent on superior research and development resources, which mean better support for universities, and research centers, and the much larger component of persons who have passed through the higher education system—thus creating a mass, high-culture market that pays for the institutions and products of the artistic community (Bell 1973). Governments are increasingly a major source of financing for intellectualdom, ranging from artists to scientists. Recognition and financial rewards from the polity conceivably should help to reduce the historic tensions and the intellectual’s sense of being an outsider. A further trend pressing in this direction is the fact that the complexities involved in “running” an advanced industrial or postindustrial society forces laymen, both political and economic leaders, to seek advice in depth from, to defer to, the scholarly-scientific community (Dahl 1989, pp. 334–335; Gagnon 1987). Many, therefore, have seen these trends as fostering the role of the intellectual as participant, as leading to the “interpenetration” of scholarship and policy (Shils 1968; Brint 1991).

These developments, however, have not led to the decline in the critical role of the intellectual in the United States, although patterns elsewhere appear somewhat different (Lerner, Nagai, and Rothman 1990, p. 26). A number of analyses of different American scholarly disciplines have emphasized the significant presence of political radicals among them and their greater alienation from the powers than in Western European societies (Lipset 1991). In seeking to explain this trans-Atlantic difference, a Swedish scholar, Ron Eyerman (1990) notes that unlike the situation in America,

Swedish (and I would add European) intellectuals are not an “alienated stratum” opposed to the state “because the avant-garde tradition was absorbed through a reformism [that] put intellectual labor to use in service of society,” that is, largely through the labor and socialist movements. While the overwhelming majority of American intellectuals view themselves as outsiders, and have had little experience in directly influencing power that could moderate their sense of alienation, many European intellectuals have worked in a somewhat more integrated context. And most are, it should be noted, still on the left politically, though less radical relative to their national spectrums than their American counterparts.

The dilemma remains for intellectuals everywhere of how to obtain the resources necessary to pursue creative activity without “selling out,” without tailoring creative and intellectual work to the demands of employer, patron, or consumer. In modern times in the West, the emphasis on originality, on innovation, and on following the logic of development in various creative fields—be they painting, music, literature, physics, or sociology—has been responsible for a recurrent conflict between intellectuals and those who pay for their works or exert control through the state, churches, businesses, the market, or other institutions. Intellectuals have often felt themselves to be dependent on philistines while wanting to do whatever they liked according to the norms of their field.

Much of the discussion has focused on the tensions created for unattached intellectuals. It has been asserted “that free-lance intellectuals are more receptive to political extremism than are other types of intellectuals . . . [since] the freelance intellectual . . . has been dependent on an anonymous and unpredictable market. . . . Rewards are much less certain to be forthcoming for the free-lance intellectual, the form of reward less predictable, and the permanence of the recognition more tenuous. . . . [They] tend to be more dependent on their audience, over which they have relatively little control, and to feel greater social distance from it (Kornhauser 1959, pp. 186–187).”

To understand the continued anti-establishment emphasis of intellectuals, even when well rewarded, it is important to recognize the relationship of this emphasis to their concern for creativity

or innovation. The capacity for criticism, for rejection of the status quo, is not simply a matter of preference by some intellectuals. Rather, it is built into the very nature of their occupational role. The distinction between integrative and innovative roles implies that those intelligentsia involved in the former, like teachers, engineers, and exponents of mass culture, use ideas—scholarly findings—to carry out their jobs; those in the latter activities, like scholars, poets, and scientists, are concerned with the creation of *new* knowledge, *new* ideas, *new* art. To a considerable extent, in such endeavors, one is much more rewarded for being original than for being correct—an important fact, a crucial aspect of the role insofar as we consider that such intellectuals tend to be socially critical.

SEYMOUR MARTIN LIPSET

INTELLIGENCE

In everyday life people commonly refer to each other as being smart or slow. The perception that individuals differ widely in mental adeptness—in intelligence—long preceded development of the IQ test, and there is indeed a large vernacular for brilliance, stupidity, and the many points in between. There has been much sparring over the scientific meaning and measurement of intelligence, both in the rowdy corridors of public debate and in the sanctums of academe. But what do we actually know about intelligence? A lot more in the last decade, and some of it surprising even to experts. Moreover, the data form a very consistent pattern showing that differences in intelligence are a biologically grounded phenomenon with immense sociological import.

MEASUREMENT OF INTELLIGENCE

The effort to measure intelligence variation among individuals is a century old. Two strategies for measuring such differences have emerged, the *psychometric* and the *experimental*. Both spring from

the universal perception that, although all people can think and learn, some are notably better at both than others. Accordingly, intelligence research focuses on how people *differ* in cognitive competence, not on what is common to all of us. (Other disciplines such as neuroscience and cognitive psychology specialize in the commonalities.) The aim of intelligence research is thus much narrower than explaining the intricacies of how brains and minds function. These intricacies are relevant to intelligence experts, but generally only to the extent that they illuminate why people in all cultures differ so much in their ability to think, know, and learn.

Psychometric (Mental Testing) Strategy. The IQ test represents the psychometric approach to measuring intelligence. Alfred Binet devised the first such test in France to identify children who would have difficulty profiting from regular school instruction. Binet's idea was to sample everyday mental competencies and knowledge that were *not* tied to specific school curricula, that increased systematically throughout childhood, and that could reliably forecast important differences in later academic performance. The result was a series of standardized, age-graded test items arranged in increasing order of difficulty. A child's score on the test compared the child's level of mental development to that of average children of the same age. Binet's aim was pragmatic and his effort successful.

Innumerable similar tests have been developed and refined in the intervening century (Anastasi 1996; Kaufman 1990). Some are paper-and-pencil tests, called *group tests*, that can be administered cheaply to many individuals at once and with only a small sacrifice in accuracy. Others, such as the various Wechsler tests, are *individually administered tests* that require no reading and are given one-on-one. Today, individually administered intelligence tests are typically composed of ten to fifteen subtests that vary widely in content. The two major categories are the *verbal* subtests, such as vocabulary, information, verbal analogies, and arithmetic, which require specific knowledge, and the *performance* subtests, such as block design, matrices, and figure analogies, which require much reasoning but little or no knowledge. The highly technical field that develops and evaluates mental tests, called *psychometrics*, is one of the oldest and most rigorous in psychology. Its products have

been found useful in schools, industry, the military, and clinical practice, where they are widely used.

Professionally developed mental tests are highly *reliable*, that is, they rank people very consistently when they are retested. A great concern in earlier decades was whether mental tests might be culturally biased. *Bias* refers to the systematic over- or underestimation of the true abilities of people from certain groups—a “thumb on the scale”—favoring or disfavoring them. There are many specific techniques for uncovering test bias, and all mental tests are screened for bias today before being published. IQ tests generally yield different average scores for various demographic groups, but the consensus of expert opinion is that those average differences are not due to bias in the tests. The consensus among bias experts, after decades of research often trying to prove otherwise, is that the major mental tests used in the United States today do not systematically understate the developed abilities of native-born, English-speaking minorities, including American blacks. The American Psychological Association affirmed this consensus in its 1996 task force report, “Intelligence: Knowns and Unknowns” (Neisser et al. 1996).

The biggest remaining question about IQ tests today is whether they are *valid*, that is, whether they really measure “intelligence” and whether they really predict important social outcomes. As will be shown later, IQ tests do, in fact, measure what most people mean by the term “intelligence,” and they predict a wide range of social outcomes, although some better than others and for reasons not always well understood.

Experimental (Laboratory) Strategy. The experimental approach to measuring differences in general intelligence is older than the psychometric but little known outside the study of intelligence. It has produced no tests of practical value outside research settings, although its likely products could someday replace IQ tests for many purposes. The approach began in the late 1800s when the great polymath Francis Galton proposed that *mental speed* might be the essence of intelligence. He therefore set out to measure it by testing how quickly people respond to simple sensory stimuli such as lights or tones. Galton's measures did not clearly correlate with “real-life” indicators of mental ability, such as educational success, so his *chronometric* approach was quickly dismissed as

wrong-headed and far too simplistic to capture anything important about the beautiful complexity of human thought.

Advances in statistics after the mid-twentieth century, however, showed that Galton's data actually had shown considerable promise. New medical and computer technology have since allowed researchers to measure elements of mental processing with the necessary precision that Galton could not. The revival of his approach in the 1970s has revolutionized the study of intelligence. It is the new frontier in intelligence research today. No longer producing "fool's gold" but the real thing, the study of elementary cognitive processes has attracted researchers from around the world. It now appears that some differences in complex mental abilities may, in fact, grow from simple differences in how people's brains process information, including their sheer speed in processing.

There is no single experimental approach, but perhaps the dominant one today is the chronometric, which includes studies of inspection time (IT) and reaction time (RT). Chronometric tasks differ dramatically from IQ test items. The aim is to measure the *speed* of various elementary perceptual and comprehension processes. So, instead of scoring how well a person performs a complex mental task (such as solving a mathematics problem or defining a word), chronometric studies measure how quickly people perform tasks that are so simple that virtually no one gets them wrong. These *elementary cognitive tasks* (ECTs) include, for example, reporting which of two briefly presented lines is the longer or which of several lights has been illuminated. In the former, an IT task, the score is the number of milliseconds of exposure required to perceive the difference. In the latter, an RT task, the score is the number of milliseconds the subject takes to *release* a "home button" (called "decision time") in order to press the lighted response button (called "movement time").

Both average speed and variability in speed of reaction are measured over many trials. It turns out that brighter people are not only faster but more consistent in their speed of stimulus apprehension, discrimination, choice, visual search, scanning of short-term memory, and retrieval of information from long-term memory. In fact, variability in speed is more highly correlated with IQ (negatively) than is average speed. ECT performance

correlates more highly with IQ as the tasks become more complex, for example, when the number of lights to distinguish among increases from two to four to eight (respectively, one, two, and three "bits" of information). Composites of various speed and consistency scores from different ECTs typically correlate $-.5$ to $-.7$ with IQ (on a scale of -1.0 to 1.0 , with zero meaning no relation), indicating that both chronometric and psychometric measures tap much the same phenomena. Psychometric and chronometric measures of mental capacity also trace much the same developmental curve over the life cycle, increasing during childhood and declining in later adulthood. Debates among the experimentalists concern how many and which particular elementary cognitive processes are required to account for differences in psychometric intelligence.

MEANING OF INTELLIGENCE.

The meaning of intelligence can be described at two levels. Nonexperts are usually interested in the *practical meaning* of intelligence as manifested in daily life. What skills does it reflect? How useful are they in school, work, and home life? In contrast, intelligence researchers tend to be interested in the more *fundamental nature* of intelligence. Is it a property of the brain and, if so, which property exactly? Or is it mostly a learned set of skills whose value varies by culture? Personnel and school psychologists, like other researchers concerned with the practical implications of mental capability, are often interested in both levels.

Practical Definitions of Intelligence. The practical meaning of intelligence is captured well by the following description, which was published by fifty-two leading experts on intelligence (Gottfredson 1997a). It is based on a century of research on the mental behavior of higher- versus lower-IQ people in many different settings.

Intelligence is a very general mental capability that, among other things, involves the ability to reason, plan, solve problems, think abstractly, comprehend complex ideas, learn quickly and learn from experience. It is not merely book learning, a narrow academic skill, or test-taking smarts. Rather, it reflects a broader and deeper capability for comprehending our surroundings—"catching on," "making sense" of things, or "figuring out" what to do. (p. 13)

The concept of intelligence refers specifically to an *ability* that is *mental*. It does not encompass many of the other personal traits and circumstances that are important in people's lives. It does not include, for instance, strictly physical skills, creativity, or traits of personality and character such as conscientiousness and drive. IQ tests are not intended to measure these other traits. Three practical definitions that are more specific may illuminate better what intelligence means in daily affairs. Each can be translated into the others, but each highlights a different practical aspect of intelligence: the ability to deal with complexity (Gottfredson 1997b), learn (Carroll 1997), and avoid making cognitive errors (Gordon 1997).

Intelligence as the ability to deal with complexity. IQ test items vary widely in content and format, but they often seem esoteric or narrowly academic. Many people in the past took these superficialities as guides to the nature of what IQ tests measure and therefore mistakenly concluded that they cannot be measuring anything of real consequence, at least outside schools. IQ tests' superficial characteristics, however, are irrelevant to their ability to measure intelligence. What matters is the *complexity*, the amount of mental manipulation, their tasks require: contrasting, abstracting, inferring, finding salient similarities and differences, and otherwise turning things over in one's mind to accomplish the mental task. Complexity is the active ingredient in tests that call forth intelligence. People who score higher on IQ tests are people who deal better with complexity, that is, are more adept at understanding and effectively solving more complex mental challenges.

Any kind of test *vehicle* or content (words, numbers, figures, pictures, symbols, blocks, mazes, and so on) can be used to create different levels of complexity. IQ tests typically do, in fact, contain subtests with different kinds of content. Forward and backward digit span (two memory subtests) illustrate clearly the notion of mental manipulation and task complexity. In digits forward, individuals are asked to repeat a string of from two to nine digits (say, 3-2-5-9-6) that is presented orally at one digit per second. In digits backward, the individual simply repeats the numbers in reverse order (in this case, 6-9-5-2-3). The one extra element in the second task (mentally reversing the list) greatly increases its complexity, nearly doubling its correlation with IQ.

Number series completion subtests can also seem trivial, but they illustrate how the same simple content can be varied to build increasingly complex mental demands. Consider the following three series: 4, 6, 8, 10, 12,— (easy item); 2, 4, 5, 7, 8, 10,— (moderate); and 9, 8, 7, 8, 7, 6,— (difficult). One must discern the relations between succeeding numbers in order to complete the series, and those relations become increasingly complex across the three series (respectively, add 2 to each successive digit; add 3 to each successive set of two digits; subtract 1 from each successive set of three digits). These are similar to the items found in one of the fifteen subtests of the Stanford-Binet Intelligence Scale (SBIS-IV) for school-aged youth. They require very little knowledge. Instead, their challenge is to use that simple information effectively—to contrast and compare, find relations, and infer rules—in order to solve logical problems in the test setting. IQ tests that require this on-the-spot problem solving are referred to as tests of *fluid intelligence*—of mental horsepower, if you will.

Some IQ subtests require test takers to bring considerable knowledge into the test setting in order to perform well, but they, too, illustrate the principle that the active ingredient in IQ tests is the complexity of their mental demands. Vocabulary, for example, is one of the very best subtests for measuring intelligence. The reason is that people do not learn most words (*love, hate*) by memorization or direct instruction, but rather by *inferring* their meanings and their fine nuances in meaning (*love, affection, infatuation, devotion, and ardor; hatred, loathing, abhorrence, antipathy, and contempt*) from the way other people use them in everyday life. Learning vocabulary is largely a process of distinguishing and generalizing concepts in natural settings.

Table 1 illustrates how vocabulary level reflects differences in the ability to deal with complexity. These results are from an earlier version of the Wechsler Adult Intelligence Scale (WAIS). All the adults tested were able to provide at least a tolerable definition of concrete items such as *bed, ship, and penny*, but passing rates dropped quickly for more abstract and nuanced concepts such as *slice* (94 percent), *sentence* (83 percent), *domestic* (65 percent), and *obstruct* (58 percent). Only half could define the words *remorse, reluctant, and calamity*. Fewer than one in five knew the words *ominous* and

tirade, and only 5 percent could provide even a partial definition of *travesty*. Anyone who has attended high school, read newspapers and magazines, or watched television will have encountered these words. Vocabulary tests thus gauge the ease with which individuals have routinely “picked up” or “caught onto” concepts they encounter in the general culture. So, too, do the general information subtests that are included in many IQ test batteries (“Why do homeowners buy home insurance?”).

Vocabulary, information, and other tests that require considerable prior knowledge are referred to as tests of *crystallized intelligence* because they measure the knowledge that has formed or crystallized from past problem solving. The greater the mental horsepower, the greater the accumulation. Only knowledge that is highly general and widely available is assessed, however, because otherwise IQ tests would also be measuring the opportunity to learn, not success when given the opportunity to do so. Tests of fluid and crystallized intelligence correlate very highly, despite their very different content, because the key active ingredient in both is the complexity of the problems people must solve.

Intelligence as the ability to learn. One of life’s unremitting demands is to learn—that is, to process new information sufficiently well to understand it, remember it, and use it effectively. This is especially so in education and training, but it is also the case in meeting the challenges of everyday life, from learning to use a new appliance to learning the subtle moods of a friend or lover.

IQ level is correlated with speed, breadth, and depth of learning when learning requires thinking, specifically, when it is intentional (calls forth conscious mental effort), insightful (requires “catching on”), and age-related, that is, when older children learn the material more easily than do younger children (because they are mentally more mature) and when the material to be learned is meaningful and hierarchical (mastering earlier elements is essential for learning later ones, as in mathematics). Learning is also correlated with intelligence level when the learning task permits using past knowledge to solve new problems, the amount of time for learning is fixed, and the material to be learned is not unreasonably difficult or complex (which would cause everyone to fall back on trial-and-error learning). In short, intelligence is the

ability to learn when the material to be learned is moderately complex (abstract, multifaceted, and so on), as distinct from learning by rote or mere memorization.

People learn at very different rates. In school, the ratios of learning rates are often four or five to one, and they can go much higher depending on the material. The military has likewise found that recruits differ greatly in how well they learn, which it calls *trainability*. One 1969 (Fox, Taylor, and Caylor 1969) study done for the U.S. Army found, for example, that enlistees in the bottom fifth of ability needed two to six times as many teaching trials and prompts as did their higher-ability peers

to reach minimal proficiency in rifle assembly, monitoring signals, combat plotting, and other basic soldiering tasks. Figure 1 illustrates the major differences in trainability at different levels of IQ. People with IQs of about 115 and above can not only be trained in a college format but can even gather and infer information largely on their own. Training for people with successively lower IQs, however, must be made successively less abstract, more closely supervised, and limited to simpler tasks. Low levels of trainability limit not only how much can be learned in a set amount of time but also the complexity of the material that can be mastered with unlimited time.

Intelligence as the ability to avoid common cognitive errors. Intelligence can also be conceived, for practical purposes, as the probability of *not* making cognitive errors. The notion is that all people make cognitive errors but that brighter people make fewer of them in comparable situations. They make fewer errors in learning, for example, because they learn more quickly and thoroughly. And they make fewer errors of judgment in new and unexpected situations because they are better able to look ahead, assess the likely consequences of different actions and events, spot incongruities and problems, factor more information into their decision making, and perceive alternative courses of action.

Just as items on intelligence tests are scored right versus wrong or better versus worse, so, too, can many decisions in everyday life be classified in this manner. And just as intelligence tests must use many items to assess intelligence level accurately, so, too, does the meaning of intelligence in daily life manifest itself in the accumulation of good and bad decisions, large and small, throughout one's life. The lifetime advantages of higher intelligence are explored later. The point here is simply that intelligence can also be described as the ability to avoid making common errors in judgment and accumulating a harmful record of them.

These three workaday definitions give an intuitive sense of what it means at the level of personal experience to be more versus less intelligent. Intelligence researchers seek to understand intelligence differences in their more fundamental sense, below the surface of everyday observation. As described next, most have adopted a new working definition of intelligence for this purpose.

Psychometric *g* (Not IQ) as the Research Definition of "Intelligence." The psychometric approach to measuring intelligence cannot by itself tell us what intelligence is fundamentally, say, neurologically. However, it has greatly narrowed the possibilities. Most importantly, it has shown that intelligence is a highly general ability and that it is the backbone or supporting platform for the more specific mental abilities. This finding rests in turn on the discovery of a single, common, and replicable means for isolating for study what most people mean by intelligence. As explained, it is not the IQ but *g*, which is short for the *general mental ability factor* (Jensen 1998). The latter has replaced the former as the gold standard for measuring intelligence. Researchers do not yet know exactly what aspect of mind or brain *g* represents, but *g* has become the de facto definition of intelligence for most intelligence researchers, some of whom would drop the term "intelligence" altogether.

From the earliest days of mental testing, researchers observed that people who do well on one test tend to do well on all others. That is, all mental tests intercorrelate to some degree. This prompted Charles Spearman, Galton's student and one of the earliest theorists of intelligence, to invent the statistical technique of factor analysis to isolate that common component from any set of mental tests. Once the common factor, *g*, is statistically extracted from a large, diverse set of tests, each individual's standing on it (the person's *g* level) can then be calculated. So, too, conversely, can the ability of different tests to measure *g* (their *g-loadings*). Among mental tests, IQ tests provide the most accurate measures of *g*. Scores on the great variety of IQ tests are all highly *g*-loaded, that is, they all correlate highly with *g* (with .9 being a typical value for tests of the Wechsler variety). This high correlation means that IQ scores are quite adequate for most practical purposes; therefore, *g* scores are generally actually calculated only for research purposes.

The replicability of g. Research reveals that the same *g* dimension characterizes all demographic groups yet studied. Virtually identical *g* factors have been extracted from all large, diverse sets of mental tests, regardless of which method of factor analysis was used and regardless of the age, sex, or race of the test takers. The same *g* is called forth by tests that require much cultural knowledge as by ones requiring virtually none. It can be called up

Figure 1

by any kind of item content (numbers, letters, shapes, pictures, blocks, and the like), a phenomenon that Spearman called *indifference of the indicator*.

Mental tests often measure more specific aptitudes in addition to *g* (say, verbal or spatial ability), but *g* is the crucial backbone of all mental tests. Efforts to create useful mental tests that do not measure *g* (for example, verbal aptitude tests that do not tap *g*) have all failed. Although mental tests are suffused by a common factor, no analogous common factor can be found among different personality tests (which test for extroversion, conscientiousness, sociability, and so on). The absence of a general personality factor illustrates that the general mental ability factor *g* is not an artifact of factor analysis but a real phenomenon.

To be sure, the existence of the *g* factor can be obscured by inappropriate testing (for example, when some test takers do not know the language well) and by narrow sampling (when all test takers are similar in intelligence). When allowed to manifest itself, however, the *g* factor clearly shows itself

to transcend the particulars of content and culture. This is not to say that culture cannot affect the development of *g* or its social significance, but only that culture does not determine its fundamental nature. The nature of *g* seems to be surprisingly independent of culture, as other sorts of research have confirmed.

The generality of g. The great generality of *g* is perhaps psychometrics' most crucial discovery about the nature of intelligence. As noted, the identical *g* factor is the major distinction in mental abilities in all groups of people and tests, regardless of cultural context or content. As also noted, all mental ability tests measure mostly *g*, no matter what specific abilities they were intended to measure (verbal aptitude, mathematical reasoning, memory, intelligence, and so on). The manifest skills most associated with intelligence in both fact and public perception—reasoning, problem solving, abstract thinking, and learning—are themselves highly general, context-independent thinking skills. The psychometric vehicles (tests and test

items) for measuring g are necessarily culture-bound to some degree, but the g abstracted from them appears not to be.

There are, of course, other mental aptitudes, but, unlike g , they seem specific to particular domains of knowledge or activity (language, music, mathematics, manipulating objects in three-dimensional space). Moreover, none of these narrower abilities seem so integral as g to the expression of all the others. Many decades of factor-analytic research on human abilities have confirmed what is called the hierarchical structure of mental abilities (Carroll 1993). As shown in the simplified version in Figure 2, abilities are arrayed from the top down, with the most general placed at the top. Research always finds g at the top of this generality hierarchy for mental abilities.

The generality of intelligence was less clear when researchers relied on IQ as their working definition of intelligence. The reason is that all IQ tests are imperfect measures of g and each often captures the flavor of some specialized ability or knowledge in addition to g . That is, all IQ tests share a large g component, but their small non- g components often differ in size and content. Attempting to understand intelligence by studying IQ scores has been akin to chemists trying to understand the properties of a particular chemical element by each studying samples that were impure to different degrees and with different additives. This ensured a muddled and fractious debate about the essence of intelligence. In contrast, the g factor is a stable, replicable phenomenon. When researchers study g , they can be confident they are studying the same thing, even when the g 's they use were extracted from different sets of tests. Moreover, g has the advantage over IQ that it cannot be confused with the attributes or contents of any particular test, because g is always extracted from some large, mixed set of them. One must look below the surface characteristics of IQ tests, to g , to explain the core phenomenon they measure.

The g -loadings of tests and tasks. The ability to classify tests according to their correlation with g is also a major advance in the study of intelligence. It allows research on why tasks vary in their ability to call forth g and thus helps predict where in life higher levels of intelligence are most useful. Stated another way, mental tests can now be used to

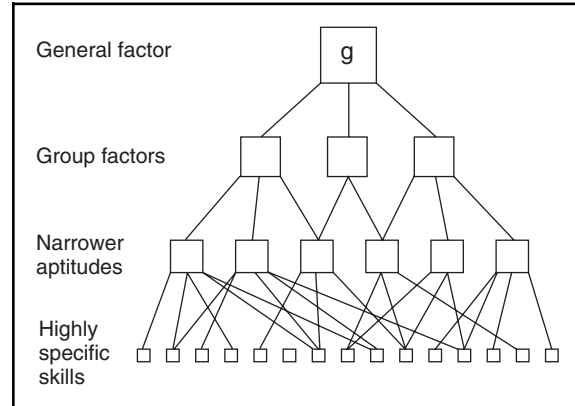

Figure 2

compare environments, not just people, and figure out why some environments are more cognitively demanding than others.

Evidence suggests that tasks are more g -loaded when they require more complex information processing, for example, when there are more pieces of information, when there are more operations to perform, and when the information is abstract, nested or incomplete. For instance, spelling and arithmetic tests pose much less complex and g -loaded tasks for adolescents and adults than do vocabulary and mathematical reasoning tests. Spelling and computing well in adolescence and beyond depends less on g level than does comprehending higher-level verbal and mathematical concepts, despite their superficially similar content.

As will be seen, many work tasks and occupations have been ranked in their demands for g . In theory, a g loading can be calculated for virtually everything we do in daily life. Life is like a series of mental tests in the sense that its demands vary considerably in complexity and consequent g -loading. This means that the advantages of being brighter will vary systematically across different life settings according to their cognitive complexity.

The finding that the subtests in an IQ test battery differ systematically in their ability to measure g has been cleverly used to explore the biological as well as the sociological meaning of g . By the method of *correlated vectors*, the g -loadings of IQ subtests are themselves correlated with other attributes of the subtests. For example, tests' g -loadings have been found to predict the genetic

heritability of their scores, degree of inbreeding depression, and the subtests' correlations with brain size, faster glucose metabolism in the brain, and greater complexity and speed of onset of various electroencephalogram (EEG) brain waves. This pattern of correlations reinforces other findings which suggest that g is a biologically grounded capability to process complex information regardless of its explicit content.

Mental test scores—including the IQ—are composed of both g and non- g components, however. The non- g component might reflect more specific abilities, specific bits of cultural knowledge, aspects of personality or the testing situation, or other unspecified impurities that are independent of g . The decomposition of test scores into their g versus non- g components is also an enormously important development for understanding the meaning of intelligence. For example, it has been shown that it is almost exclusively the g component, not the non- g components, of tests that accounts for their ability to predict later school achievement and job performance. This considerably narrows the range of possible explanations for why IQ tests predict differences in individuals' later achievement. The explanation cannot reside mostly in the context-specific bits of knowledge that an IQ might reflect, but in the highly general mental capability that g represents in all contexts and cultures.

Experimental Study of the Components of g .

If psychometrics has discovered that g is a very general information-processing capability, laboratory studies of intelligence are aimed at teasing out its components or building blocks. The debate among experimentalists has been about whether individual differences in general intelligence are more like differences in computer hardware or computer software. Both views, however, perceive differences in g or IQ as differences among individuals in the speed and quality of their information processing.

The “software” view argues that differences in intellectual performance originate in the better or worse use of the same hardware, for example, in the use of better strategies or algorithms for using information and solving problems. These *metacognitive* skills might include better allocation of time to the different components of a problem, monitoring of

progress or responding to feedback, and otherwise better controlling how the different components of a task are executed. Such studies might look, for example, at the kinds of planning subjects use in solving verbal analogies or the ways they use their time in comprehending a passage of text. In this view, the general factor g reflects not a general underlying ability but the greater conscious use of separate planning and control strategies of general value, in all of which individuals could presumably be trained.

The “hardware” view postulates that differences in the speed and quality of information processing originate in differences in basic brain physiology, such as nerve conduction velocity. The great enthusiasm over the “top-down” software view during the 1970s and 1980s waned as research began more and more to support the claims of the “bottom-up” hardware view of intelligence. People can indeed be observed to use different strategies in solving problems, but differential motivation, effort, or strategy use do not seem to account for IQ differences, and the successful strategies are fairly task-specific.

Although research has not yet proven that differences in lower-level information processing abilities actually *cause* differences in higher-level ones, measures closer to the physiological level offer more promising explanations of g (Vernon 1993). For example, simultaneous recordings of subjects' RTs and brain-wave activity (specifically, average evoked potentials [AEP] measured by the EEG) have shown that speeds of ECT responses are moderately to highly correlated with complexity and speed of onset of certain brain waves, both of which occur in less time than required for *conscious* awareness of a stimulus. Much other research shows that both ECT and AEP responses are, in turn, moderately to highly correlated with IQ scores and, most importantly, with g itself. The g factor is the only mental ability with which ECT scores correlate.

Accordingly, some intelligence researchers now argue that intelligence may not be an ability per se, but rather a chemical, electrical, or metabolic property of the brain. Specific aptitudes, such as verbal and spatial ones, appear to reside in particular regions of the brain, but g may represent a global property permeating all regions. Nerve conduction velocity is currently being investigated as

one such possible global property. Differences in velocity may in turn result from differences in nerve myelination (myelin is the fatty sheath around nerve axons). While still speculative, the velocity and myelination hypotheses are consistent with a well-established pattern of differences that any putative cause of intelligence will have to explain, namely, both the steady rise and then fall of fluid intelligence over the life cycle as well as the enduring differences in g among people at any single age.

Popular Contending Theories. Any theory of intelligence must take into account the basic facts about intelligence, whether it is measured as IQ or g . These include its high generality, heritability (discussed shortly), and correlations with elementary perceptual and physiological processes of the brain. Some of the theories that are most popular outside expert circles contradict or ignore these facts and thus are not viable contenders to the emerging g theory of intelligence. Others remain untested hypotheses. The major contenders to g theory can be characterized as either *specificity* or *multiplicity* theories of intelligence.

Specificity theories. Some scholars have argued that intelligence is not an underlying ability but merely the accumulation of specific *bits of knowledge*. For them, being “smart” is nothing more than knowing a lot, no matter how much time and effort went into that learning or what was learned. It is akin to the accumulation of marbles in a jar, signifying nothing other than that many marbles have been collected by whatever means. The apparent assumption is that people do not differ in their ability and efficiency in gathering marbles. However, intelligence has to be more than knowledge per se because, among other reasons, differences in intelligence show up on tests that require no knowledge whatsoever. Moreover, as noted, people differ greatly in their ability to acquire knowledge even when given the same opportunity to learn. There are “fast” students and “slow” students, irrespective of motivation and quality of instruction. For many experts, differences in the ability to *acquire* knowledge are at the heart of intelligence.

Another variant is the *cultural specificity* theory, which is that intelligence is merely the display of traits, whatever they may be, that are highly regarded in a particular culture. For example, one

claim is that because IQ tests are typically developed by white European males, they inevitably measure beliefs, behavior, and knowledge that white European males value but that may have no intrinsic value. Intelligence, they say, might be defined completely differently in another culture, such as skill at hunting, navigating, or cooperating for the general good. The first claim is false and the second is irrelevant, even if true. As noted, the same g is extracted from all diverse sets of mental tests and for all cultural groups. (Besides, Asians tend to do better than whites on tests developed by the latter.) Whether different cultural groups recognize, value, and reward the phenomenon represented by g is interesting and important, but it does not erase the phenomenon itself as a scientific fact any more than rejecting the concept of evolution brings evolution to a halt.

Perhaps the best-known variant is the *academic specificity* theory, which says that IQ and intelligence are simply “book smarts,” a narrow “academic” skill that is useful inside but not outside schools and bookish jobs. According to this theory, intelligence may be an enduring personal trait, but only a narrow one. As will be shown, g is indeed highly useful in education and training. However, the very generality of g —the ability to deal with complexity, to learn, and to avoid mistakes—argues against the narrow “book smarts” conception of intelligence. So, too, does much research, discussed later, on the many practical advantages conferred by higher levels of g . Carpenters as well as bank tellers, sales agents as well as social scientists, routinely deal with complexity on the job and are aided by higher levels of g .

Multiplicity theories. Robert Sternberg (1985) argues that there are several intelligences, including “analytical,” “practical,” and “creative.” Howard Gardner (1983) is famous for postulating eight and possibly nine intelligences: linguistic, logical-mathematical, musical, spatial, bodily-kinesthetic, intrapersonal, interpersonal, naturalist, and (possibly) existential. Daniel Goleman’s 1995 book on “emotional intelligence” has taken the country by storm. All three theories are engaging, are popular in lay circles, and describe undeniably important skills, knowledges, and achievements. All three theories suggest that g , if it exists, is only one of various coequal abilities. This is, indeed, why multiple intelligence theories are so popular. They are

often interpreted—wrongly—as suggesting that everyone can be smart in some useful way.

The question, however, is whether the “intelligences” these theories describe are actually comparable to *g* in any fundamental way. Specifically, are they even abilities, or might they be the *products* (literary, scientific, or artistic) of exercising *g* together with specific abilities in specific settings with specific kinds of training and experience? Are the purported intelligences even *mental* rather than, say, physical abilities or aspects of personality? And for those that are mental abilities, are they comparable to *g* in their *general applicability*? Unfortunately, the research necessary for answering these questions credibly has not been conducted. Almost none of the “multiple intelligences” has actually been measured, and none have been shown independent of *g* in representative samples of the population. Verbal descriptions of them leave many experts doubtful that they are comparable to *g* in any important way.

Some of them, like emotional intelligence, seem to be a combination of many different traits, some being abilities and others not, some being mental and others not. Verbal definitions suggest that practical intelligence (like “street smarts”) may be the accumulation of highly context-specific knowledge gathered through strictly informal experience (for example, knowing the special argot and norms of a particular neighborhood, occupation, or other subculture). Gardner’s intelligences are different forms of highly valued cultural accomplishment. As such, they require not only the ability to succeed but also the personality traits, such as drive and persistence, needed to transform that potential into a valued product. This is not to deny that personality is important for great accomplishment, but only that it is useful to distinguish between the separate ability, personality, and other factors contributing to it.

In addition, some of Gardner’s intelligences seem to mirror more specific and psychometrically well-studied traits, such as verbal, mathematical, and spatial aptitude. Much research has shown that these so-called group factors are highly correlated with *g* but appear below it in the hierarchical structure of human mental abilities (see Figure 2). Gardner himself has stated that exemplary levels of all his intelligences require IQ levels over 120,

meaning that the eight intelligences are not alternatives to *g* but narrower abilities pervaded by it. In short, they appear to be different cultural playgrounds for the cognitively rich. All the purported “multiple intelligences” are important topics for study, but they cannot be assumed to be comparable to *g* in either generality or practical importance by virtue of being labeled “intelligences.”

HERITABILITY AND ENVIRONMENTALITY OF INTELLIGENCE

Behavioral genetics is a method for studying the influence of *both* genes and environments on human behavior. In recent decades the field has shown that mental abilities, personality, vocational interests, psychopathology, and even social attitudes and life events are shaped by both genes and environments (Loehlin 1992; Plomin et al. 1997). More research has been conducted on the heritability of intelligence than on any other psychological trait, and much of it has been longitudinal.

Behavioral genetics focuses on explaining *variation* in a particular population. Its basic method is to look at similarities between relatives of different degrees of genetic and environmental relatedness: identical twins reared apart, adopted siblings reared together, identical versus fraternal twins, and so on. Such research can also test, among other things, whether *specific* environmental factors create IQ similarities and differences and, if the research is longitudinal, whether change (and stability) in IQ ranking is due to the operation of genes, environments, or both. It can also test whether two heritable traits or behaviors, such as IQ and academic achievement, share the same genetic and environmental roots.

Such research does not reveal *how* genes affect intelligence, only that they do. Explanations of how genes influence intelligence will come from molecular genetics, which has only recently isolated the first gene for intelligence. Molecular genetic research also holds promise for detailing exactly how environments might influence the actions of genes.

Individual Differences. Behavioral genetics has focused historically on explaining differences among individuals *within* a population. The following such findings should be generalized only to the sorts of populations studied so far, most of

them Western and none extreme in terms of either deprivation or privilege.

IQ is substantially heritable. Heritability (h^2) refers to the percentage of observed differences in a trait (in *phenotypes*) that is due to differences in genes (*genotypes*). Estimates of the heritability for IQ typically range between .4 and .8 (on a scale from 0 to 1.0). This means that from 40 percent to 80 percent of the observed differences in individuals' IQs are due to the genetic differences among them. This means, conversely, up to 20 percent to 60 percent of IQ differences are environmental in origin. Aptitudes measured by the most *g*-loaded tests are the most heritable. Aptitudes measured by tests of more specific abilities, such as verbal and spatial visualization, are moderately heritable, but less so than *g*.

IQ heritability rises with age. This discovery was a surprise even to behavioral geneticists because, like virtually all social scientists, they had assumed that environmental effects cumulate over a lifetime to reduce the influence of genes. Not so, apparently. The heritability of IQ is about .4 in the preschool years, rises to .6 by adolescence, and increases to about .8 in late adulthood. The reason for this increase is unclear. The major hypothesis, however, is that "genes drive experience" and lead people to seek different social niches. That is, different genotypes tend to choose, create, and elicit different environments in childhood and beyond, which in turn shape intellectual development. For example, bright and dull youth receive different encouragement and opportunities. They also tend to choose different experiences for themselves, especially as they become more independent of parents, teachers, and other authorities. As individuals take a greater hand in shaping their environments, for better or worse, their IQ phenotypes begin to mirror their IQ genotypes more closely. The correlation between IQ phenotypes and genotypes (which is the square root of heritability) rises to .9 by later adulthood.

The surprising rise in heritabilities is consistent with the disappointing results of socioeducational interventions (similar to Head Start) that were designed to raise low childhood IQs. To date, all have exhibited *fade-out*, meaning that the initial improvements in IQ dissipated within a few years. Improvements in more malleable outcomes (such as fewer children being held back a grade) may be

observed, but permanent rises in *g* are not. The same IQ fade-out occurs with genetically at risk children adopted into more advantaged families: By adolescence, their early favorable IQs fall back to the average for their nonadopted biological relatives.

IQ-relevant environments are partly genetic in origin. Social scientists have tended to think of environments as conditions strictly "out there" to which people are passively "exposed." Children's environments correlate with their genes, however, partly because they passively receive both from their parents. People's environments are also heritable to some degree because people choose, make, remake, elicit, and interpret them. Because people's genetic proclivities help shape their environments, real and perceived, behavioral geneticists often refer to people's proximal environments as, in effect, their *extended phenotypes*. That is, people's near environments are to some degree an extension of themselves because they are partly *products* of the person's genotype for intelligence, personality, and the like.

When people's environments are studied with the same behavioral genetic techniques as are their psychological traits and behaviors, research consistently shows that rearing environments, peer groups, social support, and life events are, in fact, moderately heritable. For example, one measure of individual infant and toddler rearing environments found that those environments were 40 percent heritable. Moreover, half of the environmental measure's ability to predict cognitive development could be accounted for by that measure's genetic component. In other words, IQ-relevant environments are partly genetic in origin. This is an example of what behavioral geneticists refer to as the operation of nature *via* nurture.

Shared family effects on IQ dissipate by adolescence. Behavioral genetic research confirms that environments have substantial influence in creating IQ differences. However, providing yet another surprise, the research showed that environmental influences had been completely misunderstood. Psychologists-behavioral geneticists David Rowe (1994) and Sandra Scarr (1997) call this mistaken view, respectively, "family effects theory" and "socialization theory." This is the still widespread but false assumption that differences between families in their socioeconomic circumstances (income,

parental education, occupation, income, and so on) and child-rearing styles (cold, authoritative, and so on) create differences between their children in ability and personality. These presumed effects are called *shared* or *between-family* influences because they affect all children in the family in the same way and thus make children in the same families more alike and children in different families less alike.

As it turns out, such shared effects influence IQ (but not personality) in early childhood, but they disappear by adolescence. Nor is it known what these temporary influences are. The only environmental effects that continue to influence IQ beyond adolescence are *nonshared* or *within-family* effects on IQ. Nonshared effects are factors that influence one sibling but not others in a family. What they consist of regarding IQ is not yet known, but they could include random biological events, illness, and differential experiences in parent-child or sibling relationships. Nonshared effects help to explain why biological siblings who grow up together are so different in IQ. They differ by about 12 IQ points, on the average, compared to the average 17-point IQ difference between any two random strangers. Much of that difference is due to their genetic differences, however, because biological siblings share, on the average, only 50 percent of their segregating genes.

The dissipation of “family effects” and the rising influence of genes with age can be seen clearly in adoption research. The IQs of adopted siblings are similar in childhood but not in adolescence. By adolescence, their IQs also cease to resemble the IQs of their adoptive parents but become more like the IQs of the biological parents they have never known.

Special abilities, ECTs, and school achievement have common genetic roots with g. As noted, there are many mental abilities, whether at the level of ECTs, such as choice reaction time, or at the level of group factors, such as verbal ability. However, they all correlate with *g*. To the extent that they overlap each other and *g* phenotypically, that overlap is due almost entirely to a common genetic source. Conversely, only a small portion of the genetic component of specific aptitudes—such as verbal skills, memory skills, and speed of processing—is not *g*-related. The same general pattern is

found for the sizable correlation between academic achievement and IQ. To the degree that they correlate, that similarity is almost entirely genetic; to the degree that they diverge, the cause is mostly environmental.

IQ stability is mostly genetic in origin whereas age-to-age change in IQ rank originates mostly in nonshared environments. Rank in IQ relative to age-mates is highly stable. Genes and shared environments both contribute mostly to IQ stability rather than to age-to-age change. It is the nonshared environment that causes age-to-age change. Marked change is rare and tends to be idiosyncratic, transient, and difficult to attribute to any particular event.

Cautions in interpreting heritabilities. High heritabilities do *not* mean that a trait is not malleable. Heritability and malleability are separate phenomena. Certain heritable conditions (such as diabetes) are treatable and certain nongenetic effects (such as those of lead poisoning) are not. All that a high heritability means is that current differences in environmental conditions do not create much intelligence variation beyond that owing to genetic differences. If environments were equalized for everyone, phenotypic variation might be reduced somewhat, but heritability would rise to 100 percent. In contrast, if environments could be individually tailored to compensate for genetic differences (by providing insulin for diabetics, changing the diets of those with phenylketonuria, providing the best education to the least intelligent, and the like), both heritability and variability would fall.

Moreover, heritability is the degree to which genes explain phenotypic *variance* in a trait, so a high heritability does not rule out shifts in population *averages* over time. Something that affects everyone can change a group’s average without changing its variability. Recent generations have been getting taller, but height is still highly heritable within generations. The same is true for IQ levels, which have been increasing several points a decade this century in developed countries. Both increases are still scientific puzzles, but some scholars have suggested a common explanation—societywide improvements in nutrition, reduction in disease, and the like. Researchers have yet to establish, however, to what extent the rises in IQ reflect increases in the *g* versus non-*g* components of mental tests and thus an increase in *g* itself.

What is clear, however, is that *shared* family environments that vary within the *normal* range of family environments in the developed world do *not* have create lasting differences in IQ. Within the normal range of variation, different families have basically the same effects in promoting mental growth. The key to understanding how environments create IQ differences among age peers lies in understanding *nonshared* effects. These are the environments, whether biological or social, and both within and outside family settings, that affect siblings differently and make them less alike. The shattering of shared effects theory as an explanation for adult differences in IQ is a revolutionary development, albeit one yet to be accepted by many social scientists. The discovery of lasting nonshared influences opens exciting new ways of thinking about IQ-relevant environments. We may have been looking in all the wrong places. Behavioral genetics provides the best tools at present for ferreting out what those nongenetic factors are.

To reiterate a cautionary note, we do *not* know the effects of environments that are extreme or that do not allow individuals the personal freedoms that most Westerners enjoy. We do not know, either, what the effects of entirely novel environments or interventions would be, whether social or biological. We can predict, however, that any social or educational intervention would have to fall outside the normal range of variation already studied in order to change the distribution of IQs very much. For instance, supplying a typical middle-class family environment to all lower-class children cannot be expected to narrow the average IQ gap between middle- and lower-class adolescents. Middle-class children themselves range across the entire IQ spectrum (as do lower-class children) despite the advantages (or absence thereof) of middle-class life.

Group Differences. There is little scientific debate anymore about whether valid *phenotypic* differences exist among races, ethnicities, and social classes. Average group differences in IQ are the rule, not the exception, both worldwide and in the United States. To the extent that the matter has been investigated, group IQ differences appear to reflect differences in *g* itself and are mirrored by group differences in performance on the simple laboratory tasks described earlier.

Group IQ differences can be pictured as the displacement of the IQ bell curves of some social groups somewhat upward or downward on the IQ continuum compared to others. All groups' bell curves overlap greatly; the differences consist in where along the IQ continuum each group is centered. Ashkenazic Jews tend to score as far above average (about IQ 112) as American blacks score below average (about IQ 85), with most other groups spread in between. It should be noted, however, that black cultural subgroups differ among themselves in average IQ, as do the constituent subgroups of Jews, gentile whites, Asians, Hispanics, and Native Americans.

The most contentious debate regarding intelligence is whether average group IQ differences are partly genetic in origin. The favored assumption in the social sciences for the last half-century has been that race differences are entirely environmental. However, research designed to prove this has not done so. It has succeeded in finding environmental factors that might possibly explain at most a third of the American black-white average difference. This failure does not rule out an entirely environmental explanation based on factors yet to be assessed. It does rule out several factors, however, that were once assumed to account for the bulk of the average difference, namely, family income and social class. Large average IQ differences between black and white children are found at all levels of family income and social class.

Behavioral geneticists have recently developed statistical methods for estimating the extent to which average differences among social groups (races, sexes, and so on) might be due to genetic differences among them. Perhaps not surprisingly, few behavioral geneticists have actually applied those methods to available data, and those who have been willing to do so have experienced unusual barriers to publishing their results. As a result, there is little direct published evidence one way or the other. When surveyed in 1988, about half of IQ experts reported a belief that race and class differences result from *both* genetic and environmental influences. This should be considered a reasonable but unproven hypothesis.

The earlier caution should be repeated here. Research has so far studied only the normal range of environmental variation within any race or ethnic group. American minority children may

more often grow up in extremely deprived environments. Studies of very low-IQ Appalachian communities suggest that biologically unhealthy and cognitively retarded family environments can permanently stunt cognitive development.

Some people fear that any evidence of genetic differences between groups would have dire social consequences. This fear is unwarranted. A demonstration of genetic differences would not dictate any particular political reaction. Both liberal and conservative social policy can humanely accommodate such an eventuality, as some policy analysts and behavioral geneticists have illustrated (Kaus 1992; Rowe 1997). Depending on one's politics, for example, genetic differences by race could be used to argue either for forbidding or for requiring racial preferences in education and employment. Moreover, environmentalism and hereditarianism have both on occasion helped undergird tyrannical regimes that practiced mass murder, for example, respectively, the Stalinist Soviet Union and Nazi Germany. Political extremism (or moderation) is neither guaranteed nor precluded by scientific conclusions one way or the other. Scientific facts and political reactions to them are independent issues. Developing *effective* social policy does depend, however, on working in concert with the facts, not against them, whatever they may be.

SOCIAL CORRELATES AND CONSEQUENCES OF DIFFERENCES IN INTELLIGENCE

Much research has focused on how *individuals'* own behavior and life outcomes are affected by their intelligence level. There has been little research yet on what may ultimately interest sociologists more, namely, the ways in which *interpersonal contexts* and *social institutions* are shaped by the cognitive levels of the individuals populating them.

Individual Level. American adults clearly value intelligence highly because they rate it second only to good health in importance. Differences in intelligence do, in fact, correlate to some extent with just about everything we value, including mental and physical health, success in school and work, law-abidingness, emotional sensitivity, creativity, altruism, even sense of humor and physical

coordination. The scientific question, however, is whether differences in intelligence actually *cause* any of these differences in people's behaviors and outcomes. Or might intelligence as often be their consequence as their cause?

Questions of causality. Most IQ variability is genetic from adolescence on, meaning that it cannot be mostly "socially constructed." Moreover, to the extent that it has nongenetic sources, evidence leans against their being the usual suspects in social research (parents' income, education, child-rearing practices, and the like). If intelligence is not caused (much) by its major social correlates, does it cause them?

Pieces of an answer are available from experimental and quasi-experimental research conducted by educational, employment, and training psychologists in public, private, and military settings for more than a half-century. Differences in *prior* mental ability are strong—in fact, the strongest—predictors of *later* performance in school, training, and on the job when tasks are at least moderately complex. Moreover, the correlations are stronger with objective than subjectively measured performance outcomes (for example, standardized performance rather than teacher grades or supervisor ratings). The military services also have extensive experience attempting to nullify the effects of ability differences on recruits' later performance in training and on the job. Their failed attempts testify to the stubborn functional import of such differences—as does the failure of lengthy job experience to neutralize differences in worker intelligence.

IQ is moderately highly correlated with a nexus of good outcomes—higher education, high-status jobs, and income growth over a career. In view of the *g*-loadedness of the educational and occupational worlds, it would be surprising were IQ not found to be an important precursor to these outcomes. IQ is, in fact, the best predictor of later educational level attained, and it helps predict occupational status and income growth even after controlling for education and family background.

IQ is also correlated to varying degrees (negatively) with a nexus of bad outcomes—dropping out of school, unemployment, incarceration, bearing illegitimate children, dependence on welfare, and living in poverty as an adult. This nexus of

social pathology has been the focus of recent lively debates about the role of intelligence, where protagonists typically pit intelligence against an array of external factors, including various aspects of family background, to see which is the stronger predictor. Intelligence generally equals or exceeds the predictive ability of any small set of such variables, although the relations tend to be modest in both cases. One possible explanation for the relation of IQ to social pathology is that lack of socioeconomic competitiveness may precipitate a downward social spiral.

However, IQ may play a direct role, too. Committing crimes, bearing illegitimate children, and other such personal behavior may result in part from errors of judgment in conducting one's life, perhaps due in part to lack of foresight and ability to learn from experience. Conversely, higher *g* may help insulate people from harmful environments. Research has shown, for instance, that higher intelligence is a major attribute of "resilient" children, who prosper despite terrible rearing conditions, and of those who avoid delinquency despite living in delinquent environments. The hypothesis is that their greater ability to perceive options and solve problems constitutes a buffer.

Either the genetic or nongenetic components of phenotypic intelligence might be responsible for its causal impact. Because intelligence is highly genetic, it is reasonable to assume that its causal impact is mostly due to its genetic component. This has, in fact, been found to be the case with its effect on standardized academic achievement. The latter shares all its genetic roots with IQ. Similar *multivariate genetic analyses* are now accumulating for various socioeconomic outcomes that depend on mental competence. Educational and occupational level are both moderately genetic in origin, with estimates (for males) ranging from .4 to .7 for education and .3 to .6 for occupation. Part of that genetic portion overlaps the genetic roots of IQ. In the best study so far (Lichtenstein and Pedersen 1997), occupational status was more than half genetic in origin. Half that *genetic* portion was shared jointly with the genetic roots of *both* IQ and years education, and half was independent of both. The remaining variability in phenotypic occupational status was split between *nonshared* environmental effects that (1) were shared with education (but not IQ) and (2) were unique to occupation.

One of the biggest confusions in the debate over the causal role of intelligence results from the mistaken equating of intelligence with genetic factors and of social class with nongenetic factors by some of the most visible protagonists in the debate. While the former assumption has some justification owing to the high heritability of *g*, it nonetheless muddies the conceptual waters. The latter assumption is even less warranted, however, because many social "environments" turn out to be moderately genetic. All social "environments" must now be presumed partly genetic until proven otherwise. Not being genetically sensitive, virtually all current research on the effects of social and family environments is actually uninterpretable. Progress in the causal analysis of environments and their relation to *g* will come only when more social scientists begin using genetically sensitive research designs.

Principles of importance. Although the causal role of intelligence has yet to be clarified, research leaves no doubt that people's life chances shift markedly across the IQ continuum. Those shifts in specific life arenas will be discussed later, but it would help first to state four principles that summarize what it means for intelligence to have *practical importance* in individuals' lives.

First, importance is a matter of better *odds*. Being bright is certainly no guarantee of happiness and success, nor does being dull guarantee misery and failure. Most low-IQ people marry, work, have children, and are law-abiding citizens. Being brighter than average does, however, systematically tilt the odds toward favorable outcomes. Higher levels of intelligence always improve the odds, sometimes only slightly but often substantially, depending on the outcome in question.

Second, importance *varies systematically* across different settings and life arenas. Intelligence level tilts the odds of success and failure more in some arenas of life (such as academic achievement) than others (such as good citizenship). For instance, the correlations of IQ with years of schooling completed (.6) and composites of standardized academic achievement (.8) are over twice that for IQ correlations with delinquency (-.2 to -.3). Correlations in the same life arena can also vary depending on complexity of the tasks involved. For instance, correlations of job performance with test scores

range from .2 in unskilled work to .8 in the most cognitively demanding jobs.

Third, importance is *relative* to other known influences and one's particular aims. Many personal traits and circumstances can affect the odds of success and failure in different arenas of life. Intelligence is never "everything" in the practical affairs of life. Depending on the outcome in question, personality, experience, peers, family background, and the like can tilt the odds of success, sometimes more than intelligence does and sometimes less. As noted earlier, IQ predicts standardized achievement better than it does persistence in education, probably because personality and circumstances affect the latter much more than the former. Weak prediction at the individual level does not mean the predictor is unimportant in a pragmatic sense, as illustrated by the relation between delinquency and social class. The correlation is generally below $-.2$ but usually thought quite important for policy purposes, as is the similarly low correlation at the individual level between smoking and various health risks.

Fourth, importance is *cumulative*. Small individual effects can be quite important when they cumulate across the many arenas and phases of one's life. Many of *g*'s daily effects are small, but they are consistent and ubiquitous. Like the small odds favoring the house in gambling, people with better odds win more often than they lose and can thus gradually amass large gains. Likewise, although smart people make "stupid" mistakes, they tend to accumulate fewer of them over a lifetime. Although the odds of any particular unfavorable outcome may not always be markedly higher in the lower IQ ranges, lower-IQ people face worse odds at every turn in life, meaning that their odds for experiencing *at least one* destructive outcome may be markedly higher.

Education and training. Schooling is the most g-loaded setting through which citizens pass en masse. Its unremitting demand is to learn and, moreover, to learn increasingly complex material as young people progress through it. It therefore highlights the intellectual distinctions among citizens better than does any other life setting and in ways plainly visible to the layperson. To be sure, schools enhance everyone's cognitive development, but they currently seem to have little impact on making

people either more alike or less alike in intelligence. Sociologist Christopher Jencks estimated in 1972 that if quantity and quality of schooling were made identical for everyone, such equalization would reduce the variance in test scores by only 20 percent. When Poland's Communist government rebuilt Warsaw after World War II, it allocated housing, schools, and health services without regard to residents' social class. This far-reaching equalization of environments did little or nothing either to equalize the IQs of the next generation of children or to reduce the correlation of their IQs with parental education and occupation (Stein, Susser, and Wald 1978).

As already noted, brighter students and military recruits learn much more from the same learning opportunities and often require less than one-fourth the exposure than do their less able peers for the same degree of learning. This difference in ability to capitalize on learning opportunities also greatly influences the maximum level of attainment youngsters are likely to reach. People with an IQ of 75 (the threshold for mental retardation) have roughly only a 50-50 chance of being able to master the elementary school curriculum; an IQ of about 105 is required for the same odds of getting grades good enough in high school to enter a four-year college; and an IQ of 115 is required for 50-50 odds of doing well enough in college to enter graduate or professional school.

Figure 3, similarly to Figure 1, summarizes accumulated employer experience about the most effective sorts of training for people at different ranges of IQ. Figure 3 is based on research with the Wonderlic Personnel Test (WPT), a short group intelligence test. Above the WPT equivalent of IQ 115-120 (which includes about 10 to 15 percent of the general white population), people can basically train themselves; the middle half of the IQ distribution (IQ 91-110) can learn routines quickly with some combination of written materials, experience, and mastery learning; but people below IQ 80 (10 percent of the general white population) require slow, concrete, highly supervised, and often individualized training. The military is prohibited by law from inducting anyone below this level because of inadequate trainability, and current minimum standards exclude anyone below the equivalent of IQ 85.

INTELLIGENCE

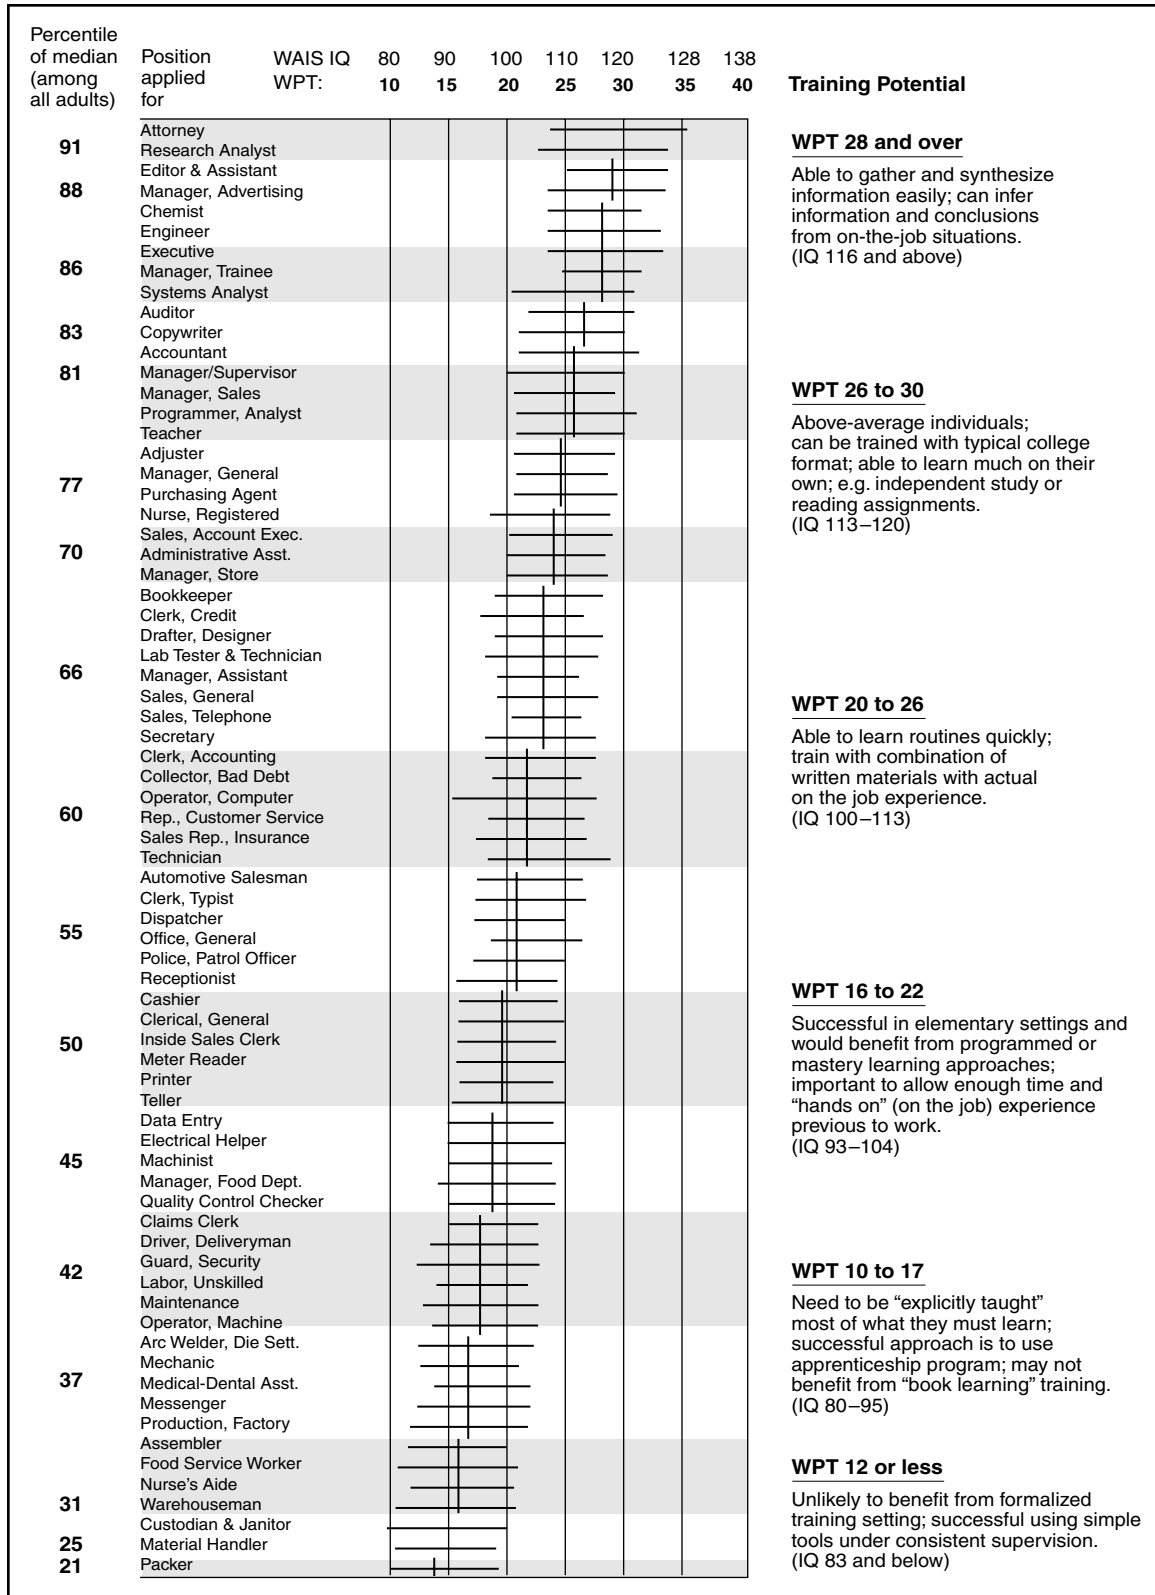

Figure 3

Employment. Many studies have found that the major distinction among occupations in the U.S. economy is the cognitive complexity of their constituent tasks. The most complex jobs are distinguished by their greater requirements for dealing with unexpected situations, learning new procedures and identifying problems quickly, recalling task-relevant information, reasoning and making judgments, and similar higher-order thinking skills that are prototypical of intelligence. Other job attributes that correlate highly with the *occupational complexity factor* include writing, planning, scheduling, analyzing, decision making, supervising, negotiating, persuading, instructing, and self-direction. So, too, do responsibility, criticality, and prestige. As already noted, mental ability test scores correlate most highly with performance in the most complex jobs. That is, differences in intelligence have a bigger impact on performance—"more bang for the buck"—when work is more g-loaded.

Not surprisingly, then, an occupation's overall complexity level correlates extremely highly with the average IQ of its incumbents. As Figure 3 illustrates, all occupations draw applicants from a wide range of IQ, but the minimum and average IQ levels rise with job level. Although wide, the typical IQ recruitment ranges for different occupations do not overlap at the extremes of job level (professional versus unskilled). The average IQ of applicants to middle-level jobs (about IQ 105), such as police work, is 15 IQ points (one standard deviation) lower than for applicants to professional jobs but 15 IQ points higher than for applicants to semiskilled work, such as food service worker. No occupation seems to recruit its workers routinely from below IQ 80.

The foregoing results for jobs suggest a high practical utility for higher intelligence in other aspects of life. Many jobs (child care, sales, accounting, teaching, managing) pose the same mental challenges (persuading, instructing, organizing, and ministering to people) that pervade nonpaid activities (parenting, home and financial management, civic responsibilities, friendships, and so on).

Daily life. Daily life has become considerably more complex during the twentieth century. Increased size, bureaucratization, and regulation of social institutions and services, together with greater

reliance on continually changing information technologies, have greatly increased the cognitive complexity of daily life. Life may be physically easier, healthier, and more pleasant today, but it has become mentally more challenging in developed societies. Some of this complexity is captured well by the U.S. Department of Education's 1992 National Adult Literacy Survey (NALS; Kirsch et al. 1993). Although the NALS was not designed as an intelligence test, it closely mimics the key attributes of an IQ test battery: Its intent was to measure complex information-processing skills by sampling a broad range of tasks from universally relevant contexts and contents; the relative difficulty of its items stems from their complexity, not their manifest content; and its three scales reflect one general factor.

Figure 4 illustrates items at different levels of the three NALS subscales; Figure 1 translates the NALS scores into IQ equivalents. These items do not involve esoteric "book smarts" but represent practical, everyday skills in dealing with banks, restaurants, transportation systems, and social agencies; understanding the news and one's options; and providing basic information about oneself. Nonetheless, about 15 percent of white adults and 40 percent of black adults routinely function no higher than Level 1 (225 or less), which corresponds to 80 percent proficiency in skills such as locating an expiration date on a driver's license and totaling a bank deposit. Another 25 percent of whites and 36 percent of blacks routinely function no higher than Level 2 (226–275), which includes proficiency in such skills as locating an intersection on a street map, entering background information on an application for a Social Security card, and determining the price difference between two show tickets.

These are examples of the myriad daily tasks that require some independent learning and reasoning as one navigates life. None may be critical by itself, but the more often one fails such tasks, the more one is hampered in grasping opportunities, satisfying one's needs and desires, and assisting family and friends. A national education panel concluded, in fact, that Level 1 and 2 skills are not sufficient for competing successfully in a global economy or exercising fully the rights and responsibilities of citizenship. Consistent with this, the

Figure 4

NALS study found that, compared to adults with Level 5 skills (376–500, reached by about 4 percent of whites and less than 0.5 percent of blacks), adults with Level 1 skills were five times more likely to be out of the labor force, ten times more likely to live in poverty, only 40 percent as likely to be employed full time, and 7 percent as likely to be employed in a managerial or professional job—if employed at all.

Two daily activities where mental competence may have life-and-death implications are driving and health behavior. A large longitudinal study of Australian servicemen found that the death rate from motor vehicle accidents for men with IQs above 100 (52 per 10,000) was doubled at IQ 85–100 (92 per 10,000) and tripled at IQ 80–85 (147

per 10,000). The study authors suggested that the higher death rates might be due to poorer ability to assess risks. Medical research has likewise documented that many nonretarded patients have difficulty reading labels on prescription medicine and following simple physician instructions about self-care and future appointments.

Nexus of social pathology. Table 2 shows how the odds of social pathology fall (or rise) the further one’s IQ exceeds (or falls below) the average IQ. It shows the percentages of young white adults in five successive IQ ranges who experience certain bad outcomes. As shown, the odds of incarceration, illegitimate births, poverty as an adult, and the like all double at each successively lower IQ range. The ratios in the last column show how the

odds of bad outcomes thus differ greatly even for people who are only somewhat below average (IQ 76–90) versus somewhat above average (IQ 111–125) in IQ. Among these young white adults, for instance, 17 percent of the former IQ group versus only 3 percent of the latter live in poverty as adults, for a ratio of about 5:1. The odds are less discrepant for some bad outcomes (3:2 for divorce and unemployment) but more discrepant for others (7:1 for incarceration and 88:1 for dropping out of high school). The disparities in odds across IQ groups are even more extreme at the extremes of IQ. Good and bad outcomes can be found at all IQ levels, but what is *typical* differs enormously, as was also illustrated with the NALS data.

Moreover, the odds of dropping out of school, illegitimate births, poverty, and welfare dependence all increase with lower IQ among siblings within the very same family and even when the families are intact and not poor. There is something about below-average IQ itself that puts individuals at serious social risk, whatever their family circumstances.

Overall life chances. Figure 1 and Table 2 together paint a vivid picture of how greatly overall life chances differ by IQ level. People with IQs below 75 are clearly in the “high-risk” zone, where trainability and employability are very low and the odds of various social pathologies are much elevated. Although risks fall substantially for individuals with IQs only somewhat below average (IQ 76–90), these people still face an “uphill battle” because they are not very competitive for many training programs and jobs. The middle 50 percent of the population (IQ 91–110) is competitive for many of a modern economy’s jobs but likely only to be just “keeping up” relative to others. Their brethren of somewhat above-average IQ (IQ 111–125) are more likely “out ahead” socioeconomically because they are highly trainable and competitive for better jobs. Their rates of pathology are also very low. People with IQs above 125 are so competitive cognitively and so seldom hobbled by *g*-related social pathology that socioeconomic success is truly “theirs to lose.”

Interpersonal Context. One of the most fascinating questions in the study of intelligence has received virtually no attention: How does the *mix* (average and variability) of intelligence levels in a

setting—its *IQ context*—affect behavior in that setting? How might one’s fate be affected by the intelligence level of the *other* people in one’s interpersonal settings—of one’s parents, siblings, neighbors, friends, and other close compatriots?

The basic issue is this: A difference in IQ of one standard deviation (about 15 points) is socially perceptible and meaningful. Interpersonal communication becomes fraught with increasing difficulty beyond this distance because of larger gaps in vocabulary, knowledge, and ability to draw inferences or “catch on,” as well as the emotional discomfort such gaps create. Figure 1 reveals how IQ ranges of about one standard deviation also mark off substantial differences in options for education, training, and career, and thus the likelihood of entering different social niches. As shown in the figure, the normal range of intelligence (IQ 70–130, which includes roughly 95 percent of the general white population) spans four standard deviations of IQ. Socially and cognitively, that is an enormous difference. How, then, do people communicate and congregate across the IQ continuum in their daily lives? The average difference between siblings and spouses is about 12 IQ points, which means that most people in a biological family fall within the range of ready cognitive communicability. Any two random people in the population, however, differ by 17 IQ points, which represents the borderline for communicating effectively and as social equals.

Communication, cooperation, and reciprocity. The ability to communicate as equals constitutes a social tie, as does the ability to trade information and assistance. Such reciprocity is the basis of longer-term cooperation. Lack of reciprocity creates not only social distance but also animosity where reciprocity had been expected. There are many bases for cooperation and reciprocity, but sharing information and helping to solve problems is crucial in many settings. Ethnographic studies of middle school children, for instance, show how patterns of mutual assistance and friendship, rather than resentment and unwillingness either to provide help to classmates or to seek it from them, evolve from similarities and differences in students’ competence in answering homework and test items. Similar *g*-driven interpersonal relations can be expected in many workgroups

Percentage of Young White Adults with Particular Life Outcomes, by IQ Level

LIFE OUTCOME	IQ: 75 and Below "Very dull"	76-90 "Dull"	91-110 "Normal"	111-125 "Bright"	Over 125 "Very Bright"	Ratio of Dull to Bright
Out of labor force 1+ mo/yr (men)	22	19	15	14	10	4:3
Unemployed 1+ mo/yr (men)	12	10	7	7	2	3:2

SOURCE: Herrnstein and Murray (1994): (respectively) 158, 163, 174, 230, 180, 132, 194, 247/248, 194, 146.

and other settings in which teammates depend on one another for technical competence.

People of markedly different ability levels also tend to have different interests, which further impedes their ability to develop rapport. Assortative mating studies show that individuals explicitly seek mates of similar IQ levels and that spouses' IQs are, in fact, moderately correlated (about .4), perhaps more so than any other personal characteristic (except gender). Cognitive incompatibility is certainly responsible for the extreme social isolation often experienced by both the mentally retarded and the highly gifted. Extremely gifted children, who may be four standard deviations or more above average (IQ 160 and above), often feel, and are treated as, alien. These children are as different from the borderline gifted (IQ 130) as the latter are from the average child (IQ 100). With extraordinary vocabularies for their age, the highly gifted speak virtually a different language from their agemates. Although less extreme, the same type of alienation develops across much smaller

gaps in IQ. In short, cognitive similarity seems to affect the formation of social bonds, which themselves are the building blocks of "social structure."

Social separation and segregation. Because rough similarity in *g* promotes interpersonal reciprocity and rapport, it should not be surprising that people segregate themselves somewhat by cognitive ability when free to do so, marriage being the most intimate example. Segregation occurs along IQ lines for other reasons as well, many related to the functional value of intelligence in obtaining higher education and better work.

In the typical school, students enter grade 1 spanning at least mental ages four to nine, which translates quickly into markedly different grade-equivalent achievement levels. By reducing *g* variability within learning groups, ability grouping and tracking represent schools' attempt, albeit a perennially controversial one, to accommodate students of different cognitive levels. Its pedagogical merits aside, grouping reinforces friendships within IQ ranges and is but the first of many ways by

which schools and employers direct individuals toward different occupational and income groups, and thence into residential neighborhoods, partly along IQ lines.

A 1933 epidemiological survey in New York City documented that the *average* IQ levels of white school children across a large sample of the city's 273 Health Areas ranged from 74 to 118, a range of three standard deviations. The parents of these children would differ even more in average IQ. Consistent with genetic expectations, parents of any ability level produce children at virtually all ability levels, but their children's average IQ is closer to the population average than is their own.

Social clustering along IQ lines can be expected to increase familiarity, communication, and mutual assistance by enhancing within-group similarity, at least when the groups are minimally competent. Enhanced similarity can elevate the risks of low IQ, however, when IQ clustering results in a *critical mass* of individuals below some *critical threshold* in IQ. That threshold may be IQ 75, which is the level below which individuals need considerable assistance from family, friends, or social agencies to live independently in modern societies. When critical mass is reached in a family or community, networks of competent help become overwhelmed by sticky webs of bad judgment, which in turn produce a physically unhealthy and socially dysfunctional environment for all members, as sympathetic social anthropologists have documented.

In any case, greater *within-group* similarity produces greater *between-group* dissimilarity and distance. A contested but reasonable hypothesis of Richard Herrnstein and Charles Murray's 1994 book, *The Bell Curve*, is that society is becoming *increasingly* stratified along cognitive lines, jeopardizing national unity. That specter raises much anxiety in democratic societies, perhaps accounting for the quick distaste the thesis roused in many quarters. Any societal divisions that *g* creates would, however, be softened somewhat by *g*'s genetic basis. The laws of genetics guarantee that many children will differ substantially from their parents, producing intergenerational mobility across IQ and social-class lines and thereby assuring some cross-group ties. Whether or not it is increasing over time or permeable in nature, social clustering by *g* is nonetheless considerable. It is therefore a

perennial matter of public debate, whether the question be where to locate Section 8 or other public housing or how to integrate social classes and races in educational settings.

Social networks and subcultures of attitudes, behavior, and knowledge. *The Bell Curve*'s thesis about the dangers of cognitive stratification rests in its assumption that different cognitive strata create distinct and somewhat discordant cultures. Sociologist Robert A. Gordon (1997) has outlined at the level of small groups how different IQ contexts do actually represent different subcultures. These different subcultures in turn expose their members to different experiences, risks, knowledge, opinions, assistance, and expectations, as suggested earlier. IQ-discrepant subgroups, for example, differ not so much in the social ideals they espouse as in tolerance for their violation. They also differ in the degree to which they diffuse news and information from the broader culture rather than propagate rumor, misinformation, and even the AIDS virus.

The New York City neighborhoods mentioned earlier differed not only in IQ but also in rates of birth, death, infant mortality, and juvenile delinquency, illustrating that different IQ contexts probably constitute notably different social milieus for developing children. Children of, say, IQ 100 surely live different lives with different opportunities when raised in IQ contexts of 85 versus 115, both of which are common in the United States. Not only is such a child substantially above average in the first context while below average in the second, which creates its own opportunities and obstacles for the child, but there are also significant differences across the two contexts in the quality of ambient advice, information, and personal examples. Children's IQ levels seem not to be permanently affected by their IQ contexts, but their more malleable behaviors and outcomes may be, as studies of youthful career aspirations and delinquency suggest. Epidemiological analyses of the *g*-related contagion of certain risky health and social behaviors would further illuminate how risks rise or fall according to the level of "local intelligence" in which one is embedded.

Societal Level. The interpersonal contexts that influence an individual's behavior are themselves shaped partly by the *g* levels of the people inhabiting them, as just described. IQ contexts thus represent an impact of *g* on an individual level that is

above and beyond the effects of that individual's own IQ. IQ contexts have "macro" as well as "micro" effects in a society, however, because they create gradients of information flow, status and stigma, power and influence across a nation. These societal-level effects of g , via IQ contexts, may be the most important of all for a society, and they cry out for sociological analysis. Only a few such analyses have been done, but they illustrate the promise of a *sociology of intelligence*.

Evolution of social structures. If knowledge is power, then brighter people can be expected to advance further in any society freely allowing its accumulation. What is less obvious, except in hindsight, is that the routes to success may themselves be shaped by enduring variation in g within a population. Wide dispersion in g is a biological fact that all societies must accommodate. What norms and institutions evolve to promote such accommodation, especially where g has high functional value?

Consider the occupational hierarchy, that gradient of occupations from high to low in status, income, and educational requirements, which sociologists have shown to be replicated around the world. The consequences for individuals of their placement in it is clear, but its evolution is not. As described earlier, the major dimension underlying the hierarchy seems to be the complexity, not the content, of the tasks comprising the occupations arrayed along it. The occupational hierarchy is, then, a set of stable task configurations ranked in desirability according to their g -loadedness.

The structural question is how tasks gradually become sorted over time by their g -loadings into more g -homogeneous sets *within* occupations, thereby creating sharper distinctions in g -loading *between* occupations. This segregation of tasks by g -loading into a g -based occupational hierarchy most likely gradually arises from the natural sorting and reassignment of people *and* tasks to each other in the effort to improve aggregate performance of an organization's or society's essential functions. When workers are sorted more consistently by g level into occupations, occupational content can evolve to better fit the typical incumbent. For example, employers can gradually remove easy tasks from, and add complex tasks to, jobs whose usual incumbents are bright, and do the opposite for

jobs typically peopled by less bright workers (Gottfredson 1985).

Of course, g is hardly the only contributor to job performance, and job performance is not the only basis for how work and workers are organized in firms and societies. But to the extent that g is the most functionally important worker attribute overall *and* that people become sorted to work by g level, there will arise a g -based occupational hierarchy whose distinctions gradually expand or contract when the g -related efficiency of sorting workers rises or falls. This theory illustrates how the biological fact of differences in g can constrain the evolution of social institutions. That biological fact clearly rules out common utopian fantasies in which all citizens are assigned, rotated through, or ascend to jobs of equal difficulty and status.

Racial politics. When two social groups differ substantially in average g and g has functional value, they can also be expected to differ in g -related outcomes. The average difference in outcomes will depend on, among other factors, the size of the average group difference in g and the g -loading of the outcome in question. The g -generated differences in outcome have many sociopolitical reverberations, because they are pervasive, frequently large, and sometimes involve races once subjugated. The societal-level reverberations have the power to alter many aspects of a nation's culture. This can be illustrated by the national effort in recent decades to eliminate racial disparities in education and employment despite continuing racial disparities in g .

A key practical dilemma for educators and employers is that unbiased, valid measures of mental ability are generally the best predictors of school and job performance but, owing to phenotypic differences in g across racial groups, they have considerable *disparate impact*. That is, they screen out disproportionate numbers of candidates from some races. Unless group disparities in g are eliminated, there will continue to be a trade-off between selecting the most able applicants and selecting a racially balanced student body or work force, especially in highly g -loaded settings such as graduate school and the professions. In both employment law and public perceptions, unequal selection rates by race constitute *prima facie* evidence of illegal discrimination, often making it risky to use g -loaded predictors.

This combination of scientific facts and legal constraints has precipitated in personnel selection psychology a desperate but unsuccessful search for non-*g* substitutes for mental tests. There turns out to be no substitute for higher-order thinking skills. This failure created additional pressure on the field to reduce employers' legal vulnerability while retaining mental tests by instituting racial preferences. Eventually the U.S. Congress banned the most efficient such "solution" as an undisguised quota (the race-norming of employment tests, which means ranking applicants on separate racial curves). That ban in turn increased the pressure to covertly reduce or eliminate the *g* component of tests (to remove crucial mental demands), the results of which led to enormous controversy—and litigation—in personnel selection psychology. The same controversial effort to reduce the *g*-loading of employee selection criteria is now occurring for college admissions in states where racial preferences have been banned or might be. Being the most *g*-loaded predictor of student performance, the SAT has been the first target. In short, *g*-related group differences in outcomes have long been driving widespread changes in standards for admission, hiring, promotion, and more, sometimes improving selection and sometimes not, but always causing controversy.

Selection psychology is only one microcosm for observing the sorts of societal waves created by *g*-related group disparities. Virtually every school practice, from instructional and grouping practices to discipline to teacher assignment and funding, has been modified in recent decades to neutralize either the reality or the appearance of racial differences in phenotypic intelligence and their real-world effects. Keen disappointment at the failure of these modifications to accomplish that neutralization has itself sparked mutual recriminations between blacks and whites, led to more expansive definitions of discrimination and racism, and in many other ways shifted national politics. As is apparent, the societal-level ramifications of group differences in *g* hinge critically not only on how large they are and whom they affect but also on how a society explains and reacts to the differences.

Inequality and the democratic paradox. A population's IQ bell curve may bunch up or spread out

somewhat with environmental change, and it may shift a bit up or down the IQ continuum over time. Nonetheless, it will remain as much a biological fact as are differences in height. The bell curves for different demographic groups may also shift somewhat relative to each other along the IQ continuum, but gaps will likely persist.

As indicated in Figure 1, the IQ continuum represents a gradient of functional advantage for the individuals and groups arrayed along it. Happiness and regard may be available to all, but money, power, and prestige all tend to flow up the continuum, especially in a free society. Accordingly, envy flows up and stigma down. The IQ continuum is thus a strong current deep within the body politic that influences its surface dynamics in myriad ways and can frustrate efforts to steer a society in certain directions. Perhaps for this reason, political efforts to regulate or defy those dynamics have sometimes been violent in spirit if not in act. A 1980 analysis of genocides earlier in the century found that all but one of the targeted groups (Gypsies) were of apparently *higher* average intelligence than those seeking to exterminate them, for instance, the Jews in Germany, Armenians in Turkey, Ibos in Nigeria, and the educated classes in Cambodia.

Any humane society will moderate the effects of unequal biological and social advantage, preventing unbridled competition and the degradation of its weaker members. If resources naturally flow up the IQ continuum, societies can consciously redistribute some of them back down it—in a word, by helping. Such is the realm of charity and, increasingly, social policy, although such measures are seldom conceived in terms of helping the less "able" because that in itself would be stigmatizing. More often today, help is couched in terms of assisting the "deprived," as though all social inequality were the result of some social groups illegitimately expropriating from others what would have otherwise naturally accrued to them. Some inequality may be, but much is not.

Extreme egalitarianism is as problematic, however, as unbridled individualism, for it hobbles talent and deadens ambition. John Gardner outlined the trade-offs between promoting individual merit and equalizing social outcomes in his 1984 book, *Excellence: Can We Be Equal and Excellent Too?*

In that eloquent little book, he asked the question that writers from both the political left and right have since tried to answer in more detail: How can we create a valued place for people of all ability levels and bring out the best in all? The proffered answers differ primarily in the difficult trade-offs the authors settle for among personal liberty, equality of socioeconomic outcomes, and an emphasis on human excellence and productivity, three principles that are somewhat inconsistent owing to meaningful differences among people.

If such are the political dilemmas that the deep current of *g* inevitably creates, the debates over their resolution seldom seem cognizant of the dilemma's roots in human variation. Democracy is itself a social leveler because it grants *political* equality to people who are in numerous ways *biologically* unequal. But this strength is also its torment, because democracy excites the desire for yet more leveling, to which biological inequalities—especially intelligence differences—pose an obstacle. Mother Nature is no egalitarian. As Alexis de Tocqueville observed almost 200 years ago ([1835, 1840] 1969), “When there is no more hereditary wealth, class privilege, or prerogatives of birth, and when every man derives his strength from himself alone, it becomes clear that the chief source of disparity between the fortunes of men lies in the mind . . . [T]here would still be inequalities of intelligence which, coming directly from God, will ever escape the laws of man” (pp. 457–458, 538).

Biological diversity in *g* is a core challenge to democratic societies and to the scholars who are responsible for helping citizens understand how their society works. The challenge is exacerbated as technology advances, because such advance favors higher-*g* over lower-*g* people owing to their better ability to capitalize on it. Western democracies view democracy and technology as their twin engines of progress, however, and so haplessly seek solutions to inequality by pursuing yet more of both. That is the *democratic paradox*. The answer to the dilemma lies not in pursuing the opposite strategy—that is, curtailing both democracy and technology, as is sometimes hinted—but most likely in better understanding how differences in *g* orchestrate and constrain social life, to the extent that they do. For sociologists of intelligence, there is much to do.

LINDA S. GOTTFREDSON

INTERGENERATIONAL RELATIONS

Throughout recorded history, concern has been expressed about relations among the generations. Historians have identified changing patterns of relationships between the old and the young, pointing out that in some epochs veneration of the aged was common, while in other eras, the aged were more likely to be held up to scorn and ridicule. In contemporary American society, these contrasts are muted, and themes of both consensus and conflict are present.

Sociologists have explored intergenerational relations extensively, using both macrosociological and microsociological approaches. Scholars who have taken a macrosociological approach have examined the discontinuity caused by the succession of different groups of individuals who were born during the same time period and therefore age together (Foner 1986). Sociologists refer to such groups as "cohorts." Many important questions have been raised regarding relations among cohorts, including: How do people differ as a result of membership in a specific cohort? How and why do cohorts come into conflict with one another? Does a "generation gap" exist?

In contrast, sociologists who have taken a microsociological approach have focused on intergenerational relations within families. These scholars have examined the content and quality of relationships among family members in different generations, posing such questions as: How much contact do adult children have with their parents? What kinds of exchanges occur between older and younger generations? What is the role of grandparents in families? Under what circumstances does conflict among the generations in families occur? To fully understand intergenerational relations, it is essential to study both levels and to draw connections between them.

MACROSOCIOLOGICAL PERSPECTIVES

Mannheim's View of Generations. Karl Mannheim provided one of the most enduring analyses of relations between cohorts (he used the term "generation," however, instead of the contemporary sociological term "cohort"). Mannheim argued that the individuals born into a given cohort experience the same set of sociopolitical events while

they are growing up; this distinguishes them as a special social group. Merely by their location in a given cohort, members are likely to have certain similarities, since they are endowed with “a common location in the historical process” (1952, p. 290).

Thus, position within a cohort—like position within the socioeconomic structure—limits members to a narrow range of possible experiences and predisposes them to characteristic modes of thought. These differences can lead to conflict between the cohorts, as younger cohorts try to impose their views on society. The older cohort, on the other hand, has a major stake in preserving the existing social order. The interaction between these divergent cohort groups, according to Mannheim, is a critically important aspect of human social life.

To be sure, Mannheim did not compare belonging to a cohort with belonging to a more concrete group—such as a family—in that a cohort lacks a clear organizational framework. Further, he noted that differences may exist within cohorts. That is, within the same cohort, subgroups (in Mannheim’s terms, “generational units”) can form that are different from, and may even be antagonistic toward, one another. Nevertheless, Mannheim viewed location in a cohort as a powerful influence on people’s lives in much the same way that class position is an influence on their lives. This concern with the continual succession of cohorts, and its effects on social life, has found its clearest contemporary expression in age-stratification theory.

Age-Stratification Theory. Age-stratification theory begins with the fundamental assumption that to understand intercohort relations, we need to see society as *stratified* by age. Consistent with Mannheim, this view holds that society is divided into a hierarchy of socially recognized age strata. Each stratum consists of members who are similar in age and whose behavior is governed by the same set of norms for behavior appropriate for their age group. Further, members of various age strata differ in their abilities to obtain and control social resources. For example, young people in most societies have less power and fewer resources than middle-aged adults.

The duties, obligations, and privileges associated with age strata vary according to individual attributes, but they are always influenced by the structural aspect of age. Thus, various cohorts in a

society may have greatly divergent views on filial responsibility, expectations for independence of children, and values on other issues.

Sociologists see such differences among cohorts as the basis for possible conflicts of interest in society. In fact, conflict regarding continuity and discontinuity has been a major theme in macrosociological approaches to intergenerational relations. As Vern Bengtson (1989, p. 26) notes, members of the older cohort desire continuity: They want to transmit to younger cohorts “what is best in their own lives.” Correspondingly, they fear discontinuity: that young people will choose to live by very different sets of values. What has come to be known as the “problem of generations” reflects “the tension between continuity and change, affirmation and innovation, in the human social order over time” (Bengtson 1989, p. 26).

As an example, an age-stratification perspective on intergenerational relations can be applied to the political realm. When the age-stratification system is viewed as analogous to other stratification systems (e.g., class or gender), it follows that group solidarity may develop within each age cohort and that conflict—both overt conflict and conflict of interests—may occur between two different cohorts.

On a basic level, members of older and younger cohorts find different political issues more salient; for example, the elderly are more likely to focus on old-age pensions and health benefits, while the young are concerned with issues such as educational loans or the military draft (Riley et al. 1988). Such differences in salience may result in differences in voting behavior; for example, older individuals may be less likely to support tax increases for educational spending (Button 1992).

Political ideology among older and younger cohorts has been examined, with the fairly consistent finding that the current aged cohort is generally more conservative than younger cohorts. (However, these cross-sectional differences do not highlight the fact that people change their political attitudes over time, in line with changes in the society as a whole; for a discussion of political shifts during the life course, see Alwin 1998.)

Do divergent interests and attitudes result in age-related collective political action? Sociologists

have examined whether the aged constitute a self-defined political group that sets its agenda against those of other age strata. This question may be particularly important because studies have shown that older people are more likely to register and vote than younger individuals (Binstock 1997). Certainly Washington politicians and the media view the elderly as a political powerhouse; however, it is not clear that a voting block can be organized around old-age interests, as political attitudes vary greatly within the cohort. In addition, the elderly are a heterogeneous group; there are differences in socioeconomic status and racial and ethnic background within the aged cohort. Finally, the interests of the "young-old" (65-75) may differ from those of the "old-old" (over 75), with the former more concerned with retirement issues, income maintenance, and leisure opportunities, and the latter more interested in funding for medical services and long-term care. The overall evidence shows that the aged are willing to act together on some issues (like Social Security) but not on others.

A political development of the 1990s, however, may create more polarization among cohorts and thus lead to an upswing in age-based politics. This is the rising concern over "generational equity." Gordon Streib and Robert Binstock (1988) have summarized the issue in the following way. The elderly in developed nations were seen as a disadvantaged group from the 1950s to the early 1970s. They were portrayed as having low economic and social status, compared with younger persons. However, by the late 1970s, some scholarly and popular literature began to assert that old people had in fact *overbenefited*, and the elderly came to be seen as potentially burdensome economically to younger generations.

The older generation has at times been viewed as a scapegoat for a number of problems (Binstock 1983). In particular, the elderly have come to be seen as demanding resources for themselves, thus depriving children of quality schooling, health care, and other services. Organizations have arisen whose goal is to advocate the interests of the young at the expense of the older cohort. These groups have the expressed goal of establishing "generational equity," by transferring resources back to the young.

In the face of such attacks, it is conceivable that the elderly will begin to coalesce into a more

unified generational unit. However, in response to these claims, a countermovement has developed that encourages cooperation among advocates for youth *and* the elderly. On the level of practice, this interest has led to the development of intergenerational programs that bring old and young together.

While the macrosociological approach just discussed provides important insights into intergenerational relations and has obvious relevance for public policy on aging issues, it is also important to examine intergenerational relations on the microsocial level.

MICROSOCIOLOGICAL APPROACHES: A FOCUS ON THE FAMILY

Many sociologists have also focused on the smaller world of the family in an attempt to further our understanding of intergenerational relations. The family resembles the larger society, in that it is the locus of both intergenerational consensus and conflict. There is considerable family solidarity, indicated by feelings of affection and attachment that result from a shared history and close contact (Bengtson et al. 1990; Silverstein and Bengtson 1997), as well as inequalities of power and social resources. These twin themes of solidarity and conflict are evident throughout sociological research on the topic.

The way in which these themes are worked out in families has been affected by the dramatic changes in the age structure of American society. In particular, average life span has increased, which means that family members will spend more time than ever before occupying intergenerational family roles. Further, increased life expectancy leads to a greater likelihood that families will spend longer periods of time caring for disabled elderly relatives.

Societal changes have also increased the complexity of intergenerational relations. For example, the high divorce rate found in contemporary American society raises the likelihood that adult children will return to their parents' homes, often bringing their own young children with them. Women's unprecedented participation in the labor force and their return to college in great numbers may also affect intergenerational relations. To be sure, the acquisition of these nonfamilial roles provides new and enriching opportunities for women; however, it may alter the time that has

traditionally been devoted to “kinkeeping” between the generations.

It is only possible to comment on a few major themes in this review. The most widely studied area is that of parent–child relations in later life, including patterns of intergenerational contact and factors that affect the quality of adult child–elderly parent relationships.

Contact Between Parents and Children. A major concern of researchers has been to understand patterns of contact between adult children and older parents. Research on this issue has gone through two major phases. First, there was a period in which the nuclear family was held to be isolated. This view was based in part on Talcott Parsons’s analyses of family relations, which held that modernization had brought about the decline of the extended family (DeWit and Frankel 1988). During this period, it was widely believed that because of the geographic mobility of children, families abandoned their elderly relatives. This view also held that most elderly persons rarely saw their children and that family members no longer provided care for older relatives (Shanas 1979).

In the second phase, many prominent researchers devoted considerable effort to demonstrating that this view is inaccurate. Investigators such as Ethel Shanas, Marvin Sussman, and Eugene Litwak, as well as later researchers, clearly established that older persons have frequent contact with family members and that few are totally isolated from kin. Further, most aged family members are involved in a network of emotionally and instrumentally supportive relationships.

Studies have shown that in most cases parents and adult children have relatively frequent and regular contact (Umberson 1992); in fact, 40 to 50 percent of adult children see their parents at least once a week (Rossi and Rossi 1990). A major factor in determining the frequency of contact is physical proximity. Numerous studies have found that the frequency of intergenerational contact is greatly affected by geographical distance between households, with more distant children interacting less often with parents (cf. Eggebeen 1992). However, it is clear that many geographically distant children continue to interact to a significant degree with parents and that parents and children are able to maintain close ties despite being separated by great distances.

Determinants of Quality of Parent–Child Relationships. Researchers have moved beyond simply establishing patterns of contact to examining factors that affect the quality of parent–child relations in later life. For a review of this literature, see Suitor and colleagues (1995). A number of factors appear to have an impact on relationship quality.

Increased parental dependency is frequently cited as a factor that negatively affects the quality of aged parent–adult child relations. Studies have highlighted imbalanced exchanges and perceptions of inequity between the generations as major causes of family disharmony. For example, several investigations have suggested that an increase in parents’ dependence upon their adult children may reduce positive feelings between the generations. Other studies have found that adult children’s feelings of closeness and attachment are reduced when parents’ health declines. As parents’ health deteriorates, adult children are likely to need to increase their levels of support to previously independent parents, as well as to accept a lessening or termination of the parents’ provision of support—thus disrupting the previously established flow of support between the generations.

A second factor affecting parent–child relations is *gender*. Research has shown that women tend to have stronger and more supportive ties with parents than do men (Silverstein et al. 1995; Spitze et al. 1994). Further, studies of the effects of gender consistently demonstrate stronger affectional ties between mothers and daughters than any other combination (Rossi and Rossi 1990). Mothers report more positive affect with adult daughters than sons and are more likely to rely on daughters than sons as confidantes and comforters. Daughters in turn report greater feelings of closeness to mothers and are more likely to turn to them as confidantes than to fathers.

Third, the *age of the child* affects relationships with parents. Theories of adult development and intergenerational relations lead to the expectation that a child’s age will be negatively related to parent–child conflict and positively related to closeness. This literature suggests that maturational changes are likely to reduce differences between parents and adult children, thus minimizing the bases for conflict between them. For example, Bengtson (1979) suggests that as children mature,

their orientations become more similar to those of their parents. Similarly, Gunhild Hagestad (1987) posits both that differences between parents and children become muted across time and that there is greater tolerance for differences that remain. Empirical findings have consistently supported these assertions.

Fourth, changes in the degree of *status similarity* between adult children and their parents may affect their relationship. In particular, some studies have found a pattern of increased closeness in intergenerational relations when children begin to share a larger number of adult statuses with their parents. For example, the mother–daughter relationship appears to assume greater importance from the daughters’ perspective when they themselves become mothers (Spitze et al. 1994; Umberson 1992). Conversely, decreases in status similarity may negatively affect adult child–parent relations. For example, the status dissimilarity that develops when daughters surpass their mothers educationally may have particular potential for creating difficulties between the generations (Suitor 1987). For a review of research regarding parent–child relationships across the life course, see Pillemer and Suitor (1998) and Suitor and colleagues (1995).

Two other areas that have received considerable attention are relations with grandparents in the family and the importance of changing dependencies among the generations over the life course.

Grandparenthood. In recent years, sociologists have shown increasing interest in studying the role of grandparents in families (see Robertson 1995 for a review of contemporary grandparenting). The demographic shifts noted above have brought about changes in the nature of grandparenthood in several ways. First, more people now survive to become grandparents than ever before. Second, the entry into grandparenthood is likely to occur in midlife, rather than in old age; thus, the duration of grandparenthood may extend to four decades or more. Third, the role of grandparent is not clearly defined in American society, and the normative expectations, privileges, and obligations are ambiguous (Hagestad 1985).

Studies have revealed several consistent findings about grandparenthood. Contrary to popular stereotypes, most grandparents do not wish to

take on a parental role toward their grandchildren. Rather, they generally prefer a more distant role in the grandchildren’s lives. Nevertheless, grandparents are often a critical resource for families in times of trouble (Hogan et al. 1993).

Perhaps the most consistent finding in more than a quarter-century of research is diversity in grandparenting styles. A number of typologies have been identified, which usually array grandparents along a continuum from intense involvement and assumption of parental responsibilities, on the one hand, to relative alienation from grandchildren, on the other (Neugarten and Weinstein 1964).

The most ambitious study to date used a representative survey to examine styles of grandparenting and to uncover factors that determine the adoption of a particular style (Cherlin and Furstenberg 1986). Andrew Cherlin and Frank Furstenberg were able to identify five basic grandparenting styles. *Detached* grandparents have little contact with their grandchildren. *Passive* grandparents visit somewhat more frequently but carefully maintain a distance from their grandchildren’s lives. *Supportive* grandparents have more contact and focus on providing services to the grandchildren. *Authoritative* grandparents exert parent-like influence to a relatively great degree. Finally, *influential* grandparents combine involvement both by providing services and by adopting a parental role.

Cherlin and Furstenberg found that geographical distance was the most critical factor in determining which style of grandparenting developed. Detached grandparents were much more likely to live far away, while the most involved grandparents lived in close proximity to the grandchildren. Further, grandparents practiced “selective investment” in their grandchildren. They had more intense relationships with some grandchildren and more distant relationships with others. Other studies have affirmed this finding and have also pointed to the importance of gender: Grandmothers tend to have closer relationships with grandchildren than grandfathers.

Research interest has also highlighted the effects of children’s marital disruption on the relationship between grandparents and grandchildren. Despite suggestions in the popular media that relations between grandchildren and grandparents are damaged when adult children divorce,

studies have shown that this is not necessarily the case. Cherlin and Furstenberg (1986) found that “custodial grandparents” (that is, those whose adult children were awarded custody of the grandchildren) tended to maintain very close ties with their grandchildren, while “noncustodial grandparents” were less likely to maintain such ties. Since custody of minor children continues to be awarded more frequently to mothers than fathers, this means that ties with maternal grandparents are more likely to be maintained or strengthened following a divorce, while ties with paternal grandparents are more vulnerable—particularly in terms of frequency of interaction.

Jeanne Hilton and Daniel Macari (1997) also found that geographic proximity and whether the grandparents were related to the custodial parent were important factors in structuring the grandparent–grandchild relationship. In a study of New York families, Hilton and Macari (1997) found that grandparents were more involved with their grandchildren when they lived nearby and were related to the custodial parent; they also found that grandmothers were more involved with grandchildren than were grandfathers. Further information on the effect of divorce on parent, adult-child, and grandchild relationships can be found in Johnson (1993).

Changing Dependencies. Social scientists have convincingly demonstrated that children and parents continue to depend on one another for both emotional and instrumental support throughout the life course (Spitze and Logan 1992). The literature on intergenerational relations, however, has focused more heavily on children’s support to elderly parents than the reverse. Thus, before turning to a brief discussion of the issue of caregiving to the elderly, it is important to emphasize the *reciprocal* nature of intergenerational assistance.

Marvin Sussman (1985) has provided a model of parent–child relations across the life span that emphasizes the cyclical shift in relations with parents. In the beginning, parents provide a substantial amount of assistance to their offspring, even into the children’s early married life. Then, as children become more independent—and possibly move away—there is a decrease in intergenerational helping. Finally, as elderly parents begin to decline in health, they come to depend more

heavily on their children. This cyclical view of support is important, in that it stresses patterns of *mutual* aid between the generations (see also Rossi and Rossi 1990). Further, it should be noted that it is usually only very late in the life course that children’s provision of support exceeds that of parents, and even then only when parents become frail and disabled (Spitze and Logan 1992).

Throughout the 1990s, several hundred articles were published examining the experiences of families at this stage of the life course. Research has documented the strains experienced by middle-aged children when parents become dependent, including practical problems of managing competing demands on their time and energy as well as emotional stress, increased social isolation, guilt, and feelings of inadequacy.

Besides establishing both the prevalence of support for aged parents and problems in providing care, researchers have attempted to determine who is most likely both to become a caregiver and to experience the greatest stress from caregiving. Two of the most consistent findings involve the issues of gender and the relationship to the elderly person. First, women are substantially more likely to become caregivers than are men, and the role of caretaking appears to result in more intensive “hands-on” activities for women than men (cf. Allen 1994; Arber and Ginn 1995; Coward and Dwyer 1990; Finley 1989; Lee et al. 1993). Second, when the elderly person is married, it is the spouse who almost always becomes the primary caregiver (Stoller 1992). Thus, adult children generally become caregivers only when the care recipient’s spouse is not available to occupy this status. In addition, the nature of caregiving is different for spouses than for other caregivers. Spouses are more likely to have sole responsibility for caregiving and to have responsibility for providing assistance with routine activities of daily living (Stoller 1992). Further, spouses appear to experience greater physical and financial strain than do adult child caregivers and they are more likely to continue caregiving at the expense of their own well-being (Horowitz 1985). For a further discussion of caregiving, see Dwyer (1995).

Although research has focused on the detrimental consequences of caregiving, some more recent evidence suggests that most caregivers can also identify positive consequences of caregiving.

These positive aspects usually involve feelings of gratification derived from helping someone they love and fulfilling expectations of filial responsibility. Thus, the issue of changing dependencies in later life reflects the twin themes of consensus and conflict evident throughout theory and research on intergenerational relations.

INTERGENERATIONAL RESOURCE TRANSFERS

The transfer of resources between individuals of different generations occurs on both the societal level, as the outcome of public policy or within the context of the private sector, and the family level, as in the exchange of emotional support and material goods. This discussion of the intergenerational exchange of resources will consider, first, the flow of resources within the context of the family; second, intergenerational transfers on the societal level; and last, the issue of equity in the transfer of resources intergenerationally. In addition, brief mention will be made of special circumstances, such as cross-cultural differences or the special case of divorce and stepfamilies.

The meaning of the word *generation* varies from setting to setting. In the family environment, the reference is primarily to lines of descent (grandparents, parents, children, etc.). However, each family member is also a member of a particular birth cohort, or group of individuals born during the same period of historical time, such as 1920-1924, and, at any given time, a member of a particular age group, such as sixty-five- to sixty-nine-year-olds. Each of these is also reflected in the intergenerational exchange within the context of the family and in the intergenerational exchange of a society's resources. Finally, the exchange process may also include the concept of generation that connotes a group of individuals, usually part of the same birth cohort, who share a common set of political or social beliefs (e.g., the "Woodstock Generation").

RESOURCE TRANSFERS WITHIN THE CONTEXT OF THE FAMILY

Resources exchanged among family members vary greatly in size and type. Examples range from the ordinary, everyday exchange of care involved in child rearing or household chores to the bequest of substantial financial or material resources to descendants in a will. The latter behavior has been explored as part of a broader practice referred to as a "legacy" (Kane 1996), which includes last wills and testaments, the transfer of property, and, even more broadly, how people want to be remembered.

Over the last several decades a number of perspectives have developed regarding such familial exchanges. One such perspective views the resource-transfer process in terms of *reciprocity of exchanges among family members*. Analysts have examined reciprocity as a motivator of interdependence over time, at different points in the family structure (e.g., parent-child, sister-brother), and within the context of individual family members' perceptions of how much each member has given or received in the past. *Exchange theory* specifically views all kinds of social interactions as the exchange of rewards between individuals where the group or individual with the greater amount of *social power* regulates the exchange process (Dowd 1975). Regarding resources to older family members, Horowitz and Shindelman (1983) view reciprocity in terms of the "credits earned" by the older individual for providing resources in the past to the family member currently on the giving end.

In contrast, the *life-cycle model* of family intergenerational transfers maintains that the distribution of resources among the generations in the family takes on a curvilinear shape: Individuals in the middle generations, and most likely middle-aged, transfer the bulk of family resources to those who are either younger or older. (For an illustration, see the works of Reuben Hill [1965, 1970] regarding his study of three-generational families in the Minneapolis-St. Paul area). In contrast, the *role continuity model of family intergenerational transfers* asserts that, except in families where the older generations are financially strained, older family members redistribute their wealth to successive generations in the family (for further discussion, see Covey 1981; Kalish 1975; Riley and Foner 1971). Still another perspective used to explore the giving and receiving of resources in the family is that of *hierarchical/sequential* activities. From this perspective, individuals first seek aid from members of their nuclear family; failing that, from members of their extended family; and, only as a last resort, from institutional sources such as government programs, banks, and the educational system (viz., Morgan 1983). A final perspective is that of altruism. *Altruism* is a helping behavior that benefits the recipient but provides no benefits, and may incur costs, to the provider. In this context, then, resources are transferred from one generation to another with regard only to the

benefit they provide to the recipient, without regard to the costs incurred by the provider. Research has investigated the relative importance of exchange versus altruism as motivators for intergenerational transfers (Cox and Jakubson 1995; Cox and Rank 1992; Schoeni 1997). This research finds that intergenerational transfers are more likely to be part of an exchange process rather than behaviors conducted out of altruism.

A great variety of resources, both material and psychosocial in nature, are exchanged among members of nuclear and extended families. These include the giving and receiving of material gifts of all manner and size; the provision of help during emergencies, as when a family member is ill or in need of sudden and immediate shelter; providing physical or financial resources in time of need, such as babysitting or nursing, offering advice, taking care of household maintenance, and providing financial support; the passing on of family legacies, including pictures, artifacts, recipes, and family lore; and inheriting assets of all kinds upon the death of family members.

In Western societies prior to industrialization, inheritance was a mechanism for passing on from father to son the means of family economic support, the farm or business (milling, smithing, etc.) that traditionally remained within the family for generations. With the arrival of industrialization and the movement of economic support to the factory or the office, the content and impact of inheritance grew more varied. While monetary and property assets are still very common, items with more symbolic significance, such as mementos or heirlooms, are often the most cherished (Rosenfeld 1979; Schorr 1980; Sussman et al. 1970).

The provision of care to family members is a resource transfer that occurs in every emotionally healthy family the world over. Most caregiving involves the many ordinary, everyday activities that are necessary to the survival and well-being of family members, for example, the typical care and feeding of infants and children, the performance of daily chores and house repairs, the giving of advice and emotional support, and the nursing of relatives during episodes of acute illness. In some instances family members give or receive care for conditions that are quite taxing and of an indefinite duration, such as Down's syndrome in a child

or Alzheimer's disease or physical impairment or frailty in a spouse or older parent.

The intergenerational nature of this transfer is underscored in data from numerous studies, including nationally representative surveys, such as the one conducted by Louis Harris and Associates (1975) in conjunction with the National Council on the Aging, as well as many studies of family caregiving, including the National Long-Term Care Survey and the Longitudinal Survey of Aging. The general findings of this research indicate that the vast majority (perhaps as many as 80 percent) of older adults who need help with activities of daily living receive such help from relatives, particularly children or grandchildren (Stone et al. 1987; Stull 1995). A variety of motives for such care provision have been explored. Biegel and associates (1991) suggest that there are two types of explanations for the motives to provide care. Egoistic explanations argue that helping others is done with the anticipation that rewards will be forthcoming for such care provision. This includes payment for care, avoiding censure, gaining social approval, or complying with social norms. Some evidence for payments for care yields inconclusive results. For example, McGarry and Schoeni (1997) report that they found no evidence that parents provide financial assistance to their children in exchange for caregiving. On the other hand, Lillard and Willis (1997) report that in Malaysia, a country with neither Social Security nor Medicare, children are an important source of financial security in old age and that this is, in part, a repayment for parents' investments in children's education. They find further that parents and children engage in the exchange of time help for money.

A second set of explanations for providing care encompasses empathy and altruism. In these motivations, the interest is in benefiting the other, not oneself. As noted earlier, altruistic explanations of intergenerational transfers have not found much empirical support.

Noninheritance economic transfers within the family take a variety of forms: gifts, loans, payment of bills or down payments, and emergency financial help, for example. The directionality of this assistance, in both nuclear and extended families, is from parents of all ages to children of all ages and from adult children to older parents. Evidence (Schoeni 1997) indicates that people in

their twenties and thirties receive more time and money assistance than do people of other ages, including the very old.

The transfer of goods and services among family members includes sharing the same household; making major purchases such as furniture, a car, or a large appliance; making smaller purchases such as clothing; and doing major repairs. Data show that substantial intergenerational transfers occur. For example, 90 percent of those Americans 65 years of age and older who had children or grandchildren gave those offspring gifts, while between 92 percent and 96 percent of adults 18 to 64 years old gave gifts to parents or grandparents (Harris and Associates 1975).

**INTERGENERATIONAL RESOURCE
TRANSFERS ON THE SOCIETAL LEVEL:
FROM ONE BIRTH COHORT/AGE GROUP
TO ANOTHER**

On the societal level, the concept of intergenerational transfers shifts from resource exchanges among specific individuals of the same lineage to transfers to and from large groups of people of one birth cohort or age group to large groups of people in the same or other birth cohort or age group. These exchanges take place in several arenas: (1) the public policy arena, where the transfer is usually in the form of resources defined in statutes and laws (examples in the United States include the Social Security system, Head Start, Temporary Assistance to Needy Families, school bonds); (2) the private sector, where transfers are in the form of wages or goods (examples include jobs that support workers and nonworkers, corporate profits that supply tax revenue); and (3) the creative arena (examples of these transfers include art, music, literature, and the fruits of social and physical science research).

Products of Public Policy. The outcomes of public policy are transfers that affect everyone in a society. Frequently, these resources are multifaceted, affecting a broad range of individuals. For instance, in the United States the term *Social Security* is commonly used to refer to Old-Age and Survivors Insurance retirement income and the death survivors' component of a larger piece of legislation that also includes a disability insurance program, an unemployment insurance component,

and the public assistance Supplemental Security Income program. As a totality, then, these components of the Social Security legislation go to a wide range of individuals in a number of different circumstances. Moreover, it is important to note that, while resources stemming from public policy may be received by specific individuals at a particular point in time or over a particular span of time, in another sense each has a larger impact that far exceeds that exchange. For example, the issuance of a school bond in a community directly and immediately provides educational resources to a particular cohort of school-age residents. However, indirectly, those resources affect the lives of other members of the family, resulting in improved quality of life for them as well. Additionally, from a longitudinal perspective, the resources invested in educational infrastructure and materials benefit future generations of the community's students.

Discussion about the relative contribution of public and private transfers has led to conflicting expectations. For example, if one expects altruistic motivations, then private transfers would neutralize the impact of public transfers. On the other hand, if exchange motivates transfers, then private transfers would reinforce the effects of public transfers on economic well-being. Cox and Jakubson (1995) find that private transfers can enhance public transfers, the reverse of previous expectations that public transfers merely supplant private ones.

Outcomes of the Private Sector. Intergenerational resource transfers resulting from private sector activity affect both the *active working population*, composed of individuals who are primarily in their young adult and middle years, and the so-called *dependent population*, composed of children and older people supported by the active working population. This transfer occurs through both the wages that workers earn and the tax revenues, funneling through the public sector, those workers provide. The precise age boundaries for these classifications vary from society to society according to culture and the primary means of economic support (agricultural or industrial). However, even within the age span of the active working population, one finds individuals who are part of the dependent population, such as those who are

disabled or unemployed in their age groups. Moreover, within the age span of the dependent population, one finds working school-age children and retirees working part-time or part-year.

In the United States, the *total dependency ratio* is generally considered to be the number of persons under eighteen and those age sixty-five and over (together, the two dependent populations) for every 100 working-age individuals eighteen to sixty-four years of age. The *youth dependence ratio* is generally the number of persons under eighteen for every 100 individuals eighteen to sixty-four, while the *old-age dependency ratio* is the number of persons sixty-five and older for every 100 persons eighteen to sixty-four years of age. In the United States, while the youth dependency ratio has declined from 51 in 1950 to 34 in 1994, the old-age dependency ratio climbed from 13.3 in 1950 to 20 in 1994. Additionally, the old-age dependency ratio is expected to increase to 37 by 2030, at the height of the so-called baby boom retirement years (U.S. Bureau of the Census 1996).

However, none of these ratios take into consideration the possible impact of the following on intergenerational resource transfers: (1) the current and future contributions of elderly persons and youth who are employed; (2) the potential for increased labor-force participation among those sixty-five and older; (3) the changes in the Social Security Act to gradually increase the age of eligibility for full Social Security retirement benefits to sixty-seven over a twenty-seven-year period, beginning in the year 2000; (4) the growing number of working women, who have different and, as yet, somewhat uncharted labor-force participation patterns; and (5) the growing economy (Crown 1985; Kingson et al. 1986).

Current Cohorts of Children and the Heterogeneity of the Elderly: Two Special Considerations of Intergenerational Transfers. In the United States, intergenerational resource transfers that are the products of public policy and private sector activity support individuals of all ages. Of growing importance, however, is a consideration of the effect of the nature of such transfers on two groups, current cohorts of children and the elderly, at any time when they are viewed as a heterogeneous group. Regarding the former, it is clear that, at present, many children live in poverty or near poverty and, thus, are not receiving from older

generations (either older family members or older generations on the societal level) the resources they need to live satisfactory lives as children. Moreover, limited access during childhood to such resources as health care and education, in particular, leads to reduced economic opportunities and productivity in adulthood. Thus, without the infusion of such resources, children are unable to prepare themselves for a productive adulthood in which they are capable of successfully joining the active working population to sustain themselves. Moreover, they will also be unable to provide support for those individuals, young and old, who will then compose a large part of the dependent population of the future. For instance, persons age seventeen and under in 1990 will be twenty to thirty-seven years of age in 2010, when the first wave of the baby boom cohort will begin to retire, and forty to fifty-seven years of age in the year 2030, when the full weight of the baby boom retirement will be felt.

Regarding the heterogeneity of the elderly, it is important to keep in mind that older people in Western societies vary greatly not only in chronological age (forty marks the onset of protection under the U.S. Age Discrimination in Employment Act; eighty-five is generally considered the beginning age of the "oldest-old") but also in income, health, and activity status. In addition, the elderly vary, on these and other factors, according to race and gender. As a result, in old age *chronological age alone is not an adequate indicator of the need for a substantial infusion of public or private sector resources*. Indeed, some older people are still greater producers than consumers of society's resources. Likewise, for any particular individual, certain times *during* old age require a greater amount of societal resources than other times.

Outcomes of Creativity. The fruits of research, music, literature, systems of jurisprudence, and other cultural and scientific products represent very important types of societal-level intergenerational transfers. As long-term transfers that cross the generations of a society and frequently move from one society to another, these are resources that traverse both time and geography. (For instance, disease-resistant hybrid strains of rice developed in the United States and used in agricultural settings around the world benefited not only Americans alive during and after the mid-1950s but also people in other societies over succeeding

decades.) Frequently, especially regarding the products of scientific research, those in the same birth cohort as the originator(s) or creator(s) do not feel the full impact, positive or negative, of the outcome themselves; this becomes part of the birthright, for better or worse, of the generations that follow. For example, those in the generation of the developers of the diphtheria/pertussis/tetanus vaccine, given routinely to infants, faced the risk of these diseases themselves during childhood. On the other hand, individuals in the same birth cohort as the developers of the atomic bomb have not lived the entire span of their lives, including childhood, coping with the implications of this scientific outcome.

THE ISSUE OF EQUITY IN THE INTERGENERATIONAL TRANSFER OF RESOURCES

In the mid-1980s, the equity of intergenerational transfers was a prominent topic of discussion in both the press and various academic settings. This topic is receiving renewed interest. Consideration usually centers on the allocation process for resources resulting from public policy. However, it is important to keep in mind that much of the time these resources affect individuals within the context of the family. While there are many perspectives regarding the justification and procedure for transferring resources across generations, four particular factors appear to underlie each of these perspectives, each one subject itself to multiple meanings. When there is disagreement about the procedure for and direction of resource distribution across generations, it is frequently due to disagreement regarding the meaning of one or more of these factors (Hirshorn 1991). These are (1) the concept of the generation, discussed previously; (2) the issue of whether the resource transfer results in one party's experiencing an absolute or relative gain or loss in comparison with others; (3) the perception of the resource "pie" to be allocated (e.g., Is it constant in size? expandable?); and (4) the idea of *distributive justice*, or fairness in the rationale for deciding how to allocate resources (e.g., transfers can be based on level of need, on merit, or on equal shares for all, among other criteria).

Intergenerational Inequity Perspective. One of the most discussed perspectives in recent years

argues that there is *intergenerational inequity* in the transfer of resources in the United States, particularly resources resulting from public policy. It focuses on the relative welfare of current cohorts of youth and current cohorts of the elderly. This perspective maintains, moreover, that, in the United States in recent decades, the welfare of the young, especially those under the age of eighteen, has diminished as a result of the enhanced status of the elderly, who have been accumulating sizable proportions of the nation's personal wealth and, at the same time, been on the receiving end of the bulk of the resources stemming from social policy (Medicare and Social Security retirement funds are singled out especially). Moreover, those adhering to this view maintain, the absolute size of public expenditures directed at the elderly is a major cause of the current budget deficits and other economic problems facing the United States. The assumption is that sufficient funds will not exist in the future to ensure that those who are currently children and young adults will receive their fair share of these very resources—Social Security retirement and public sector health care support—in their own old age (Cornman and Kingston 1996). Among the problems with this perspective is that it assumes that the elderly, as a group, are all doing well in absolute terms; thus it does not take into consideration the variation within the older population that makes this group, which is quite heterogeneous regarding health status, economic status, living arrangements, and other factors. Moreover, this perspective relies on the idea that the correct concept for use in assessing the equity of public resources transferred across generations—one that would result in social justice—is *numerical equality*. Yet equal expenditures do *not* result in equal levels of return, no matter who receives the transfer. Finally, given the wide range of types of resources transferred within the context of the family and in the public and private sectors, it is meaningless even to try to arrive at an accurate measure of which generation/birth cohort/age group is faring better as a whole (Kingston et al. 1986).

Common Stake Perspective. An alternative view of intergenerational resource transfers notes the *common stake* that all generations/birth cohorts/age groups have in the wide variety of intergenerational exchanges. This perspective emphasizes the importance of using the concept of the *life*

course in assessing the giving and receiving of resources at all levels and in all contexts, societal and familial. Thus, it emphasizes that, at some points along the life course, one generally takes more of certain kinds of resources than one gives, while at other points along the life course the opposite is true (e.g., hands-on care is very strong in infancy and sometimes in old age; use of tax revenues for education is very prominent during childhood). Moreover, generally we do not give the same resources from the very same people, not within the context of the family or on the societal level. For instance, usually we do not provide the unstinting, continuous, and comprehensive care we received in infancy to our *parents*, but we do to our own children.

This perspective also stresses the fact that the same intergenerational resource transfer affects some individuals directly and others indirectly. For example, the public sector program Temporary Assistance to Needy Families, provides *direct* support to children in families headed by parents who are unable to provide sufficient work-related income; thus, family funds are freed to purchase such items as needed medical supplies for, say, an ailing grandparent. *Indirectly* affected by another public transfer that flows intergenerationally is the schoolchild, living with a grandparent, whose lunch money comes from the latter's monthly Social Security check. Finally, the common stake viewpoint underscores the need for current and future generations of the elderly to concern themselves with the welfare of children and young people and vice versa—for the sake of all concerned (Kingston et al. 1986).

INTERGROUP AND INTERORGANIZATIONAL RELATIONS

The focus here is first on the meaning of intergroup relations and next on interorganizational relations. Although the emphasis in both cases is mainly on research and conceptualizations based in the United States, we consider to some extent research based in other nations and cultures. We also occasionally consider the uses of sociological research.

INTERGROUP RELATIONS

A *group* is a collection of persons who have shared problems and act together in response to those problems, have shared expectations, and have a sense of common destiny. There are many kinds of groups, ranging from informal friendships to ethnic groups, to societies, and even to intersocietal groups. *Intergroup relations* refers to patterns of relationships that develop between groups. Extensive reviews of the literature in intergroup relations may be found in Seeman (1981) and Stephan (1985).

Although intergroup relations refers to all types of groups, it is not possible to avoid focusing on ethnic-racial group relations, because this has been the central concern in the United States since the social sciences and sociology, in particular, became established academic disciplines. Intergroup relations has been approached from the level of analysis of the group on the one hand, and from a social psychological perspective on the other.

This latter approach examines intergroup relations from the point of view of the individual and his or her relations with a group. In the latter part on the nineteenth century, the United States experienced huge immigration from southern, central, and eastern Europe. Since the new immigrants arrived from cultures that were markedly different from those of Americans who were already established here, conflicts developed, a pattern in some ways not materially different from conflicts that now exist between U.S. citizens and recent immigrants from Central and Latin American and Asia. The history of research on intergroup relations in sociology shows a profound emphasis on problems created by these massive immigrations.

Liebertson (1980) has thoroughly studied the question of why those who migrated to the United States from south, central and eastern Europe after 1880 in large numbers (such as Italians, Russians, Lithuanians, Poles) have been so much more successful than blacks. He found that blacks, in part because of their visibility, confronted much more serious social and competitive disadvantages than did these groups, even though the European groups did have many obstacles to overcome. Because of the slave period and the initial contacts with Africans, white society had and still has very unfavorable dispositions toward blacks, much more unfavorable than their dispositions toward white Europeans and even more unfavorable than their dispositions toward Asian immigrant groups. The competitive threat of Asian groups at the same time period was not nearly as great, since the Asian immigration was much smaller. Blacks also faced greater barriers than did Europeans from labor unions. Thus, Liebertson asserts that blacks and Europeans confronted intrinsically different situations that produced very different sets of opportunities for socioeconomic advancement.

Conflict and competition between groups is only one—albeit important—pattern that may develop, although it is the adaptation that is most likely to make headlines and be reported on the television news. William Graham Sumner (1906) applied the concept of ethnocentrism to explain intergroup conflict. Ethnocentrism is a “view of things in which one’s own group is the center of everything, and all others are scaled and rated with reference to it” (p. 13). Sumner believed that ethnocentrism served to highlight and then exaggerate differences between groups and hence contributed to in-group cohesion and strong hostility to the out-group.

One of the oldest social-psychological theories of intergroup relations stresses personality determinants. The leading exponent of this view is Gordon Allport (1954). Allport’s definition of prejudice has two components: attitude and belief. Allport defines ethnic prejudice as “an antipathy based upon a faulty and inflexible generalization” (p. 9). In his book, Allport refers to the generality of prejudice. A number of studies in this tradition report large intercorrelations of prejudices—that is, persons who are anti-Semitic are also anti-Catholic and antiblack (Epstein and Komorita 1965). The claim is that these views stem from a deep-seated personality syndrome, called by Allport “the prejudiced personality.” The prejudiced person is highly moralistic and has a need for definiteness, among other features. As Seeman (1981) has noted, the evidence on cross-group generality and its personality basis is easily challenged on both methodological and theoretical grounds. In general, the trait approach has slowly given way to a more situationalist view.

A note on discrimination and prejudice is in order, since much of the intergroup relations literature concerns these concepts. *Discrimination* is typically defined as treating people unequally due to their group membership, while *prejudice* is often seen as “a rigid emotional attitude toward a human group” (Simpson and Yinger 1972, p. 24). As Seeman (1981) points out, in prejudice persons are categorized wrongly or prejudged, and this process is a complex rather than a simple one:

The error comes in misconceiving and misjudging such a group, and the individual members thereof, as a consequence of misreading the

nature of the category involved. Often enough the misreading occurs because the cultural and historical sources of supposed category qualities are not taken into account or are attributed to irrelevant features of the category, that is, to blackness, Jewishness, and so on. What makes all this extremely tricky is that (a) it is difficult to demonstrate what, in fact, the appropriate characterizations are for the social categories we find it necessary to employ; and (b) given the powerful control that majorities exercise, pressures are generated that tend to socialize the members of a given category into the very features we discern: to make Jews "intellectual," blacks "hostile," Chicanos "indolent," and women "dependent." Thus, though demonstrable relevance (correctness) of the attributed qualities to the category is critical, there is typically a seeming relevance (a misread relevance) that beclouds the issue both for the participant and the analyst (p. 380).

Robert E. Park was one of the first leading sociologists of race relations and is identified with ecological theory (Park and Burgess 1921). Park viewed human beings as competing for territory much like plants and other animals. Ecological processes foster competition for limited resources. The distribution of the population is itself shaped by competition over scarce resources, and this competitive process structures the economic interdependence of groups and individuals. Competition also makes people aware of their status and induces them to view themselves as of superior or of inferior status depending on their social situation. Those who see themselves as superior express their consciousness of felt superiority and seek to maintain their privileged position through prejudice. Hence, the intergroup competitive process expresses itself through the development of moral and political order. This order is a product of such processes, in addition to competition, as conflict, accommodation, and assimilation. Racial consciousness is therefore seen as developing out of the competitive process, which is born in the competitive struggle for status. An "inferior" status group might not wish to compete and instead establish a niche within the division of labor, and this might lead to a stable equilibrium.

A dominant intergroup relations paradigm is derived from Marxist thought and is called conflict

theory. In this view, race relations and their consequences emerge from the system of social stratification in the society. Societies are seen as constantly changing. Societies distinguish between and among their members and award some greater rewards, such as power, prestige, and money, than others. The result is social inequality, which becomes an essential part of the stratification system. Hence, the stratification system is simply the structured inequalities of groups or categories or individuals. The different groups in the society, such as classes or ethnic-racial groups, compete for the limited resources available. Three conditions are necessary for intergroup conflict and inequalities to result (Cox 1948; Vander Zanden 1983).

First, there must be at least two identifiable groups. People must be aware of their group and another group on the basis of some characteristic or set of characteristics. These may be physical or not—that is, beliefs or values are sufficient.

Second, the two groups must compete with one another or feel they are competing for a limited pool of resources for themselves, if necessary at the expense of members of the other group.

Third, the two groups cannot have exactly the same amount of power, so that one group can claim an advantage in obtaining resources that another group also seeks. Under these conditions, one group becomes more dominant as the competition develops. The more powerful group defines the other group as inferior. As the group with less power seeks to protect and assert its interests, the dominant group may feel threatened and aggrandize to an even greater degree, and tension may mount. Most members of the dominant group soon find it easy and appropriate to view the other group in very negative terms.

Assimilation involves adapting another culture in place of one's native culture and usually is applied to the process that occurs when person adjust to a new society and culture by adopting it. For example, many Asian groups have recently immigrated to the United States. Typically their children learn English, dress in American style, eat American food, and are seen as and regard themselves as Americans. However, many adult Asians, although completely or partially bilingual, will retain an affinity for their native culture and understandably are more comfortable conversing in their original tongue.

Accommodation refers to a decision by two or more groups to put aside a significant difference that exists between them in order to stress common interests. This leads to cultural pluralism—that is, a number of different cultural patterns coexisting in the same society. The United States is a pluralist society in that it permits many distinctive religious, ethnic, and racial groups to exist side by side. The need of new Asian groups to retain their cultural identities is reflected in the existence in many large cities of Chinatowns, Koreatowns, and Japantowns. Some areas in large cities have signs only in Chinese or in both Chinese and English. This has produced some conflict with non-Chinese residents in these communities and has sparked “English-only” movements and resistance to bilingual instruction in public schools.

A great deal of research has been undertaken examining the impact of intergroup contact on intergroup hostility and prejudice (see reviews by Stephan 1985; Williams 1977). Many of the early studies looked at naturally occurring intergroup contacts. A substantial number of laboratory and field investigations have been undertaken focusing on those characteristics of intergroup contacts that foster positive intergroup outcomes. Stephan (1985) summarizes the findings with regard to this problem in a list of thirteen propositions, such as: “Cooperation within groups should be maximized and competition between groups should be minimized” and “Members of the in-group and the out-group should be of equal status both within and outside the contact situation” (p. 643).

There is a wealth of information and research on intergroup relations. However there is a definite lack of application of this information when dealing with intergroup conflicts, especially in the area of public policy. Brewer (1997) identifies several reasons for this gap between research and practice in reducing intergroup conflicts.

There have traditionally been different approaches to researching the processes involved in intergroup conflict. Research traditions focus on different levels of aggregation, with some focusing on interpersonal processes and others focusing on the group level of analysis. Additionally there are theoretical perspectives that study intergroup conflict with a primary focus on concepts in the cognitive, affective, or behavioral realm. These different

approaches tend to generate literatures that remain isolated, rarely citing research outside their own perspective.

While these separate research traditions might use different conceptual frameworks, they do have one thing in common that contributes to a lack of direct participation in the policy arena. Science has a norm of objectivity, and this leads many researchers to avoid advocating for specific action by governments or groups. Scientific research is seen as producing facts, and the role of the scientist is to produce those facts, not to decide what to do about them. The expert is hesitant to become the advocate.

History may contribute to this feeling, both for the researchers and the policy makers. In the 1950s and 1960s, much social science research (specifically the “contact hypothesis”) was used as the basis for public policy designed to reduce racial tension and conflict through the integration of schools. The research outcomes on desegregation were mixed, due in part to an oversimplified application of theoretical ideas that were very specific and conditional in nature. Additionally, the social science research on which desegregation was in part based was developed in carefully controlled laboratory experimentation. In real-life situations, which are far more chaotic and complex, the mechanisms of the theories might be overwhelmed by other factors, factors the theories were never intended to deal with. While the research community might be happy to learn from the failure of experiments and to argue about the failure of the assumptions of models to be met, the policy maker sees failure of a program and an increase in conflict among constituents. So the scientists see the politicians as understanding neither the restricted nature of most theories nor the process of the growth of knowledge as including failures. The policy makers see only that the experts were wrong and that their advice created conflict (or a perception of increased conflict) when a reduction was expected.

While research on desegregation was based on the contact hypothesis and ideas of assimilation, current research is based more on ideas of pluralism and multiculturalism. This perspective focuses on promoting positive in-group attitudes by emphasizing group identities and characteristics, and trying to make these identities respected

and recognized by other groups; to be proud of one's own ways while recognizing the pride of other's for their own ways. This creates some tensions and potential pitfalls when using this branch of theory and research as a basis for public policy.

Much of intergroup theory has focused on and developed from the situation in the United States; however, recently more attention and research have been applied to the problem in other areas of the world. With increasing migration and diversity in western Europe has come a concurrent increase in tension and conflict, and this has generated a surge of research. Pettigrew (1998) shows that "despite sharp differences in national histories, political systems, and minorities, this new work reveals considerable consistency across the nations of western Europe. It also largely replicates and extends, rather than rebuts, the North American literature" (p. 98). He shows similarities such as the higher level of "subtle" prejudice compared with "blatant" prejudice. Blatant prejudice is tied to perceived biological differences between groups and is "hot, close and direct" (p. 83). Subtle prejudice is tied to the "perceived threat of minority groups to traditional values" (p. 83) and the "lack of positive feeling towards minorities" (p. 83). In addition, the mechanisms of intergroup contact and relative deprivation seem to function in similar ways in many North American and European populations.

Given the tension between Arabs and Jews in the Middle East, it should not be surprising that theories of intergroup relations should be tested there in attempts to reduce conflicts. One such study attempted to use the contact between Jewish and Arab citizens of Israel that occurred in joint medical teams to mitigate intergroup stereotypes and prejudice (Desivilya, 1998). The study found that while the contact reduced prejudice in the local work situation, that reduction was not carried into the larger societal context and overall national image and ethnic stereotypes were not changed.

INTERORGANIZATIONAL RELATIONS

An *organization* is a group with three main features: a goal or set of goals, a boundary, and a

technology (Aldrich 1979). Although we say organizations have goals, what is meant is that much of what organizations actually do seems as if it is directed to a shared objective or set of objectives. This may be for the sake of appearance, and/or the organization may really be goal-oriented. The boundary feature simply refers to the distinction that an organization makes between members and nonmembers. Finally, technology refers to the organization's division of labor or to the set of activities that the organization performs as part of its daily routines in processing new materials or people.

Each of these characteristics can be illustrated by the university. Its goals are often set forth, albeit in glowing and idealized terms, in its general catalogue. These typically include teaching, research, and public service. One must apply to become a member of the university—student, faculty or staff. And such statuses are frequently difficult to come by. The university's technology includes its classrooms and laboratories as well as the lecture and discussion methods of instruction.

Interorganizational relations refers to the relations between or among two or more organizations. There have been several overviews of the field of interorganizational relations (Aldrich 1979; Aldrich and Whitten 1981; Galaskiewicz 1985; Mulford 1984; Van de Ven and Ferry 1980).

Every organization has relationships with other organizations. In the case of the university, if it is to function it must have students, and to recruit them it must have relationships with high schools, junior colleges, and other universities. These students (and faculty and staff) must eat, work, and play, so the university has relationships with food, housing, energy, and other suppliers of various kinds in the community. And, of course, the university needs other resources, especially funds, and therefore must relate to government agencies and alumni to obtain them (Clark 1983).

Organizations are ambivalent about establishing an interorganizational relationship to obtain resources (Yuchtman and Seashore 1967). On the one hand, they want and need resources if they are to survive; but on the other hand, organizations wish to maintain their autonomy, and insofar as they establish an interorganizational tie, they will

be expected to reciprocate, and hence their freedom will be constrained. It is assumed that organizations want their autonomy from other organizations, but their survival needs induce them to relinquish some autonomy.

Galaskiewicz (1985) claims that interorganizational relations take place for three major reasons: to obtain and to allocate resources, to form coalitions to enhance power, and to achieve community acceptance or legitimacy.

Interorganizational relations research has been undertaken at three levels: the dyad (Hall et al. 1977), the action set (Hirsch 1972), and the network (Burt 1983; Galaskiewicz 1985). The simplest form of interorganizational relation is the dyad, which simply refers to the relationships of two organizations to each other. The action set concept developed from Merton's (1957) notion of role sets. Caplow (1964) and Evan (1966) took Merton's idea and applied it to the relationships between a focal organization, such as a university, and its pairwise relationship with other organizations with whom it interacts. One might examine the relationship between a university and the office of the mayor of the city within which it is located, and then study the effects of changes in this relationship as they influence other relationships in the set of organizations (Van de Ven and Ferry 1980). Aldrich (1979) has termed the group of organizations that constitute a temporary alliance for a particular or limited goal the "action set." Networks of organizations contain the complete set of ties that connect all the organizations in a population of organizations (Aldrich 1979; Hall 1987; Van de Ven and Ferry 1980). Although the approaches of Aldrich and Van de Ven and Ferry are not identical conceptually, both orientations toward networks focus on identifying all connections of specified kinds that take place within a particular organizational population. Hence, the analysis of networks is far more complex than that of action sets or dyads.

The body of knowledge in the area of interorganizational relationships is not extensive, and what there is has focused on social services. There exists quite a bit of theoretical information but very few large databases. With the exception of research on corporate board of directors' interlocks (Burt 1983; Burt et al. 1980), there is little work on the private sector.

An early area of interest to theorists was the general state of the organizational and interorganizational environment. Aldrich (1979) identified six dimensions of environments: capacity, homogeneity/heterogeneity, stability/instability, concentration/dispersion, domain consensus/dissensus, and turbulence. Capacity refers to the relative level of resources available in the organization's environment. A rich environment refers to one where resources are plentiful, while a lean environment is the opposite.

Homogeneity/heterogeneity refers to the extent to which organizations, individuals, or even social forces that influence resources are relatively similar or different. For example, does a focal organization deal with a relatively uniform and a highly heterogeneous population? If one contrasted the labor forces that a Japanese and an American firm draw from to recruit, one would find that the Japanese firm confronts a more homogeneous environment than does its American counterpart. This is, of course, because American workers are much more heterogeneous than are Japanese workers in education, ethnic-racial background, and many other features (Cole 1979).

Stability/instability concerns the degree of turnover in various elements of the environment. Again, if Japanese and American firms are compared, we would anticipate greater turnover in the latter than in the former. The advantage of low turnover or a stable environment is that it permits the organization to develop fixed routines and structures.

Aldrich (1979) refers to the extent to which resources are distributed evenly in the environment or concentrated in a particular area as concentration/dispersion. For example, the RTD is the major bus company in Los Angeles, and its potential ridership is dispersed over an area of more than 400 square miles. Such long transportation lanes present major problems, in contrast, for example, with the Santa Monica Bus Company, whose ridership is concentrated in a much smaller and geographically homogeneous area.

Organizations differ in the extent to which their claim to a specific domain is contested or acknowledged by other organizations. Domain consensus refers to a situation wherein an organization's claim to a domain is recognized, while domain

dissensus refers to a situation where disagreement exists over the legitimacy of an organization's domain.

The final organizational dimension is turbulence. This term refers to the extent to which there are increasing environmental interconnections; the more interconnections, the greater the turbulence. Areas where many new organizations are emerging are generally areas of greater turbulence.

Some factors have been shown to be involved in the dissolution of interorganizational relations. Institutional forces, power, and competition are factors involved in the stability of these relations (Baker et al. 1998). Institutional forces reduce the likelihood of ties being broken. Personal relationships and structural attachments (such as coordination of accounting methods) represent "sunk costs" for the organization. To break ties with one organization and forge them with another takes significant effort and time. Power may increase or decrease the tendency for relations to dissolve. Given a client-provider relation, if the client has high power it increases the likelihood of the relation being broken, while high power for the provider decreases the tendency for the relation to break. Competition tends to destabilize ties between organizations, although the effect of competition is weak relative to power and structural attachments. In situations where there is much competition, there are more opportunities for defection from a relation and more incentive to do so.

A great deal of the work on interorganizational relations has concerned delivery systems and stressed coordination (Mulford 1984; Rogers and Whetten 1982). This is because a central problem in service delivery involves overcoming the segmentation and fragmentation of services created by the large number of organizations with overlapping responsibilities and jurisdictions. Bachrach (1981) has identified a number of factors that discourage coordination among organizations serving the chronically mentally ill, including budget constraints, lack of a mandate to engage in interorganizational planning, and confusion due to separate funding streams for care. Other factors also discourage coordination, such as differences in organizational activities and resources; multiple network memberships and consequent conflicting obligations felt by constituent organizations; and a lack of complementary goals and role exceptions (Baker and O'Brien 1971).

Each organization in a delivery system relies on the other organizations in the system, since no single unit can generate all the resources necessary for survival. Hence, the organization in a system enters into exchanges with other organizations and consumers. It is assumed that each organization or system seeks to better its bargaining position. This perspective on delivery systems as interorganizational networks is generally labeled the resource dependence perspective (Pfeffer and Salanick 1978).

Contingency theory (Lawrence and Lorsch 1967) assumes that organizational functioning depends on the intertwining of technological and environmental constraints and the structures that emerge to deal with these constraints. The theory assumes, as does system theory more generally, that there is no single most effective way to organize (Katz and Kahn 1966), that the environment within which an organization functions influences the effectiveness of an organization, and that different organizational structures can produce different performance outcomes.

Scott (1998) uses systems theory to describe how organizations manage their task environments and their institutional environments, and adapt to their changing organization-environment interdependencies. Scott stresses the differences between technical and institutional environmental controls.

Although there is not a great deal of comparative research on interorganizational relations, some comparisons have been done, for example, on the differences in the patterns of relations in Japan and the United States. American companies tend to be connected to more organizations, have a more formalized and more extensive body of rules for the relationship, and exchange more information across the relations than their Japanese counterparts (Aldrich et al. 1998; Jang 1997). Claims such as these must be taken with a degree of caution, as there is a great deal of influence between Japanese and American firms. For example, Japanese auto assembly plants, which started in the United States, brought both intraorganizational and interorganizational patterns of organization, for example, team-based work groups and "just-in-time" delivery of parts needed in product assembly (Florida and Kenney 1991). Since that time,

these organizational characteristics have become more common in the United States, and this increasing interdependence and connection between organizations can be seen in the impact of labor disputes extending through the economy at an increasingly rapid rate. A strike at a parts production facility that makes transmissions can shut down numerous auto production plants in a few days. A strike at Federal Express or United Parcel Service leads to economic impacts nation- and world wide literally overnight.

This globalization of economic relations mirrors a globalization of international relations. Both on an ongoing basis (e.g., the G-7, or Group of Seven Economic Conferences; the European Union; the United Nations) and on a temporary basis (e.g., the Gulf War, U.N. peacekeeping missions), interorganizational relations are becoming more and more common and vital to the peace and prosperity of the world (Alter and Hage 1993).

OSCAR GRUSKY
JEFF ERGER

INTERMARRIAGE

Intermarriage among people of different races, religions, nationalities, and ethnicities would be a subject of little concern in many societies (Degler 1971). It should be expected of a culturally diverse society such as the United States. Indeed, the United States is the most racially and culturally diverse nation in the Western, industrialized world. The heterogeneous composition of the United States should lend itself to a high degree of tolerance and acceptance of diversity in marriage patterns among its constituent groups (Spickard 1989). Since the 1960s, we have seen a rise in the number of intermarriages between different racial groups (U.S. Bureau of the Census 1998) and also an increasing number of interfaith marriages (Kalmijn 1993; Lehrer 1998). In order to discuss past, current, and future intermarriage trends, this article examines historical and contemporary trends in black/white intermarriages, past and future directions in Asian American intermarriages, the state of interfaith marriages, and reasons for the increasing number of intermarriages.

HISTORY OF BLACK/WHITE INTERMARRIAGES

Slavery had its greatest impact on the interracial relations of the Africans brought to the United States. Most of the slaves who came in the beginning were males, with the number of black females not equal to the number of males until 1840. As a result, the number of sexual relations between black slaves and indentured white women was fairly high. Some of these interracial relationships were more than casual contacts and ended in marriage. The intermarriage rate between male slaves and free white women increased to the extent that laws against them were passed as a prohibitive measure. Before the alarm over the rate of intermarriages, male slaves were encouraged to marry white women, thereby increasing the property of the slavemaster, since the children from such unions were also slaves (Jordan 1968).

The end of slavery did not give the black woman any right to sexual integrity. What slavery began, racism and economic exploitation continued to impose on the sexual lives of black women. In the postbellum South, black women were still at

the mercy of the carnal desires of white men. According to historians, black women were forced to give up their bodies like animals to white men at random. Many have noted that many southern white men had their first sexual experience with black women. In some cases, the use of black women as sexual objects served to maintain the double standard of sexual conduct in the white South. Many white men did not have sexual relations with white women until they married. Some southern white men were known to joke that until they married, they did not know that white women were capable of sexual intercourse (Cash 1960; Dollard 1957).

It was the protection of the sexual purity of white women that partially justified the establishment of racially segregated institutions in the South. The southern white man assumed that black men had a strong desire for intermarriage and that white women would be open to proposals from black men if they were not guarded from even meeting with them on an equal level. As Bernard (1966) writes, "The white world's insistence on keeping Negro men walled up in the concentration camp was motivated in large part by its fear of black male sexuality" (p. 75).

The taboo on intermarriage was mostly centered on black men and white women. One reason for this is that white men and black women had engaged in coitus since the first black female slaves entered this country. Some black slave women were forced to engage in sexual relations with their white masters; others did so out of desire. Children resulting from these interracial sexual unions were always considered black, and the prevalent miscegenation of black women and white men has produced much lighter skinned American blacks than their African ancestors.

Traditionally, white fear of interracial relations has focused on the desire to avoid mongrelization of the races. Such a fear lacks any scientific basis, since many authorities on the subject of racial types seriously question that a pure race ever existed on this planet. Most authorities note it as an actual fact that the whole population of the world is hybrid and becoming increasingly so. At any rate, the rate of miscegenation in the past almost certainly casts doubt on any pure race theory for the United States (Day 1972).

Intermarriage is certainly nothing new in the United States. Its meaning and dynamics have, however, changed over the 400 years since blacks entered this country. In the era before slavery, black male and white female indentured servants often mated with each other. During the period of black bondage, most mixed sexual unions took place between white men and female slaves, often involving coercion by the white partner. A similar pattern of miscegenation occurred after slavery, with a white man and a black woman as the typical duo. When blacks moved to larger cities outside the South, the black male-white female pairing became more common. As is commonly known, legal unions between the races were prohibited by law in many states until 1967. But legal prohibitions were not the only deterrent to such biracial unions. This country's history is replete with acts of terror and intimidation of interracial couples who violated the society's taboos on miscegenation. While blacks and whites came together in love and marriage over the years, it was generally at a high cost, ranging from death to social ostracism (Stember 1976).

CONTEMPORARY BLACK/WHITE MARRIAGE

Between 1960 and 1990, black/white intermarriages increased fourfold (U.S. Census Bureau 1998). Among the reasons for this increase has been the desegregation of the public school system, the work force, and other social settings. Around 1968, American society witnessed the first significant increase in interracial dating. This was the year that blacks entered predominantly white college campuses in comparatively large numbers. Contemporaneous with this event was the sexual and psychological liberation of white women. While white society disapproved of all biracial dating, the strongest taboo was on the black male-white female bond. These bonds became the dominant figures in the increments of biracial dating. The college campus became an ideal laboratory for experiments in interracial affairs. In the university setting, the blacks and whites who dated were peers, with similar educational backgrounds, interests, and values. Young white women, who were not as racist as their parents, were liberated from parental and community control. Their student cohorts were more accepting of or indifferent to

their dating across racial lines. Those changes in interracial dating practices coincided with the civil rights movement and a greater white acceptance of blacks as racial equals.

In the 1970s through 1990s, integration of work settings, neighborhoods, schools, and other public settings has meant that blacks and whites interact much more as equals than in the past. According to a Gallup poll (1997), a majority of blacks go to school, live, and work in places where the population is at least half white or even predominantly white. Only 15 percent of blacks work with mostly or all blacks and 41 percent of blacks live in a mostly or all-black neighborhood. Therefore, it is not surprising that with increasing social interaction there would also be an increasing number of interracial unions.

In addition to these systemic changes, there has been a major change in public attitudes toward biracial couples. According to a Gallup poll (1997), a majority of blacks and whites under the age of 50 say they accept and approve of interracial unions between blacks and whites. Of all the different race-related trends, this change in attitude is the most significant. In 1958, only 4 percent of white Americans approved of marriages between blacks and whites; in 1997, 61 percent approved. However, negative attitudes toward black/white intermarriages still persist. About a quarter of blacks and about 40 percent of whites say they disapprove of interracial marriage. Much of this can be attributed to how different generations view interracial marriages, as well as regional differences. Younger people approve of such marriages, while older black and white Americans are less likely to approve. According to Wilson and Jacobson (1995), age and education are strong predictors of those who are accepting of black/white intermarriages. In their study, they found younger, educated cohorts to be more accepting of such unions, compared to older, less educated cohorts. Moreover, acceptance of such marriages is much lower in certain regions of the United States, such as the South (Gallup Organization 1997). Although these changes in attitudes toward intermarriage seem positive, this poll result could be misleading. Many people tend to give the liberal answer they think is proper or expected when asked about controversial issues such as interracial marriage. However, when confronted with the issue on a very personal level, their response may be much different.

In the past, white families in particular frequently refused to have anything to do with children who entered into interracial marriages (Gold- en 1954; Porterfield 1982; Spickard 1989). According to Rosenblatt and colleagues (1995), white families compared to black families were most often in opposition. Opposition by white family members was most often based in racist assumptions and stereotypes, but also based in concern about the racism that the couple would face from society at large. Moreover, white families were concerned that marrying interracially meant a poor economic future. Other concerns raised by white families included issues of safety and well-being, as well as the issue of raising a biracial child. The authors found that there was less opposition in black families. Close family members might have been militantly against the marriage, but mothers in black families played a key role in providing acceptance of the interracial marriage. On the other hand, in white families, fathers were the key person in providing acceptance. In both black and white families, families were particularly concerned about their daughters' marrying interracially. Rosenblatt and colleagues (1995) explain that "for white families, the roots may include the racism of a dominant group and fear of loss in status. For black families, the roots may include the fear and pain of being connected with the oppressor" (p. 69). St. Jean (1998) discusses how black males in families may be more ambivalent about such unions. In previous studies, black women more than black men had tended to disapprove of such intermarriages (Paset and Taylor 1991); however, St. Jean (1998) found quite the opposite. She found that black men had a more difficult time accepting such marriages.

Although many black/white couples are drawn together because of nonracial factors, such as common interests and personal attraction (Lewis et al. 1997), race remains a major factor in their interactions with family, friends, and society at large. Given the persistence of racism, many interracial marriages face rough going. Based on her qualitative research findings, St. Jean (1998) found that although for the "couples the salience of color seems to diminish after marriage, race consciousness does not diminish. In their everyday lives, they are reminded by Blacks, Whites, relatives and nonrelatives of the inappropriate nature of their association" (St. Jean, p. 12). It is a fact that the

scars of nearly 400 years of the worst human bondage known are not healed, and disapproval by many black and white people of interracial love affairs is one of the wounds.

PAST AND FUTURE DIRECTIONS IN ASIAN AMERICAN INTERMARRIAGES

Since 1990, fueled by immigration from Asia, the Asian and Pacific Islander population has grown at a rate of 4.5 percent per year (U.S. Bureau of the Census 1995). By the year 2000, this population had reached 12.1 million. As this group increases in size, intermarriage will probably occur more frequently (Lee and Fernandez 1998). According to Gordon (1964), the acculturation to American beliefs and values by new immigrants has meant that intermarriage would follow and is an important sign of the assimilation process. Hwang and colleagues (1997) report that Asian Americans with high levels of acculturation and structural assimilation have a high incidence of intermarriage: "Asian Americans who speak fluent English and who have lived longer in the US were found to have a higher tendency to marry persons from different racial and ethnic groups" (p. 770).

Despite the increase in population growth, the intermarriage rate for Asian Americans has declined overall. However, there are several explanations that account for these changes. According to Lee and Fernandez (1998), Asian-American outmarriage from 1980 to 1990 declined significantly from 25 percent to 15 percent based on their analysis of the 5 percent Public Use Microdata Sample (PUMS) of the 1990 U.S. census. They note that intermarriage levels dropped for Koreans, Filipinos, and Vietnamese. While outmarriage rates among American-born Asians increased, they declined for those foreign-born. They also note that Asian-American women were more likely to outmarry than men and that outmarriage was more common among Japanese Americans, Filipinos, Chinese, and Asian Indians. Lee and Fernandez (1998) further suggest that even though the Asian-American outmarriage rate overall has fallen, Asian interethnic marriages, made up of partners from two Asian ethnicities, has increased from 11 to 21 percent.

According to Shinagawa and Pang (1996), these marriage patterns can be explained through a

sociohistorical framework. They define five different historical cohorts: Pre-World War II and World War II (prior to 1946), post-World War II (1946-1962), the civil rights era (1963-1974), the post-1960s (1975-1981) and the Vincent Chin cohorts (1982-1990). Because the pre-World War II and World War II cohort experienced antimiscegenation laws, they intermarried with other nonwhites. Those in the post-World War II cohort lived in an era when antimiscegenation laws were struck down and Asian immigrants could now become citizens. At the same time, American soldiers fighting wars in Asia brought back Asian wives. The civil rights era cohort experienced radical changes in terms of race. Racial groups, no longer segregated from each other, were interacting more, and laws were enacted to bar racist discrimination. Asians could now intermarry with whites, and this era saw an increasing number of Asian women marrying white men. The post-1960s cohort experienced the beginning politicization of the Asian-American community. However, intermarriages were still mostly between whites and Asians. Major changes started to happen in the Vincent Chin cohort. In 1982, Vincent Chin, a Chinese American autoworker in Detroit, was beaten to death by two whites who mistakenly identified him as a Japanese American, angering the Asian-American community and fueling community mobilization and politicization. The murder, which became symbolic of anti-Asian hate crimes and discrimination, brought diverse Asian communities together to eradicate discrimination against Asians and bring justice to Vincent Chin's family (Espiritu 1992). This era was defined by an emerging increasingly coalesced Asian-American community as well as by a growth of the Asian Pacific American population. According to Shinagawa and Pang (1996), these dramatic developments contributed to the growth of interethnic Asian marriages.

Shinagawa and Pang (1996) hypothesize six major reasons why pan-ethnic intermarriages and pan-ethnicity among Asian Americans are on the ascent: (1) the growth of the Asian-American population; (2) the growth of personal and social networks due to these population increases; (3) the growth in the number of educated, middle-class Asian Americans; (4) the acculturation of Asian Americans; (5) shared racial identity; and (6) most importantly, the growing racial consciousness

among Asian Americans. According to Espiritu (1992), the construction of pan-Asian ethnicity arose out of a need for political strength and power. Shinagawa and Pang (1996) stress the importance of a pan-Asian ethnic consciousness that has shaped not only political but also marital patterns: "Deindustrialization, white flight, increased economic competition, anti-immigrant sentiments, hate violence against Asians, the growing sense of despair and hopelessness in the inner cities, and interracial conflicts not only between Whites and Asian Americans but also between racial minority groups all signify racial consciousness by Asian Americans" (p. 144).

TRENDS IN INTERFAITH INTERMARRIAGE

Although interracial marriages have increased, interfaith marriages are much more commonplace. Inter-marriage between white ethnics is quite the norm (Lieberson and Waters 1988). Marriages between members of different faiths also happens much more frequently and seems to carry less stigma than interracial coupling. In fact during 1990, 52 percent of Jews were married to non-Jews, while Protestant/Catholic intermarriages have increased significantly (Kalmijn 1991). According to Kalmijn (1991), the increasing importance of similar educational levels in spouse selection and the declining importance of religious differences explains the increase in Protestant/Catholic intermarriages. Using data from the 1987-1988 National Survey of Families and Households, Lehrer (1998) also suggests that intermarriages between Protestants and Catholics have increased steadily. She identifies key variables that play a role in the decision to intermarry. She reports that those with higher levels of education are more likely to intermarry than those with lower levels of education. She also discusses how a premarital pregnancy will increase the likelihood of an intermarriage. Those who are strongly committed to their faith are least likely to intermarry. Despite these increases, Lehrer and Chiswick (1993) report that interfaith marriages are more likely to end in divorce, attributing these high divorce rates to the different religions of the couple. However, they also suggest that conversion by one spouse to the faith of the other produces less conflict and a more harmonious relationship.

FACTORS IN INTERMARRIAGES

Although the increasing trend toward intermarriage across ethnicity, religion, and race can be attributed to the increasing interaction between diverse individuals and to the elimination of institutional barriers, there are also other sociological, demographic, and psychological factors at work. According to psychotherapist Joel Crohn (1995), the decision to intermarry is not based on one single element—there may be many psychological influences operating. From his work as a therapist, he identifies four reasons that individuals from different religious, cultural, or ethnic backgrounds may be attracted to each other. First, stereotypes about a particular group may attract persons to each other; for example, black men are masculine, Jewish men are good providers, and Asian women are sexy.

Second, Crohn (1995) suggests that outmarriage can also be due to a partner's struggle with his or her identity. Those who outmarry may find members of the opposite sex from their ethnic, racial, or religious group unappealing and unattractive. Marriage can then be the arena in which individuals deal with their ambivalent attitudes toward their racial, ethnic, or religious identity: "Marriage to an outsider represents the ultimate strategy in trying to erase the stigma of a minority identity" (Crohn 1995, p. 52). At the same time, minority groups may outmarry into the dominant group to gain acceptance by that group. According to Pang (1997), Asian-American women who choose relationships with white men "participate in a language of assimilation that minimizes essential core parts of their self" (Pang 1997, p. 295). She found that Asian-American women who outmarry do not place importance on their race or culture and rather take on the identity of their white husband. According to Pang (1997), assimilation and incorporation into white society for these Asian-American women was of importance.

Third, Crohn (1995) suggests that whites may feel like they lack a particular cultural tradition and thus be attracted to a partner with a certain cultural and ethnic distinctiveness. Crohn further suggests that intermarriage is also a way for adult children to separate themselves from their family emotionally and/or physically. In fact, other studies have documented that those who chose to intermarry were more rebellious and had huge

conflicts with family due to objections to their marital choice (Sung 1990).

Fourth, Crohn discusses how attraction across religious, ethnic, or racial barriers may be grounded in cultural values and traditions, such as collectivism or individualism, that the individual is attracted to.

According to social exchange theory, relationships are exchanges of valued resources and involve an analysis of costs and benefits. Pierre Van den Berghe (1960) theorizes that racial or ethnic intermarriage is an instance of such an exchange, in this case that of hypergamy. *Hypergamous* means that women marry up in status; while *hypogamous* means that the racial and ethnic status of the husband is lower than that of his wife. In the past, most black men who married white women were of a higher social status than their wives. In fact, this marrying down was so common that sociologists formulated a theory about it, hypothesizing that the black groom was trading his class advantage for the racial caste advantage of the white bride (Davis 1941; Merton 1941). Kalmijn's (1993) study of marriage license data from 33 states between 1968 and 1996 indicates that black/white intermarriages have been on the rise, most prominently between black males and white women. Kalmijn notes that these marriages involved white women and high-status black men, meaning that white women moved up in socioeconomic status.

Other factors may propel people into an interracial marriage. Some students of the subject assert that uneven sex ratios are a basic cause. Whenever a group near another group has an imbalance in sex ratio, there is a greater likelihood of intermarriage. If the groups have a relatively well-balanced distribution of the sexes, members will marry more within their own group (Guttentag and Secord 1983; Parkman and Sawyer 1967).

As for the sociocultural factors that promote or deter interracial marriages, several explanations have been put forth to explain the variation in intermarriage patterns in the United States. Tucker and Mitchell-Kernan (1990) hypothesized that certain environments are more racially tolerant of intermarriage than are others. Their hypothesis is based on findings from U.S. census data showing that interracial marriage rates are highest

in the West and lowest in the South (U.S. Bureau of the Census 1985). Similar to their explanation is the argument by Blau and Schwartz (1984) that the larger the group size as a proportion of the population, the less likely it is that members will marry outside their group. Second, they suggested that the more heterogeneous an area's population, the more likely it is that people will marry outside their group. Both the aforementioned propositions imply that intermarriage is a function of environmental forces, not individual motivations.

In addition to the normal problems of working out a satisfactory marital relationship, interracial couples must cope with social ostracism and isolation. While the motivation for an interracial marriage may or may not differ from that of intraracial marriages, there are problems that are unique to interracial marriages. When researchers studied interracially married couples they discovered that courtship in most cases had been carried on clandestinely and, further, that many of them were isolated from their families following the marriage. Other outstanding social problems encountered by the couples centered on such factors as housing, occupation, and relationships with family and peers. Several of the spouses lost their jobs because of intermarriage, while others felt it necessary to conceal their marriages from their employers.

In addition to these strains, intermarried couples also face stressors within the family. Conflicts with in-laws contributed to marital instability (Chan and Smith 1995). Moreover, intermarried couples experienced not only the greatest conflict with in-laws but also differences that arose in terms of child rearing. According to Chan and Smith (1995), intermarried couples may face more problems because of their concerns with raising biracial children. They may worry about the children's psychosocial development because of their mixed heritage. The children may look more black than white and "this may create more stress for the mother who is most likely to be the primary caretaker and have to deal with the prejudice others might have about her children" (Chan and Smith 1995, p. 383).

Further research needs to be done to investigate the factors involved in intermarriages, as well to assess marital stability and instability among

intermarried couples. However, there are several data problems in conducting research on intermarriages. First, marriage data collected by the National Center for Health Statistics (NCHS) is incomplete, since not all states are required to submit data and only about forty states submit such information (Besharov and Sullivan 1996). Moreover, many states do not ask questions about race on marriage licenses. Currently, only thirty-two states report race information to the NCHS (Besharov and Sullivan 1996). Even if data on race and ethnicity are available, the analysis is quite limited when conducting research on the second-generation intermarriage experience (Roy and Hamilton 1997). Moreover, data on interfaith marriage are also sparse, since the census and other government surveys rarely ask a respondent's religion (Salins 1997). In addition, the General Social Survey, which collects information on attitudes toward intermarriages, is quite limited because only two questions are presented in this survey: "How do you feel about having a close relative or family member marry a Black person?" And "Do you think there should be laws against marriages between Blacks and Whites?" According to St. Jean (1998), these questions do not adequately address current attitudes on intermarriages. Rather, St. Jean (1998) suggests that qualitative research, such as focus groups, provide more insight and information than the existing quantitative research on the topic.

SUMMARY

As barriers between different groups of people come down, intermarriage will continue to take place. This article has discussed the history and trends of black/white intermarriages, past and future directions of Asian-American intermarriages, trends in interfaith marriages, and factors involved in intermarriages. High intermarriage rates have been mostly among white ethnics (Salins 1997). Despite the increases in interracial marriage, black/white intermarriages are still quite low compared to other interracial and interfaith marriages. Racist attitudes still persist. Of these various types of intermarriage, black/white intermarriage is still one that is fraught with controversy. Those who oppose it often combine a hostility toward racial equality with invidious assessments of the private

thoughts and lives of interracial couples. Many men and women mate for no more complex reasons than meeting, liking each other as individuals, and choosing to transcend the societal barriers to their relationship. Only in societies similar to that of the United States does a biracial union take on any greater significance. For centuries, Latin American nations have undergone such a fusion of the races that only nationality, language, and religion remain as sources of identity. But the painful history of race relations in North America militates against the natural mixing of individuals from different races. Instead of regarding interracial dating and marriage as a matter of personal choice, many minorities have taken up the call for racial purity so common to their white supremacist adversaries of the past.

Despite the opposition to biracial unions, they will continue to increase as long as the social forces that set intermarriage in motion exist. There is, for example, the class factor. As long as middle-class blacks occupy token positions in the upper reaches of the job hierarchy, most of the people they meet in their occupational world will be white. Considering the fact that the job setting is the paramount place for meeting mates, it is only natural that many blacks will date and marry whites. Those whites will be the people they most often encounter and with whom they share common values, interests, and lifestyles. In the 1950s, E. Franklin Frazier (1957) predicted:

The increasing mobility of both white and colored people will not only provide a first-hand knowledge of each for the other but will encourage a certain cosmopolitanism. That means there will be a growing number of marginal people who will break away from their cultural roots. These marginal people will help create not only an international community but an international society. In becoming free from their local attachments and provincial outlook, they will lose at the same time their racial prejudices, which were a product of their isolation. Many of these marginal people will form interracial marriages because they are more likely to find suitable marriage partners in the cosmopolitan circles than within their native countries.

A careful reading of history indicates that the intermarriage rate often rises or falls for reasons

related more to political and economic factors than individual desire. Within the developed world, the United States has the lowest rate of interracial marriage because it is the most racially diverse of all those nations. Due to a combination of economic factors, many white Americans feel less secure about the racial privileges they have long enjoyed and the impact intermarriage would have on their life chances and that of their children. The increasing presence of people of color and their competition for the best jobs, houses, incomes, and lifestyles heighten these insecurities. Increasingly, they are willing to turn back those challenges by racial scapegoating in the political arena, resulting in a number of reactionary voting patterns by the Anglo majority on affirmative action and immigrant issues, which largely affect African Americans, Asian Americans, and Latino citizens. In defense of their right to participate equally in the political and economic life of the United States, people of color have forged movements of racial and ethnic solidarity to counter the white backlash.

However, racial divisions are doomed to eventual failure in large part because race itself is a social construct used more as an opiate or divisive strategy than for any other purpose. Just as religion is the divisive force in much of the world, racial differences serve to mask the underlying causes of class inequality in the United States. The political and economic elite have found it expedient to exploit minor differences in physical traits among groups to detract from public consciousness of the most pronounced case of economic inequality in the developed world. Only when economic justice becomes a social reality can we expect to see dating and marriage choices based on merit and not a group's standing in the racial and class hierarchy.

INTERNAL MIGRATION

Migration is the relatively permanent movement of individuals or groups over varying distances to change places of residence; permanence and distance are its major defining dimensions. Internal migration occurs within the boundaries of a given country. (International migrants, not considered here, are called immigrants.) Internal migration, therefore, is a type of geographic mobility status.

DEFINITIONS

The following definitions are standard in the field of social demography (Bogue 1985):

Mobility status. A classification of the population based on a comparison between the place of residence (destination) of each individual in a census enumeration or survey and the place of residence (origin) at some specified earlier date. Mobility status in terms of the distance of the move falls into four main categories: nonmovers, local movers, intrastate migrants, and interstate migrants.

They may be examined more specifically in the list below:

- I. *Nonmovers*, or nonmobile persons, live in the same house at the time of the census as at the date of origin.
- II. *Movers*, or mobile persons, live in a different house and are further classified as to where they were living at the earlier date.
 - a. *Local movers* are mobile persons who live in the same county at census time as at the date of origin.
 - b. *Internal migrants* are mobile persons who live in a different county at census time than at the date of origin. Internal migrants may be further subclassified:
 1. *Intrastate migrants* live in a different county but within the same state.
 2. *Interstate migrants* live in a different state.
 3. *Interregional migrants* live in a different geographic division or census geographic region; they are also interstate migrants.

Mobility interval. The lapsed time between the date specified for previous residence and the date of enumeration is usually either one year or five years. Recent census enumerations specify five years, and the Current Population Surveys have specified intervals of one, two, three, four, and five years.

Metropolitan mobility. A system of subdividing mobile persons into categories by place of residence at the beginning and the end of the mobility interval and, according to metropolitan statistical areas (MSAs), is as follows:

1. Within the same MSA
2. Between MSAs
3. From outside MSAs to MSAs
4. From MSAs to outside MSAs
5. Outside MSAs at both dates

Mobility rates. The number of persons in a specified mobility status per 100 or 1,000 in the

population of the area in which they resided at the end of the mobility interval is a mobility rate. Such rates may refer to any of the categories of nonmobile or mobile persons specified above. Mobility rates may be specific for age, race, sex, or other traits. The denominator may also be the origin date or the midpoint of the migration interval.

Migration flows. The key distinction of flows is that either the origin or the destination is unknown. There are two types of flows:

1. *In-migration* is comprised of migrants arriving at a particular place of destination, with no reference to the place of origin. In-flows could also arrive at specified types of places, such as central cities or metropolitan areas.
2. *Out-migration* is comprised of migrants departing from a particular area, with no reference to the place of destination. Out-flows may also depart from specified types of places, such as places outside MSAs or suburban metropolitan rings of MSAs.

Migrations streams. These connect an origin to a destination. There are three types of migration streams:

1. *Specific streams.* Streams that connect particular places within a category, such as streams between specific cities, counties, states, or regions. This is the major use of the term.
2. *Typological streams.* Streams that connect types of places, such as streams between all central cities and suburbs in a state or the nation.
3. *Counterstreams.* When a stream between two places endures, it usually generates a counterstream, a smaller stream in the opposite direction. The stream and counterstream are referred to as an *exchange*.

Net migration. This is the difference obtained when the number of out-migrants is subtracted from the number of in-migrants in a particular place or type of place. A location that experiences a loss of population through migration is said to have a negative net migration; one that gains

population through migration has a positive net migration. Because of its birth and death rates, an area may have a negative net migration and continue to have a growing population. There is no such thing as a net migrant, however.

Return migration. The census contains an item that identifies the state of birth. Return migrants are those persons who return to their state of birth during the mobility interval. There is no way of knowing how long they have been away from their state of birth when they return.

WHY STUDY MIGRATION?

Migration is important to social scientists because an increase or decrease in the size of a population, due to excess in- or out-migration, causes many social conditions to change. Community infrastructure, such as highways and schools, may become overburdened due to population growth, while public services may become difficult to maintain when population declines. Furthermore, social scientists study the equilibrating effects of population movement on national and regional economic systems. Growth or decline in the local economy is an incentive for people to move, which redistributes the population to balance the system.

The ability to predict the impacts of population growth or decline on the institutional sectors of a community and the ability to understand regional population dynamics, of course, provide many practical benefits to government and business planners.

MIGRATION RESEARCH

Net migration rates before 1940 were estimated using a survival-rate method. This method takes the population in one census as its base. It adjusts the number by adding births and subtracting deaths during the next decade. The amount of population change not accounted for is attributed to migration (Bogue and Beale 1961). The 1940 census was the first to include a mobility item. It asked where persons lived five years earlier. In 1950, after World War II, there was so much population movement that a one-year interval was substituted in the census. In 1960 the five-year mobility interval was restored and has been retained in subsequent decades. Because of these measurement

changes, the 1960 and 1970 censuses were the first from which decade changes could be derived. Thus several landmark studies appeared in the 1960s, breaking new ground and setting patterns for future migration research (Long 1988). Shryock's (1964) work showed the importance of studying gross migration flows in addition to the prevailing dependence on net migration. Lowry (1966) introduced econometric modeling to migration research. Finally, Lansing and Mueller (1967) helped introduce survey approaches to analyzing internal migration.

U.S. MOBILITY

Americans are unusually mobile (Bogue 1985). Only Canada and Australia have populations as mobile as that of the United States. In a single year, from March 1995 to March 1996, 17 percent of U.S. inhabitants moved from one domicile to another and about 6 percent changed their county of residence. At current mobility rates, average Americans live at fourteen different addresses during their lifetimes. Of these thirteen moves, three are as a dependent moving with parents and ten are of their own volition. People who have lived their entire lives at the same address account for no more than 2 or 3 percent of the adult population. Perhaps no more than 10 to 15 percent of people spend their entire lives in their county of birth.

When using the five-year mobility interval, mobility rates are not five times as large as those for a single year because persons who move several times within the interval are counted only once. Nearly one-half of the population is mobile over a five-year period, and more than one-fifth are migrants. Since 1980 there appears to have been no diminution in the tendency to migrate, but there has been an apparent reduction in local mobility.

One can discover contradictory findings in mobility literature. These contradictions are often due to the specific databases under analysis. Some databases use mortgage data and leave out renters; others, such as the Annual Housing Survey, use households; and some, such as most census publications, use individuals as units of analysis, each database giving somewhat different results. In addition, some data sources offer little information on the characteristics of migrants. The individual

master file of the Internal Revenue Service includes state and county migration data but no personal characteristics, and several large moving companies provide data on their customers also without personal characteristics (Kahley 1990).

Reasons for Migration. Migration may occur in response to changing economic, social, or political conditions. Push factors are conditions in the sending population that impel or stimulate migration. Conditions that attract in-migrants are classified as pull factors (Ravenstein 1889).

Declining economic opportunities, political instability, or the weakening of place ties may stimulate out-migration. Expanding economic opportunities, potential for advancement, the presence of family members and friends, or previous vacationing or residential experience tend to attract migrants. Not surprisingly, rural communities with high birthrates and regions with limited opportunities are areas of high out-migration, whereas urban, industrial regions and communities with expanding opportunities tend to have high in-migration (Prehn 1986). Marriage, divorce, increasing or decreasing family size, and housing adequacy top the list in surveys. A sizable majority of respondents to the Annual Housing Survey reported housing or family dynamics as reasons for their move (Gober 1993).

The average age at which young adults leave home declined from the low twenties to the upper teens between 1920 and 1980, and then the median age began to rise again. These trends mirror another one; for the Vietnam cohort of young adults forward, those who return to live at home at some time holds at about 40 percent. About 25 percent had moved back in earlier cohorts. The expectation of a permanently empty nest for parents of young adults now seems a less certain one (Goldscheider and Goldscheider 1994).

Zelinski (1971) proposed a macro-level three-stage model of national internal migration. First, with the onset of modernization, the overall level of migration increases, primarily in the form of rural-to-urban moves. Second, as industrialization and modernization spread to more regions, migration may continue to increase; improved transportation and communication increase the availability of information and decrease the uncertainty of

moving. Interurban moves become the majority of all moves. Finally, at advanced stages, when level-of-living differences among areas have diminished, there may be more urban-to-rural movement and more “consumer-oriented” migration toward warm climates or locations with other amenities (Long 1988).

Differential Migration. What population characteristics predict migration? Characteristics that indicate less entanglement with social obligations, greater need for employment, and higher job skills are good predictors. Men are more mobile with respect to residence than women, although the difference is small. The single migrate at higher rates than the married. For several decades, blacks have been more mobile than whites. However, in 1980 whites migrated at higher rates than blacks, although blacks continued to be more mobile locally. Hispanics migrated internally at a rate between those of the black and white populations. Persons with higher levels of education are more likely to migrate than those who are less well educated.

Age and Mobility. The shape of the age profile of migrants in the United States has been consistent for decades, changing only gradually over time. The younger children are, the more likely they are to migrate. The migration rate of children bottoms out in the early teens and does not increase rapidly until the late teens. More than one-third of Americans in their young adult years, ages twenty to twenty-four, the peak migration years during the life course, moved at least once between 1982 and 1983, and nearly one-half of this mobility was migratory. Not surprisingly, this age corresponds with college graduation and marriage for many. The increasing age of children in the home, particularly once they begin their formal schooling, dampens the attractiveness of migration for parents. The age-specific migration rate declines slowly at first, then more steeply until age thirty-five, after which it slowly declines throughout the middle years to a life-course low point just before the retirement years. The retirement migration hump between ages sixty and seventy is small by comparison to the early adulthood migration bulge. The final increase in age-specific migration rises at the end of life and relates largely to health issues. The elderly as a broad category are

only about one-half as mobile as the general population.

MIGRATION AND REGIONAL DISTRIBUTION OF POPULATION

Three large interregional flows of internal migration have been occurring in the United States for many decades.

Westward Movement. For a long time, there was a high-volume flow of persons into the Pacific region, principally California, as well as a high-volume flow into the mountainous southwestern states. The 1970–1980 decade had a higher volume of westward movement than any previous one. Mountain states that previously suffered losses all made positive gains, and Colorado, Nevada, and Arizona continued the large gains of the previous decade. In the 1990s, there was a net flow out of California, largely to other western states, reversing a long-term trend for that state.

Northward Movement from the South. The southern region lost population heavily between the close of the Civil War and 1950. Industrial centers in the northeast and east-north-central regions absorbed a very large share of the migrating population. Both white and black migrants flowed along these channels in great numbers. Some southern states, however, particularly Florida and Texas, were exceptions. Between 1970 and 1980 the net outflow from the South completely disappeared. Those who left the South preferred the West to the North as a destination, and in-migrants to the South balanced the out-migrants. Every state in the northeast and north-central regions suffered a net migration loss during the decade, resulting in a major regional migration turnaround (Bogue 1985). By 1990 there were no net flows out of the South to other regions, but the Northeast, Midwest, and West all contributed to the southern region (Gober 1993).

The Southward Movement to the Gulf Coast and the Southern Atlantic Seaboard. The entire Gulf Coast, from the mouth of the Rio Grande in Texas across the coastal portions of lower Louisiana, Mississippi, and Alabama and on to include all of Florida, experienced much more rapid and intensive economic development than the southern and southeastern parts of the United States

lying away from the coast. Although this trend is a very old one, it accelerated rapidly in the 1970s.

As of 1980 there were only two regional migration streams instead of three: movement toward the South and Southwest and movement toward the West. The northeast and the north-central regions are the sources from which these migrants came (Bogue 1985). But in the 1980s, the South gained more through net migration than did the western states (Weeks 1996), a trend that accelerated by 1990. The geographic redistribution of knowledge-based industries of the information age carries in its wake a college-educated work force to the Sunbelt, including the South (Frey 1995).

Metropolitan Deconcentration. One of the macro-level processes that affects geographic mobility in our time is metropolitan deconcentration. Many nonmetropolitan counties in the United States experienced a slowing of population decline in the 1960s, and in the 1970s their net migration rates climbed above the break-even point, which signaled a genuine and widespread “rural–urban turnaround.” Older people seem to have been in the vanguard of migration to nonmetropolitan counties; the turnaround for them happened in the 1960s rather than the 1970s. This reversal of a long-term trend of rural-to-urban migration is of great interest to demographers. Mounting evidence now indicates that although deconcentration continues in nonmetropolitan America as a whole, by the late 1980s metropolitan counties were outgrowing nonmetropolitan ones (Long and DeAre 1988). In the 1990s there is an uneven urban revival, with a few metropolitan areas with more flexible and diverse economies, mostly outside the Northeast and Midwest, gaining migrants. The new dominance of the suburbs over the central city is key to metropolitan deconcentration in the 1980s and 1990s. During this period, the suburbs are capturing the bulk of employment and occupational growth (Frey 1995).

RETIREMENT MIGRATION

Demography traditionally tends to focus on youthful migration, and labor-force migration in particular. Increasing attention, however, is being given to non-labor-force-motivated migration, particularly to the migration of persons of retirement

age (Longino 1996). For the elderly, interstate flows are highly channelized—that is, half of the interstate migrants, regardless of their origin, flow into only eight of the fifty states. Florida dominates the scene, having received about one-quarter of all interstate migrants aged sixty or over in the five years preceding the 1960, 1970, 1980, and 1990 censuses. Although Florida, California, Arizona, and North Carolina have different major recruitment areas, they are the only states that attract several unusually large streams from outside their regions. Florida and North Carolina draw primarily from east of the Mississippi River, and Arizona and California draw from west of it. Among the elderly, the special characteristics of the destination tend to be more important than the distance. Warm climate, economic growth, and lower cost of living are still important pull factors.

Distance selectivity of elderly migration has been studied. Local movers are generally not as economically and socially well-off as nonmovers, and migrants are more well-off. Interstate migrants tend to have the most positive characteristics.

Permanence is an important but difficult dimension of migration to study. The census assumes that one's "usual place of residence" is not temporary. In reality, however, much of the migration among older people may be temporary. So far, studies of elderly seasonal migrants show them to be relatively advantaged, attracted by non-labor-force issues such as climate, cost of living, and the locations of family members and friends.

Metropolitan-to-metropolitan migration predominates among the elderly. Of the one-third who changed environmental types, no increase occurred between the 1960 and 1980 censuses in the proportion moving out of metropolitan areas in each decade. However, the movement in the opposite direction, up the metropolitan hierarchy, declined, both among older intrastate and interstate migrants. The net difference made it appear as though the flow from cities increased. Metropolitan-to-metropolitan migrants, especially those moving longer distances, tend to have more income, to be married, and to live in their own homes. A higher proportion of nonmetro-to-metro migrants is older, widowed, and living dependently, especially with their children. Coding revisions in

the 1990 census made updates of these comparisons impossible to calculate.

The cycle of migration for a job when one is young and returning to one's roots after retirement is an appealing notion to theorists. In contrast, Rogers (1990) demonstrated that elderly persons are not any more likely to return home than are the nonelderly; in fact, the probabilities of return migration by the elderly are lower than those of the general population, even after controlling for the different mobility levels of the two populations. There is wide state variability, however. The southeastern region is unusually attractive to older return migrants, and return migration is uncommonly high among the older black population moving into that region. Some evidence from the 1990 census shows that regional return migration patterns are shifting away from the Sunbelt states. Some migrants, apparently, return to their home states after an earlier retirement move (Longino 1995).

Some dubbed retirement migration as the growth industry of the 1990s. The amount of income transferred between states through retirement migration is quite substantial. Not surprisingly, economic development agencies are mounting efforts to attract mature migrants. This is leading to sharp competition among destinations for these migrants as new residents. The impact of elderly migration as a social phenomenon has yet to generate enough research to provide definite statements.

INTERNATIONAL COMPARISONS OF INTERNAL MIGRATION

Little research exists to compare countries on internal migration because measures, data sources, and units of analysis differ widely among nations. Consequently, international organizations have not published compendia of national comparative data on migration as they have on fertility and mortality. In addition, certain types of cultures conceive internal migration differently. In some small countries, such as England, lack of new housing stock limits residential movement. Migration is also limited in countries such as France, where transportation routes primarily connect the peripheral towns to a central national capital for historical reasons. Conversely, internal migration is amplified and culturally expected in nations of

immigrants with widely dispersed regional centers and major cities, such as the United States, Canada, and Australia.

Nonetheless, existing studies provide some tentative generalizations that compare internal migration in the United States with that in other countries (Long 1988). The U.S. national average for moves is higher than that of most other countries because (1) cities in the South and West are growing; (2) a relatively large minority of people who repeatedly move elevates the U.S. average for lifetime moves above that for most other countries; and (3) during the 1980s and 1990s the baby boom generation in the United States has moved through the life-cycle stages that have the highest rates of geographic mobility.

Comparative studies also give attention to older migrants, although their mobility rates are lower than for the young. Rogers (1989) argues that as the populations of industrialized nations age, the internal migration patterns of elderly persons will change. Elderly migration levels are low in countries in the first stage of this population transition. In the second stage of the transition, large, long-distance flows to particular principal destination regions appear. The third stage continues to exhibit large numbers of elderly migrants, but their moves now include a significant number of short-distance moves to more dispersed inland regions. Rogers and colleagues (1990) argue from comparative data that England is in the third stage, the United States is transitioning between the second and the third stages, Italy is well into the second stage, and Japan is in the first stage.

Since 1970, for most developed countries, population aging has brought declining national rates of internal migration (Long 1988). For the United States, the decline appears to be greater for local moves than for long-distance movement. Urbanization was the dominant redistribution trend in the 1950s in fourteen European countries studied by Fielding (1989). The relationship between net migration and settlement size began to break down, however, in the 1960s—first in the countries of northwestern Europe in the mid-1960s, then in the countries and regions of the southern and western European periphery through the 1960s, and in the case of Spain, into the 1970s. By the 1970s, most of the countries of western Europe were recording counterurbanization, where

the net flow was away from cities and toward small settlements. That counterurbanization became less dominant in the early 1980s but was not replaced by urbanization. Only in West Germany and Italy did the counterurbanization relationship persist. The United States experienced a similar pattern of long-term urbanization, reversed in the 1970s and then nearly reversed again in the 1980s (Frey 1990).

PREDICTING FUTURE MIGRATION

Migration rooted in labor movement will change in the future as the geographical basis of the economy changes. Robust new industry will attract migrants. Such developments in the southern region may extend several more decades into the future. On the other hand, migration not related to the labor force, such as retirement migration, is more sensitive to lifestyle issues. Eventual overcrowding, which results in a decline in the quality of life of local residents, will tend to discourage retirement migration. Florida's dominance of retirement destinations in 1990 lost 2 percent of the migrant retiree market.

Migration for better jobs increases in times of economic expansion. Thus, studies of the late 1990s may find migration to have increased in response to an improved economy. Other trends could also increase migration rates. First, the age composition is always shifting. In the 1980s, there were more persons in the twenty-to-thirty age range, their prime mobility years. The baby boom generation has a lower migration rate for long moves than others. However, because of its large size, a large number of baby boomers migrated. In the 1990s, the incidence of moving will likely dampen as baby boomers age and leave their prime mobility years. Second, the rising level of education may increase migration. Each new cohort of adults has a higher level of education than its predecessor. The third factor, household change, contains counterindicators. Married couples are increasingly likely to divorce, a situation favoring migration, but at the same time there are more dual-career couples in the population, a situation favoring nonmobility (Long 1988).

As we have seen, many factors motivate migration. These factors need further study, which will certainly generate new research hypotheses to be tested by migration researchers in the twenty-first century.

CHARLES F. LONGINO, JR.

INTERNATIONAL ASSOCIATIONS IN SOCIOLOGY

Founded by Rene Worms in Paris in 1893, the International Institute of Sociology (IIS) is the oldest continuous sociological association of any kind in the world. The IIS also happens to be the oldest continuous international association in the social sciences. Indeed, Worms's models for the IIS were the recently formed international institutes in law and in statistics. In the same year that he founded the IIS, Worms (1869-1926) also started the *Revue internationale de sociologies* (two years before Durkheimians would found the *Annee sociologique*) and a book series, the *Bibliothèque Sociologique Internationale*, which would in time publish more than fifty volumes.

In 1893 Worms was twenty-four years old. His organizational skills are even more impressive when we consider where the IIS's founding falls in relation to that of other major associations in the discipline of sociology, including the discipline's only other major international association. In 1895, Worms himself founded the *Société de Sociologie de Paris*, an association that held monthly meetings. A full ten years later, in 1905, C. W. A. Veditz of George Washington University founded the American Sociological Society (now the American Sociological Association) at a constituent meeting

held at Johns Hopkins University. Another five years later, in 1910, the German Sociological Society held its first meeting—in Frankfurt, with Simmel presenting the opening paper. Three years after that, in 1913, Tongo Takebe founded the Japan Institute of Sociology (now the Japan Sociological Society).

Then some time passed before other major associations were formed. The Italian Society of Sociology was not founded until 1937, by Corrado Gini (who in 1926 established Italy's equivalent of the Census Bureau and who developed the Gini Scale). The International Sociological Association, which is discussed below began after World War II, in 1948—under broad sponsorship from UNESCO and informed by Cold War rivalries. Finally, the British Sociological Society was founded even later, in 1951; indeed, Britain had only one chair in sociology from 1907 through World War II, housed at the London School of Economics.

Like so many of sociology's founding figures, from Auguste Comte to George Herbert Mead, Worms was trained in philosophy and began his academic career in that discipline. The son of political economist Emile Worms, he earned his philosophy degree at the Ecole Normale Supérieure and then also degrees in law and economics. His first teaching assignment was at the secondary school level while he also substituted for Henri Bergson at the College de France. And like other philosophically trained sociologists of the mid- and late nineteenth century, including Auguste Comte and Herbert Spencer, Worms's early way of thinking about society was by analogy to biological organisms. Within a decade, however, Worms moved, under increasing criticism from Gabriel Tarde (and also Durkheim), to a far more eclectic theoretical position, one that treated sociology essentially as the philosophy of the social sciences. After 1907 he taught an annual course in the history of sociology at the Ecole des Hautes Etudes Sociales. During this period he also taught on the law faculty at the University of Paris and served on important advisory bodies of the French government. By 1924 he had risen to Conseiller d'Etat.

The first World Congress of Worms's IIS was held a year after its founding, in September 1894, and the first volume of the Institute's *Annales* appeared a year after that. Not only scholars but

also politicians and other influentials throughout the West found both the *Revue* and the IIS to be tolerant and supportive of heterogeneous ideas. This hospitable environment reflected Worms's own broad work experience and interdisciplinary training—along with his own general openness to differing theoretical approaches. Worms respected the work being done, for instance, by the circle around Durkheim, but he also kept a healthy independence from its influence. Thus, we find among the IIS's earliest members major figures not only in sociology but also in economics, the other social sciences, and the natural sciences: Franz Brentano, Enrico Ferri, Ludwig Gumplowicz, Achille Loria, Alfred Marshall, Carl Menger, Edward Ross, Gustav Schmoller, Georg Simmel, Albion Small, Gabriel Tarde, Edward Taylor, Ferdinand Tönnies, Alexandre Tchouprov, Thorsten Veblen, Lester Ward, Sydney and Beatrice Webbs, and Wilhelm Wundt. Indeed, in the early years sociologists were a minority among IIS members. Yet, with the exception of Durkheim, all major sociologists, Weber included, participated in the Institute at one time or another in its first three decades.

In casting his net well beyond the academy, Worms was known to play on the vanity of the famous from many walks of life in order to bring them into his international organization (D'Antonio 1994, citing Gephart). Often he granted influentials an honorary membership or officership in order to exempt them from paying dues. The first president of the IIS was Sir John Lubbock, vice president of the Royal Society of London, president of the London Chamber of Commerce, and a member of the House of Commons. A year later, Albert Schaeffle became the second IIS president, reflecting the fact that until 1914 IIS Congresses tended to be held annually. Aside from exchanging ideas frequently with Tönnies, Durkheim, and Simmel, Schaeffle served as director of the *Zeitschrift für gesammte Staatswissenschaft* of Tübingen. The IIS's third president was a senator from Russia, Paul de Liliensfeld. One founding member, T.G. Masaryk of Prague, became both president of Czechoslovakia and president of the IIS. IIS vice presidents were no less successful in other pursuits: Bernardino Machado, Raymond Poincaré, and Woodrow Wilson were past presidents, respectively, of Portugal, France, and the United States.

The first sociologist to serve as IIS president was Lester Ward, in 1903; two years later, Ward became the first president of the American Sociological Society. Indeed, Ward, Franklin Giddings, and Albion Small were all active in the IIS and would be prime movers in the formation of the American Sociological Society. All would serve as IIS presidents and, together, they comprised three of the American organization's ten original officers.

Worms himself was always more a technical director than a research sociologist, serving as IIS secretary general and treasurer for thirty-three years. During his tenure, eleven different countries were represented in the presidency of the IIS (and in 1924 Worms was made an honorary member of the American Sociological Society). The first French sociologist to serve as IIS president was Charles Letourneau.

In the interwar years, IIS Congresses were held biannually and IIS leadership was strongly influenced by Célestin, Bougle, Secondo Bouthoul, Corrado Gini, Maurice Halbwachs, Robert MacIver, William Ogburn, Joseph Schumpeter, Pitrim Sorokin, and Luigi Sturzo. Each World War disrupted the frequency of Congresses and, as it turned out, each of these periods also marked general passages for the institute as an organization. For instance, a Congress scheduled for Vienna in 1915 was canceled because of war, and then planning did not resume until 1925. In that year Worms became ill, and he died the following year: the Congress ended up being held in 1927. A decade passed. Then the 14th Congress, scheduled for Bucharest in 1939, had to be canceled—again due to war. It would not be held until 1950, now relocated to Rome and placed under the leadership of Corrado Gini. Earlier, in 1932, Gini had founded the Italian section of the IIS.

At the turn of the century, international associations in all scholarly disciplines typically called themselves “institutes”; they were more “traveling academies, as Scheuch (1997) put it, than bureaucratically established organizations. All drew membership by invitation, all placed numerical limits on total membership, and all organized plenary sessions around particular themes. The IIS continues this tradition to this day. Thus, the format for its biannual Congresses is quite distinct from that of today's meetings of the International Sociologi-

cal Association (ISA) held every four years. In the first place, the IIS tries to keep attendance to around 500 total participants (whereas ISA meetings draw anywhere from 3,000 to 5,000 participants). In the second place, all participants are encouraged to attend morning plenary sessions organized around a particular conceptual theme selected by each Congress's program committee. The afternoons are then devoted to working groups in which members present papers spanning a far broader range of topics.

This “traditional” format is designed to serve both interpersonal and intellectual ends: Interpersonally, IIS Congresses stage events that are designed to create a sense of community among scholars from different national traditions of training and thereby to encourage collaboration and other scholarly exchanges. This is the case not only with the collective morning plenary sessions in which presentations are simultaneously translated in three languages—the language of the host country, French, and English. It is also the case with collective lunches, dinners, receptions, and local sightseeing trips. Intellectually, themes of IIS Congresses are intended to have a cumulative impact on social science disciplines.

The *Annales* served as the IIS's official publication through 1931 (and the 10th Congress held in Switzerland in 1930), at which time it was discontinued. From this period until 1989, IIS activities were reported in the *Revue*, which also informally took over publication of IIS Congress papers. In 1989 the *Annales* were revived and the *Revue* became independent of the IIS. Recent World Congresses were held in Morelia, Mexico (1982), Albufeira, Portugal (1986), Rome (1989), Kobe (1991), Paris (1993), Trieste (1995), Cologne (1997), and Tel Aviv (1999).

The International Sociological Association was founded in 1948 under an initiative of the Social Science Department of UNESCO—as part of a broad effort that spanned comparable associations in economics, law, and political science. All of these new international bodies very much reflected the geopolitical situation of the day, and all were both considerably larger in membership and looser in thematic focus than the IIS. Today, the major scholarly contribution of the ISA revolves not around its plenary sessions but rather around

nearly fifty specialized Research Committees, some of which rival in size an entire IIS Congress.

After WWII, the Allies were interested in undercutting the conditions that could foster any return to fascism, and they saw the dissemination of the social sciences as one important factor in fostering democracy. Indeed, UNESCO had already opened an Institute for Social Research in Cologne, the Rockefeller Foundation had financed another in Dortmund, and the American government still another in Darmstadt. Given that UNESCO was based in Paris, the first discussions leading to the ISA were held in that city beginning in October 1948 under the leadership of Arvid Brodersen. Also attending this first meeting were Georges Davy, Gurvitch, Gabriel Le Bras, Arie den Hollander, Rene Konig, Louis Wirth, Paul Lazarsfeld, Erik Rinde, and Otto Klineberg.

At the time, national sociological associations existed in eight countries (Belgium, Brazil, China, Germany, Italy, Japan, Netherlands, and the United States). In four other countries sociology was included in other social science associations, and in another ten the discipline was organized as institutes on the IIS model—with membership limited to selected individuals (Platt 1998). In September 1949, ISA organizers invited leading sociologists in twenty-one countries to a Constituent Congress in Oslo. Louis Wirth, the noted American sociologist of urban life, was named the first president, and Erik Rinde in Oslo was appointed Executive Secretary and Treasurer (Platt 1998). Unlike the IIS, membership in the ISA was by national association (including general social science association), not by individuals directly. As such, the rise of the ISA itself contributed to the founding of eleven national affiliates, including the British Sociological Association and its counterpart in Mexico (Platt 1998).

The ISA's first World Congress was held in Zurich in 1950, organized by Rene Konig with Wirth serving as president. One hundred fifty-four individuals participated, and eleven national associations and eighteen other bodies were admitted as members. In part, this Congress was held jointly with the newly formed International Political Science Association (and the Research Committee on Political Sociology remains a joint committee of both associations). Shortly thereafter, the ISA's

first Research Committee was formed, focusing on social stratification and mobility. This Committee's issues dominated the 2nd World Congress in 1953 in Liege, Belgium. By 1959 other Research Committees were being formed, at first referred to as subcommittees. Throughout the 1950s, another seventeen national associations were founded and joined the ISA, and then in the 1960s twelve more were added (Platt 1998). By 1952 the first issue of *Current Sociology*, the journal of the ISA, had appeared, and papers of early World Congresses were published separately as *Transactions*—a practice that ended in 1970 due to the cost and effort involved (Platt 1998). Originally, ISA World Congresses were held every three years, but beginning in 1962 they were moved to today's four-year schedule. Tracing the locations of World Congresses to this point, the 1956 Congress was in Amsterdam, the 1959 Congress in Stresa on Lake Maggiore in Italy, and the 1962 Congress in Washington, D.C.

Because the ISA relied on UNESCO for funding, its activities were heavily influenced by the agenda of UNESCO's Social Science Department (SSD). Early ISA presidents often had served earlier on SSD staff (Platt 1998). One early item on the SSD agenda was using the teaching of sociology to promote international understanding (Platt 1998). Only in the 1960s did teaching steadily lose priority to research, and this same period of transition, not coincidentally, marked the rise to preeminence of the Research Committees—at the expense of the Congress's general program topic and plenary sessions (Platt 1998). By 1970 and the World Congress in Varna, Bulgaria, there were seventeen different Research Committees (Platt 1998).

One issue facing the ISA leadership in its early years was how to deal with the earlier, well-established international association, the IIS. IIS activities had lapsed during WWII, and after the war some of its leaders were tainted with affiliations with defeated Axis regimes (Platt 1998). The same controversy split the national sociological association in Germany by 1960 but not the national associations in Italy or Japan. Regardless, as early as 1953 the leaders of sociology's two international organizations agreed to "friendly collaboration," including a willingness to schedule meetings at different times and to exchange proceedings. Relations between the two organizations have been

relatively amicable ever since. Both international bodies have had to deal with the state of sociology in communist countries during the Cold War, the rising prominence of sociology in Third World countries, and addressing cases of political and scholarly repression in selected countries (Platt 1998).

In 1970 the ISA made two major changes in its founding statutes, one that introduced general individual membership and another that opened up the governance of the Research Committees. ISA leadership saw the Research Committees as a force moving the organization beyond national associations toward a grander internationalism. One result, however, is that the Research Committees became the equivalent of the internally pluralistic “sections” of the American Sociological Association (ASA), as opposed to remaining more coherent research groups. Thus, like ASA sections, the number of Research Committees has increased and many “working groups” and “thematic groups” within each Committee operate relatively independently of each other. In 1994, more than 3,000 sociologists attended the ISA World Congress in Bielefeld, Germany (76 percent from North America and Western Europe), and forty-five national associations were admitted. By 1997 there were fifty-nine identifiable research groups of one kind or another. Concerns abound, therefore, that the organization’s centrifugal tendencies are overwhelming whatever centripetal forces remain (Platt 1998).

One consequence of the increasing internal pluralism of the ISA is that its funding base became and remains “increasingly problematic” (Platt 1998). ISA dues have been raised considerably for individual members, particularly for those living in economically advanced societies (Platt 1998). Throughout the 1970s and 1980s, communist bloc countries continued to support the voting rights of collective members, along with subsidies by affiliated governments. Still, the only ISA World Congress held in a socialist country was the 1970 meeting in Bulgaria. Looking back in 1994, the chair of a Constitutional Revision Committee held that the ISA’s founding statutes had been premised on Cold War politics. His proposal then was that the organization needed to stress even more the importance of membership by dues-paying individuals, as opposed to relying on government

subsidies. Two years earlier, in 1992, the Research Council had voted to give the Research Committees power equal to that of member national associations. For the first time, the Research Committees voted for ISA officers (Platt 1998).

Increasingly in the 1980s, the ISA was concerned about the dominance of First World sociology to the detriment of contributions from sociologists in the Third World. With this in mind, the journal *International Sociology* was founded in 1986 with the mandate to favor scholarly submissions from “disadvantaged areas” (Platt 1998). The first ISA World Congress held in a Third World country was in 1982 in Mexico City (followed by the 1986 Congress in New Delhi).

INTERNATIONAL LAW

NOTE: Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.

International law is the system of rules and principles governing relations at the interstate

level. It originally developed in response to the needs of states but in recent times has grown to include international organizations and, to some extent, individuals.

International law as a systematic body of rules began in Europe in the seventeenth century. Before then, and from earliest history, rules existed governing the interrelations of various groups of people (Nussbaum 1958). But the rules were systematized in Europe only when the contacts among peoples became regular and frequent and the idea of a single ruler for all known society foundered. That occurred with the collapse of the Holy Roman Empire during the Thirty Years War (1618–1648). The state system developed in its place, characterized by a number of kingdoms and principalities, each equal to the others, sovereign within its own borders, and subject to no outside sovereign. Hugo Grotius, a Dutchman who lived during this time, wrote a seminal book, *De Jure Belli ac Pacis* (1620–1625), describing legal rules, derived from natural law, by which these states could achieve peaceful coexistence and, when they failed, how they could conduct their wars with some semblance of humanity. His book popularized international law, and he is generally considered the founder of international law.

The rules and principles Grotius described reflected the characteristics of states. The fundamental notion that states were sovereign and equal became a principle of international law. And because the rulers of states respected that principle as law, they were less likely to wage war or to annex their neighbors. International law helped create the success of the state system and in turn reflected the features of the system.

Grotius derived his rules from natural law, thus suggesting that nature was superior to states. By the nineteenth century, however, theorists abandoned natural law as a source of international law. Instead, they looked at the behavior of the states themselves as the source of international law. International lawyers became positivists, and the state became for international law the ultimate political entity. The rules of international law could guide and could set out regular procedures to ensure the smooth and peaceful conduct of international relations, but they permitted states wide prerogatives. Governments acquiesced in international legal rules because their states benefited

from an orderly system of international relations in which they gave up few of the attributes of absolute sovereignty. For example, the rules did not speak to what states did internally, no matter how egregious. Individuals were not considered subjects of international law. Nor did the rules restrain states from the use of force. International law described permissible uses of force, but states could in effect use force whenever they chose.

By the twentieth century pressures for change began to develop. Technological advances in war and communications accounted for movements aimed at restraining states in their use of force and abuse of human beings. People such as Elihu Root, U.S. Secretary of State in Theodore Roosevelt's administration, wanted international law to provide the vehicle for restraint. Governments started experimenting with dispute settlement through arbitration and courts. They formed the League of Nations to help them control states' uses of force. International law and international institutions were being substituted for unbridled state sovereignty. The concept was a radical departure from the past and came about only over the course of half a century and two world wars.

After World War II, governments were willing in theory to contemplate real restraints on their ultimate sovereign prerogatives. The United Nations was created as an entity under international law. Its charter committed states to uphold human rights, to cooperate in solving world problems, to abandon the use of force, and to follow the commands of the organization itself. The idea was to lessen state sovereignty for the good of the whole world community. Thus, the state began to lose its place as the ultimate political entity almost exactly 300 years after its rise.

Certain international legal norms are now theoretically superior to the wills of the states. In other words, a certain amount of natural law now characterizes the system again. In addition, the state is making way for other types of political institutions such as regional arrangements, although if the state should ever become finally obsolete so will international law. The current form of international law and many of its rules and principles presuppose a system of coequal entities without a single sovereign.

While the state system remains intact, however, international law has taken on an increasingly

important role in governing the relations of states in an interdependent, technologically linked world. It does this even though international law has never had the institutions typical of domestic law: a legislature for making law, an executive to enforce it, and a judiciary to adjudicate and interpret it. In some respects international law still functions as it did in the nineteenth century because the system benefits the state. Nevertheless, law does get made, enforced, and adjudicated, and social movements are at work putting demands on states to form and live by new norms of international law.

Because of the informal condition in which international law exists, however, some legal thinkers argue it is not law at all but rather moral precepts or mere guidelines. Most prominent of these thinkers was John Austin, who described law as a series of commands backed by sanctions. International law has no overarching authority to issue commands, and the sanctions are irregular. But Austin's criticism depends on his definition of law. If law is defined as behavior or behavioral restraint induced by a sense of obligation, international law, in its sphere, is law. Positivist international lawyers also point out that in the end the states acknowledge that international law is law, and that is the relevant indicator.

International legal rules have two basic sources: custom and treaty. Rules of customary international law are created through practices that states engage in because they believe they have a legal obligation to do so. Treaties are the explicit agreements states make with each other to be bound. As the need for international law has grown, states have relied on treaties as a law-making vehicle more and more. The general multilateral treaty has become a common form of law making for important international concerns. For almost ten years nearly every state of the world attended a conference to negotiate a comprehensive treaty on the law of the sea. Because so many states attended and the treaty was so long in the making, the treaty began to take on the characteristics of customary international law, irrespective of its status as a treaty. A similar conference will convene in 1992 to discuss climate, and suggestions have been made to convene such a conference for trade.

When no rule of custom can be found and no treaty exists, international courts have in some disputes turned to a third source of law—general principles of law. These are principles commonly found in domestic legal systems and can serve to fill any gaps in international law, which suffers from its ad hoc law-making process. Theorists consider general principles a subsidiary source of international law because general principles are not made in a positive sense by all the states of the system, and they may be applied to a state that did not wish to be bound by them. Custom and treaty, however, generally allow states to opt out of a rule, thus reflecting the traditional view that the states are superior to the system of law. In the last thirty years, however, states have accepted that certain principles cannot be derogated from because they are considered peremptory norms or *jus cogens*. Examples of such norms are the prohibitions on genocide, the slave trade, and the use of force to advance a state's political agenda. With the concept of *jus cogens*, international law has again taken on some elements of natural law.

Jus cogens also exemplifies the extent to which international law has overcome cultural relativity. As new states emerged in the 1960s, scholars from these states questioned whether international law should be binding on them since it was a European product that had aided in perpetuating colonialism. These criticisms have faded, however, because it became clear that international law also created the thing desired most by newly independent countries—statehood. Moreover, because international law is made by states, the new majority could begin to re-create international law. The process of international law has succeeded to the point of bringing states together in accepting that certain principles are overriding, despite the particular value systems of individual states.

Like the law-making system, the law-adjudicating system in international law depends on states volunteering to use it. The system does have courts, in particular, the International Court of Justice. But no state needs to subject itself to the court unless it wishes to do so. The court does have limited compulsory jurisdiction in the case of states that agree to submit cases to it in advance of disputes arising. Nicaragua brought a case against the United States under such an agreement in

1986. States can also agree on an ad hoc basis to submit disputes to arbitral tribunals. The vast majority of international law is adjudicated informally, however. If a state violates international law, such as when Iraq invaded Kuwait in 1990, most states in the system will pronounce their views regarding the legality of the action. Assessing these evaluations leads to conclusions regarding lawfulness. Thus, states make and adjudicate the law themselves.

States also enforce international law themselves. International law is notorious for being poorly enforced. In fact, however, most international law is in fact observed most of the time. Because the states must agree to the law, they tend to make only the laws they want and are willing to live by. Otherwise they opt out of the rules, as the United States has done for some of the new law of the sea. Law is not so well observed, however, in those areas that make headlines—war, human rights, terrorism—which perhaps accounts for international law's poor reputation for enforcement.

When a rule of international law is violated, the state that is harmed is allowed to take action against the perpetrator. For example, if a fishing treaty between state A and state B is violated because state A's fishermen overfish in state B's waters, state B might be entitled to terminate the treaty and prevent future fishing by state A. This system works to some extent, but states have tried to improve on it in recent decades by, first, giving the United Nations and, in particular, the Security Council authority to police some violations of international law and to expand the ability of domestic institutions in enforcing international law by expanding the concept of universal jurisdiction.

The Security Council has authority to maintain peace. In article 42 of the U.N. Charter, it is given the power to call on member states to contribute troops to fight at the direction of the council. The idea comes very close to having an international police force. It has only been used once, however—in Korea in the 1950s. Other attempts have been stymied by the cold war antagonism of the United States and the Soviet Union, each of which has a veto over invocation of article 42. As a sort of substitute, the Secretary General has regularly sent troops, contributed voluntarily by U.N. members, to serve a peacekeeping role. Peacekeeping troops are not supposed to

take enforcement action. But enforcement action may be a possibility again with the end of the cold war. Following Iraq's invasion of Kuwait in 1990, the council ordered worldwide economic sanctions and permitted the use of force, both to enforce the sanctions and to push Iraqi troops out of Kuwait.

Another solution to enforcement has been the widening of universal jurisdiction. To prevent states from interfering in each other's affairs, international law contains principles of jurisdiction defining when and where a state may enforce rules of domestic or international law. In some instances any state may take action. This concept of universal jurisdiction is as old as international law. It was originally developed to handle the problem of piracy. Pirates are defined as persons who commit crimes for profit on the high seas. Generally they do not fly any state's flag, and they act outside the territorial jurisdiction of any state. Typically, the state where the act took place or the state of the pirate's nationality would have jurisdiction, but those categories often do not exist for pirates. The state of the victim might have jurisdiction, but the international system developed the rule that any state may board a vessel that fails to fly a flag and that any state may arrest, try, and punish pirates.

After World War II, universal jurisdiction was expanded to include the concept of crimes against humanity. The victorious allied powers tried German and Japanese individuals, holding them personally responsible for human rights abuses, characterized as crimes against humanity and thus crimes for which any state in the world could take jurisdiction. The Nuremburg and Japanese War Crimes Trials broke new ground in international law by holding that individuals had rights and responsibilities not only under their nation's law but under international law and by expanding the scope of a state's jurisdiction.

Individual responsibility and expanded state jurisdiction are being included today in a variety of treaties, especially related to human rights, narcotics, and terrorism. Customary international law now permits universal jurisdiction over persons who have committed genocide or war crimes. The International Court of Justice has also suggested that important human rights may be enforced by any state regardless of its connection with the

violation because the obligation to respect human rights is an obligation owed to all people; it is a right *erga omnes*.

International law will need these improvements in enforcement. The scope of questions now covered by international law grows annually with the increasing interdependence of the world and the technological advances that bring peoples into conflicting contact. The need to protect the global environment is the newest challenge for international law. States may soon decide they need an international organization to regulate the world trading system. The problems of development, health, communications, education, population, and use of space on earth and in outer space are all new problems in need of attention. Add to them the old problems of war, territorial disputes, governing international organizations, treaties, dispute resolution, refugees, human rights, diplomatic immunity, law of the sea, air space, recognition of new states, and so on, and the growing importance of international law becomes apparent. International law will continue to serve as a means of conducting smooth international relations, its traditional role, but it will also continue to assume new importance as a means of solving problems. In order to achieve this, however, international law must improve its institutions and be accepted by more states, whose own sovereignty will diminish as international law advances.

MARY ELLEN O'CONNELL

INTERNATIONAL MIGRATION

International migration is a term used to refer to change of usual residence between nations. The number of international migrants is always much smaller than the total number of persons traveling across international frontiers, because the overwhelming majority of such travelers do not intend to change their usual residence. International migration is contrasted with *internal migration*, which refers to a change of usual residence within a nation. The term *immigration* is used to denote the flow of persons establishing a usual residence in a given nation whose last residence was in some other nation. The term *emigration* is used to denote the flow of persons relinquishing a usual residence in a given nation to establish residence in some other nation. *Net international migration* denotes the difference between the number of persons immigrating to a given nation in a given period and the number emigrating from that nation in the same period.

Immigratory and emigratory events constitute two of the four components of national population change; the other two components are births and deaths. For most nations, population change is determined predominantly by the balance of births and deaths (natural increase). However, for a few nations in certain periods, the net international immigration has also been an important component of the total population change.

In determining the number of persons who have changed residence among nations, national

statistical agencies must specify the meaning of a change in usual residence. The United Nations (1978) suggests that international movements with an intended stay of more than one year be classified as international migration. Unfortunately, there is considerable lack of uniformity among nations with respect to how international migration is defined. For example, according to data of the Mexican government, some 46,000 Mexicans emigrated to the United States in 1973; according to data of the U.S. government, the number of permanent legal immigrants from Mexico was about 72,000 (United Nations 1978). Also, many governments, including that of the United States, collect data on immigration but not on emigration. Finally, all data on immigration published by governments refer to legal immigration only. Data on illegal or undocumented immigration cannot be tabulated.

Certain terms useful for the study of either international or internal migration will now be explained. A *migration stream* is defined as the total number of migratory events from place A to place B during a given time. The *counterstream* is defined as the total number of migratory events from place B to place A. The sum of events in the stream and counterstream is termed the *gross interchange* between A and B. The *effectiveness of migration* is defined as the ratio of the net migration between A and B and the gross interchange between the two places. The effectiveness of migration can therefore vary from a low of 0 to a high of 1. For most pairs of geographic units, the effectiveness of migration tends to be much closer to 0 than to 1.

Petersen (1975) makes very useful distinctions among the concepts of free, impelled, and forced migrations. In free migration, the will of the migrant is the main factor. In impelled migration, the will of the migrant is subordinated to the will of other persons. In forced migration, the will of other persons is paramount, and the will of the migrant is of no weight at all. Another useful term is *return migration*, defined as migration back to a place in which one had formerly resided. *Chain migration* (MacDonald and MacDonald 1964) is also a frequently used concept. It refers to the common pattern whereby a given individual migrates to a particular destination in which he or she already has kin or friends who have previously migrated from his or her own area of origin.

MIGRATION DIFFERENTIALS

It is universally observed that the propensity for international migration is strongest among young adults. Other differentials in migration tend to be limited to particular cultures or locales. Because the highest propensity for international migration is among young adults, the contribution of international migration to population change is often considerably greater than the net international migration by itself. This is because the birthrate for migrants is higher than for the total population, and the death rate is lower.

DETERMINANTS OF THE VOLUME OF INTERNATIONAL MIGRATION

Demographers analyze the determinants of the volume of a migratory stream into two components. The first concerns the specific propensity to migrate for individuals of each given type. The second concerns the number of individuals of each given type. The volume of a migratory stream can be calculated as the sum of the products obtained by multiplying the specific propensity to migrate for individuals of each given type by the number of individuals of that type.

The determinants of the propensity to migrate may conveniently be analyzed in terms of a preference system, a price system, and the total amount of resources available for all goals (Heer 1975, 1996). The preference system describes the relative attractiveness of various places as goals for potential migrants, compared to other goals that their resources would allow them to pursue. An area's attractiveness is the balance between the positive and negative values it offers.

Among the most important of the positive values is the prospect of a better-paying job. Other positive values achieved by migration include the chance to live in a more favorable climate, freedom from persecution, opportunity for marriage, and continuation of marital ties. In the case of forced migration, the positive value achieved is simply to save one's own life.

However, international migration also creates negative values. A major disincentive to migration is that it involves a disruption of interpersonal

relationships with kin and old friends. Chain migration is so attractive precisely because it mitigates the disruption of such relationships (Massey et al. 1987). Other negative values created by international migration are the necessity of learning new customs and, often, a new language. Laws restraining legal entry or departure are also, of course, very important deterrents to international migration and will be discussed later in more detail.

The price system describes the costs in money, energy, and time, which cannot be used in the pursuit of other goals, imposed by a given migration decision. Since the cost of international migration generally varies in direct proportion to the distance traveled, the number of immigrants to a given place tends to vary inversely with the distance.

The total resources available for all goals also affects the decision to migrate. If the only drawback to migration is the expense of the move, an increase in monetary income should increase the probability of migration.

MAJOR STREAMS OF INTERNATIONAL MIGRATION

Certain major streams of international migration deserve mention, either because they have had important historical consequences or because they otherwise exemplify unusual patterns. One of the earliest streams of international migration with historical significance was the westward movement of nomadic tribes in Europe and Central Asia at the time of the fall of the Roman Empire. The many tribes that moved westward during this period included those speaking Celtic, Germanic, and Ural-Altai languages. As the easternmost tribes moved westward, they pushed forward the tribes in front of them. One suggested explanation for this extensive migration is that the grasslands of Central Asia had become desiccated. A second possibility is that an expanding Chinese Empire disrupted the life of the nomadic tribes near its borders and, thus, provoked the movement of all the other tribes (Bury 1928; Huntington 1924; Teggart 1939).

The European and African migrations to North America, South America, and Oceania have probably had more important historical consequences

than any other migratory stream. This flow began slowly after Columbus's voyage to America in 1492. It has been estimated that more than 60 million Europeans have left for overseas points in the centuries since then. However, net migration was lower, since many of those leaving Europe later returned (United Nations 1953, pp. 98-102). The migration from Africa to the New World was almost wholly a forced migration of slaves. The first slaves were brought to the colony of Virginia in 1619, and the slave trade in the United States was not legally ended until 1808. During the period of slave trade, about 400,000 Africans were brought to the United States (U.S. Bureau of the Census 1909). The impact of the migration of slaves is revealed by the fact that, in 1790, 20 percent of the 4 million persons in the United States were black.

During the twentieth century, the origin of immigrants to the United States shifted drastically away from Europe and toward Asia and the Americas. This change is illustrated in Figure 1, which shows the number and percentage distribution by region of last residence of immigrants to the United States by decade from 1891-1900 to 1991-96.

The emigration from Puerto Rico to the mainland United States, of major magnitude in the years following World War II, is of interest because it exemplifies an extremely high rate. According to the 1970 census, the combined total of the population of Puerto Rico and of persons in the United States of Puerto Rican birth or parentage was about 4.1 million, of which around 1.4 million were in the United States. Thus 33.9 percent of all Puerto Ricans were on the mainland (U.S. Bureau of the Census 1971, 1973).

Immigration into Israel following World War II is likewise noteworthy because it exemplifies an extremely high rate. In 1948, when independence was established, the total population of Israel was 650,000; by 1961, after the influx of more than 1 million immigrants, it had risen to 2.2 million (Bouscaren 1963; United Nations 1966).

Perhaps the world's largest gross interchange in a short time took place in India and Pakistan following the 1947 partition of British India and the establishment of these two areas as independent states. This migration is also of interest because it was impelled rather than free. In the face

of violence, Hindus and Sikhs in Pakistan moved to India and Muslims in India moved to Pakistan. From 1947 through 1950, 10 million persons migrated from Pakistan to India and 7.5 million from India to Pakistan (Spate 1957).

The two most recent major streams of international migration exemplify what has been termed *labor migration*. Labor migration is said to occur when immigrants are legally admitted to a nation for defined time periods in order to alleviate a shortage of labor. Labor migrants are not given the right of permanent residence. The first stream was the large-scale migration of workers into the prosperous nations of northern and western Europe from poorer nations in the Mediterranean region such as Italy, Spain, Portugal, Yugoslavia, Greece, Turkey, Algeria, and Morocco (Massey et al. 1998). This stream began around 1960 and ended in 1973, following the sudden elevation of petroleum prices by the Organization of Petroleum Exporting Countries (OPEC). The proportion of the total population that was foreign increased substantially in all of the northwest European nations. For example, from 1960 to 1970, the foreign population of the German Federal Republic increased from 1 percent to 5 percent and that of Switzerland from 9 percent to 16 percent (Van de Kaa 1987). The second major stream was the large-scale migration of workers into the major oil-producing nations in the Persian Gulf region out of such nations as Jordan, Egypt, Yemen, Pakistan, and India (Massey et al. 1998). For example, from 1957 through 1975, 70 percent to 75 percent of the total labor force in Kuwait consisted of foreigners (Birks and Sinclair 1981).

CONSEQUENCES OF INTERNATIONAL MIGRATION

One may examine the possible consequences of international migration for the individual, the area of net emigration, the area of net immigration, and the larger social system, which includes areas of net emigration and net immigration. The discussion must be in part speculative, since knowledge about these topics is incomplete.

Before a move, an immigrant will have anticipated a net balance of favorable consequences. Sometimes, however, reality will fall short of expectations, and dissatisfaction will provoke the

Figure 1

immigrant to either return to the nation of origin or, on occasion, to move on to some other nation.

Net emigration may have several important consequences for an area. By relieving population pressure, it may cause the average level of wage and salary income to rise. Remittances from emigrants may also be helpful. On the other hand, net emigration may cause the value of land and real estate to decline. Moreover, areas of net emigration suffer the loss of investments made to raise and educate children who spend their productive years elsewhere. This loss is particularly large when the individual receives a higher education prior to emigration. Such a loss is termed *brain drain*.

Finally, since emigration rates are selective by age, nations with substantial net emigration may have relatively few young adults relative to the number of children and the aged.

Net immigration may also have important consequences. If the area is definitely underpopulated, the resultant population increase may help the nation to achieve economies of scale (reduction in the cost of goods obtainable by increasing the scale of production and marketing) and, thus, raise the general standard of living. Under other circumstances, net immigration may result in some decline in average wage and salary income. In either case, a net flow of immigrants tends to raise

the price of land and real estate. Furthermore, in general, net immigration increases the proportion of young adults in the total population. Dependent on their composition, immigrants may receive either more or less in government benefits than the amount of their tax payments. Finally, net immigration may make the population more heterogeneous with respect to race, religion, or language.

For the system comprising the nations of both net inflow and net outflow, the direct effect of international migration is of course to promote a redistribution of population. If migrants have been responsive to differences in job opportunities, this redistribution may further the economic development of the total system. Moreover, a substantial amount of international migration responsive to job opportunities might also induce a decline in the degree to which there is economic inequality among nations. Unrestricted international migration might make the poor nations richer and the rich nations less prosperous. However, there is substantial disagreement among scholars as to what the effect of unrestricted immigration from the poor nations might be on the prosperity of the rich nations such as the United States. Simon (1984) believes that net immigration to the United States will serve to increase its average income. Davis (1981), on the other hand, takes a much more pessimistic view. Additional analysis of the consequences of immigration from poor nations to the United States is found in a study sponsored by the National Research Council (Smith and Edmonston 1997, 1998).

LEGISLATION AFFECTING IMMIGRATION AND EMIGRATION

National laws concerning immigration have varied from almost complete prohibition to positive encouragement. Laws restricting emigration are now relatively rare but have been of important consequence in modern times for at least one nation, the USSR.

In the seventeenth and eighteenth centuries, a mercantilist ideology, which saw a large population as the key to national wealth and power, encouraged many of the governments of Europe to attempt to prohibit emigration and to encourage immigration. In the late seventeenth century, the French minister Colbert enacted legislation

prescribing the death penalty for persons attempting to emigrate or helping others to emigrate, except to a French colony. In 1721, Prussia passed a similar law. Moreover, the Prussian emperor Frederick the Great invested state funds in subsidizing the settlement of immigrants. In eighteenth-century Russia, both Peter the Great and Catherine the Great subsidized colonists from abroad, mostly from Germany (Glass 1940).

The nineteenth century, influenced by the economic doctrine of *laissez faire*, was the great period of unrestricted international migration. During this century the European governments freely permitted emigration, and the newly independent United States of America welcomed millions of immigrants.

After World War I, the United States took a more active role in restricting international immigration. The major events in this connection were changes in immigration law in 1921 and 1924 that greatly restricted the number of immigrants to the United States, establishing a quota for each of the countries outside the Western Hemisphere. Furthermore, the nations of northwestern Europe was given much larger quotas relative to their populations than those of southern and eastern Europe. This was done even though, in the immediately preceding years, rates of immigration from southern and eastern Europe had been much higher than those from northwestern Europe. The justification made at the time for the quota differentials was the presumed greater ease with which immigrants from northwestern Europe could assimilate (Eckerson 1966).

By the 1960s, a changing climate of opinion with respect to the inferiority or superiority of different ethnic groups made it possible for President Kennedy to advocate the abolition of the discriminatory national-origins quota system, and a law accomplishing this was enacted in 1965 under the Johnson administration. The 1965 law called for the abolition of the national-origins quota system as of July 1, 1968, but, nevertheless, imposed an overall annual quota of 170,000 immigrants from outside the Western Hemisphere and 120,000 from within it (exclusive of immediate relatives of U.S. citizens). This legislation granted preference to persons with relatives already in the United States, to persons with needed occupational skills, and to refugees. Additional legislation

passed in 1976 abandoned the separate quotas for the two hemispheres and imposed a 20,000 limit on immigrants from any nation in the Western Hemisphere (the 20,000 limit had previously been in existence only for Eastern Hemisphere nations). The major effect of the 1976 legislation was to make it more difficult for Mexicans to enter the United States legally.

Some nations, while placing severe restrictions on immigrants in general, have made use of positive inducements to encourage immigration from selected nations or groups. Currently the best example of such legislation is that of Israel, which has committed itself to encouraging the immigration of Jews from anywhere in the world. Formerly, Canada and Australia also exemplified such policies of selective encouragement. Each of these nations subsidized immigrants from European nations while placing severe restrictions on the immigration of nonwhites (Bouscaren 1963; Petersen 1964).

The United States, Australia, Canada, and Israel have laws that allow immigrants permanent residence leading to citizenship. Since 1950, other nations, particularly in northwestern Europe and in the Persian Gulf, have had policies that encourage only labor migration, that is, migration of workers, mostly male, who were supposed to return to their native countries following a fixed term. In the case of the European nations at least, these policies had unintended results. The contract workers were allowed to bring their dependents to live with them. Hence, they became permanent immigrants even though this was not the result intended by original policy (United Nations 1982).

In many nations of the world, particularly in the United States, a major phenomenon is the existence of illegal, or undocumented, immigrants. A necessary condition for the existence of illegal immigration is a lack of congruence between the laws regulating the supply of legal immigrant opportunities and the demand for them. For example, the demand to immigrate to the United States from a particular nation should be a reflection of that nation's population size and the average propensity to immigrate to the United States if there were no legal restrictions. Accordingly, nations with large population size are likely to have more

immigrant demand than nations with small populations; yet all nations, without regard to population size, have the same annual quota. Furthermore, national differences in individual propensity to immigrate to the United States should be a function of such variables as the difference in standard of living compared with that of the United States, difference in degree of public safety compared to the United States, proximity to the United States, degree of similarity with the language and culture of the United States, and prior existence of immigrants that allows for chain migration. According to the official estimate of the U.S. Immigration and Naturalization Service, there were 5 million undocumented immigrants in the United States in October 1996. Of these, 2.7 million, more than half the total, were from Mexico. An additional 335,000 were from El Salvador and 165,000 from Guatemala (U.S. Immigration and Naturalization Service 1997, p. 198). Given Mexico's population size and presumed high average propensity for immigration to the United States, one can easily explain why such a very large proportion of all undocumented persons in the United States have been from that nation (Heer, 1990). An additional fact of interest is the high proportion of undocumented immigrants residing in California. According to the official Immigration and Naturalization Service estimate for October 1996, 40 percent of all undocumented immigrants were living in that state (U.S. Immigration and Naturalization Service 1997).

Rising concern over the extent of undocumented immigration into the United States led the U.S. Congress to enact the Immigration Reform and Control Act of 1986. The intent of the legislation was to eliminate the presence of undocumented aliens in the United States either by legalizing their status or by forcing them to leave the country. This act had two key provisions. The first was the imposition of sanctions upon employers who knowingly employed illegal aliens. The second was the provision of a process whereby undocumented persons who had lived in the United States continuously since January 1, 1982, or had worked in U.S. agriculture for ninety days in the period from May 1985 to May 1986 were allowed to become temporary legal residents. After a short time, they would be allowed to become permanent legal residents. The success of employer sanctions is problematic because sanctions can be applied only

if the employer knowingly hires illegal aliens and because it is relatively easy for an undocumented person to present to the potential employer either fake documents or the documents of some other legally resident person. On the other hand, more than 3 million persons applied for legalization of status after the act was passed, among whom about 2.3 million were from Mexico (U.S. Immigration and Naturalization Service 1990).

In 1998 more than 80 percent of the world's 5.9 billion persons lived in one of the less developed nations. The annual rate of natural increase in these nations was around 1.7 percent; in the developed nations it was only 0.1 percent. In the developed nations per capita gross national product was \$20,240; in the less developed nations, only \$1,230 (Population Reference Bureau 1998). These facts imply a strongly increasing demand for immigration to the developed nations from the less developed. Given the current barriers to legal immigration imposed by the developed nations, undocumented immigration will be of increasing prevalence unless the governments of the developed nations take extraordinary measures to curb it.

INTERNET

The Internet is a curious phenomenon. It's a vast international institution of critical and growing importance, yet in another sense its properties are so evanescent that it's tempting to say that Internet does not exist; there's no *there* there except the process itself. The reason is that at heart Internet is nothing more than a highly specific collection of rules or standards for computers called communication protocols. Even the name comes from the U.S. Department of Defense standard TCP/IP (terminal control protocol/internet protocol). What we now see as institutional Internet—the fiber optics and copper cabling, the billions of dollars of computer hardware and software, the business and governmental organizations, and body of human skill and knowledge that's both on the Net and in the user community—emerged and grew with volcanic force inside the purely formal boundaries of the protocol system. What the protocols allowed, the world's social and economic system instantiated.

A critical part of this development was that the protocols in question were public and open, that they were standards and not products per se. This is in contrast to the course of other communications systems, such as the telephone, radio, and television, for which key components were held proprietary or otherwise regulated by patents,

and both governmental and private monopolies. No one would claim that what has become the Internet was created for the common welfare of all humankind, or that it is guaranteed to work for that welfare in the future. In fact, some of the key components of the Internet came from the bowels of the Pentagon at the height of the Cold War, and the overall moral valence of the Internet is as unsettled a question as one could imagine. But it is useful to note that in many ways the Internet is government work that made good and that its ongoing success appears to depend on public and open standards. Attempts to commercially supplant the Internet or take it proprietary have so far been unsuccessful, despite the huge upsurge of Net-based commerce.

HISTORY

The history of the Internet is partly the history of technology, the hardware of the system. But more important are the social aspects of computer-mediated communication, the human networks created by the hardware system. There are two polar points of view on the social impact of the Internet on communities and society. On the one hand, enthusiasts have argued that the Internet removes barriers that have historically divided people and opens the way to unprecedented equality in social interactions and for social opportunities (Rheingold 1993). On the other hand, critics contend that the Internet removes humanity from social interaction and strands people in an impersonal virtual world without touch, dignity, or personhood (Stoll 1995). The earliest empirical research to address the actual uses and impact of the Internet in social life seems to suggest that people experience Internet interactions in ways similar to their face-to-face social experience. But the technology is young and the scope of its use has broadened only in the 1990s. A decade into the twenty-first century, the prognosis may become clear.

Hardware. If the Internet is anything physical it is a network of computers—actually, a network between networks, an internetwork. Computer networking is not new. Many of the house-sized 1960s-style computers, called mainframes, were often linked into larger networks, although this typically required that computers be in the same

building if not the same room. This constraint was partly overcome by using radio-frequency messaging over coaxial cables similar to those now used for cable TV.

Computer networking using coaxial cable became common and useful in the 1960s. But a problem arose when the University of Hawaii decided to adopt a multicampus computer network. Cable connections in Hawaii would not only have to span long distances, they would have to span those distances deep under the Pacific Ocean. The cost was too high even to contemplate. Computer scientists began a search for alternatives and settled on radio-based computer communications—network messages would be broadcast on special channels. The result was called AlohaNet.

A problem immediately arose. The distance between islands in Hawaii is typically only a few hundred miles. It took only a few thousandths of a second (or less) for radio messages to span that distance, but that's a fairly long time for a computer. This meant that two computers at remote locations could start talking at once, each not hearing the other immediately, which garbled their messages. Garbling of this sort was called a message collision. To solve this problem, the AlohaNet designers had to build collision-detection circuitry into their network controllers. A computer would not only have to send messages and listen for other's messages, it would have to check for message collisions, and re-send if a collision occurred.

Such a scheme sounded awkward, but in practice it was elegant. Collision detection and retransmission overhead turned out to be a tiny part of the overall cost in time and speed of the network. Broadcast-style, collision-detecting networks have a number of advantages. First, the number of computers in network (usually called nodes) is not necessarily fixed. If rules are set up to allow it, any computer in a broadcast system can chime in and negotiate to be part of the network. Once that computer is known to the network, messages can be routed to it as if it had been there all along. Second, as long as there are two or more computers up and running in a given network segment, they can talk; their peers could go on- or off-line as it suited them without bringing down the net. The flexibility of broadcast-style networks led to a revolution in computer communication.

ETHERNET AND LOCAL AREA NETWORKS

Of course, networks actually broadcasting would soon fill up the available radio-frequency spectrum. Consequently, most systems that actually were put in use contained their transmissions inside dedicated runs of coaxial cable, or, later, telephone-like twisted-pair conductors. The most popular of these was the Ethernet system developed by a consortium of computer makers. The Ethernet system allowed a fairly high-speed (1 million bytes per second) network based on coaxial cable to span a physical space one kilometer end-to-end, longer with repeaters to boost the signal. This meant that all but the largest of buildings and many whole complexes and campuses could be served by a single, fast local area network (LAN). Originally, in the early 1980s, Ethernet was used mostly to tie together collections of mainframes and smaller minicomputers, but within a few years it was possible inexpensively to integrate most organizations' growing collections of personal computers (PCs—IBMs and clones, Macintoshes, and others) into an Ethernet system. The easy availability of fairly fast, fairly cheap Ethernet LAN systems, and the rising tide of PCs that could use them, was half the nascent Internet equation. You could call it the demand side. Computers increasingly were used not so much as solo workstations but as components in LANs; their interoperability became one of their principal virtues.

ARPAnet and DOD Connectivity. The supply side of the Internet equation actually preceded the growth of LANs by a few years. In the late 1960s, the Department of Defense (DOD) began pumping increasing amounts of money into the softer side of computer science: artificial intelligence, computer graphics, computer voice and hearing, visual processing, natural-language processing, computer-based language translation, and computer networking. The source of the funding was the Defense Advanced Research Projects Administration (DARPA, or more commonly, ARPA). The mode of funding was unusual for DOD, in that the research was mostly unclassified and public, in the form of grants to universities and think-tanks.

Public (or partly public) projects seemed to call for a method of openness and interchange different from the Pentagon's historic need-to-know procedures. The method that was suggested

was the development and use of a computer network to accomplish document and data interchange and what would now be called electronic mail (e-mail). ARPAnet was built by the Massachusetts Institute of Technology (MIT) and a think-tank—Bolt, Baranek and Newman (BBN)—to link together ARPA grant sites and allow ARPA investigators and their staffs to communicate electronically. Physically, ARPAnet used high-speed and expensive leased AT&T telephone long lines to connect to fairly large computers, like the DECsystem 10s and 20s and PDP 11/70s from BBN's neighbor Digital Equipment Corporation (DEC). Human users typically used simple display terminals to interact with to their local host computers, which sent the messages out over the network. Specialized and proprietary interface gear made the whole thing work. Only members of the ARPA grant club were allowed to participate, which led to hard feelings among those excluded—although cost would have excluded many others anyway. Even in the early 1980s, after ARPAnet had been taken over by the National Science Foundation and become NSFnet (the Internet's immediate ancestor), the cost of participation included about \$10,000 up front for network gear, substantial use of a \$150,000 minicomputer, and quite a few hundred dollars each month for leased lines.

At least two university-based networking systems sprang up in the late 1970s and early 1980s in an attempt to provide ARPAnet-like connectivity to non-ARPA institutions. Both used a mail-drop scheme to avoid the high costs of leased phone lines. In other words, the participating computers used modest-speed, dial-up modems (like those of most contemporary home PCs in the 1990s, only slower) to phone a predetermined list of their peers at fixed intervals, usually once or twice a day after long-distance rates went down. It worked like an activist organization's telephone tree: each computer called *N* neighbors, who called *N* neighbors, and so on, until all the messages were delivered. The process was slow—e-mail sent this way might take overnight or longer to arrive—but it was much less expensive than the full-time alternatives. Mail-drop networks tended to be organized by host-machine type. Universities with big IBM mainframes tended to support Bitnet operation, while sites using the AT&T Unix operating system or clones typically adopted a scheme called Usenet.

The obvious advantages of intersite networking to university researchers and others created a strong demand for this kind of service. Full-time live service such as that provided by ARPAnet was particularly advantageous, since it allowed sharing of computer facilities and easy access to scarce computing resources, such as supercomputers. When the U.S. National Science Foundation (NSF) began supporting such supercomputer facilities at about the same time DOD was losing interest in its specialized networking, NSF essentially took over the ARPAnet infrastructure and renamed it NSFnet. (ARPAnet lived on for a while inside NSFnet.) NSFnet was initially set up along the same lines as ARPAnet—only institutions that were NSF grant recipients were welcome as members. But interest from other academic and research entities (as well as the broader scope of NSF) caused the system to grow into what is now the Internet.

The Internet in the 1980s and early 1990s was still for the most part a network between networks, the lower-level networks being the university and commercial LANs. Real participation on the Internet by a PC required a dedicated LAN connection, usually a coaxial or twisted-pair link using Ethernet technology, and a high-speed leased link to the Internet backbone. These were available in most university environments but were prohibitively costly to arrange at home. Software developers soon came up with a solution: an Ethernet emulator that ran over ordinary telephone lines using relatively low-cost commercial modems. Serial Line Interface Protocol (SLIP) and its successors allowed ordinary PCs in ordinary homes to dial into Internet Service Providers (ISPs) and function as full-fledged peers on the Internet system. Now, commercial ISPs brought the Internet into homes and small businesses at prices comparable to ordinary voice telephone service.

NSF decommissioned NSFnet in 1995 amidst political fanfare, creating a generic Internet and opening the door to a growing swell of private and commercial development. The electronic marketplace surged, with on-line shopping in the 1998 holiday season topping \$1.2 billion over America On-Line (AOL) alone. Private citizens routinely communicated electronically with families and strangers, and located services and information readily from PCs in libraries, schools, businesses, and homes.

Meanwhile, NSF turned its attention to development of the next wave of innovation. In partnership with MCI WorldCom, NSF created and supports the Very High Performance Backbone Network Service (vBNS), also known as Internet 2 and Next Generation Internet. This network links the two leading-edge supercomputing sites and at the end of the 1990s, connected 150 research institutions nationwide. Internet 2 seeks to accelerate Internet development and enable a new generation of applications to improve media integration, real-time collaboration, and interactivity. Although not yet generally accessible by ordinary users, Internet 2 clearly suggests that real time multimedia virtual interaction will soon be possible around the globe. (See King, Frinter, and Pickering 1997, for more detailed history of the Internet.)

INTERNET MODALITIES

E-mail. Probably the most common form of Internet communication is electronic mail, which is text-based messaging from a single computer user to one or more recipients. Internet routing services are used to send the message from a sender's address (e.g. gwjones@msn.com) to a recipient's (e.g., tbsmith@udom.edu). Individual addresses represent dedicated mailboxes—actually, special computer files—maintained by the users' ISPs. The mailbox address precedes the @ symbol, and the ISP's address follows it. E-mail has traditionally been plain, unformatted text, but newer e-mail software has the capacity to handle styled text, display graphics, even sound and video. Although these facilities are not yet universal, they suggest that e-mail will become more fluid, stylized, and expressive. In text-based e-mail, emotions are commonly expressed with “emoticons,” symbol combinations with a cartoonish character such as :-) for humor or :-(for sadness.

E-mail can take a mass or bulk form. For example, persons with a common interest can sign up to be members of a mailing list under the control of a computer program called a list server, usually called a listserv or mail list. Mail sent to the listserv is relayed to all list members, so that the resulting interchanges have the form of a public broadcast to other listserv members. Some listservs automatically broadcast all messages received, while others are moderated by a member who screens messages for conformity to the group's purpose.

Sometimes mass mailings take a hostile or abusive turn, as in the case of unsolicited commercial e-mail (UCE), usually labeled spam. (“Spam” is not an acronym but an unflattering reference to the lunchmeat; apparently, the usage is an allusion to a Monty Python skit in which a restaurant patron can't get any meal that doesn't contain Spam. Most precisely, spam is abusive mass broadcasting to a Usenet newsgroup, as described below, but the term has been borrowed by the e-mail world.) UCE, or spam, is bulk mail sent inappropriately to computer users who have not requested it. UCE is abusive because it is analogous to junk surface mail sent with postage due—the UCE victim, after all, has to pay for the connection over which the message is delivered, and all Internet users pay indirectly for the infrastructure that carries spam.

Spamming is one example of cultural conflicts that emerge from the migration of commercial practice to the Internet. The Internet grew up in military and academic subcultures where norms and expectations for behavior are explicitly not-for-profit. With the commercialization of the Internet in the late 1990s, many business practices were translated to the new medium without adaptation to existing prescriptions and proscriptions. “Netiquette”—etiquette for the Internet—continues to evolve and issues of social control over the Internet are largely unsettled at the turn of this century.

People tend to assume that e-mail is a relatively private medium. Historically, no one knew an e-mail address unless the user disclosed it. Today, institutions and ISPs publish e-mail addresses, and search engines on the World Wide Web (WWW) can locate many user addresses. In some ways, the e-mail address is coming to replace the telephone number as a direct personal identifier. People seem increasingly to use e-mail instead of the telephone to reach friends, family, and business contacts. With the rise of telephone answering machines and whole-family participation in the work force in the 1990s, delayed responding to any kind of messaging has become normative. E-mail allows people to receive and respond to messages at their convenience, 24 hours per day. Because it is written, messages can be clearly stated and thoughtfully framed. For communication across long distances, e-mail is less expensive than the telephone and can communicate documents

much more rapidly than any postal or delivery service. These uses plainly are not revolutionary, just partial replacements of existing communication methods (c.f. Kraut, Patterson, Lundmark, Kiesler, Mukophadhyay, and Scherlis 1998).

Unlike telephone calls, e-mail is usually archived by the servers that send and receive messages, the nodes between corresponding users. In the United States, the legal precedent is that information on the server, or on machines owned by business or government, is owned by the owner of the machine and is not private information. E-mail correspondence may be subject to review by superiors, may be subpoenaed by courts, and may even be considered public records in some states. The privacy protection of telephone wiretapping laws was not extended to e-mail.

E-mail and listservs have become important tools for passing announcements and other information among members of existing face-to-face groups. Listservs are common forums for professional communications and announcements and are often used in classroom study groups to encourage open questioning and discussion. Researchers use listservs to disseminate new findings, share resources, locate grant programs, and even to recruit study participants.

For professional and other formal communications, e-mail has successfully facilitated social contact, social networking, and information distribution (Wellman and Gulia 1999). However, in private communications with family and close friends, e-mail has increased the amount of contact people have, but has not replaced the telephone or face-to-face meetings. People sometimes e-mail even to those they see daily. But they do not replace their visits with e-mail. This suggests that people are missing something when e-mailing to their close others. Perhaps it is the experience of seeing another's face, or hearing another's voice. It remains to be seen whether voice- or video-enhanced e-mail will become accepted as a face-to-face surrogate.

Usenet. Usenet, often called the Internet news facility, is a giant messaging system through which loosely organized thematic discussion takes place on-line. Worldwide, millions of users linked to hundreds of thousands of computer sites write messages that they post to one of more than 30,000 topical newsgroups. These posts are then

distributed by Usenet-serving computers to Usenet users. Usenet began in 1979 as a mail-drop messaging alternative to the then-exclusive ARPAnet (see earlier) but evolved into a broadcast-based medium on the Internet.

Usenet topical areas or newsgroups vary by seriousness, from the highly focused to the totally whimsical. Newsgroups with names like "sci.archaeology" or "comp.lang.c++" tend to be largely topic-oriented, while many others have no real purpose other than to offer forums for freewheeling electronic banter and disreputable, nuisance advertising. Newsgroups are loosely organized and vary considerably in their scope and traffic. There are newsgroups offering social support to the ill and grieving and newsgroups offering sexual information to the naive and inexperienced. Information on starting newsgroups is available in the newsgroup news.groups.

Users are not required to wade through thousands of newsgroups to find messages of interest. Most Web browsers now have news-reading functions, or specialized programs are available for this purpose. People typically subscribe to selected newsgroups that they want to examine regularly, so that when they go on-line they will see these 10 or 30 or 200 newsgroups, not 30,000. Messages posted to Usenet are organized in discussion threads, that is, messages related by reference to the same initial post or topic. Users may skip some threads on their subscribed newsgroups, reading only those threads of personal interest.

Usenet has a character similar to that of e-mail-based listservs, although its explicitly public nature gives it a somewhat different feel. Usenet newsgroups historically predate listservs, so that much of netiquette evolved from these public discussion forums. Admonitions against spam originated on Usenet, as did the tendency for people to flame norm violators and discussion rivals. Flaming involves posting a hostile and insulting message to the group, intended to shame the author of a prior post. Flaming may have had its origin in a puerile effort to enforce group norms, but it is just as often a deliberate attempt to violate them for shock value or amusement. A deliberate attempt to provoke a hostile response on Usenet is called trolling; trolling/flaming battles dominate some newsgroups.

Usenet norms are discussed and described in newsgroups devoted to this topic, and summaries are posted in news.announce.newsusers. Additionally, most newsgroups have a document called the Frequently Asked Questions list (the FAQ) that deals with local norms and standards. Beyond these formal statements, something not unlike a community character emerges and is maintained by regular participants in some newsgroups over time. New users, seeking to fit in there, need to go through a process of socialization first, usually by lurking and observing. Other newsgroups, however, are anarchic, and still others are abandoned and ignored.

Research has suggested that newsgroups provide a setting intermediate between the public and the private where stigmatized social identities can be established and supported. For example, McKenna and Bargh (1998) found that homosexuals who had never made their sexual orientation public found the courage to do so through social support on Usenet. In another domain, however, Mickelson (1997) found that mediated social support on Usenet was less helpful to parents of attention-deficit/hyperactive children than face-to-face support in therapy groups. Researchers may investigate other socially unacceptable phenomena by identifying populations and soliciting volunteers on Usenet. Moreover, the messages posted to newsgroups are considered public behavior. As such, they offer a rich resource for social researchers. There is at least one important possible problem: Usenet users may be deceiving others in their self-presentations and in their messages. However, this problem permeates all self-report research and is not specific to Internet phenomena.

Chat. Computer chat evolved from grassroots networking attempts somewhat oblique to the development of the Internet. Chat was initially a feature of old-fashioned local bulletin-board systems (BBS), in which a system operator, or sysop, with (usually) a DOS PC allowed a dozen or so outside parties to dial in with modems and read Usenet-like delayed messages, or to communicate with each other in real time, by typing messages that appeared on the screen with labels indicating from whom they came. Some of the early national time-sharing services such as CompuServe offered this feature, too, often with a name like “CB simulator,” indicating the metaphor of the period,

citizen-band radio (CB). The idea was that people who were basically strangers would adopt “handles” (later called screen names) that concealed actual identity while advertising proclivities, and that these strangers would engage in streams of banter like CB radio operators out on the highway.

With the advent of mass-marketed national services such as AOL, Microsoft Network, and the like, chat facilities—now organized into topical areas or chat rooms—became one of the principal attractions. Chat and chat metaphors soon became second only to the World Wide Web as the public image of the Internet. Most users access chat facilities through commercial providers where it is implemented on private servers. There are also pure peer-to-peer Internet chat programs, such as Internet Relay Chat (IRC), that don’t require a host chat provider. Participation in IRC and related free-floating chat is probably dwarfed by use of AOL and similar commercial services.

Like Usenet, topical options in chat are numerous and variously populated. Users interact in real-time with minimal constraints. As with Usenet, the degree of group norm enforcement in chat rooms varies from high to nonexistent. On commercial providers’ chat facilities, broad norms of conduct often are officially enforced by staff members and user volunteers. Other hand-me-downs from Usenet were adapted to the constraints of chat. For example, the chat equivalents of Usenet’s emoticons are one-letter abbreviations in angle brackets, like <g> for grin. Apparently, these are both easier to type and to parse than graphic emoticons when one is engaged in chat activity.

With the emergence of chat came a wave of real-life chatter about the development of close relationships between people who met on the Internet. People arranged marriages to others they had never met face-to-face but with whom they had chatted endlessly. The self-disclosure and narrow scope of interactions, as well as the sheer number of encounters, provided a fertile breeding ground for social relationships. Many marriages and friendships founded there have endured, while others have dissolved. While the surge of new relationships and the awe of onlookers have stabilized, chat shows no signs of losing popularity.

Another chat phenomenon, cybersex, involves graphic verbal descriptions of sex acts, exchanged

in real time by couples and groups. It is the Internet equivalent of a graphic romance novel, except it is interactive and participatory. Participants may self-stimulate while generating messages to other users. Touted as an opportunity to free the libido from social restriction and personal inhibition, users may engage in unusual acts with minimal personal risk. Cybersex has been controversial. Like arguments over pornography in print, issues of access and censorship remain unsettled as we enter the twenty-first century.

Research on chat has focused primarily on two aspects of chat: the effect of anonymity in chat rooms on the negotiation of social identity (Turkle 1995); and the development of community among interacting users (Wellman and Gulia 1999). Most of this research has involved qualitative analysis or sometimes merely impressionistic characterization of chat activity. Many case studies have been conducted that describe activity in novel chat rooms or the chat experiences of particular individuals. Like Usenet, some chat is public behavior that is ripe for empirical study.

Chat is engaging, just as conversation with similar others is engaging in face-to-face interactions. But with chat, users hear all the conversations in the room, not only their own. Moreover, self-presentations can be well controlled to avoid sharing unflattering information. For these reasons, some people become obsessed with chat activity and seem to develop a dependency on this type of social contact. Others, particularly those who are homebound, have found fulfillment of their social needs through chat. Chat seems to attract a different type of user, relative to Usenet. The chat user seeks the interaction, perhaps more than the information available from topical discussion. Usenet users may seek the information and prefer not to be distracted by the interaction.

Multi-User Domains (MUDs). In the late 1970s and early 1980s, as the Net was still in its infancy, the fantasy role-playing game of Dungeons and Dragons swept through high schools and colleges. MUDs (Multi-User Domains or Multi-User Dungeons) originated as electronic platforms for similar fantasy games. They have become more elaborate and more free of goal-based game character as they have grown in popularity. They are based on different kinds of software (specified by names

such as MUSE, MOO, or MUSH) that can be accessed through the Internet.

Users, known as players, join MUDs through a command that connects their computer to the computer running the game program. Connection gives players access to a shared database of rooms, exits, and other virtual objects, which are created and manipulated through simple commands. Players create a character to play (called an avatar) by giving the character a name and a description, and enter rooms. Players interact with each other using simple commands such as “say” to talk to others in the room, “whisper” to talk to specific others, or “emote” for nonverbal expressions. Avatars grow and develop through interaction and game experience.

While some MUDs have graphical interfaces that allow characters and objects to be represented by icons, most interfaces so far have been textual. MUDs require the player’s imagination to create the objects, the actions, and the outcomes of the process. There is no necessary goal, and rules can be fluid. The interactions are the thing of interest. The Usenet news group `rec.games.mud` periodically lists Internet-accessible MUDs with their complete network addresses.

There has been tremendous interest in MUDs because they are the most unusual modality on the Internet, most different from RL, that is, real life. Avid players remain connected for days, cycling between RL and several different MUDs. Players may be especially susceptible to Internet dependency as some are drawn deeper into the fantasy world of the MUDs. There, identity is self-described and under the complete control of the player. One may be whoever one wishes to be. And actions are free of RL consequences, so freedom is perfected in the MUDs. Finally, anonymity is complete, with no means available to identify players in RL. These features allow MUDs to offer a utopian existence in a virtual world that is forever changing and changeable.

Researchers interested in the effects of simulation and role play on the development of identity are flocking to MUDs to investigate. Researchers interested in the effect of special types of relationships, or exposure to violence, on the family are also observing MUDs. And researchers interested in Internet dependence are focused on MUDs as well (e.g. Turkle 1995).

While interesting and entertaining environments, it may be premature to generalize findings based on observations of MUDs to other types of Internet experience. Although MUDs are anonymous, as are some chats, most Internet activity is identifiable and public. Although MUDs, and some chats, are user-created and malleable fantasy forums, most Internet activity is quite constrained both by norms and technical requirements, as well as considerations of cost and practicality. MUDs will likely continue to appeal to certain subpopulations, but they are not expected to become primary activities of Internet users. In fact, the trend at the turn of the century suggests that traditional games are becoming available as network software that can be shared and played interactively with others (Monopoly, bridge, Risk, etc.). They are appealing to a broad audience, both young and old. These games involve no avatars and no explicit fantasies about social identity. It is too early to tell whether they will compete effectively with MUDs for player time in RL.

World Wide Web (WWW). E-mail, Usenet, and chat facilities are to some extent immediate and ephemeral. They depend on user activity to generate their subject matter, and they require a constant stream—in the case of chat, a stream in real time. Other Internet-based facilities arose in an attempt to provide access to more fixed corpora of text: public-domain literature, programs, documents, and so forth.

Information protocols were an attempt to link data-storage facilities and user software to make Internet-based information search and retrieval convenient. A rudimentary form was File Transfer Protocol or FTP. FTP allowed external users to go to a foreign computer—if they knew where it was, what they were looking for, and how to sign on—and retrieve some of the files to which they were given access. Gopher, another information protocol, was similar in that it put selected parts of a computer file directory on the Net in a form suitable for browsing. A network of cooperating Gopher servers built a large-scale index of their total contents that was available as an entry point. Wide-Area Information Service (WAIS) was a more industrial-strength and business-oriented approach to the problem.

Gopher, WAIS, and to a significant extent most of the rest of the Internet have been superceded

by World Wide Web, a generalized hypertext facility that has submodalities corresponding to most other computer communication tasks. The idea of hypertext had been around since the 1960s—a computer-driven book with interconnected parts. Users could browse the hyperbook by following the linkages. Hypertext had been implemented on single computers or networks in various ways in the 1970s and 1980s. In 1990, at the European high-energy physics lab CERN (Conseil Européen pour la Recherche Nucléaire, Council for European Nuclear Research), Tim Berners-Lee developed a method of doing this over the Internet, which he called World Wide Web. WWW, or the Web as it is more often called, uses coded tags and descriptors (e.g. URLs, HTTP, HTML) to specify dynamic behaviors on a user's computer screen when links are invoked. This selection opens a file or otherwise triggers an event, spilling information to the user's screen.

WWW caught on explosively when inexpensive ISP access and Web service became widely available. Many individuals established WWW sites to describe their personal lives, their work, families, friends, and even their pets. For academics, Web sites typically described professional interests. Many course materials were posted to Web sites where students could retrieve them at any time. Businesses posted their personnel directories, and cities posted their public officials. Cinemas posted their playing times. It became a kind of instant, paperless desktop publishing mixed with features of a home broadcasting studio.

WWW is not socially interactive in the sense that e-mail or Usenet are interactive. Instead, interaction is scripted and restricted to some fixed set of user actions, somewhat like a video game. But the coupling of WWW with database applications and complicated scripting languages gave it a dynamic feel. Animations, sounds, and other types of sensory stimulus contribute to this feeling, and these frills will become the norm with Internet 2.

While mainstream business, institutions, and interest groups have WWW sites describing themselves, so do deviant interests. Because interaction is controlled by the Webmasters, criticism for deviance can be avoided. Militant and extremists groups, pornographers, and political interests abound and freely argue their unpopular opinions

on WWW. Issues of censorship and access restrictions, particularly for children, are largely unsettled.

Information is located on the Web by search engines that use logical operations to specify criteria for matching against hypertext found on registered servers. Different search engines, such as Yahoo or AltaVista, work with different subsets of WWW sites, so search results vary. Webmasters link together related sites and improve their odds of appearing in the search results of interested users. And respectable information is very prevalent, although sometimes difficult to distinguish from the propaganda. WWW does not provide a reference librarian or tour guide, and the only requirement to post information is access to a Web-serving computer. For this reason, educators were encouraged to emphasize strategies for evaluating source credibility and information integrity in their curricula, and researchers are scrambling to understand how people may effectively discern valid information.

Professionals already disseminate their research results and theories on WWW. Many electronic journals are available only on-line; some print journals are also published electronically. Many researchers post their own work to a personal Web page for others to easily access and reference. However, publishing a work on the Web may interfere with journals' claims to copyright on the same material, so many professional organizations are discouraging the posting of research papers prior to mainstream publication. Still, post-print abstracts and full-text articles are available in on-line databases and libraries. This wealth of information has made literature searching simpler and more useful than ever before.

Researchers have also established Web sites for data collections for studies of almost everything imaginable. Research materials (e.g., questionnaires, stimuli) are posted to a site accessed by a code provided by researchers to participants. Some studies simply recruit all comers to participation. Some research sites are scripted, so that the user follows a specified sequence of activities. Others require relatively few and simple actions. Participants prefer the convenience of WWW administrations to face-to-face meetings with researchers. But researchers cannot verify that participants are who they say they are, and some control over

the situation is lost. Early comparisons of pencil-and-paper questionnaires to WWW questionnaires found no differences in responding due to administrative mediums for short, self-report data where sampling was controlled (Kardas and Milford 1996).

WWW as a platform for propaganda, commerce, and entertainment has not been lost on the public. In fact, many people are betting large sums of money in development and investment that WWW is revolutionary. Already, users can read about a new vocalist, find her latest recording, listen to it, buy it, and order tickets to her upcoming concert—all accomplished in a few minutes without leaving home or waiting in lines! For many users, WWW has replaced their telephone books, mail-order catalogues, newspapers, and libraries, as all of this information is easily accessed on the Web.

Since live audio, live video, live telephone transmissions, and similarly active content can be transmitted and manipulated inside WWW, on the Internet, we would seem to have arrived at a stage at which function does not necessarily follow the network form. The old Internet, with text-based messaging and 48-hour relay turnarounds, seems hopelessly outdated, even quaint. What we've reached seems to be a stage of pure mediation: The Internet, through the mechanism of WWW, has the capacity to be a conduit for nearly any form of information, limited only by the available network bandwidth, transmission speed, and user patience. The extent to which the social conduct of life on the Net carries traces of its ancestry remains to be seen.

INTERPERSONAL ATTRACTION

Everyone meets many people. With some, there is a natural fit; with other, there isn’t. Liking a person is quite different from liking chocolate or liking to ski. Liking someone implies feelings of warmth, intimacy, and consideration and a desire to spend time together. Interpersonal attraction plays a large part in the formation of all relationships except those into which a person is born, that is, all nonascriptive relationships. Everyone uses tactics that are expected to recruit potential partners; the specific tactics used in presenting oneself, as well as the characteristics an individual looks for in others, will vary depending on whether what is sought is friendship or love or a good working partner (McCall 1974). In earlier studies, questions of affiliation were confused with questions of attraction. You may be attracted to many people, but only those who are available in terms of physical proximity and who are defined as appropriate by social norms will actually become interaction partners (Berscheid and Reis 1998, p.204).

Even though liking someone is based on many factors that can’t always be defined, a person does know, upon meeting someone, whether he or she is in fact liked. This perceived liking in turn draws us toward the other (Sprecher and Hatfield 1992).

Men and women operate differently in the area of choosing people as being attractive. For example, men are more inclined to reject a person who disagrees with them than are women and more likely to choose the same type of person as a friend and as a marriage partner (Lindzey and Aronson 1969).

First impressions don’t necessarily last. Nisbett, reanalyzing Newcomb’s data in 1989, found that people’s liking of other people after sixteen weeks’ acquaintance was not predicted very well by their initial liking of these others after one week’s acquaintance (Nisbett and Smith 1989, p.72)

THEORETICAL EXPLANATIONS OF INTERPERSONAL ATTRACTION

Homans, working from the perspective of exchange theory, states that people consider the rewards versus the costs of any potential relationship (Lindzey and Aronson 1969) and are attracted to those people who provide the most reward at the least cost. From this perspective, the ideal relationship is one in which both participants have equal costs and rewards, so that neither feels cheated or exploited. Newcomb asserts that frequency of interaction is an important determinant of attraction, a view known as the *propinquity perspective*. The basic assumption is that the more frequently one interacts with others, the more attractive they become. It is expected that frequency of interaction will lead to increasing similarity of beliefs and values and that this *assumed similarity* will in turn lead to increased attraction. This perspective ignores the possibility that getting to know a person better may actually reveal many differences (Lindzey and Aronson 1969). Despite the idea’s appeal to common sense, there is little evidence of increasing reciprocity of interpersonal attraction over time (Kenny and LaVoie 1982).

People do prefer those who are similar in background, interests, and values. They want to talk about things that interest them and do things familiar to them. A person who can provide social support by having similar beliefs and values is a likely potential friend. Despite the folk wisdom that opposites attract, similarity is more powerful than complementarity. The exceptions are those with strong needs on either end of the dominance–submission continuum or the nurturance–succorance continuum (Argyle 1969, p. 213); when

strong needs exist in these areas, complementarity is more powerful.

TRYING TO ATTRACT OTHERS

Though different factors come into play when one is evaluating someone as a potential friend or a potential work partner or a potential romantic partner, there seem to be inferred qualities that make a stranger appear to be likable or not likable. One study found that when videotapes of women were shown to males and females to judge, those most often chosen were apt to be described as sociable, cheerful, and positive emotionally; the underchosen were more apt to be described as negative and moody (Hewitt and Goldman 1982).

In a culture, like the United States, that values openness, psychological awareness, and emotional vulnerability, self-disclosure increases likability. Those who disclose little are less apt to be found attractive by others (Montgomery 1986).

Revealing yourself to another person is a sign that you like and trust them. It also signals that you trust them to respond appropriately. There seem to be three specific links between self-disclosure and attraction and likeability: (1) the more you disclose about yourself, the more you are liked; (2) people disclose more to those they initially like; and (3) the very act of disclosing makes you like the person to whom you disclosed (Collins and Miller 1994). A modern form of self-presentation that tells quite a bit about what people think makes them appear attractive is the personal ad. No longer are these dismissed as being for the desperate; rather, they are seen as just another way to introduce oneself. A study of the responses to different sets of physical characteristics referred to in ads showed that tall men and thin women received the greatest number of responses (Lynn and Shurgot 1984). In these ads it can also be seen that people present themselves as happy, able, capable, and very successful. It is interesting to note that the richer a man claims to be, the younger, taller, and prettier a woman he wants. The younger and prettier a woman presents herself as being, the more successful a man she wishes to meet.

FORMING RELATIONSHIPS

First meetings proceed cautiously. In every cultural group there are conventions about how long the

preliminaries must last. These conventions vary depending upon the age and gender of the participants, as well as where the meeting takes place. The goals of the encounter determine the interpersonal attraction tactics used. For example, when characteristics of potential dating partners were varied along two dimensions, physical attractiveness and personality desirability, undergraduate males chose physical attractiveness as the deciding variable (Glick 1985). Therefore, a female hoping for a date would find that increasing physical attractiveness would be more effective than showing what a nice personality she had. Not all initial encounters develop into relationships. In general, whether the individual develops an expectation that future encounters will be rewarding is critical to the continuation of relationship. Several studies have shown that perceiving the relationship as being better than others' relationships facilitates commitment to and satisfaction with the relationship (Rusbult et al. 1996).

Relationship satisfaction also positively correlates with evaluating your partner more positively than he or she evaluates self. Such evaluations are also positively related to more effectively resolving any conflicts that occur and thus to continuation of the relationship (Murray and Holmes 1996).

The goals of the encounter determine the interpersonal attraction tactics used. For example, when characteristics of potential dating partners were varied along two dimensions, physical attractiveness and personality desirability, undergraduate males chose physical attractiveness as the deciding variable (Glick 1985). Therefore, a female hoping for a date would find that increasing physical attractiveness would be more effective than showing what a nice personality she had.

PLAYING AND WORKING TOGETHER

Competition has an interesting relationship with interpersonal attraction. Rees found that during intragroup competition, football players reported the most liking and respect for those who played their own position yet outperformed them (Rees and Segal 1984). Riskin also found that males, when given background data indicating both the degree of competitiveness and the degree of work mastery in target males, rated the most competitive as most attractive, as long as they were also

seen as having ability. In addition, these competitive males were assumed by the male subjects to be more attractive to women (Riskin and Wilson 1982). Numerous studies have shown that emergent leaders are given high interpersonal-attraction ratings by both sexes.

The workplace provides a setting where qualities of competitiveness, ability, and leadership are displayed. It might be assumed that this leads to the formation of romantic attachments. Though this does in fact occur, the work setting also provides for additional complexity in the handling of personal attraction. Attraction and intimacy must be seen in the context of outsiders' view of the relationship. Attempts must be made to balance the demands of the job and those of the relationship. Role relationships within the workplace are expected to contain a degree of distance that is at odds with the demands of "getting closer." Despite these problems, people do get romantically involved with co-workers. One study of 295 adults (average age: thirty-two) revealed that 84 had been involved in a romantic relationship with someone at work and 123 had been aware of a romance in their workplace. Such relationships are more likely to occur in less formal organizations, especially those that are very small or very large. The person most likely to enter into such a relationship is a female who is young, new, and of low rank (Dillard and Witteman 1985, p. 113).

FRIENDSHIP

Being perceived as friendly, pleasant, polite, and easy to talk to increases a person's ability to attract potential friends. If in addition similar values, interests, and backgrounds are present, the likelihood of friendship is even greater (Johnson 1989). In ongoing relationships, friendship has nothing to do with the participants' rating of each other's physical appearance. Nevertheless, at the initial meeting stage a person judged as being too physically attractive will be avoided. In one study, sixty undergraduate males were shown a male target population (previously rated from 1 to 5 by a male and female sample) and were asked who among this group they would like to meet. The most attractive were chosen less frequently; they were judged to be more egocentric and less kind. It was the moderately attractive who were seen as being the type of person most of the subjects would like

to meet. Explaining these findings in terms of exchange theory, one would say that most people rate themselves as bringing moderate attractiveness to a relationship and feel that extreme attractiveness throws off the equality (Gailucci 1984).

Though it is often assumed that young people do not see older people as potential friends, a review of forty research reports reveals that perceived agreement in attitudes tends to neutralize young adults' general perception of older adults as unattractive. Elders may perceive young people as attractive or unattractive, but they still prefer to associate with individuals who are middle-aged or older (Webb et al. 1989).

SEXUAL ATTRACTION AND ROMANTIC RELATIONSHIPS

While males and females alike differ in their ability to distinguish between friendly and sexually interested behavior, males are more likely to see sexual intent where females see only friendly behavior. When shown videotapes of five couples, each showing a male and a female behaving in either a friendly or a sexually interested way, males consistently saw more sexual intent (Shotland and Craig 1988).

Men and women also differ as to the relative importance of physical features and personal qualities in determining the choice of romantic partners. Even though both sexes rated personal qualities as being more important than physical features, males placed greater emphasis on the physical than did women (Nevid 1984). Despite this, there seems to be a point at which attempting to increase physical appeal by dressing to reveal the body has a negative effect on one's appeal as a marital partner. Hill reports that when male and female models wore very tight clothes that displayed a great deal of skin, they were rated as being very attractive as potential sex partners but their marital potential was lowered. High-status dressing had the opposite effect for both males and females: Ratings of physical, dating, sexual, and marital attractiveness all increased as the status of clothing increased (Hill et al. 1987).

A shared sense of humor is another important component of loving and liking. When a humor

test comprising cartoons, comic strips, and jokes was given to thirty college couples, along with a test that measured how much the partners loved and liked each other, a strong correlation between shared humor and a predisposition to marry was found (Murstein and Brust 1985). It can probably be assumed that the shared humor comes before the relationship, as well as serving as a factor that enhances it. How people feel about their romance at any given time tends to cause them to rewrite history. For example: When people involved in romantic relationships were asked, once a year for four years, to describe how the relationship had changed during the past year, it was found that current feelings had more to do with the ratings that actual changes (Berscheid and Reis 1998, p. 211).

ARDYTH STIMSON

INTERPERSONAL CONFLICT RESOLUTION

Most of us understand conflict as a negative aspect of social interactions and therefore are inclined to avoid it if possible. Yet theorists contend that conflict is an inevitable part of human association and, to some extent, a necessary one (Straus 1979). In fact, conflict, either intrapsychic or interpersonal, is a pivotal concept in theories of human development (Shantz 1987). Even with its acknowledged importance in human development, however, research on conflict has been relatively recent. This may perhaps have been due to the perception of conflict as largely a negative occurrence and the equating of conflict with aggression (Shantz 1996). If interpersonal conflict is not aggression, what is it? How do individuals respond to interpersonal conflict? What is our theoretical understanding of individual behavior in interpersonal conflict, and what are the factors that are related to how individuals resolve conflicts with others? This entry addresses the above questions with a focus on childhood and adolescence. The term *conflict* will refer to interpersonal conflict unless otherwise stated.

WHAT IS CONFLICT?

Interpersonal conflict is an event that occurs between two individuals in the course of interactions. Thus, it requires at least two individuals for conflict to occur; conflict is not an attribute of a single individual (Shantz 1987). According to conflict theory, which draws from symbolic interactionism, exchange theory, and systems theory, conflict is defined as "a confrontation between individuals, or groups, over scarce resources, controversial means, incompatible goals, or combinations of these" (Sprey 1979, p. 134). From the sociolinguistic perspective, conflict is a "social activity, created and conducted primarily by means of talking" (Garvey and Shantz 1992, p. 93). Thus, the main elements of conflict are an interactional

context, which is at least dyadic, and the presence of behavioral opposition (Joshi 1997).

An important condition for sustained interactions is the maintenance of interpersonal equilibrium. Conflict causes disequilibrium, and the individuals involved in the conflict can use different ways to move the interactions to an equilibrium. These different ways are conflict resolution strategies and can be defined as "sets of behaviors that seem to subserve a social goal. They may be either conscious, planned means to foreseeable ends (as these terms usually connote), or unconscious, automatic or habitual behaviors that have the effect of subserving goals" (Shantz 1987, p. 289).

THEORETICAL MODELS RELATED TO INTERPERSONAL CONFLICT RESOLUTION

There are two theoretical models that attempt to explain how individuals respond in conflict situations—the social information processing model and the interpersonal negotiation skills model. The social information processing model focuses on the intraindividual cognitive processes that take place in social situations. The INS model, on the other hand, describes the developmental changes in conflict resolution strategies that occur with cognitive changes.

Social Information Processing. According to the social information processing model (Dodge et al. 1986), individuals go through a set of steps in which they process social information contained in social situations. However, the person is generally not aware of these information-processing steps. The individual must respond skillfully at every step to successfully negotiate the situation. The first step is to encode the social cues in the situation, which means that the person assesses the situation in terms of what exactly is happening. The next step is to interpret the cues in the light of previous knowledge, thus forming mental representations of the cues. Thus, the understanding of the situation—why is this conflict happening? why is the other person behaving in this way?—is constructed. Once the cues are interpreted, the individual must generate possible ways of responding to the situation, which in conflict situations would be conflict resolution strategies. This is followed

by the choice of an appropriate response, and finally the individual must enact the chosen response behaviorally.

A revision of the model (Crick and Dodge 1994) highlighted the role of arousal regulation, especially between the steps of cue interpretation and generation of strategies. This means that the emotions experienced by the individual may influence the goals and responses generated, and eventually chosen. Thus, the social information processing model focuses on the intrapersonal processes that underlie interpersonal conflict resolution.

Interpersonal Negotiation Strategies Model.

The interpersonal negotiation strategies (INS) model (Selman and Demorest 1984; Yeats et al. 1990) draws from both the cognitive-developmental and the information-processing perspectives. It predicts that cognitive development is accompanied by an increased sophistication in the ability to coordinate the social perspective of the self and the other. Three factors implicated in the choice of an interpersonal negotiation strategy determine the developmental level of the strategy—the understanding of the self's and the other's perspective, the purpose of the strategy, and the affective control, or the way in which individuals understand and balance the affective disequilibrium. A fourth factor, the orientation, determines the type of strategy that the individual uses, namely, self-transforming or other-transforming. Children move through four developmental levels of social perspective taking—undifferentiated/egocentric, differentiated/subjective, self-reflective/reciprocal, and third-person/mutual. At the undifferentiated/egocentric level, children are not able to differentiate between the thoughts and feelings of self and the other. Their strategies, therefore, tend to be unreflective and impulsive, using either force or obedience. The differentiated/subjective level is characterized by the recognition that different persons have different perspectives on the situation. However, children understand the perspectives only from one person's point of view. The next level, called the self-reflective/reciprocal level, is the level at which a child is able to mentally step outside the self and take the other person's perspective. Children also understand that people's actions do not have to reflect their thoughts and feelings. Finally, at the third-person/mutual level, the individual is truly able to take a third-person

perspective and understand the situation in terms of mutual goals.

One of the strengths of this model is that it views interpersonal negotiation strategies in an interpersonal context, juxtaposing the understanding of the self in relation to the other. However, the focus remains on the individual, not on the interpersonal process of conflict resolution.

FACTORS RELATED TO CONFLICT RESOLUTION STRATEGIES

Age. There appear to be developmental trends in the use of certain conflict resolution strategies. In the case of aggression as a strategy, the evidence is somewhat contradictory, especially during preschool years. Some findings indicate the use of aggression (Dawe 1934), while others indicate a predominant use of insistence and rare use of aggression (Laursen and Hartup 1989). Overall, the use of power assertion decreases with age and the use of compromise increases with age. The use of compromise, however, may be restricted to hypothetical situations (Laursen and Collins 1994). Thus, adolescents may offer compromise as a solution to hypothetical situations but may report using disengagement as often as compromise (Collins and Laursen 1992). For example, a study of conflict occurring in family talk (Vuchinich 1990) revealed that adolescents are more likely to use standoff (disengagement from the conflict) or withdrawal (physical disengagement from the situation). The use of disengagement may be evident as early as middle childhood (Joshi 1997). Also, the use of compromise may emerge during middle childhood (Joshi 1998). Longitudinal studies are needed to confirm developmental patterns evinced by cross-sectional studies.

Gender. The clearest gender differences are in the use of aggression, with girls being less likely to use physical aggression than boys. During middle childhood, girls may be more likely to end conflicts with friends with disengagement (Joshi 1997). Using the INS framework, an investigation of adolescents reporting hard-drug use suggested that boys are more likely to use other-transforming strategies, whereas girls use both self-transforming as well as other-transforming strategies (Leadbeater et al. 1989). Overall there appear to be no clear gender differences other than in the use of aggression.

The Relationship. The relationship as the context of the conflict is another factor that influences how the conflict is resolved. Relationships that are defined by kinship norms may be considered by individuals as a “safer” context in which to disagree and argue, since there is no immediate threat of dissolution of the relationships (Berscheid 1985; Laursen 1993). Thus, adolescents may be more likely to use compromise with friends than with adult family members (Laursen and Collins 1994). Another dimension along which relationships vary is the distribution of power. Peer relationships are more egalitarian, while a hierarchy typifies parent–child relationships (Maccoby and Martin 1983). We could, therefore, hypothesize that children are more likely to use negotiation and compromise with peers than with parents. How does the resolution of conflict differ between peers and between parents and children?

CONFLICT RESOLUTION WITH PEERS

Research on conflict resolution with peers reveals some general patterns. In one of the earliest observational studies on conflict resolution, Dawe (1934) found that in naturally occurring conflicts in 2- to 5-year-olds, the use of aggression increased with age. Aggression was expressed in behaviors such as pushing, pulling, and striking. Talking during conflict also increased with age. Children resolved most conflicts themselves. When preschoolers’ conversations were examined, Eisenberg and Garvey (1981) found that children used verbal strategies such as insistence and repetition, reasoning, and asking for explanations. Subsequent observations of preschoolers (Killen and Turiel 1991) indicated that in a natural setting as well as a lab setting, children ended more conflicts without active resolutions. Laursen and Hartup (1989) found somewhat similar results from their observations of preschoolers. Insistence was the most frequently used strategy, negotiation and aggression were rarely used, and most conflicts were resolved without adult intervention.

At an older age (7 years), children report using predominantly direct strategies (50 percent), such as leaving the scene of interaction, using physical force, or getting help from a third person (Shantz 1993). About 28 percent of the strategies reported were conventional, such as saying “please” or

apologizing, and about 20 percent of the strategies used involved reasoning and/or compromise. As mentioned earlier, the use of compromise increases during adolescence but may be restricted to hypothetical situations.

CONFLICT BETWEEN FRIENDS AND NONFRIENDS

Children, at least until middle childhood, may not be able to understand that friendships can be both supportive and conflictual (Berndt and Perry 1986). Conflict between friends and nonfriends does appear to proceed differently, especially the strategies used to resolve the conflict. An observational study (Hartup et al. 1988) of young children (approximately 3.5 years to 5.5 years of age) revealed that the frequency with which children used disengagement strategies, such as mutual turning away, was greater with friends than with nonfriends. This resulted in different outcomes, with equality occurring with greater frequency with friends than with nonfriends. Also, conflict with friends was more intense than conflict with nonfriends.

In another study, Hartup and colleagues (1993) found that 9- and 10-year-olds showed differences in management of conflict with friends and nonfriends in a closed-field situation, that is, “a situation in which the children cannot choose with whom, what and where their interaction will occur and how long their interaction will last” (p. 446). Children in a dyad were taught conflicting versions of a board game. In this situation, friends disagreed more frequently than nonfriends, and their disagreements lasted longer. Conflict resolution per se was not a focus of the study.

Regarding conflict resolution strategies specifically, young adolescents aged 11 to 14 years showed a greater skill at generating alternatives for resolving conflicts by reacting to hypothetical situations with friends than with nonfriends (Caplan et al. 1991). Similarly, in another study investigating differences in conflict resolution strategies used with friends and acquaintances, Vespo and Caplan (1993) found that children were more likely to use conciliatory gestures with friends than with acquaintances.

At least three reasons can contribute to differences in young adolescents’ conflict resolution skills with friends and nonfriends (Caplan et al.

1991). First, friendship is characterized by intimacy and tolerance. Second, children learn and practice conflict resolution in the context of friendship. Third, friendships shape young adolescents' understanding of conflict and expectations regarding outcome (p. 105).

Thus, no clear patterns emerge regarding developmental changes in conflict resolution strategies, except for a decline in the use of aggression. Perhaps individuals use a range of strategies depending on contextual factors, such as the issue of the conflict. Whether this is true is an important question that needs to be answered. Research has indicated that children who are able to resolve conflicts skillfully are more likely to be socially better adjusted (Asher et al. 1982). Theoretically, the use of compromise is considered both desirable and developmentally more sophisticated. How is it, then, that compromise is not one of the strategies frequently used until adolescence? Skillful conflict resolution may be more a matter of the using a strategy more appropriate for a particular conflict than of using a particular conflict resolution strategy.

CONFLICT RESOLUTION WITHIN THE FAMILY

The context of family relationships is a powerful influence in the development of social skills. Interactions with different family members foster the development of the ability to understand others' feelings (Dunn 1988). During the second year of life, children begin to get into conflict with their parents and siblings with increased intensity and frequency (Dunn and Slomkowski 1992). During the elementary school years, children are most likely to use assertion or insistence at the beginning of a conflict and end the conflict with submission (Joshi 1997). As noted earlier, adolescents may use standoff or withdrawal in their conflicts with parents and siblings (Vuchinich 1990). There is a need for replication of these findings to trace developmental trends, if any, in the use of conflict resolution strategies with family members.

While individuals might use different strategies to resolve conflicts in different relationships, it could be argued that conflict resolution skills learned in the family may transfer to other contexts. Every relationship is embedded in a network of relationships, and thus it must affect and be

affected by other relationships (Hartup and Laursen 1991; Hinde 1981; Lewis et al. 1984). How does conflict resolution in one context relate to conflict resolution in another?

LINKAGES IN CONFLICT RESOLUTION BETWEEN CONTEXTS

Studies indicate that patterns of interactions with parents serve as models for children that they can use with peers (Parke et al. 1992). The level of conflict in the family was found to be predictive of adjustment in school (Tesser et al. 1989). Most of the research related to conflict resolution between parents and children uses parental disciplinary style as the indicator of parents' conflict resolution strategies with children. Also, these studies are conducted within the social information processing framework. Overall, the findings indicate that children who experience power-assertive styles of discipline are likely to misinterpret social cues and use ineffective conflict resolution strategies (Dodge et al. 1990; Hart et al. 1990; Weiss et al. 1992). However, these studies examine conflict resolution at a more general level, with some emphasis on aggression. When the correspondence between the conflict resolution strategies parents use with children and strategies that children use with peers is examined, some interesting findings are revealed (Joshi 1997). First, parents use different strategies depending on the issue of the conflict. Second, both children and parents use more than one strategy to resolve conflict. For example, a child may use assertion to begin with and then resort to reasoning, and if the conflict does not get resolved, eventually withdraw from the conflict. The use of multiple strategies makes the one-on-one mapping of conflict resolution strategies used in two contexts a difficult task. The one correspondence that was found was between the last strategy that mothers used with children and the last strategy that children used with peers. Specifically, children who used reasoning as the last strategy with a friend had mothers who used reasoning as a last strategy with them (Joshi 1997).

FUTURE DIRECTIONS IN RESEARCH AND THEORY

One of the features of the research and theory in the area of interpersonal conflict resolution, at

least during childhood and adolescence, is that it focuses more on intraindividual processes than it does on interindividual processes. We still need more research on how individuals involved in a conflict situation influence each other's behavior. The risk of focusing on the individual lies in its inevitable outcome—that the strategy that the person uses comes to be denoted as the person's attribute, which is a stable characteristic. If we know that individuals may use different strategies in different conflict situations, and that they use a combination of strategies, then it would be erroneous to describe conflict resolution styles in terms of single strategies. Thus, the important variables that need to be examined along with conflict resolution strategies are the issue of the conflict, the relationship between the individuals, and the strategies of the other individual.

The conceptualization of interpersonal conflict resolution as a process will be better accomplished by measurement that reflects process. Therefore, interpersonal interactions must be characterized by the assessment of the behavior of one person as contingent on the behavior of the other person. This would require the development of newer models that would predict individual behavior in conflict based on the aforementioned contextual variables.

Besides achieving the goal of depicting conflict resolution with greater accuracy, the study of contextual variables will help us better understand what exactly constitutes general conflict resolution skills. This knowledge will be particularly useful in planning interventions for individuals who find interpersonal conflict situations challenging.

ANUPAMA JOSHI

INTERPERSONAL POWER

In its broadest sense, interpersonal power refers to any cause of any change in the behavior of one actor, B, which can be attributed to the effect of another actor, A. It sometimes refers to the capacity to cause such change (Weber [1918] 1968), sometimes to actual use of that capacity (Dahl 1957; Simon 1953) but always to overcoming the "resistance" of B (Weber [1918] 1968), hence causing B to do something B would not otherwise do (Dahl 1957). Interpersonal power is therefore

the power of one individual "over" another as opposed to an individual's power to do something, the capacity of an actor to attain some goal (as in Russell 1938). "Power over" always implies a relation between two actors rather than referring to an attribute of an actor. It is sometimes thought of as "micro" power and contrasts with "power to," which is attributed to collectives (Hawley 1963; Parsons 1963) and is thought of as "systemic" or "macro" power.

Adequate description of a power relation will typically refer to: (1) the *bases* of power (the bases of A's power over B are the resources that are possessed by A that are instrumental to the goals of B); (2) the *means* of power (the ways in which A uses these resources to change the behavior of B); (3) the *strength* of power (the costs to B if B does not comply with demands by A); (4) the *costs* of power (the costs of A of having to exercise power over B); (5) the *amount* of power (the extent to which A is able to get B to do something that B would not otherwise have done); (6) the *scope* of power (the acts with respect to which the amount of A's power over B is greater than zero); and (7) the *domain* of power (the persons over whom the amount of A's power is greater than zero). However, there is a great deal of disagreement over which of these constitute power and what kinds of bases, means, costs, and particularly compliance the word covers.

CONCEPTS OF POWER

In his work on power, Simon (1953) treats the effects rather than the causes of power and covers by the one word a whole family of concepts describing the effects of all the human causes of human conduct. Force, power, influence, authority, and manipulation all have a strong family resemblance to each other, and Dahl (1957), March (1955), and Simon (1953) have all treated them as one process. But French and Raven (1959) have pointed out important ways in which the dynamics of different kinds of power differ, and March (1966) has shown compellingly that treating them all as one unitary process leads only to a dead end.

The laws of *force*, for example, differ in a fundamental way from the laws governing power. In using force, A does not require B to choose between compliance or noncompliance. A kills B,

imprisons B, drags B, wrestles B to the ground, but does not require choice by B. Threat of force requires a choice, but threat of force is a different process (Goode 1972). A threat may be futile if B has decided to die for a cause; the threat may not accomplish its purpose. Actual force will accomplish its purpose whether B chooses to comply or not. It simply removes B as a factor opposed to A's wishes.

Like force, *manipulation* does not require that B choose between complying or not complying with the wishes of A. A may control B by controlling the information at B's disposal, by preventing certain choices being open to B, or by activating motives of B known to lead B to do what A wants. In some sense, B may be said to make choices (hence the difference from force), but A does not require B to choose between compliance and noncompliance. A controls the conditions that govern how B analyzes the choice to be made.

Although there are more than one narrow senses of the term *power*, all are distinguished from force and manipulation by the fact that power involves a choice by B between compliance and noncompliance. But this is true also of influence and authority. What distinguishes power is that it involves external sanctions. In Blau (1964) B is coerced to do something, X, by threat of a penalty for noncompliance. In Festinger (1953), B is induced to do X by a promise of reward for compliance or coerced to do X by threat of a penalty for noncompliance. Both rewards and penalties are external to the actor. They make no internal change, no change in the actor's state of mind. B does not change views privately, even if B conforms publicly. *Influence*, on the other hand, persuades B that X is right according to B's own interests; hence B complies privately as well as publicly. Compliance is willing in the case of influence, "forced" (Festinger 1953) in the case of power. If compliance were not observable to A, B would still comply in the case of influence but would not in the case of power. Hence, power is highly dependent on observability, but influence is not (French and Raven 1959).

Authority differs from both: It refers to a claim by A, accepted by B, that A has a legitimate right to expect compliance by B, even if compliance runs counter to B's own preferences (Barnard 1938). It differs from influence because whether B likes or does not like X is irrelevant. It differs from power

in that B is expected to comply (and, if B accepts A's authority, does comply) because it is right, not because it is expedient. If B accepts A's legitimate authority, then B complies with A's commands whether compliance is observable to A or not. Furthermore, the power that legitimate authority makes possible has different effects because it is legitimate. Power exercised outside the scope of legitimate authority creates "reactance" (Brehm 1966), but power exercised inside the scope of legitimate authority does not (French and Raven 1959).

French and Raven (1959) also distinguish reward from punishment power and hence inducement from coercion. Coercion causes reactance; inducement does not. But they are so indissolubly connected that it becomes difficult to treat them as distinct processes. A reward forgone is a cost, and a penalty forgone is a reward. Hence, withholding a reward is equivalent to imposing a penalty, and withholding a penalty is equivalent to giving a reward. In order to distinguish the two, one would have to be able to separate giving something from withholding something. This might be possible in principle, but not in the case of power. Power depends on the contingency of sanctions; that is, A must be able to give *or* withhold something, depending on whether B does not comply. It is difficult to have one without the other. Thus, probably the most satisfactory concept of interpersonal power is Festinger's forced compliance (1953), compliance that is public but not private, caused either by threat of penalty or promise of reward.

This still leaves the question of whether power is potential or actual. Weber ([1918] 1968) emphasized the capacity of one actor to overcome the resistance of another whether or not the capacity is actually used. Simon (1953) and Dahl (1957) have objected to making inferences from a potential that might or might not actually be used. Research in fact consistently shows that not all potential power is used (see below), and Dahl in particular has argued that power has an effect only if used. On the other hand, Friedrich (1937) has argued that B might comply with the preferences of A because of anticipated reward or punishment, even if A says or does nothing that overtly demands compliance by B. Bachrach and Baratz (1963) go further and argue that certain kinds of acts that involve B doing nothing (nondecisions) occur without B even needing to know what A will

do, simply because B knows what A *could* do (a hypothesis confirmed by Zelditch and Ford, 1994). Both arguments imply that sheer existence of potential power has an effect whether used or not. The effect does not even have to be intended.

The issue of intentionality is another of the disputed questions in conceptualizing power, but not only can potential power have an effect without being used, there are even theories, such as those of Cartwright (1959) and Emerson (1962, 1972), in which "use" of power occurs without necessarily being intended by anyone.

The dispute over potential versus actual power refers more to causes, the dispute over broad versus narrow concepts of power more to effects. Thus, another ambiguity of power is whether one is referring to causes, effects, or the process relating the two.

THE CAUSAL APPROACH TO POWER

As process, power most typically refers to an exchange of "resources" (characteristics or objects instrumental to the attainment of goals). The only exception is the "causal" approach to power. Simon (1953) pointed out the similarity between the concept of "power over" and causality, leading to a longstanding tradition in which the former is defined in terms of the latter (as in Dahl 1957; Nagel 1975). But this led to so many difficulties that March (1966) concluded that the concept of power was superfluous. Although Nagel (1975) attempted to give the concept more explanatory power by narrowing it (to the effects of A's preferences on B), this led to little further advance, possibly because causal modeling gives one little insight into the process relating causes to effects.

But "process" theories themselves divide into four types: field theory; rational choice, or decision, theories of exchange; behavioral exchange theory; and a neo-Weberian "resistance" theory of exchange.

THE FIELD THEORY OF POWER

In field theory, power is the ability to activate forces in the life space of another in the direction of X (Cartwright 1959). The capacity to activate such forces depends on the motive base of B,

thought of as a tension system, which, when activated by A, produces a vectored force that reduces the tension. Thus, power depends on the needs of B as much as on the wishes of A. It was this approach that gave rise to the concept of a “resource”: Transferable resources give rise to power. But use of power by A faces not only opposing forces leading B away from X but also resistance due to the exercise of power itself. (This resistance was later termed *reactance* by Brehm 1966 to distinguish it from resistance due to B’s dislike of doing X itself.) A’s “control” over B is the outcome of the opposing forces acting on B. Thus, the outcome of the reduction of tension in the force field is distinguished from A’s power in a manner corresponding to the distinction between actual versus potential power. In field theory, therefore, success—that is, actual compliance by B—is not the measure of A’s power since there are many forces other than A affecting B’s behavior.

Field theory, like the causal approach to power, treats the whole family of power concepts as power, excluding only physical force. But research in this tradition was much concerned with differences between different types of power, including reward power, punishment power, expert power, legitimate power, and referent power (power arising from B’s attraction to A, which causes a desire to be similar to A). It was found that both reward and punishment power depend on A’s ability to observe B’s behavior, while the other forms of power do not. Coercion increased but reward decreased reactance. Legitimacy normatively constrained power so that using it outside its legitimate scope reduced its effect. Use of coercion when it is legitimate decreased reactance, while use of rewards when they are not legitimate increased reactance (French and Raven 1959). Because of reactance, use of coercion depends on restraints that prevent B from leaving the field.

EXCHANGE THEORIES OF POWER

The most important difference between field theory and exchange theories is that in the latter alternatives become the most important factor in the analysis of power. The reason is that, assuming voluntary relations, an actor may do things that she or he would prefer not to do because they are nevertheless preferable to any available alternative. Thus, an abused wife may not leave her

husband because separation or divorce are either even less desirable or even more costly. But exchange theories themselves come in three somewhat distinct forms: rational choice, or decision, theory; behavioral exchange theory; and resistance theory.

Rational Choice Theories of Exchange and Power. Thibaut and Kelley (1959) offer perhaps the earliest rational choice model of the exchange process applied to power. They treat all interaction by analogy to the exchange of goods and services, each actor’s participation in exchange being determined by choice among alternatives, the outcomes of which are characterized by their rewards and costs. Rewards are simply the positive values, costs the negative values, associated with the consequences of choosing an alternative. The value that results from the algebraic sum of rewards and costs is the payoff for a given act. Given interaction between two actors, A and B, payoffs are a joint function of the choices made by each. A matrix of joint payoffs for alternative actions by A and B formulates the conditions determining interaction between the two, in particular whether a relation forms and persists. Thibaut and Kelley treat payoffs in terms of their subjective value for the actors, hence in terms of their “utility” (although they do not use the term). In general, actors are assumed to maximize utility and continue in a relation only if for each actor a course of action is better than the best available alternative.

Thibaut and Kelley deal largely with stable relations rather than with particular acts. Power in a relation arises out of the “dependence” of the actors on each other. It can take either (or both) of two forms: A may be able to control the outcomes of B independently of any act by B, hence controlling B’s fate, or A may be able to make rewards and costs contingent on B’s behavior, hence controlling B’s behavior. But an important principle of the theory is that control of an individual’s fate can be converted into behavioral control.

There are many variants of the decision-theoretic approach to exchange, each differing with respect to how they treat the choice that underlies it. Value can be treated as objective (e.g., in monetary terms) or subjective (e.g., in terms of the meaning of money to the actor). The latter gives rise to a utility theory, such as in Thibaut and Kelley (1959), Blau (1964), and Bacharach and

Lawler (1981). The relation between choice of an alternative and its outcome can be treated deterministically (as is true of all three of the utility theories just cited) or probabilistically. If value is treated objectively and outcomes probabilistically, one has an *expected utility* theory as in Harsanyi (1962). Among probabilistic theories, probability itself can be treated objectively or subjectively: In March (1955) the probabilities are objective, in Nagel (1968) and Tedeschi and colleagues (1973) they are subjective. In the latter case one has a *subjective expected utility* theory. In all these variants of decision theory, the central axiom is that the actor maximizes whatever the theory's criterion of choice.

Despite the variations among these theories, in general they predict that, given a conflict of interest, A is more likely to use power when more is at stake, when the cost of exercising power is less, when the likelihood of compliance is greater, and when there are fewer alternative means of obtaining compliance. The costs of exercising power include the relative depletion of A's stock of resources, the likelihood of retaliation, and the effect of reactance on subsequent relations with B. In general, the evidence supports these predictions, although "use" sometimes refers to whether or not A prefers to impose his or her will on B; sometimes to whether or not, if A does have such a preference, it is accomplished by manipulating rewards and punishments rather than by other means; and sometimes to whether or not A's behavior is overt and explicit, communicating threats or promises, or is covert. Rational choice theories will also in general predict that B is more likely to comply with A's preferences the larger the reward attached to compliance, the larger the penalty attached to noncompliance, the greater the credibility of A's promises of reward or threat of penalty, and the fewer the alternatives available to B. Again, the evidence largely supports these predictions. But it is well to keep in mind that with respect to both use and compliance, the evidence deals largely with voluntary relations.

Unlike other decision theories, subjective expected utility theory (especially Nagel 1968) makes use of Friedrich's (1937) "law of anticipated reactions," in which compliance occurs without directives, threats, or promises by A. In the case of punishment, not only is there no visible exercise of power by A, but compliance by B may appear to be

willing because there is no visible resistance. In addition, if one takes into account that the law of anticipated reactions can be applied to A as well as to B, A may know in advance that B will comply and therefore know that it is unnecessary visibly to exercise power in order to achieve A's objective (Samuel and Zelditch 1989).

Bacharach and Lawler (1981) have pointed out that even though relative power in a relation is necessarily zero-sum, meaning that a gain by one actor implies loss by the other, relative power can be distinguished from absolute power, the sheer quantity of resources controlled by an actor. Hence, relative power can be distinguished from total power, the sum of the resources possessed by A and B. Total power, unlike relative power, is a variable that can increase for both actors at the same time. Bacharach and Lawler argue that total power has an effect independent of relative power, especially on the use of punitive power capabilities. Given a conflict of interest, if punitive power is an available tactic, the likelihood of its use by the more powerful actor increases as his or her relative power increases but decreases as total power increases.

Thibaut and Kelley note that all these ideas are more useful as the pattern of exchange becomes more stable; hence, the focus of exchange theory is often not only on the fact that power is relational, which is true even at the level of a unit act, but on the structure of relations arising from enduring patterns of repeated exchanges. The most influential theory of this kind has been Emerson's theory of power-dependence relations (1962, 1972). Though it originally grew out of Thibaut and Kelley's work, this theory has come to be associated more recently with behavioral exchange theory, a theory originating in the work of Homans.

Behavioral Exchange Theory. Homans (1961) behaviorized exchange theory by transforming rewards and costs into reinforcement contingencies and the process of exchange into mutual operant conditioning. Many fundamental concepts of decision theory, however, survive in behavioral exchange theory. Choices are determined by maximizing profit, which is the difference between rewards and costs. Costs in Homans take a form more like costs in economics than in Thibaut and Kelley, becoming opportunity costs, that is, profit forgone by choosing X over not-X. But, as in

Thibaut and Kelley, exchange occurs at a point at which for both actors exchange is more profitable than each actor's best available alternative. Thus, A uses power in Homans—where “use” means attempts to direct the behavior of another—when it is more profitable than any alternative available to A, and B complies when compliance is more profitable than noncompliance. Homans, however, gives more emphasis than do Thibaut and Kelley to the effect of satiation on the value of a reward: Accumulation of rewards brings diminishing returns. Hence, poor actors are more responsive than are rich ones to offers of any given level of reward for doing an otherwise undesired act.

Emerson's power-dependence theory, perhaps the most influential theory of interpersonal power, was originally a utility theory of relations like Thibaut and Kelley's (Emerson 1962). But Emerson (1972) followed Homans in behaviorizing exchange theory, except that, unlike Homans, Emerson again dealt with relations rather than acts. Power-dependence theory is formulated in terms of two actors whose social relations entail ties of mutual dependence. “Power” is the amount of B's resistance that can be overcome by A: It is potential rather than actual power that is used to describe the relation. Power is a function of dependence, which arises from the control by one actor of resources on which another depends for achieving his or her goals. Dependence varies directly with an actor's motivational investment in goals but inversely with the availability of alternative sources of resources outside the relation. The “power advantage” of one actor over another is a function of the net balance of each one's dependence on the other. If the net balance is zero, power is equal, or “balanced.” A relatively unique feature of Emerson's theory is that balanced power is assumed to be stable, while imbalance creates pressures to change the power relation in the direction of balance. There are four kinds of balancing operations. B may (1) reduce motivational investment in the goals mediated by A, withdrawing from the relation; (2) increase the number of alternative sources of the resource (extend networks); (3) increase A's motivational investment in goals mediated by B (e.g., by offering status to A); or (4) deny to A alternative sources of resources mediated by B (coalition formation). Attention to these operations leads one to distinguish use of power from change of power—increasing or decreasing

dependence in the relation. These assumptions about balance have had a major impact on the study of organizations (beginning with Thompson 1967), but other exchange theories have tended to reject the balance assumption, especially Blau (1964), who instead treats the balance mechanisms as means by which A maintains or increases power over B.

“Use” in power-dependence theory comes to mean something quite different from what it means in decision or field-theoretic formulations: It refers now to asymmetries in the outcomes of reciprocal exchange. It is assumed that use of power, in the more usual sense, increases until an equilibrium is reached, at which point the less powerful actor is receiving no more benefits than the best alternative source could provide. While power imbalance does in fact increase asymmetry of exchange, it has been consistently found that its use is suboptimal. It is constrained in part by search costs (Molm 1987s) and in part by commitment to the other and concern for equity (Cook and Emerson 1978). Furthermore, use of punishment power depends not only on punishment capability but also on reward capability: Those weaker in reward power are, other things being equal, more likely to use punishment power (Molm 1997). Molm argues they have more to gain and less to lose by the use of coercion than those with more reward power: It is muggers, who gain nothing at all without coercion, who have nothing to lose by using it.

Molm also finds that, given mutual dependence, the effectiveness of coercion is directly proportional to its use, providing that its use is: (1) instrumental rather than symbolic, that is, a specific consequence of a specific behavior rather than a personal challenge; (2) highly contingent on the undesired behavior; and (3) consistent, that is, the punishment of equivalent behavior is equivalent. Coercion is perceived as more symbolic if it is noncontingent, inconsistent, or threatened but not actually used, increasing the side effects of coercion (resistance, negative affect, retaliation, loss of the relation). If it is perceived as instrumental, on the other hand, a high probability of punishment for a specific behavior, because it is effective in the short run, actually increases the net frequency of rewards in the long run, while “weak”—that is, sporadic—coercion decreases the

long-run net frequency of rewards and increases the side effects of coercion.

The most significant development in the behavioral exchange theory of power has been its extension to networks of dyadic relations. Interpersonal power is not necessarily confined to a dyadic relation, as Coleman (1973) has shown. But except for Coleman, interpersonal power has usually been treated as dyadic. More complex structures are possible, however, by connecting dyads into networks (Emerson 1972). Study of such networks has rapidly developed as a central preoccupation of research on interpersonal power, especially preoccupation with the question of determinants of power at a position within a network. Most of this research has been concerned with negatively connected networks. A negative connection is one such that exchange in one relation decreases the value of exchange in another, while a positive connection increases its value. Thus, if A must choose which of two offers of exchange to accept from two others, B and C, AB is negatively connected to AC because choice of AB excludes exchange between A and C. Subsequent research has concentrated on the effects of varying structures of negatively connected networks. Centrality of a position turns out not to predict asymmetry of exchange very well; hence, much theory and research has been directed at discovering what alternative concept of power of a position does predict asymmetry of exchange. Cook and Emerson (1978) proposed "vulnerability" as an alternative and defined it as the effect that removing a position would have on the total quantity of resources available for exchange in a network. An intuitively appealing concept, this idea works well for many networks, though Markovsky and colleagues (1988) have objected that there are certain structures for which it does not accurately predict asymmetries. Their alternative conception derives from resistance theory.

Resistance Theory. Willer's (1981) resistance theory objects to the importance of satiation in behavioral exchange theory and as an alternative goes back to Weber's concept of power as overcoming resistance. Willer conceives of interaction as exchange of sanctions. The value of a sanction is a function of its objective value multiplied by its quantity, but value is not itself a function of quantity; hence, there is no satiation effect. Willer focuses instead on the "preference alteration state" of

the actor (P_A), consequent on sanctions, and defines resistance as the ratio of two differences: the best possible outcome minus the value of P_A is divided by P_A minus the worst possible outcome B will accept, called P_A at confrontation. Exchange occurs at equiresistance.

The emphasis on resistance leads the theory to incorporate coercion and conflict more easily within the same framework as voluntary exchange. But in addition it leads to a different understanding of power at a position in a network. As in Cook and Emerson (1978), power at a position depends on alternatives, but Markovsky and colleagues (1988) propose a graph-theoretic index of power based on exclusion—B, bidding for exchange with A, is "excluded" if, having no alternatives, B does not exchange at all if outbid by another. The difference between the two is that in Markovsky and colleagues, exclusion is relative to the number of exchanges sought, while in Cook and Emerson actors seek to make a single exchange at a given point in time. It is "advantageous" in resistance theory to be connected to positions that have few alternatives relative to the number of exchanges sought and disadvantageous to be connected to positions that have many alternatives relative to the number sought. In exclusive networks, an odd number of positions is advantageous because in them a position has alternatives or a partner's alternatives have alternatives. An even number is disadvantageous because a position has one or more rivals for exchange with a partner. The ratio of advantageous to disadvantageous paths leading out from a point in a network (counting overlapping paths only once) gives the graph-theoretic index of power at that point in the network. The logic of the argument can be extended to inclusion as well as to exclusion. An inclusive connection is one such that exchange in one cannot occur until exchange in another also occurs. Inclusive relations, for example, increase the power of peripheral positions in a network. However, in mixes of the two, exclusion overwhelms inclusion and power is as centralized as in exclusive networks (Szmatka and Willer 1995).

Exclusion is more certain in some networks than others, and the magnitude of outcome differentials is sensitive to the certainty of exclusion. Outcome differentials are greater in "strong power" networks, in which the less powerful have no

alternatives if they reject the terms of exchange of the more powerful, than in "weak power" networks, in which no position is assured of excluding another without cost to itself (Markovsky et al. 1993). Markovsky and colleagues argue that, in general, the strength of power is inversely proportional to the density of a network because the greater the density of a network, the more alternative opportunities for exchange. Hence, outcome differentials should be inversely proportional to the density of a network. They also show that weak power networks are more sensitive to strategy. Strong power maximizes outcome differentials even if the powerful are passive. In weak power networks, structural forces keep the division of profits more nearly equal, but strategy makes a difference: The more experienced demand more if they are in powerful positions and yield more if they are in less powerful positions, thus magnifying outcome differentials. Weak power networks are also more sensitive to the actual experience of exclusion (Skvoretz and Willer 1993): Potential exclusion, determined by structure, determines outcomes in strong power networks, but (given full information) outcomes are sensitive to both the potential and actual experience of exclusion in weak power networks.

MORRIS ZELDITCH, JR.

ITALIAN SOCIOLOGY

The birth of sociology in Italy is variously dated, depending on the causes that are adduced for it or on the perspective from which it is viewed. Indeed, even the conceptualization of sociology differs; hence, in a certain sense it is more important to determine when *each* "sociology" was born. We can distinguish two types of sociology and two

corresponding ways of providing cultural and professional training. The first type is positivist (or neopositivist) sociology, tied to quantitative empirical research, which aims to discover the laws and the causal relationships that can be drawn from the data and from experience; the second type is humanistic sociology, which interprets its role as a critical science, raises questions, is more an approach to science than a science proper, and places social phenomena in their historical context. The two places for training professional sociologists are the research center and the university, respectively; each type of institution has an ambivalent and fluctuating relationship with the two sociologies.

Both types of sociology and both kinds of training, together with their origins, take on specific meanings according to the historical period; and hence they depend on the process of complexification of Italian society and the parallel development of different Italies (at least the three indicated by Bagnasco 1977).

THE ORIGINS OF ITALIAN SOCIOLOGY

Many historians of sociology see Italian sociology as deriving from the political thought of Niccolò Macchiavelli (1469–1527), because of his interest in leadership and its connection with the structures within which the prince must exercise his will. The political sociology of Vilfredo Pareto, Gaetano Mosca, Scipio Sighele, Roberto Michels, and Camillo Pellizzi can also be seen as belonging to this current of thought. This school, largely academic in origin, is based in political science, the philosophy of politics, and the philosophy of law. Associated with and grafted onto it is a sociology of law, also rooted in the universities, reflected by the great number of articles published in the first issues of *Quaderni di sociologia* (*Notebooks of Sociology*), a review founded in 1951. Philosophy (Roberto Ardigò), political science (Gaetano Mosca), and law (Carlo Francesco Gabba, Rodolfo Laschi, Enrico Ferri, Icilio Vanni) became "godfathers" to Italian sociology. This may be explained by its dominant themes: the legitimation, explanation, and order that accrue to leadership and political structures as they develop. There were also economists, often (though not always) with a socialist background and orientation—Ginseppe Toniolo, Achille Loria,

and Pareto—always attempting to study society in macroscopic terms in a way closely linked to political science.

Besides these currents concerned with the sphere of public action, there was the study of the private sphere as it deviated from the established order, as examined from the perspectives of political science, philosophy, and economics. Cesare Lombroso, Enrico Morselli, Scipio Sighele, and Alfredo Niceforo—some of them with medical training—studied the criminal personality, constructed typologies of the “delinquent man,” elaborated pseudobiological explanations of deviant behavior, and thus attempted to interpret the relationship between society and the deviant (the duty of society being to lock up and prevent the deviant from causing further harm).

The sociological bent of these Italian protosociologists, who were generally university professors, was rooted in the work of Auguste Comte and Herbert Spencer. Hence, in their work we find a search for the laws underlying the social phenomena studied, the confidence that one can understand these phenomena by means of an inductive method borrowed from the natural sciences, and the belief that it is possible to describe and explain social reality with the positivist method. Italian sociological positivism (from 1865 to the rise of Fascism) worked out a paradigm of social analysis that was fairly homogeneous and characterized by naturalistic determinism in the form of evolutionary organicism. It was carried out by means of a positivist inductive method, although the basis of determinism varied during the history of positivism. For Lombroso, Niceforo, and others, the bases of such determinism were in biology and evolution (the theories of instinct and atavism), while for Pareto the structure of social activity took its model from economics. Another distinctive characteristic of this positivism was to consider society, social phenomena, and subjects in normative but exclusively objective terms. Roberto Ardigò worked along these lines as a theorist of human action, but after a certain point he became increasingly aware of the importance of “nonlogical” actions, of interiorization, and of socialization—the possibility of a voluntaristic theory. It is thus possible, in his case, to speak of a positivism of the subject, which foreshadows the work of Pareto.

The positivist approach was used by Socialist and Catholic scholars, as well as by liberals. This perspective was shared by the founders of *Rivista italiana di sociologia* (*Italian Review of Sociology*), which was published from 1897 to 1922.

Positivism, mainly a French and English current of thought, began to decline when its naturalistic–determinist presuppositions were left behind and other variables had been introduced, thus leading to interpretations of society in more complex terms (Mosca, Pareto, Michels, Gaetano Salvemini); also, it was questioned when a progressive and optimistic determinism was replaced by a pessimistic determinism (as in Michels, with his iron law of oligarchy). Positivism was reborn with the formation of the Chicago School of urban and ecological studies at the end of the 1930s.

In Italy, positivism was replaced by the idealism of Benedetto Croce and Giovanni Gentile, who were strongly critical of positivism’s main ideas and naturalistic research methods. The polemical debate in 1900–1901 between Pareto and Croce in the pages of *Il giornale degli economisti* (*The Journal of Economists*) is emblematic.

The technologically hard core of positivism is the research method, particularly “the experimental method that has given such brilliant results in the natural sciences,” as Pareto wrote in his “Discorso per il Giubileo” (Borgatta 1917; “Discourse for the Jubilee”).

This explains why, among the positivist sociologists, there were many demographers and statisticians (including Angelo Messedaglia, Loria, Niceforo, and Livio Livi) during the years of Fascism (1920–1940) and why the preeminence of idealism—the point of reference for sociology—lay primarily in statisticians such as Corrado Gini, Vittorio Castellano, Marcello Boldrini, and Nora Federici.

Gini, in particular, was active in founding the Istituto Centrale di Statistica (Central Institute of Statistics) in 1926; this agency was set up to organize census taking in Italy. In 1928 he founded the Comitato Italiano per lo Studio dei Problemi della Popolazione (Italian Committee for the Study of Population Problems), the school of statistics at the University of Rome (1929), the Italian section of the Institut International de Sociologie (1932), the Società Italiana di Sociologia (Italian Society of

Sociology) in 1937, and the Facoltà di Scienze Statistiche, Demografiche e Attuariali (Faculty of Statistical, Demographic, and Actuarial Sciences) at the University of Rome (1936). In this period Gini also founded, or was a founding member of, many journals, such as the *Bollettino bibliografico di scienze sociali e politiche* (1924; *Bibliographical Bulletin of Social and Political Sciences*), *La vita economica italiana* (1926; *Italian Economic Life*), and *Gems* (1934).

To sum up, Italian sociology was born through the importation of positivist ideas, paradigms, and methodological creeds, and it tried to solve the problems that society or the classes in power considered important in the second half of the nineteenth century and the first half of the twentieth—the existing forms of power and their legitimation, as well as the control of deviance. Its content therefore concerned the philosophy of law, political doctrines, socialism, the social thought of the Catholic Church, criminality and alienation, and related matters. In the first half of the twentieth century, in particular during the Fascist period, the study of demographics and statistics remained alive, as did the study of the charismatic components and fatal distortions of power (Michels) and investigation of the irrational and subjective element in society, in the form of residues and derivations (Pareto).

The themes and problems of concern were closely linked to the period in which Italian sociology developed. Socially, Italy was still traditional, and sociology was developed within the universities, in the context of more or less formally recognized courses.

1945 TO THE 1960S

The postwar period witnessed a profound rupture in Italian society, in its culture, and hence in its sociology. That society became much more complex, and its emerging culture became part of sociological study. Thus problems such as those in the South of Italy—urbanization, migration, the large concentrations of workers—were brought to the forefront. In addition, Italian sociologists were very receptive to foreign ideas and schools of thought. Thus, alongside the survival in academic circles of the influence of Comte, Spencer, and Darwin and the work of Gini, Livi, and Castellano, the American influence became dominant and the

German tradition regained importance, primarily in research institutes.

In other words, there was first an accumulation of theory and research that was incorporated into university sociology courses; later came the first chair of sociology, which was awarded to Franco Ferrarotti, at Rome in 1962. Scholars did not yet have sociological training, since no academic structures for that purpose existed; therefore they came from fields such as classical studies, political science (still very much oriented toward law), economics and commerce, medicine, law, and so forth.

One effect of this complexity was the subdivision of sociology into many branches: development and modernization; urban and rural sociology; the sociology of labor, of the economy, of migrations.

This period lasted from the end of World War II to the founding of the first faculty of sociology at Trento and the reform of the faculties of political sciences; it saw the incubation of a new direction in Italian sociology. Since that time there has been the development of the faculty of sociology at the University of Rome, and many other universities have acquired significant faculty strength in sociology. Let us now examine these currents.

The Sociology of Development and the Mezzogiorno. One of the problems the new Italy had to face was how to reduce the developmental gap between North and South, in particular how to enable the society of the South and of Sicily and Sardinia to overcome their state of underdevelopment. Even before World War II the “Southern question” had been posed and announced by the actions and writings of Guido Dorso and Salvemini, among others. But it was only after 1946 that the problem became a subject of study and institutional intervention. Some of the institutions that deal with intervention and training, as well as with sociological research on the problems of the Mezzogiorno, are the Associazione per lo Sviluppo dell’Industria nel Mezzogiorno (SVIMEZ; Association for the Development of Industry in the Mezzogiorno), the CENTRO per la Formazione e studi per il Mezzogiorno (Center for Professional Training and Studies of the Mezzogiorno), the Associazione Nazionale per gli Interessi del Mezzogiorno (ANANI; National Association for the Interests of the

Mezzogiorno), the Movimento di Collaborazione Civica (Movement of Civic Collaboration), the Unione Nazionale per la Lotta contro l'analfabetismo (National Union for the Fight Against Illiteracy), and UNRRA-Casas (Istituto per lo Sviluppo dell'edilizia Sociale; the Institute for the Development of Public Housing).

Projects and plans were drawn up within and in cooperation with these agencies. They include the pilot project for the Abruzzi, the Sardinia project, the Center for Studies and Initiatives in western Sicily, the Center for Community Development at Palma di Montechiaro, and the Molise and Avigliano projects. It was in these institutions that sociological and anthropological studies on development, modernization, and the community were carried out. Tullio Tentori (1956), Guido Vincelli (1958), Danilo Dolci (1955, 1957, 1960), Gilberto Antonio Marselli (1963), Lidia de Rita (1964), Maria Ricciardi Ruocco (1967), Luca Pinna (1971), Gualtiero Harrison and Maria Callari Galli (1971), and Giovanni Mottura and Enrico Pugliese (1975) are among those whose works reveal a social commitment together with testing of the theories of modernization. They show an awareness of their limits as well, as elaborated by the English-language sociological tradition; moreover, there was a strong element of utopianism in this mixture of social commitment and scientific rigor.

It was not just the ideas of American and northern European scholars that were studied and applied to the modernization of the South of Italy; scholars themselves were committed to the task. At the same time, some classic research was carried out, important both because it was cited by Italian scholars and because it was rejected by them (in particular by Alessandro Pizzorno and Marselli). One of the books that became an object of controversy was Edward C. Banfield's *The Moral Basis of a Backward Society* (1958). Other frequently cited foreign research works included Joseph Lopreato's "Social Stratification and Mobility in a South Italian Town" (1961), Feliks Gross's "Value Structure and Social Change" (1970), and Johann Galtung's *Members of Two Worlds: A Development Study of Three Villages in Western Sicily* (1971).

Sociological study of modernization also entered the universities through sociology courses that took their place alongside courses in rural economics. The most important center for these

courses was the Faculty of Agriculture at Portici, and the most significant sociologists were Marselli, Pugliese, Mottura, and Emanuele Sgroi.

The Sociology of Work and Economics. The sociology of work and economics arose in the research agencies, in research centers of large industries, and in labor unions.

One very important research center for the training of Italian sociologists was Olive Hi's Ufficio Studi e Relazioni Sociali (Research and Social Relations Office) at Ivrea. Adriano Olivetti, building a company and a community, surrounded himself with sociologists, economists, communications experts, and planners. Ferrarotti, Pizzorno, Luciano Gallino, Paolo Ceri, and Antonio Carbonaro worked and studied at the facility. They, and many more, devoted themselves to industrial relations and the rationalization of staff selection in large industries operated by enlightened and paternalistic entrepreneurs like Olivetti. Very often, however, the left-wing slant of their training and their impression of being manipulated led these sociologists to leave the research center after a short stay and to continue their sociological training at universities in the United States. In this cultural climate, which also was indebted to nineteenth-century models of integration of the company, the community, and territorial planning, the review *Comunità* (Community) published essays with a strong cultural and social commitment. The publishing house of the same name made available to the Italian public the classics of German and, especially, American sociology.

Another forum for the training of sociologists (especially in the sociology of labor) was the research offices of the labor unions (and, to a lesser extent, of the political parties). In particular, future sociologists such as Aris Accornero, Guido Baglioni, Gian Primo Cella, and Guido Romagnoli were directed toward studies of factory work. The factory and labor union conflicts were the main subjects of their volume, with a consequent tendency to identify the "organization" with the factory (a pamphlet on the sociology of organizations by G. Bonazzi is, significantly, entitled *Dentro e fuori la fabbrica* (1982); *Inside and Outside the Factory*) and the labor union. These sociologists had few contacts with foreign scholars; when they did, such contacts were oriented toward France and particularly toward the Institut des Sciences Sociales du

Travail (Institute of the Social Science of Labor) in Paris.

Urban Sociology and the Sociology of Planning. Other institutions in which sociologists (this time urban sociologists) were trained in the 1950s and 1960s were the planning offices set up by the territorial governments (large municipalities and provinces in northern Italy), particularly the Istituto Lombardo di Studi Economici e Sociali (ILSES; Lombard Institute of Economic and Social Studies) in Milan and the Centro Studi Sociali e Amministrativi (CSSA; Center for Social and Administrative Studies) in Bologna. The former trained the sociologists Pizzorno, Gianni Pellicciari, Massimo Paci, Alberto Martinelli, Guido Martinotti, Paolo Guidicini; the latter, Achille Ardigò, Paolo Guidicini, Giuliano Piazzi, and Pietro Bellasi. There was also the Ufficio Studi Sociali e del Lavoro (Office for Social and Labor Studies) in Genoa, where Luciano Cavalli carried out his *Inchiesta sugli abituri* (1957; *Survey on Slums*).

ILSES dealt with research on neighborhoods, on participation in neighborhoods, and, in general, on the structure of the city. The approaches were borrowed from the concepts and research of the Chicago School and the group that had formed around Paul Henry Chombart de Lauwe. Thus, among other things, Ernest W. Burgess's model of concentric areas was verified for Italian cities (in Rome and Milan), as was Hoyt's model of sectors. The results of these researches found expression in anthologies on the Chicago School: such as Guido Martinotti's *Città e analisi sociologica* (1968; *The City and Sociological Analysis*); manuals of urban sociology, such as Franco Demarchi's *Società e spazio* (1969; *Society and Space*); and a manual of urban research based largely on that carried out by ILSES and CSSA, Paolo Guidicini's *Manuale della ricerca sociologica* (1968, 1987; *Manual of Sociological Research*).

The sociologists who worked at ILSES developed close contacts with the United States (particularly Martinotti, Paci, and Martinelli) and with the United Kingdom (Guidicini).

International Sociology. Sociology entered the universities where both theoretical and empirical sociologists were trained but no attention was given to international sociology. International sociology in Italy was developed by the Istituto di

Sociologia Internazionale di Gorizia (ISIG; Institute of International Sociology of Gorizia), founded by Demarchi in 1969. This branch of sociology seeks its identity in the synthesis of ideas from political sociology; the sociology of international relations; and the sociology of ethnic relations, of borders, of towns, and of territories. Relations were developed with scholars from the United States, from Eastern Europe, and from the countries of the European Economic Community. From the United States, the institute took the research methodology of multivariate analysis, under the direction of Edgar F. Borgatta; it was one of the first institutions in Italy to adopt these techniques. Its researchers later held important positions in various universities: Renzo Gubert, Alberto Gasparini, Raimondo Strassoldo, Bruno Tellia, Bernardo Cattarinussi, and Giovanni Delli Zotti.

Among the cited research organizations, ISIG is one of the few that carries out an active program that is not encompassed by university activities. There are at least two reasons for this. First, Italian sociology has tended not to be interested in international relations. Second, there has been an acceleration of international interdependence; in recent years there has been great change in the relations between Western and Eastern Europe, and between Europe and the rest of the world. Under the direction of Alberto Gasparini, ISIG has responded to the need for such study, with an emphasis on Eastern Europe and the countries of the former USSR.

Academic Institutionalization of Italian Sociology. The most intense activity of the research agencies occurred in the 1950s and 1960s; it was scientific in the full sense of the word, since concrete problems were tackled empirically, starting from a theory (generally developed abroad) and ultimately returning to the theory. This way of doing research, and of training for research, is quite different from the method adopted in the universities, because it is tied to concrete problems and specific deadlines.

Moreover, in this period, together with the ideas and plans designed to establish sociology in the universities (the first chair in sociology was awarded to Ferrarotti in 1962), sociology was taking on an identity as an academic discipline. The first issue of *Quaderni di sociologia* (*Notebooks of Sociology*) was published in 1951, edited by Nicola

Abbagnano and Ferrarotti, and in 1957 the Associazione Italiana di Scienze Sociali (AISS; Italian Association of Social Sciences) was founded. In 1959 the Centro Nazionale di Prevenzione e Difesa Sociale (National Center for Prevention and Social Defense) in Milan, together with AISS, organized the Fourth World Congress of Sociology at Stresa; and from then until 1974 Italian sociologists (Angelo Pagani and Guido Martinotti) held the post of secretary of the International Sociological Association. Italian sociology was now mature and ready to enter the universities with its own sociologists, their empirical experience, and their theoretical preparation; hence it was able to extend the discipline.

SOCIOLOGY IN THE UNIVERSITIES (SINCE 1960)

Italian sociology, as a discipline and as scientific research, has developed strongly. The heart of this development lies more in the universities and university teachers than in the nonacademic institutes that played such a large role until the 1960s. All this happened with the consolidation of sociology in the university system (which had the function of training young researchers and became the channel for legitimizing the scientific character of sociological research). Subsequent developments included the publication of dictionaries and encyclopedias of sociology, the foundation of the Associazione Italiana di Sociologia (Italian Association of Sociology), and the formation and coordination of sociological interests in specific areas.

Sociology in the Italian Universities. The complexity of Italian society requires a strong sociological reading of reality, and the nonacademic agencies discussed above could not long meet this need. Moreover, a strong impulse to legitimize sociological analysis came from the student protest movement, which in the mid-1960s reached Europe from the United States.

Thus sociology entered the universities mainly with the establishment in Trento of the Istituto Universitario di Scienze Sociali (University Institute of Social Sciences, later the Faculty of Sociology) in 1962 and with the reform of political science faculties in 1968.

The Faculty of Sociology at Trento. The Istituto Universitario di Scienze Sociali was officially founded on September 12, 1962, on the initiative of the Provincia Autonoma di Trento (the Autonomous Province of Trento), the Istituto Trentino di Cultura (the Trento Institute of Culture), and of Professor Giorgio Braga, lecturer at the Università Cattolica in Milan. The governing body is composed of ten professors: three jurists, two economists, one statistician, one mathematician (the director, Mario Volpato), one ethicist, and the sociologists Braga (vice director) and Franco Ferrarotti. The first sociologists to teach there were not from the Milan area. Later Milanese came to Trento: Francesco Alberoni and Guido Baglioni. The first teachers at Trento were from several regions: Giorgio Braga (from the Università Cattolica in Milan), Franco Ferrarotti (Rome), Filippo Barbano (Turin), Sabino Acquaviva (Padua), Franco Demarchi (Trento), and Achille Ardigò (Bologna). The students who enrolled in the first year (226), and even more in the immediately following years, were strongly motivated to study social problems and came increasingly from regions far from Trento.

The Faculty of Sociology, with its four-year program, grants two types of degrees in sociology: general and special. The general course in the sociological disciplines trains teachers and researchers who will work in universities, international institutions, and centers of research on economic and social problems. The special sociology course prepares students for management careers in public administration and in private firms (in particular, for research, public relations, and personnel), social insurance offices, agencies for agricultural development, welfare agencies, labor unions and political parties, business consultancy agencies, marketing research offices, and town planning bodies.

As can be seen, this university planning aimed at the extension of the university; moreover, it set out to deal with a society that was both complex and predictable in its organization of problems and phenomena to be studied and, if possible, solved.

Things changed with the arrival of the student protest movement. At the University of Trento, different models of teaching and organization were experimented with, leading it to occupy a unique position in the Italian university system. A "critical university," managed by a joint committee of teachers and students, was formed. The director of the

institute and experimenter with this model was Francesco Alberoni, who attracted other teachers interested in this project, in particular from Milan. This situation lasted until 1970; meanwhile, it triggered experimentation at other Italian universities and to some extent contributed to the reform of the faculties of political science. In subsequent years, when the institute was transformed into the first Faculty of Sociology in the Italian university system, *corsi di laurea* (degree courses) in sociology emerged, often within existing *facoltà di magistero* (education faculties) at Rome, Naples, Salerno, and Urbino.

The Reform of the Faculties of Political Science. Sociology was offered in twenty-three Italian universities in 1964–1965, a total of thirty-eight courses taught by twenty-seven professors. It was episodically and marginally introduced into the faculties of law, letters, arts, economics, and political science, and often the same person was asked to teach several courses; for example, Alberoni taught four different courses in sociology at the same time at the Università Cattolica of Milan. The courses were scattered throughout Italy: four courses each in Rome and Milan (Università Cattolica); three courses each in Bari and Florence; two courses each in Bologna, Cagliari, Milan (Università Statale), Naples, and Palermo; and one course each at the universities of Catania, Ferrara, Genoa, Messina, Milan (Polytechnic), Padua, Pavia, Pisa, Salerno, Siena, Turin, Trieste, Urbino, and Venice. For the most part the teachers were “masters”: Achille Ardigò, Gianfranco Morra, Anna Anfossi, Franco Leonardi, Camillo Pellizzi, Giovanni Sartori, Luciano Cavalli, Renato Treves, Francesco Alberoni, Sabino Acquaviva, Eugenio Pennati, Agostino Palazzo, Franco Ferrarotti, Vittorio Castellano, Antonio Carbonaro, Filippo Barbano, Angelo Pagani, and Alessandro Pizzorno.

At the end of the 1990s, the situation has completely changed, both in terms of the number of universities in which sociology is taught (now forty-two), obviously expanded by the establishment of new universities—and in terms of the number of courses and teachers (now 827). Moreover, some very substantial centers of sociology have been established, and sociology is taught in all the Italian universities. The universities with the greatest numbers of sociology courses are (in descending order): Rome (eighty-four), Bologna (thirty-nine), Turin (sixty-three), Milan (forty-three),

and Trento (fifty-two). Those with fewer than twenty but at least ten courses are Padua (seventeen), Naples (sixteen), Calabria (fourteen), Florence (thirteen), Salerno (twelve), Catania (eleven), and Palermo (ten).

One very important technical reason for these profound changes in the teaching of sociology was the reform of the faculties of political science. The first faculty of political science in Italy was established in 1875 at Florence (and called Cesare Alfieri). It was designed to train public officials and, in general, it prepared men for an active life and public debate. As time passed, while it kept these functions, this faculty tended to become transformed into a faculty of social science. After World War II the need was increasingly felt to reform the faculties of political science, detaching them from other faculties (particularly from the law faculties) and giving them an updated cultural core. Subsequently such faculties were divided into two two-year courses of study: The first is based on fundamental courses (including sociology), and the second is organized into five *indirizzi* (courses of study)—international, historical, economic, administrative, and social. In this last course (political-social) some true sociological curricula are offered; they are obviously more concentrated in the faculties of political science at Rome, Bologna, Turin, Padua, and Milan. At present, the political-social course of studies is available in the following universities: Turin, Milan (Università Statale and Università Cattolica), Pavia, Trieste, Padua, Bologna, Florence, Pisa, Cambrino, Rome (LUISS), Naples, Bari, Messina, Catania, and Palermo.

The Future of Sociology in the Universities.

At present, the teaching of sociology is concentrated in the Faculties of Sociology at Trento, Rome, Naples, Milan, Urbino, Salerno; in the degree courses in sociology at others universities; and in the several faculties of political science. Sociology courses are also offered by other faculties (such as economics and commerce, architecture, medicine, letters and philosophy, and arts), but the current tendency is to reduce this spread. There are at least two reasons for this: the “zero growth” of sociology (i.e., sociology departments have the right only to replace sociologists who leave the university or switch to other disciplines) and other disciplines’ expansion of their number of chairs.

In the future, there will therefore be a tendency to strengthen sociology where it is already strong (in the faculties of political science) or through the creation of new degree courses in sociology; however, it is likely to disappear or to be excluded from the mainstream where it is peripheral (in the faculties of economics and commerce, architecture, and others). There are other ways in which the universities can train sociologists, such as Ph.D. programs (they are at the moment thirty-one: thirteen in the North; twelve in the center of the country; five in the South, one in Sicily and Sardinia) courses or schools of specialization for those who already have a degree and special-purpose schools or diploma courses for those who plan to attend the university for only two years after their secondary schooling.

THE 1990S: IN THE SHADOW OF INTERNATIONAL CHANGE AND SOCIAL CHANGE IN ITALY

The themes explored by Italian sociology, like those of any national sociology, are closely tied up with the contemporary state of society.

Italian society in the 1990s is undergoing profound changes. Of these, the most evident has resulted from the fall of communism in the Soviet Union and its satellites. The Christian Democratic party, whose *raison d'être* was as a bastion against communism, lost this purpose and no longer found itself "condemned to govern." Because of the increasing secularization of Italian Catholicism, the Christian Democrats also lost their function as the party of the Church, and it became widely acknowledged that the party was corrupt, as were the other parties. "Tangentopoli" ("Bribe City"—the name given to the massive system of the political fixing of public contracts in return for cash from industry) was uncovered, and "Mani pulite" ("Operation Clean Hands"—the attempt to eradicate it) was launched by the magistrature. The alliances between large organizations and their joint vested interests (large-scale capitalists, big trade unions, protected labor), the "Soviet" component of the state economy (state-owned industries), and the big political parties lost legitimacy with the birth of new political players (the Northern League), new economic players (Small and Medium-Sizes Enterprises), and new trade unions

(smaller, autonomous, and more trade-specific) that claimed resources and reduced the size and authority of the large organizations.

The fall of the Iron Curtain has de-ideologized international relations between Eastern and Western Europe, establishing national or ethnic identity as the criterion of statehood. But in Italy, the fall of the great central organizations has made obvious the importance of the role of highly fragmented local political, social, cultural, and economic forces. The burgeoning importance of ethnicity and local parties (more in the North than the South) and demands for federalism (especially in taxation) and even independence point to a new society, with the marks of the postmodern.

Growing of affluence has put an end to internal emigration and emigration abroad and directed interest toward women's rights, communications, and information technology, and new religious solutions within and outside the traditional Western religions. By contrast, however, the welfare state, designed and constructed by the society of large organizations and by "big" government, has entered a massive solvency crisis, burdened as it is with a level of debt that is unsustainable in comparison with other developed countries and that it cannot pay. Solutions have been sought in cuts in public spending and pensions, the growth of the service sector, the involvement of individual citizens, and the campaign for convergence to the Maastricht criteria.

Sociology has responded to these changes with the expansion of some areas of study and the contraction of others. The former have shifted to incorporate related disciplines such as political science, theology, computer science, constitutional law, and migration; the latter have been subsumed into disciplines such as economics. Research institutes have regained an important position, both inside and outside universities, and the spread of sociology courses in universities has stopped.

One relatively new theme for sociological research and reflection is national identity, both in terms of establishing whether an Italian national identity actually exists in the minds of Italians and in terms of exploring the local identities that may drive toward claims for independence or forms of federalism. A classical study in this regard is Gian

Enrico Rusconi's "*Se Cessiamo di Essere una Hazioue*" ("If We Cease to be a Nation"), which carries the emblematic subtitle *Regional Ethno-Democracies and European Citizenship*. Here the theme of national identity is combined with ethnic and European identity, and accentuated localism with accentuated cosmopolitanism. Work has also been produced in this field by Carlos Barbe, Loredana Sciolla, Carlo Tullio-Altan, and Riccardo Scartezzini. The futures studies journal *Futuribili* has devoted an edition to the future of Italy and the Italians entitled "The Italians Are Here, When Will Italy Be?"

Another theme of political sociology centres on changes in the structure of parties and consensus in the wake of the "discovery" that the existing political system is illegal. Much research has been conducted into the mechanisms of political corruption (Donatella Della Porta, Mauro Magatti, Vaclav Belohradsky), the renewal of the political class, and the formation of new ruling classes as a result of the transformation of the original illegalities into new legalities (Belohradsky 1994). These political transformations have changed the way voters feel about politics. Increases in the numbers of floating voters and nonvoters have given new life and direction to electoral sociology. Opinion polls have become a tool of fundamental importance, and sociologists are studying voting behavior in specialized institutes set up outside universities. Another dimension in the relaunching of political sociology is international relations, especially the study of post-communist Eastern Europe, including scenario building and forecasts of the workings, duration, and results of the transition there. In this field, too, research and studies have been carried out and conferences organized by institutes, both independent of universities or based in them. The funds used for these initiatives are provided by European programmes—such as Phare, Tacis, Intas, and Democracy—with the aim of creating international scientific and fact-finding networks.

Such scientific institutions have been set up in a large number of Italian towns, first and foremost ISIG in Gorizia, which has specialized for the last thirty years in the ethnic, border, and international questions in the Balkan–Danube area and the former Soviet area. ISIG has established a Forum for European Border Towns, an Ethnic Minorities Observatory, an Italian Futures Studies Academy,

and a Permanent Forum for peace initiatives specializing in pilot studies, databases, and the organization of parallel diplomatic meetings for the solution of conflicts. These initiatives frequently result in the publication of journals and books. Heading the journals are *Futuribili*, (along the lines of *Futuribles* and *Futures*), devoting each issue to special themes. *ISIG Magazine* is a journal, published in English and Italian, that also deals with particular themes on a monographic basis. Books frequently tackle international subjects: *International Solidarity and National Sovereignty* (Picco and Delli Zotti 1995) discusses the increasing intrusion upon national sovereignty by international organisations (the UN, NATO, and the EU); "The Future of the Moment Before" (Gasparini 1993) deals with Russia and its future. Other studies analyze: the factors driving toward the formation of a new Russian empire and the persistent character of Russian religiosity and mysticism; the Balkans and the solution of conflicts through international solidarity to bring in a new order based on protectorates (Mroljub Radojkovic, Kosta Barjaba, Alberto Gasparini); ethnic groups and borders in Europe (Luca Bregantini, Alessandro Pannuti, Moreno Zago, Alberto Gasparini); Arab and Israeli nationalism in the Middle East (Elie Kallas); the transition of the former socialist countries in Eastern Europe.

Other themes undergoing strong development are connected with the modern affluent society: They include women and their position with regard to work, equality, self-fulfilment outside the family, and the family as an institution (Chiara Saraceno, Laura Balbo, Pierpaolo Donati); poverty, and extreme poverty in cities rather than widespread poverty (Paolo Guidicini, Giovanni Pieretti); and the role played by poverty in immigration from the Balkans, Eastern Europe, and the Mediterranean Arab countries (Umberto Melotti, Maurizio Ambrosini, ISMU). Connected to these developments and to the relationship between politics and civil society as seen in an increasingly crisis-bound welfare state are studies (Pierpaolo Donati, Ivo Colozzi, Guido Lazzarini, Giuliano Giorio) that seek solutions to the crisis through the service sector and that explore Europe and its new forms of citizenship. Other emerging themes indicating change in Italian society and the need for certainties in an uncertain situation are to be found in the relaunching of studies on Italian religion and

religiosity (Roberto Cipriani, Franco Garelli, Stefano Martelli, Salvatore Abruzzese) and the solutions offered by traditional religions and new movements (also dealt with in an edition of *Futuribili*).

Another important theme is the relationship between communications and a changing society, with specific reference to the role of communications in mass emergency risk management (Bruna De Marchi, Luigi Pellizzoni, Daniele Ungaro, Alberto Abruzzese, Laura Bovone, Mario Morcellini). Community studies show a prevalence of territorial belonging and a decline in metropolitan expansion in favor of restricted urban areas forming a city system in which individuals retain their own identity while relating to other people (Alberto Gasparini, Reuzo Gubert, Gabriele Pollini).

Finally, a theme reemerging after the explosion and subsequent decline of the studies launched in the early 1970s by the Club of Rome is prediction. Here again, ISIG and *Futuribili* are at the fulcrum heart of an interest that is particularly strongly felt at a time of uncertainty and transition toward a society that is as yet unclear (Eleonora Masini, Giorgio Nebbia, Alberto Gasparini, Luca Bregantini, Moreno Zago).

In contrast to these themes, produced by contingent and transient situations, others have been declining in the 1990s. Less attention has been devoted to large companies, and the factory and the trade union movement have lost some of their importance as an area of study. The same applies to the study of social classes. These fields have felt the effects of a crisis in the culture of the defense of workers' rights and in the paradigm—very often a Marxist one—use to explain social classes and the relations between them.

In short, the profound external and internal changes overtaking Italian society have worked to the advantage of some themes of study and undermined the previous importance of others. As was the case with postwar sociology, the driving force in this development has been institutes outside universities (especially in international studies) or at least consortia and niches inside universities but only loosely tied to their teaching function. This has produced a strong movement to strengthen existing journals and create new ones; these include *Futuribili*, *Ikon*, *Polis*, *Quaderni di sociologia* (*Notebooks of Sociology*), *Rassegna italiana di sociologia* (*Italian Review of Sociology*), *RES* (*Ricerca e sviluppo*

per le politiche sociali: Research and Development for Social Policies), *Religioni e società* (*Religions and Society*), *La Società* (*The Society*), *Sociologia del lavoro* (*The Sociology of Work*), *Sociologia della comunicazione* (*The Sociology of Communication*), *Sociologia e politiche sociali* (*Sociology and Social Policies*), *Sociologia e professione* (*Sociology and Profession*), *Sociologia e ricerca sociale* (*Sociology and Social Research*), *Sociologia urbana e rurale* (*Urban and Rural Sociology*), *Studi di sociologia* (*Sociology Studies*), and *Teoria sociologica* (*Sociological Theory*).

JAPANESE SOCIOLOGY

Japanese sociology divides roughly into four stages of development: pre-World War II, with emphasis on theoretical and philosophical orientations, influenced primarily by European (especially German) sources; post-World War II, with growing emphasis on empirical orientations, influenced primarily by the United States; diversification, with emphases on both theoretical and empirical orientations (on various aspects of the history of Japanese sociology, see, e.g., Halmos 1966; Koyano 1976; Odaka 1950); and globalization, with emphasis on theoretical orientations and an increasing number of empirical orientations, some encompassing cross-national and foreign area studies. In a general sense, the development of Japanese sociology reflects the country's social and cultural change, as well as shifting national policies. The significant Western influence generally exhibits a time lag in terms of its expression in Japanese sociology.

PRE-WORLD WAR II STAGE (1893–1945)

Japanese sociology began as a European import and reflected a conservative stance. This occurred shortly after the Meiji Restoration of 1868. E. F. Fenollosa (1853–1908), an American professor, first taught sociology at the University of Tokyo in 1878. Three years later, Masakazu Toyama (1848–1900) began teaching at the same university; in 1893 (just one year after the founding of the University of Chicago's sociology department), he

became the first professor of sociology in Japan and is regarded as the founder of Japanese sociology. Toyama, and later Nagao Ariga (1860–1921), a student of Fenollosa and the first sociologist in Japan to publish, both introduced aspects of Herbert Spencer's organic analogy for society. The works of Spencer and John Stuart Mill were particularly significant during these early years and were translated frequently.

Tongo Takebe (1871–1945), successor to Toyama in 1898, introduced Auguste Comte to Japan, combining Comte's positivism with Confucian philosophy and social thought to fit Japanese society. In 1913 Takebe also founded the Japan Institute of Sociology, an organization replaced by the Japan Sociological Society in 1924. A new approach began to take hold in the 1910s—the psychological approach initiated by Ryukichi Endo (1874–1946), who drew on Franklin Giddings's theory of consciousness of kind to explain social phenomena.

During the 1910s, other Western sociological theories came to Japan, largely through the work of Shotaro Yoneda (1873–1945). Yoneda, who looked at society and culture from a sociopsychological perspective, was an important teacher who introduced the ideas of many Western sociologists to Japan, including those of Gabriel Tarde, Emile Durkheim, Georg Simmel, and Franklin Giddings. Yoneda laid the groundwork for the subsequent strong influence of the German school of sociology.

From this point forward, until the end of World War II, the German school dominated

Japanese sociology. There were two major divisions that grew out of the German school: *formale Soziologie* (formal sociology) and, later, *Kultursoziologie* (cultural sociology). The major proponent of the former was Yasuma Takata (1883–1972), a student of Yoneda. Takata (1922, 1989) successfully changed the view of sociology from that of a synthesis of the social sciences to one in which sociology stood as separate and independent, drawing in particular on the work and influence of Max Weber, Georg Simmel, Ferdinand Tönnies, and Robert MacIver.

New influences, however, emerged in the 1920s. Formal sociology was deemed abstract and out of touch with the real world. As a consequence, cultural sociology gained a stronger foothold in both Germany and Japan. Pioneering the work in cultural sociology in Japan was Eikichi Seki (1900–1939). No doubt a reaction to the Depression of 1929, cultural sociology gained popularity for its closer ties with the social realities of the day. Although a theory of cultural sociology fitting the Japanese society seemed imminent, it never really unfolded.

While there were also French and American influences on Japanese sociology during the prewar period, they were minor compared with those of Germany. Jyun'ichiro Matsumoto (1893–1947) saw a need to synthesize formal and cultural sociology into what he would call “general sociology.” At the same time, Masamichi Shimmei (1898–1988) sought to take Matsumoto's thoughts and combine them with Simmel's general sociology and the thinking of Karl Mannheim.

Because Western theory and thought dominated Japanese sociology in the prewar period, little of the work analyzed Japanese society. There were, however, a handful of notable empirical studies, especially in family and rural sociology, a tradition begun at the University of Tokyo by Teizo Toda (1887–1955). Toda had studied at the University of Chicago, where he learned about survey methodologies being used in the United States. Toda analyzed statistics on the Japanese family structure, using census and other then-current and historical data. Kizaemon Aruga (1897–1979) worked in the area of rural sociology, linking his findings with previous folklore studies and working toward clarifying the condition of social strata in prewar Japan. Lack of financial support,

however, hindered the development of empirical research during this time.

Two phenomena in particular worked against the development of Japanese sociology prior to World War II. First, Japanese sociology focused on European sociology rather than on studies of its own society. The second phenomenon, bolstered by government officials and scholars inclined toward nationalistic militarism, involved a distorted public image: that sociology and sociologists were associated with socialism because of the two words' similarity in the Japanese language (“sociology,” *shakaigaku*; “socialism,” *shakaishugi*). Many thought that sociology was the study of socialism or social revolution and that sociologists were socialists and, therefore, a sinister threat to national security. As World War II grew closer, and during the war, publications were often censored, academic freedom was severely curtailed, and meetings and conventions were forbidden.

POSTWAR STAGE (1946–1960s)

Defeat and U.S. occupation brought drastic social changes to Japan. The traditional family system collapsed, and land reform became the order of the day. Favorite prewar survey subjects centering on village and family were replaced by issues related to land reform and revision of traditional family values. Indeed, the traditional Japanese value system was pulled out from under the nation. “Democratization” was the new buzzword. The term “sociology” was released from taboo. Educational reforms in the 1950s now required sociology courses as part of the general university education, especially for freshmen and sophomores. More and more departments of sociology or sociology programs within other departments were formed, particularly at private colleges and universities. Suddenly, many sociologists were needed. American influences were rampant in all areas of Japanese society, and sociology was no exception. Many American sociological theories came to influence Japanese sociology, the strongest being that of Talcott Parsons.

As the importance of empirical study was growing in the United States, Japanese sociologists also began to develop a strong interest in empirical

work. Social research, positivism, and functionalism were key words. Marxism had significant impact on Japanese sociology as well. "Democratization" and "modernization" were major fundamental themes in sociological studies. Japanese sociologists studied American research methods, ultimately leading to a rapid increase in surveys and research based on the results of these surveys. To many, the empirical studies of Japanese sociology moved the entire discipline from one of art and humanity to one of social science. However, many surveys were carried out for fact-finding purposes rather than hypothesis testing for theory construction.

Tadashi Fukutake (1917–1989) significantly influenced the postwar stage and the subsequent stage of Japanese sociology. Fukutake's studies focused on rural sociology (see, e.g., 1967) in the context of Japanese society's postwar democratization. Also influential was Kunio Odaka (1908–1993), a positivist, who played an important role in industrial sociology (see, e.g., 1975) as well as general sociology, especially during the period of extraordinary economic development from 1955 through 1965. Odaka and Fukutake were two of Japan's leading empirical researchers conducting field research in real social settings during this stage in the development of Japanese sociology.

Mentioned earlier, the Japan Sociological Society is a nationwide organization for Japanese sociologists. It holds annual meetings and publishes a journal, and it joined the International Sociological Association (ISA) in 1950. Two years later, a survey on social stratification and mobility was conducted under the auspices of the Japan Sociological Society, led by Odaka, in cooperation with the ISA. This survey was repeated three years later on a nationwide scale and subsequently every ten years.

In 1954, the Institute of Statistical Mathematics in Tokyo began a nationwide time-trend survey of the Japanese national character, a survey conducted every five years since, with the objective of analyzing changes (or lack thereof) in general social attitudes among the Japanese since World War II (Hayashi 1998). This ongoing survey pioneered the use of identical questions over time and as such became a model for the General Social Survey of the National Opinion Research Center at the University of Chicago. Both these ongoing

surveys continue as the most well-known nationwide social surveys in Japan.

Although the postwar period saw great social change in Japan, within academic circles, senior sociologists, most of whom belonged to the prewar generation, prevailed. A generational change among leading Japanese sociologists occurred in the 1960s, marking the end of the postwar period (Koyano 1976).

DIVERSIFICATION STAGE (1960s–1990s)

Since the 1960s, American sociology has gained an ever-stronger influence on Japanese sociology. With the exception of Talcott Parsons and his structural-functionalism, however, no major American sociologists have significantly influenced the theoretical aspects of Japanese sociology. Whereas Marxist sociology had tended to influence many of the younger Japanese sociologists from a theoretical perspective, "the entire history of [Japanese] sociological development to the 60s was criticized and thrown into examination by more or less radical criticism. . . . Thus many talented younger sociologists turned from Marxism to structuralism or structuralist social theory . . . [or] alternately accepted rather subjective methodologies and theories such as phenomenological sociology, symbolic interactionism and ethnomethodology . . . [i.e.] phenomenological trends" (Shoji 1996). Interests among some Japanese sociologists also shifted from macro- to micro-sociological analyses. Multi-dimensional paradigms became prevalent, such as those of Michel Foucault, Jürgen Habermas, Niklas Luhmann, Pierre Bourdieu, Anthony Giddens, and Alfred Schutz, all of whom have consequently influenced Japanese sociology. Much as the prewar emphases of the theoretically oriented Japanese sociologists tended toward the purely theoretical, the new attractions continued the inclination toward speculative and interpretive theory—more like social philosophy—as against the empirical science tradition represented by Fukutake and Odaka. Though Japanese sociologists have been quite keen on the general trends in Western social and sociological thought, there is about a ten-year lag from introduction to translation and analysis of the works of Western sociologists.

Along with the vast changes in Japanese society in the postwar period came a nearly unlimited

number of topics for sociological study and investigation, particularly from an empirical standpoint. This, too, accounted for diversification in Japanese sociology and signaled the establishment of a number of subdisciplines in the field. Thus, as a result of American influences, economic development, and a host of other factors, Japanese sociology continuously diversified from the early 1960s on. This is partially attributable to the fact that the industrialization of Japan, into the early 1970s, led to serious social and environmental problems, which in turn led to student uprisings, increases in delinquency and other expressions of social unrest, and, in response, the emergence of environmental-protection, feminist, and other movements, even though many of these social phenomena and movements waned in the 1980s.

These circumstances brought forth a wide variety of challenging research topics for sociologists and coincidentally created a situation in which there are no especially influential figures in Japanese sociology, although each subdiscipline does have its major proponents. These scholars include, among others, Eiichi Isomura (1903–1997) in urban sociology; Michio Nagai, who later became Japanese Minister of Education, in the sociology of education (cf. 1971); Kazuo Aoi in the field of small groups; Kiyomi Morioka in the sociology of religion and the sociology of the family (cf. 1975); Saburo Yasuda (1925–1990) in sociological methodology (cf. 1964); Akira Takahashi in social movements; Joji Watanuki in political sociology (cf. 1976); Ken'ichi Tominaga in social stratification (cf. 1969); and Tamito Yoshida in communication.

From the 1960s on, the number of sociologists in Japan grew markedly, to the point where, based on memberships in national sociological organizations, there are more sociologists in Japan than in any other country except the United States. While there were about 300 sociologists teaching at colleges and universities in Japan in the 1970s, their number grew to about 1,000 by the late 1980s. The Japan Sociological Society's membership rosters totaled 870 in 1957; 1,931 in 1985; 1,945 in 1988; 2,200 in 1990; 2,450 in 1992; and 3,034 in 1999.

In 1988, Japanese sociology had about thirty subdisciplines. On the basis of first-, second-, and third-choice subdiscipline selections by the 1,945 members of the Japan Sociological Society at that time, the most prominent were: (1) rural sociology

and community studies, 17.7 percent; (2) sociology of the family, 17.2 percent; (3) general sociological theories, 16.4 percent; (4) social welfare, social security, and medical sociology, 16.2 percent; (5) social thought and the history of sociology, 14.9 percent; (6) management, industry, and labor, 13.0 percent; (7) social pathology and social problems, 12.5 percent; (8) culture, religion, and morality, 12.4 percent; and (9) the sociology of education, 11.6 percent. Among other things, we see that sociology of the family and rural sociology held their significance from the prewar era.

Sociologists who study industrial sociology—including management; urban sociology; and social welfare, social security, and medical sociology—have increased in number continuously since World War II. And, over time, foreign sociologists have shown more and more interest in industrial sociology; the sociology of education; and social welfare, social security, and medical sociology, as these are seen as particularly successful elements of Japan's economic and social development.

Derived from lists of publications in the *Japanese Sociological Review* between 1984 and 1988, publication of articles originating from the various subdisciplines broke down as follows: (1) sociology of the family, 7.4 percent; (2) social thought and the history of sociology, 7.2 percent; (3) general social theories, 6.5 percent; (4) the sociology of education, 6.5 percent; (5) urban sociology, 6.2 percent; (6) rural sociology and community studies, 5.8 percent; (7) industrial sociology and management, 5.2 percent; (8) social pathology and social problems, 5.1 percent; and (9) social welfare, social security, and medical sociology, 5.1 percent. Articles totaled 7,426 (books, 927) during the five-year period, most of which appeared in Japanese.

Unlike in the United States, in Japan there is no rigid screening or referee system for publications, with the exception of a few well-known journals such as the *Japanese Sociological Review* (*Shakaigaku Hyoron*, the official journal of the Japan Sociological Society), *The Study of Sociology* (*Shakaigaku Kenkyu*), and *Sociology* (*Shoshioroji*). With regard to presentations at meetings of the Japan Sociological Society, the five regional associations, and the associations of the various subdisciplines, there have been, in many cases, no rigid referee systems. Heated debate is rare, and

thus academic stimulation from published or presented controversies is quite limited.

By the late 1980s, 33 of Japan's 501 colleges and universities had doctoral programs in sociology. The major institutions with such programs included the public universities of Hokkaido, Tohoku, Tokyo, Hitotsubashi, Tokyo Metropolitan, Nagoya, Kyoto, Osaka, Kobe, and Kyushu, and the private universities of Waseda, Keio, and Hosei. Also during the period, there were about 700 graduate students studying sociology, 490 of whom were doctoral candidates (see Committee on Education for Sociology 1988). In general, two years are required to obtain a master's degree and an additional three years to finish coursework for doctoral programs. A much higher percentage of those who complete a master's program at public universities go on to a doctoral program than do those at private universities. Most who obtain master's degrees do not complete their doctoral theses within three years. Rather, after finishing their doctoral coursework, they obtain teaching or research positions and often complete their doctorates at a later stage in their careers. Forty-one persons obtained doctoral degrees in sociology during the period 1977–1986. During this time, there was a surplus of sociology graduates versus the number of teaching positions available. In the late 1980s, of those teaching at Japanese universities who obtained their doctoral degrees from Japanese universities, twenty-four sociology professors held doctoral degrees in literature, about thirty held doctoral degrees in sociology, and several others held doctoral degrees in related fields. Compared to other social sciences such as economics, the number of professors who obtained their doctoral degrees in sociology from foreign educational institutions is limited. For instance, only about twenty Ph.D. holders who taught at Japanese colleges and universities in the late 1980s obtained their degrees in the United States, although their numbers have been increasing.

GLOBALIZATION STAGE (1990s AND BEYOND)

As a whole, Japan has recently seen substantial movement toward globalization (or internationalization), and Japanese sociology is no exception. However, before exploring the implications of

globalization for Japanese sociology, it is appropriate to look at the changes that took place in the 1990s.

In 1997, out of 586 universities and colleges in Japan, 65 had master's programs and 47 had doctoral programs in sociology. In 1997, more than forty-five Ph.D. degree holders (obtained from non-Japanese universities) in sociology were teaching at Japanese universities and colleges. Also, more than sixty-five doctoral degree holders (obtained from Japanese universities) in sociology were teaching at various universities and colleges in Japan. It should be noted that these numbers are not at all significant compared to those in the West.

The Japan Sociological Society polled its members in 1998 for their preferred subdisciplines and research fields. They identified (1) general sociological theories, 15.6 percent; (2) sociology of the family, 15.2 percent; (3) communications and information, 15.1 percent; (4) social thought and the history of sociology, 14.7 percent; (5) social welfare, social security, and medical sociology, 14.3 percent; (6) culture, religion, and morality, 13.6 percent; (7) social psychology and social attitudes, 13.1 percent; (8) rural sociology and community studies, 12.2 percent; and (9) cross-national and foreign area studies, 11.3 percent. Note that the first three choices, including communications and information, are effectively tied for first place. We can see, compared with the figures from 1988, that management, industry and labor, social pathology and social problems, and the sociology of education all dropped out of the top nine fields, having been replaced by communications and information, social psychology and social attitudes, and cross-national and foreign area studies. That communications and information made such a showing is particularly notable and reflects the changes in information infrastructure (the Internet, among others) that are in large part responsible for globalization.

During the period 1989–1996, publication of articles originating from the various subdisciplines broke down as follows: (1) social thought and the history of sociology, 8.7 percent; (2) the sociology of education, 7.2 percent; (3) sociology of the family, 6.6 percent; (4) general sociological theories, 6.6 percent; (5) urban sociology, 6.2 percent; (6) communications and information, 5.6 percent;

(7) culture, religion, and morality, 5.6 percent; (8) management, industry, and labor, 5.4 percent; and (9) rural sociology and community studies, 5.2 percent. These figures were derived from lists of publications in the *Japanese Sociological Review*. Notice that, compared to the publications listed from 1984 through 1988, social pathology and social problems and social welfare, social security, and medical sociology dropped from the top nine while communications and information, and culture, religion, and morality appeared. That communications and information did not rise to the top here is not surprising, as publishing traditionally carries with it varying degrees of time lag.

As in the United States and western Europe, aging has become a serious issue; in 1998, about 16 percent (i.e., 20 million persons) of the Japanese population was over 65. Therefore, more and more sociologists are involving themselves in this field and contributing to national and local policy formation.

In Japan, there are no major university research centers such as the Institute for Social Research at the University of Michigan or the National Opinion Research Center at the University of Chicago, nor does Japan have any colleges or universities that are especially well known for their sociology departments or programs. However, there are some survey sections within organizations (e.g., research institutions, government organizations, the press and mass media) that have carried out major surveys since the 1950s, some on a continuing basis, including surveys targeting trends in social attitudes. Among others, these include the Japanese Prime Minister's Office; the Institute of Statistical Mathematics, as mentioned above; the Mainichi Press; Jiji Press; and Nippon Hoso Kyokai, a Japanese broadcasting organization (see Sasaki and Suzuki 1991). Each one of these endeavors is independent and generally does not provide its data to outside researchers, making secondary analysis of such data a difficult task in Japan. This hinders those in graduate training, as they often lack access to such data for thesis work.

On occasion, surveys, including cross-national studies, are funded by agencies such as the Japanese Ministry of Education, the Japan Society for

the Promotion of Science, and the Toyota Foundation. On a regional or local basis, funds are sometimes provided by prefectural or municipal governments. Findings from some of these studies have had significant impacts on policy formation at the local and national levels. Most research grants for sociologists, for both domestic and international (cross-national and foreign area) studies, are provided by the Japanese Ministry of Education. The Japan Society for the Promotion of Science provides grants for foreign area and cross-national research projects, for joint research conferences and seminars, as well as travel allowances for visiting scholars.

Japanese sociology does not enjoy a wide-ranging reputation in the rest of the world. This has been attributed to lack of integration and coordination, as well as a descriptive rather than analytic focus. Indeed, Japanese sociology has relied substantially on foreign influence, particularly that which is *au courant*, and has not excelled in the development of original theoretical or empirical ideas, rather having a stronger commitment to theory interpretation than theory testing and theory building. With the exception of a few research groups doing cross-national studies, in general Japan's sociologists have had limited contact with researchers in other nations. This can be attributed primarily to the language barrier and lack of experience in exchanging ideas. Despite these apparent shortcomings, sociology is comparatively popular in Japan, where there is a strong demand for books on the subject. As a consequence, Japanese scholars often feel little need to publish in foreign languages.

Broader publication—in English, in particular—will be essential to the mutual exchange of ideas and research results now and in the future, as well as to enhancing the reputation of Japanese sociology. To encourage scholars, the Japan Sociological Society has published the *Bibliography of Japanese Sociological Literature in Western Languages* in 1982, 1986, 1990 and 1994 (see Japan Sociological Society 1982, 1986, 1990, 1994). Research Committee meetings of the ISA have been held from time to time in Japan, and occasionally Japanese sociologists have served as ISA Executive Committee members. Japanese sociologists will need to host, and invite their foreign colleagues to, more international meetings and conventions, as occurred in 1991 when the 30th World Congress of

the International Institute of Sociology (IIS; founded in 1893 and the oldest sociological association in the world) met in Kobe, Japan, for the first time in the history of Japanese sociology. In 1998, a Japanese sociologist became the first IIS president ever elected from Asia.

Japan's globalization has fostered opportunities for sociologists through studies of Japanese communities with growing contingents of foreign workers and studies of communities with Japanese administrative and managerial personnel in foreign countries. In these instances, Japanese sociologists are able to examine social, ethnic, and multicultural issues stemming from these circumstances. In this respect, Japanese sociologists are able to contribute to policy implications for community formation in the globalizing environment. Recently, too, the number of Japanese sociologists conducting cross-national and/or foreign area studies has increased (see, e.g., Japan Sociological Society 1997). In 1992, the Japan Sociological Society began publishing the *International Journal of Japanese Sociology*, its only English-language journal and one of the few in Japan to employ a referee system.

Although the language barrier also hinders foreign scholars from coming to Japan to study, again, this is changing, and more and more such activity has been observed recently. In 1998, there were about 340 Japanese sociologists who reported internationally comparative sociological research or foreign area studies as one of their top three research interests, although many of these were not officially collaborating with other nations' researchers. Of these, the most popular areas of emphasis were ethnicity and nationalism; rural sociology; community studies; social history and ethnology; and sociology of the family, culture, and religion. The popular locations for study were Asia, the United States, and western Europe.

There are also less pragmatic reasons why Japanese sociology has not enjoyed a wide-ranging reputation in the rest of the world. Despite a history now spanning more than a century, Japanese sociologists have made few efforts to integrate their considerable empirical research findings with sociological theory. Japanese sociology has had a long history of importing "fashionable" theories from the West. Japanese sociologists with theoretical orientations have tended more toward

social philosophy, with its emphasis on pure theory. Japanese sociological researchers, on the other hand, have tended to limit their studies to specific features of Japanese society, often without sufficient hypothesizing aimed at investigating the underlying social structures and processes thus potentially revealed. This lack of originality, this reluctance to carry through to a complete synthesis of empirical findings and structures and processes, has contributed to Japanese sociology's limited outside appeal. The foreign influences inevitable in and attendant with globalization will no doubt encourage Japanese sociology to finally integrate empirical research results with original thought about Japanese social structures and processes, toward the construction of viable theories of Japanese society as well as society as a globalizing whole. This suggests the need for greater theoretical and methodological training—in the context of their synthesis—in Japanese graduate sociology programs.

While Japanese sociology commands a significant amount of useful empirical data, it is nonetheless disparate. The establishment of a central data archive would be imperative for secondary analysis, graduate training, and empirical study in general. As data gathering becomes increasingly expensive, the usefulness and need for such archives will become even more important.

In conclusion, in terms of the disciplines within Japanese sociology that will take on greater and greater importance, cross-national and foreign area studies will certainly become more popular. Along these same lines, time-trend studies will increase in popularity, in an effort to discover what changes and what does not change in society. Major research funding is likely to continue to center around empirical studies, both within Japan and comparatively with other nations. Finally, whereas Japanese sociologists traditionally have seldom been consulted in the industrial, business, and governmental environments, this will change as Japanese sociologists acquire greater methodological skills and theoretical knowledge, as well as empirical research experience and findings. And, from a strictly practical standpoint, growth in the number of teaching positions in sociology has not kept pace with the growth of sociology's popularity in Japan, nor with the output of sociologists from Japanese and foreign graduate schools, forcing

many to seek teaching positions in junior high and high schools or nonacademic positions in government, research institutes, and industry. This diffusion of the discipline outside the traditional academic environment will no doubt impact Japanese society as a whole, and it could well become a two-way medium for idea exchange.

While Japanese sociology will no doubt become more pervasive and useful in Japanese society, it will nevertheless take time. The same is true outside of Japan, as Japanese sociology becomes more internationalized and demonstrates greater tangible offerings to the sociological community in the rest of the world. Certainly more and better cross-national and foreign area studies will emerge, as this is an area where Japanese sociology has already made particularly beneficial contributions. In turn, in the tradition of comparativists such as Machiavelli, Marx, Weber, and Durkheim, who sought to construct universalized theory based on comparison, Japanese sociology may finally be able to make its mark. Given the methodological expertise demonstrated by Japanese sociology, these efforts may ultimately assist Japanese sociologists in positing social theories of use to the rest of the world's sociological community. Of course, such a vision requires that Japanese sociology strive to broaden its horizons internationally—for Japanese sociologists to recognize that they must cooperate and join with the global sociological community to achieve these objectives.

JUVENILE DELINQUENCY AND JUVENILE CRIME

The twentieth century ended amid an explosion of violence in all corners of the globe. However, juvenile violence has probably been center stage more in the United States than in any other industrialized nation. As the 1998-1999 school year ended, we had just experienced a massive display

of violence by two young men at a high school in Littleton, Colorado. Both seniors, these two killed twelve of their fellow students and a teacher before turning their assault weapons on themselves. The decade of the 1990s ended in the way it started, with a public grown increasingly apprehensive of its youth. This increase was not limited to the United States; it has been detected in many other countries—England, Spain, France, Italy, and Germany, among others.

It is important to note here also that this anxiety and disquiet induced by youth is not limited to the modern area. Citing the code of Hammurabi, which dates back to 2270 B.C., Regoli and Hewitt (1991) note that “legal prohibitions of specific behavior by juveniles is centuries old” (p.6). Still, they note that in the Middle Ages “little distinction was made between juveniles and adults who were older than 12” (p. 6). In a comment made in 1959, but which is still relevant to those who are intrigued, frightened, or perplexed by the “heedlessness” of today’s youth, Teeters and Matza (1959) stated: “It has always been popular for each generation to believe its children were the worst” (p. 200). We are also reminded by them that “Sir Walter Scott in 1812 deplored the insecurity of Edinburgh where groups of boys between the ages of 12 and 20 years scoured streets and knocked down and robbed all who came in their way” (p. 200). Apropos of delinquency, such remarks underscore the relativity of opinions and the brevity of trends. They also remind us that while juvenile delinquency is a relatively new legal category that subjects children to court authority, it is also a timeless and ubiquitous part of life. Regoli and Hewitt (1991) suggest that postcolonial American delinquency was similar to that found in Spain in the seventeenth century and in Britain in the eighteenth century. By the mid-1800s, teenage gangs were frequently found in the larger cities in the United States. “The habits of hanging out on street corners, verbally abusing pedestrians, and even pelting citizens with rocks and snowballs were among the least threatening of their behaviors. More serious were the violent gangs of juvenile robbers” (p. 7). They also note that “the latter decades of the nineteenth century saw a number of changes in the public’s understanding of the causes of delinquency and [of] appropriate approaches to its control and treatment . . . the

common law distinction between child and adult had changed for purposes of criminal prosecution” (p. 7). The change contrasted greatly with practices in the early part of the century: In America, children as young as three years of age could be brought before the court, while in England a girl of seven was hanged. In Massachusetts, in 1871, 1,354 boys and 109 girls were handled by the courts. Reform schools proliferated during the nineteenth century and were criticized for failing to prevent the apparent increase in delinquency. Reformers—called “child savers”—believed that juveniles required noninstitutional treatment that would reflect the natural family (Platt 1969). This legal and humanitarian concern for the well-being of children led to the establishment of the first juvenile court in Cook County, Illinois, in 1899. By 1925, all but two states had followed the Illinois example. Thus, it seems fair to say that the idea of “juvenile delinquency” is a relatively modern construction, a notion shared by writers such as Gibbons and Krohn (1991), Empey (1982), and Short (1990). The data on delinquency, however, are not limited to the legal status of “juvenile delinquent,” because sociologists are just as interested in unofficial as in official acts of delinquency. More specifically, it is well known that much of the behavior defined by law as delinquent is not detected, not reported, or not acted on by legal agents.

Moreover, different jurisdictions have different legal definitions of delinquency. In the United States, for example, while the statistics defining delinquency are similar in the fifty states and District of Columbia with respect to age and type of offense requiring juvenile court control, there are more differences than similarities. First, laws vary in terms of the age limits of juvenile court jurisdiction: thirty-one states and the District of Columbia set seventeen years of age as the upper age limit, twelve states set sixteen years, six set fifteen years, and one sets eighteen years. Moreover, in many states the delinquency laws empower the juvenile court to remand youths under the maximum juvenile court age to criminal courts. In such cases, the offenses are often those for which adults may be arrested: index crimes (see below). In addition, some states have passed legislation that requires certain cases, such as homicides, or youths charged with other serious offenses, to be dealt with by the criminal court. In these cases, the

juvenile acquires the legal status of criminal. Finally, it should be noted that all U.S. state jurisdictions contain an omnibus clause or provision, referred to as status offenses, that awards the court jurisdiction over youths who have behaved in ways not forbidden by criminal law. While these provisions differ from state to state, it is of interest to note a few examples of these conditions. They include engaging in indecent behavior, knowingly associating with vicious or immoral persons, growing up in idleness or crime, being incorrigible, and wandering the streets at night. Critics note that these behavior categories are so vaguely defined that nearly all youngsters could be subjected to them.

Such different procedures and practices caution us against making easy generalizations both within and between countries when examining official data. Indeed, other shortcomings likewise warn against drawing firm conclusions when unofficial data are examined. Although methodological shortcomings may exist in the study of delinquency, there may be advantages in utilizing all the data of delinquency (official and unofficial) in pursuit of its understanding. Thus, the study of official delinquency data places much of the focus on the actions of official agents of control (the police, the courts), while the study of unofficial—including hidden—delinquency often allows students to examine the processes leading to the behavior. Moreover, as Vold and Bernard (1986) and others have noted, unofficial data, especially self-reports, frequently focus on trivial offenses, while the more serious offenses often do not appear in self-reports but are limited to reports of official agencies.

In sum, our concern here will be to discuss those topics of delinquency that are of the greatest concern: the frequency, severity, and duration of delinquency. Attention will also be devoted to trends. In the following section, the focus is on the extent of delinquent behavior.

EXTENT OF AND TRENDS IN DELINQUENCY

In addressing the matter of the extent of delinquency, it is important to note the admonitions of Empey and Erickson (1966), Hirschi (1969), Matza (1964), and others that delinquency is not only transient but also widespread. Many juveniles engage in delinquency only occasionally, but some

engage in it more frequently. Gibbons and Krohn (1991) call delinquency “a sometime thing,” while Matza (1964) describes the process of drifting into and out of delinquency. Moreover, it should be kept in mind that some acts of delinquency are serious acts of criminality and others are petty, trivial acts. As we consider both official and unofficial data on juvenile delinquency and juvenile crime, we will encounter these various clarifying factors.

Official Delinquency. The most serious crimes committed by youths and adults in the United States are referred to as index crimes; data on them are compiled by the FBI, based on reports of law enforcement agencies throughout the country. These index crimes, reported in Uniform Crime Reports, are divided into two major types: violent (homicide, rape, robbery, and aggravated assault) and property (burglary, larceny-theft, motor-vehicle theft, and arson). Nonindex offenses are those considered to be relatively petty, such as liquor law violations, disorderly conduct, sex offenses (except forcible rape, prostitution, and commercialized vice), and drug-abuse violations.

Readers are warned that various official reports of offenses should be treated with caution since there are inconsistencies in reporting processes. While great efforts are being made by federal agencies to improve reporting mechanisms, it is well to remember that the number of reporting agencies fluctuates regularly, and the number of cases involving persons with unknown characteristics (such as age, sex, and race) also fluctuates (sometimes by as much as 30 percent). In 1987, the U.S. Department of Justice reported that there were 10,747 contributing agencies covering approximately 84 percent of the U.S. population. This number appears to be higher than the number reporting in 1996. Moreover, the news media have occasionally reported that some jurisdictions have been accused of irregular reporting habits in apparent efforts to demonstrate improved efficiency.

Index crimes are reported annually by the FBI; sometimes estimates for the United States as a whole are derived from a sample of reporting agencies. In 1996 the FBI's Uniform Crime Reports (UCR) indicated that of all arrests in the United States in 1996, approximately 18.9 percent were of youths under eighteen years of age; 18.7 percent of the arrests for violent crimes in 1996

(murder, manslaughter, forcible rape, robbery, and aggravated assault) were of persons under eighteen years of age. For property crimes, youth under 18 years of age comprised 35 percent of offenders. For index crimes as a whole, the FBI Uniform Crime Report indicates that 30.9 percent were contributed by persons under 18 years of age in 1996. (U.S. Department of Justice 1996).

Perhaps it is surprising to learn that over the last quarter of the twentieth century, contrary to fears, delinquency has declined. According to the *Sourcebook of Criminal Justice Statistics* for 1997, in 1971 arrests of youths under age 18 comprised 45 percent of all arrests for index crimes reported to the UCR program, 23 percent of violent crime arrests, and 51 percent of property crime arrests. In 1996 persons under age 18 comprised 31 percent of index offense arrests, 18.8 percent of violent crime arrests, and just 35 percent of property crime arrests. Thus juvenile crime, as measured by arrest data, has decreased during this quarter-century.

During this same period, a number of criminologists have argued that fluctuations in the delinquency crime rates are due to changes in the age structure of the population. The UCR presented data showing a substantial decrease in delinquency arrests between 1979 and 1988, following an increase in such arrests between 1965 and 1977. Kratcoski and Kratcoski (1990) suggest that this dramatic change could be due to "movement of the 'baby boom' segment of the population through the high offense years during the mid-70s followed by a reduction in the under 18 population since 1978" (p. 15). Gibbons and Krohn (1991) also suggest that such trends may be due to shifts within the delinquency-eligible youth group. Further, the latter authors suggest that such trends may reflect increased or decreased concern about youthful misconduct.

There was apparently a substantial increase in juvenile crime between 1988 and 1991, followed by another dip in rates after 1991. Blumstein (1995) suggests that a projected increase in the proportion of the population in the high-crime-rate age group will probably lead to higher crime rates by early in the twenty-first century. Still, the FBI UCR for 1996 suggests that there has been a strong decline in juvenile delinquency in recent years.

Juvenile Crimes of Violence. In contrast to this apparent improvement, an examination of murder and non-negligent manslaughter shows a different picture. While the national murder rate in 1996 (7.4 per 100,000 inhabitants) was down 11 percent since 1987, the proportion of murder and non-negligent manslaughter offenders who were under age 18 increased from 9.7 percent in 1987 to a whopping 15.2 percent in 1996, an increase of about 50 percent. Editors of the *Sourcebook of Criminal Justice Statistics* for 1997, and other analysts such as Conklin (1998), Gall and Lucas (1996), and Blumstein (1995) have commented on the increasingly serious nature of crimes by juveniles.

Conklin (1998), reviewing data presented by Fox (1995) and by Blumstein (1995), says that between 1985 and 1993 "the homicide arrest rate for people twenty-five and over declined by 20 percent, while the rate for eighteen-to-twenty-four year olds increased by 65 percent and the rate for fourteen-to-seventeen year olds rose by 165 percent" (p. 124). An increasing number of researchers fear that there will be a continued surge in violent crimes by the under-eighteen population.

This increase in youth violence in the United States has apparently been mirrored in a number of industrialized nations. In a study of juvenile violence in Great Britain, Oliver (1997) states that the number of violent juveniles increased by 34 percent between 1987 and 1993, an increase he attributes to the growth of inequality and family stress in Britain. In France, Bui-Trong (1996) has written about the recent escalation of juvenile violence, noting especially the increased severity of scale. This author, noting a decline in family morals, predicts that this problem can be expected to worsen. During the 1980s even Japan experienced an increased rate of juvenile delinquency, which some observers attributed to the stress of competition for academic success (Conklin 1998).

School violence has been most dramatic, of course, in the United States and is a focus of great national attention. Presenting data gathered by the National School Safety Center, the *Boston Globe* reported in 1999 that since the 1992-1993 school year there had been 248 deaths from violent acts in schools. ("U.S. Police Chiefs" 1999). Although many school shootings and other violent acts have not resulted in deaths, they *have* resulted in injuries and heightened fears. The 248 school deaths

between 1992 and 1999 included cases of multiple deaths in seventeen states. Many of these incidents involved the use of assault weapons. This increase in school violence has elicited a spate of explanations, including weakened parental supervisions, ostracism by schoolmates, bullying and its effects (Farrington 1993), the easy availability of guns, and the poor examples set by our leaders. The search for the causes of violence among the young will, no doubt, have to be accompanied by an examination of violence in the adult population as well. Certainly the official data on violence show that the population over age eighteen is also engaged in a substantial amount of violent behavior.

Cohort Study. One of the first longitudinal studies of delinquency was conducted by Wolfgang and colleagues (1972) in Philadelphia. They traced the police contacts of all boys born in 1945 who lived in the city between their tenth and eighteenth birthdays. One of their aims with this cohort of 9,945 was to trace the volume and frequency of delinquent careers up to age eighteen. They found that 35 percent of these boys (3,475) were involved with the police at least once between their tenth and eighteenth birthdays. Of these 3,475 boys with police contacts, 54 percent were repeaters. The total number of delinquent events (offenses) for the 3,475 delinquent boys amounted to 10,214 through age seventeen. It is clear that the number of offenses far outnumbers the number of offenders in the cohort. One must note, then, that longitudinal (i.e., over an extended period) studies of delinquents yield data with important differences from those obtained when cross-sectional (i.e., single point in time) studies of persons arrested are conducted. Examples of other longitudinal studies include the Provo Study, the Cambridge-Somerville Study, the Vocational High Study, and, in Britain, the National Survey of Health and Development.

Self-Reports: Offender Reports and Victim Reports. Official reports of crime and juvenile delinquency have been criticized for years because they are widely believed to underreport the volume of offenses. Moreover, many scholars, especially those with a conflict perspective, believed that official reports underreported middle-class crime and delinquency. In an effort to detect "hidden" delinquency, sociologists developed a technique designed to produce a more accurate picture. The technique used by Short and Nye

(1958) in a number of studies of hidden delinquency consisted of having juveniles in a school or other population complete questionnaires on the extent to which they engaged in law-violating behavior. They found that delinquency was widespread throughout the juvenile population. Subsequently, Williams and Gold (1972) and Empey and Erickson (1966) embarked on studies employing self-reports. These writers found that 88 percent and 92 percent of their study groups, respectively, had engaged in violations. Hindelang and colleagues (1981) present a similar volume of law-violating behavior in their Seattle study. Criticisms of the self-report method followed many of these studies, centering on issues of respondent misrepresentation, respondent recall, and inappropriateness of study groups. A major criticism (by Nettler, 1984, for example) was that self-reports elicited admission of only minor or petty infractions for the most part. Because of its obvious utility, the self-report technique has been greatly improved in recent years, becoming an important, if not the dominant, method of measurement in studies focusing on the extent and cause of delinquency.

A number of students of delinquency agree that many of the improvements in self-report studies have been contributed by Elliott and Ageton (1980): (Bartol and Bartol 1989; Gibbons and Krohn 1991; Regoli and Hewitt 1991). Elliott and colleagues have created a panel design that employs periodic interviews instead of questionnaires. The study, called the National Youth Survey (NYS), utilized a 5-year panel design with a national probability sample of 1,726 adolescents aged eleven to seventeen and covered more than a hundred cities and towns in the United States. In contrast with earlier self-report studies, Elliott asked his respondents about a full range of activities designed to get at serious as well as minor infractions. In addition, his respondents were asked whether they were caught when engaging in delinquent and criminal activities.

Another attempt to ascertain the volume of delinquency in the United States is represented by the National Crime Survey (NCS). This survey, an effort to determine the extent of victimization in the population of the United States, was begun in 1973 after an initial study sponsored by the President's Commission on Law Enforcement and Administration of Justice in 1967. Interviews are conducted semiannually by the Bureau of the

Census with a large national sample of 60,000 households (Bartol and Bartol 1989). The survey was intended to supplement the Uniform Crime Report data and measures the extent to which persons and households are victims of rape, robbery, assault, burglary, motor-vehicle theft, and larceny. Binder and colleagues (1988) note that one of the major findings of the 1967 study of victims by the President's Commission was the revelation that "actual crime was several times that indicated in the UCR" (p. 34). In the current victim interviews, if the respondent has been victimized, he or she will be asked questions about both self-characteristics and characteristics of the offender. Binder and colleagues warn about the difficulties of age discrimination by a victim under stress and suggest that this method cannot be relied on too heavily in measuring delinquency.

Nevertheless, Laub (1983) has found NCS data useful in addressing the issue of the extent and change in delinquency volume. In an analysis of NCS data obtained between 1973 and 1980, he found no increase in juvenile crime over those years. He further noted that data from the National Center for Juvenile Justice supported this conclusion. It would seem, then, that the NCS data, UCR data, and juvenile court data have been fairly consistent regarding the volume of delinquency. While self-report data indicate that violations are consistently widespread in American society, it is important to note that these reports involve primarily minor violations. Indeed, to the extent that almost everyone engages in minor violations, it may make sense to focus mainly on serious violations. Nettler (1984), noting that self-report studies find a large number of minor infractions, suggests that such violators are best described as lying on a continuum rather than as being "delinquent" or "nondelinquent." The cohort studies of Wolfgang and colleagues (1972) show that only a small proportion of the study groups were involved in serious violations.

FACTORS RELATED TO DELINQUENCY

Age and Gender. In the United States, Britain, and other European countries where delinquency is recognized and studied, there is general agreement that it peaks in adolescence (ages fifteen to eighteen) rather than in childhood. (This is not to

say, however, that delinquency is not on the increase among younger children. A study by the FBI in 1990 found that the arrest rate for rape among males aged twelve years and under had more than tripled since 1970 (Parmley 1991). The UCR shows that 18.9 percent of all arrests in 1996 involved persons under eighteen years of age. This age group accounted for 31 percent of arrests for index crimes, however. Male arrests peaked at age eighteen in 1996 and female arrests at age sixteen. Earlier studies and analyses by Empey and Erickson (1966), Wolfgang (1983), and Braithwaite (1981) are consistent with this picture, with age sixteen being the peak year for juvenile misconduct.

It has consistently been found that males outnumber females in UCR arrest data. Thus in both 1988 and 1989, among those under eighteen, males were arrested four times more frequently than females. For those under eighteen in both 1988 and 1989, males outnumbered females 8-to-1 in arrests for violent offenses. In 1990, Short pointed out that the gender ratio had declined substantially. Between 1980 and 1989 violent crime increased by 4.5 percent for males under eighteen and by 16.5 for comparable females. Considering all arrests for males and females under eighteen, males showed a *decline* of 8.5 percent between 1980 and 1989, while females showed an *increase* of 1.1 percent for the same period.

Indeed, as reported in the Uniform Crime Reports, female delinquency, compared to male delinquency, has been rising steadily since the 1960s. In 1960, there was a 6-to-1 ratio of male to female juvenile arrests. The ratio has declined steadily since then and in 1987 was 3.4-to-1. In 1996 the FBI data revealed a male-female ratio of just 3-to-1.

Moreover, the ratio for violent offenses has dropped from 8-to-1 in 1989 to 5.5-to-1 in 1996, according to FBI data reported in the *Sourcebook* for 1997. Finally, it must be mentioned that FBI data reveal a decline of 15.3 percent in the murder and manslaughter charges for males under age 18 between 1995 and 1996 but reveal no change for females in that age group. It should also be noted, however, that for those aged thirteen to nineteen, 92 percent of murder offenders in the UCR in 1996 were males and only 8 percent were females. Also sobering is the fact that 29 percent of all

murder victims in the under-eighteen age group were females in 1996.

Perhaps Hagan's power-control theory is relevant here. Hagan and colleagues (1987) suggest that child-rearing styles in the home (the power structure) are determined in part by the nature of the parents' occupations. The two main types of child-rearing styles are patriarchal and egalitarian. The two types of occupations are command (managerial) and obey (subject to others' authority). In the egalitarian family where both parents work in authority positions, the mother's authority means she has a substantial amount of power in the home, and this leads to daughters having increased freedom relative to sons. This situation is reversed in patriarchal families, which are controlled by fathers and sons. In the egalitarian family, the adolescent daughter has an increased willingness to take risks. Hagan assumes that willingness to take risks is a fundamental requirement for delinquency. He also predicts that female delinquency will be high in mother-only homes. The absence of a father leaves a void in male power, allowing the adolescent girl more freedom, greater risk taking, and an increased tendency to deviate. The theory needs to be tested more fully.

With respect to self-reports, the reports of the NYS suggest that gender was not strongly related to involvement in delinquent acts. Although males admitted to more infractions than did females, the differences were much less pronounced than those seen in the UCR. Again, it should be emphasized that efforts are being made to enhance the ability of self-report studies to elicit information on more serious infractions.

Race and Class. UCRs for 1985 and 1989 present data on arrests by race in the United States. Among persons arrested and under eighteen years of age, the number of blacks increased from 23 percent in 1985 to 28 percent in 1989, but declined slightly to 27 percent in 1996; the number of whites decreased from 75 percent in 1985 to 70 percent in 1989 and remained at 70 percent in 1996. The remainder of the arrests were categorized by race as Native Americans, Asians, Pacific Islanders, and Alaskan Natives. The proportion of violent index crimes committed by blacks under age eighteen increased from 52 percent in 1985 to 53 percent in 1989 but declined to 47 percent in 1996. The comparable proportions for whites were

46 percent, 45 percent, and 50 percent. Also of interest are the figures for murder and non-negligent homicide. Here, blacks under eighteen accounted for 51 percent, 61 percent, and 57.5 percent of these crimes in 1985, 1989, and 1996, respectively; whites accounted for 48 percent, 37 percent, and 39 percent during the same three years. This slight decline in the proportion of murder and non-negligent manslaughter accounted for by blacks under eighteen is accompanied by the fact that the number of such crimes increased by 25 percent for blacks and by 18 percent for whites under eighteen during the period between 1988 and 1996. This is a decided improvement over the period between 1985 and 1989, when there was a doubling of the number of such crimes for blacks and a 30 percent increase for whites under age eighteen. Aggravated assaults also increased substantially during this period for both whites and blacks under eighteen, increasing for blacks by 25 percent and for whites by 50 percent during the eight-year period ending in 1996. Forcible rapes by blacks under age eighteen showed an improving picture, declining by 12 percent between 1988 and 1996. On the other hand, forcible rapes by whites under age eighteen increased by 15 percent during this time frame. Overall, despite short-term improvements in the murder rate for those over age 18, there is no denying the fact that serious and violent crime increased among those under age 18 between 1988 and 1996. This violence has been growing among white youth as well as black youth.

William J. Wilson (1996) and other sociologists have long suggested that social class and inequality are important concepts in the attempt to understand the increase in violence among blacks. The move of businesses to suburban locations with consequent loss of job opportunities, educational inequities, and the growth of female-headed households have combined to limit the coping resources in inner cities where most black youth reside. Wilson suggests that the resulting stresses hit lower-class blacks particularly hard and contribute to the high rates of violent crime in these areas. In addition, Bernard (1990) suggests that anger is reinforced by the social isolation that comes from being confined to communities that have high rates of crime. Policies by local departments of justice with respect to police routines, bail practices, and sentencing as these apply to

blacks have also come in for considerable comment (Teele 1970b). In 1999 news media reported that the U.S. Department of Justice was investigating allegations of racial profiling—targeting minorities for an unjustified amount of police attention—by police in New Jersey, Michigan, and Florida (“US Police Chiefs” 1999).

While there are those who say that the nation has not paid enough attention to the causes of black teenage violence, an increasing number of analysts say that we have paid a lot of, perhaps too much, attention to black violence in urban areas while ignoring the rising tides of violence by white youths in suburban and rural areas. While income inequality has seemed appropriate to an explanation of urban violence, it may appear less relevant in the analysis of violent behavior in our affluent suburban areas. This situation brings to mind Toby’s (1967) classic work on delinquency in affluent society as well as Durkheim’s (1951) discussion of rising expectations in his theory of anomie.

In Toby’s case, he was trying to account for the rise in theft crimes in a variety of countries. Although he took special note of adolescent crime in industrial countries such as Japan, Sweden, and Great Britain, he also included developing countries such as Nigeria and India in his analysis. Toby suggests that the resentment of poverty is likely to be greater among the relatively poor in an affluent society than among the poor in a poor society. He suggests, however, that envy is at work not only in the more affluent societies, such as Japan, but also in countries with rising standards of living, such as India and Nigeria. Moreover, he suggests that not only adults but also the young are subject to rising expectations. It may be that relative deprivation can account for at least some of the rise in youth violence in the United States. Toby’s work also suggests that the presence of such envy could be heightened where the inhibiting effect of schools or families or jobs is missing in either affluent or developing societies. Here Toby’s thesis greatly resembles control theory. The increase in single-parent families among blacks, persisting educational inequalities for blacks, and chronic employment problems for black youth may tend to lessen social controls and could be factors in the greater increase in violence among them.

Toby’s discussion of “resentment” seems somehow applicable to the school violence discussed

earlier, but with a different twist. There seems present in these cases something besides income inequality—especially since in many of these instances the youth are from apparently affluent families, as in the Littleton, Colorado, case. While assault weapons were certainly available and parents seemed loathe to invade their sons’ privacy, there was at school, perhaps, a certain intolerable inequality that alienated the assaulters and pulled them into circles of violent schemes, feelings, and, eventually, behavior. Most of the youths—usually white—felt rejected by their peers, their teachers, their parents, or their girlfriends. In Colorado they resented the athletes and those who were generally in the “in crowd.” There apparently were feelings of jealousy toward those who did not invite them to join their group. While such feelings, involving relative deprivation, seem to be far removed from considerations of wealth, they fit the phenomenon of inequality. This form of inequality is probably anathema to children who are deprived of neither their basic needs nor considerable luxuries.

Social class has been by far the most controversial of all the factors studied in connection with juvenile delinquency. The argument seems to revolve around both method and theory. Some argue about the impact of social class, others debate the measurement of social class, and a few argue about both. Several writers have attempted to review the research on class and delinquency or crime. Tittle and colleagues (1978), noting that nearly every sociological theory of crime or delinquency had class as a key factor, reviewed thirty-five such studies. Their findings suggested that the class and crime–delinquency connection might be a “myth” because the relationship could not be confirmed empirically.

Subsequently, Braithwaite (1981) criticized Tittle’s study not only as incomplete but also as having come to the wrong conclusions. He reviewed fifty-three studies that used official data and forty-seven studies that used self-reports in the study of delinquency. Braithwaite forcefully argues that the class–crime relationship is no myth. Of the studies using official records, Braithwaite found that the vast majority (forty-four) showed lower-class juveniles to have substantially higher offense rates than middle-class juveniles. Of the forty-seven self-report studies, he concluded that eighteen found lower-class juveniles reported higher

levels of delinquent behavior, seven reported qualified support for the relationship, and twenty-two found no relationship. Braithwaite is critical of self-report studies when (1) they do not closely examine the lowest group on the social-class continuum (the lumpen proletariat) and (2) they do not include serious offenses and chronicity in their data gathering. While the argument may continue, Braithwaite and others seem to be less critical of self-report studies when they correct these apparent shortcomings.

Apparently the work of Elliott and Ageton (1980) has done much to defuse this issue. They found, for example, that the relationship between class and self-reported delinquency is totally a consequence of the difference between the lowest class group and the rest of the sample, with no difference between the working and middle classes. Writers such as Messner and Krohn (1990), Hagan and Palloni (1990), and Colvin and Pauly (1983) have apparently profited from these debates; their work shows an inclination to refine the "objective" measure of class, using insights from conflict theory as they formulate explanations of delinquency. Indeed, it is safe to say that social class is alive and well, but it is more broadly conceptualized now; many of the new theories include patterns of child rearing, job experiences, and family structure that are incorporated into the framework of a more radical neo-Marxist perspective. The effort by sociologists in the United States and in other countries to better understand juvenile delinquency appears to have entered a new and more urgent phase.

JAMES E. TEELE

JUVENILE DELINQUENCY, THEORIES OF

The topic of juvenile delinquency is a fertile area for construction of sociological theory. Three major sociological traditions, including structural functionalism, symbolic interactionism, and conflict theory, contribute to the explanation of delinquency. Much of the work in this area seeks to explain why officially recorded delinquency is concentrated in the lower class, or in what is today more often called the underclass. This entry considers the most prominent theories of delinquency under the theoretical rubrics noted above.

STRUCTURAL FUNCTIONALISM AND DELINQUENCY

Structural-functional theories regard delinquent behavior as the consequence of strains or breakdowns in the social processes that produce conformity. These theories focus on institutions, such as the family and school, that socialize individuals to conform their behavior to values of the surrounding society and on the ways in which these institutions can fail in this task. Wide agreement or consensus is assumed about which behaviors are valued and disvalued in society. The question structural-functional theories try to answer is: Why do many individuals during their adolescence behave in ways that challenge this consensus? That is, why do many adolescents violate behavioral norms that nearly all of us are assumed to hold in common?

Anomie Theory. The roots of functional theory are found in Durkheim's notion of *anomie* ([1897] 1951). To Durkheim, this term meant an absence of social regulation, or normlessness. Merton (1938, 1957) revived the concept to describe the consequences of a faulty relationship between goals and the legitimate means of attaining them. Merton

emphasized two features of social and cultural structure: culturally defined goals (such as monetary success) and the acceptable means (such as education) to their achievement. Merton argued that in our society success goals are widely shared, while the means of or opportunities for attaining them are not.

Merton's theory is used to explain not only why individual adolescents become delinquents but also why some classes are characterized by more delinquency than others. Since members of the lower- or underclass are assumed to be most affected by the disparity between the goals and the means of attaining success, this class is expected to have a higher rate of delinquent behavior. Merton outlined a number of ways individuals adapt when faced with inadequate means of attaining their goals. Among these, *innovation* revolves substituting illegitimate for legitimate means to goal attainment; it is the resort to this adaptation that is thought to account for much theft among adolescents from the underclass.

Subcultural Theory. Group-based adaptations to the failure to attain success goals involve the *delinquent subculture*. Cohen (1955) suggests that children of the underclass, and potential members of a delinquent subculture, first experience a failure to achieve when they enter school. When assessed against a "middle-class measuring rod," these children are often found lacking. A result is a growing sense of "status frustration." Underclass children are simply not prepared by their earliest experiences to satisfy middle-class expectations. The delinquent subculture therefore emerges as an alternative set of criteria or values that underclass adolescents can meet.

Cohen argues that these subcultural values represent a complete repudiation of middle-class standards: the delinquent subculture expresses contempt for a middle-class lifestyle by making its opposite a criterion of prestige. The result, according to Cohen, is a delinquent subculture that is "nonutilitarian, malicious, and negativistic"—an inversion, of middle-class values. Yet this is only one possible type of subcultural reaction to the frustration of failure. As we see next, many subcultural responses are elaborated in the theoretical tradition of structural functionalism.

Differential Opportunity Theory. Cloward and Ohlin (1960) argue that to understand the

different forms that delinquent and ultimately criminal behavior can take, we must consider the different types of illegitimate opportunities available to those who seek a way out of the underclass and where these opportunities lead. Different types of community settings produce different subcultural responses. Cloward and Ohlin suggest that three types of responses predominate, each one leading to its own respective subculture: a stable criminal subculture, a conflict subculture, and a retreatist subculture.

The *stable criminal subculture* offers, as its name suggests, the most promising (albeit still illegitimate) prospects for upward economic mobility. According to Cloward and Ohlin, this subculture can emerge only when there is some coordination between those in legitimate and in illegitimate roles—for example, between politicians or police and the underworld. One pictures the old-style political machine, with protection provided for preferred types of illegal enterprise. Only in such circumstances can stable patterns be established, allowing opportunities for advancement from adolescent to adult levels of the criminal underworld. When legitimate and illegitimate opportunity structures are linked in this way, the streets become safe for crime, and reliable upward-mobility routes can emerge for aspiring criminals.

Violence and conflict, on the other hand, disrupt both legitimate and illegitimate enterprise. When both types of enterprises coexist, violence is restrained. However, in the "disorganized slum," where these spheres of activity are not linked, violence can reign uncontrolled. Cloward and Ohlin see these types of communities as producing a *conflict subculture*. A result of this disorganization is the prevalence of adolescent street gangs and their violent activities, making the streets unsafe for more profitable crime.

The *retreatist subculture* includes adolescents who fail in their efforts in both the legitimate and illegitimate opportunity structures. These "double failures" are destined for drug abuse and other forms of escape.

Cloward and Ohlin's theory played a role in encouraging the Kennedy and Johnson administrations of the 1960s to organize the American War on Poverty, which attempted to open up legitimate opportunities for youth and minorities in the underclass (see Moynihan 1969). However,

another important variant of structural-functional theory argued that the most important cause of delinquency was not a strain between goals and means but rather a relative absence of goals, values, commitments, and other sources of social control.

Social Disorganization Theory. The earliest North American efforts to explain crime and delinquency in terms of social control focused on the absence of social bonds at the community level. Entire neighborhoods were seen as being socially disorganized, as lacking the cohesion and constraint that could prevent crime and delinquency. This work began in the late 1920s, when Clifford Shaw and Henry McKay (1931, 1942) sought to identify areas of Chicago that were experiencing social disorganization. They explored the process that characterized these communities. What they found were indications of what they assumed to be social disorganization— truancy, tuberculosis, infant mortality, mental disorder, economic dependency, adult crime, and juvenile delinquency. In Chicago, the rates of these conditions were highest in the slums near the city center; they diminished in areas farther away from the center. Since these problems were assumed to be contrary to the shared values of area inhabitants, they were taken as indications that these areas were unable to realize the goals of their residents. In other words, they were taken as indicators of social disorganization.

Shaw and McKay also attempted to determine the sorts of community characteristics that were correlated with delinquency so that they could infer from these characteristics what the central components of social disorganization were and how they caused delinquency. Three types of correlates were identified: the economic status of the community, the mobility of community residents, and community heterogeneity. The implication was that poverty, high residential mobility, and ethnic heterogeneity led to a weakening of social bonds or controls and, in turn, to high rates of delinquency. All of this was being said of the neighborhoods Shaw and McKay studied; it was left to later theories to spell out the meaning of weakened neighborhood bonds or controls for individuals.

Control Theory. At the level of individuals, to have neither goals nor means is to be uncommitted and thus uncontrolled. Hirschi (1969) has

argued that the absence of control is all that really is required to explain much delinquent behavior. There are other types of controls (besides *commitment* to conformity) that may also operate: *involvement* in school and other activities; *attachments* to friends, school, and family; and belief in various types of values and principles. Hirschi argues that delinquent behavior is inversely related to the presence of these controls. Alternatively, as these controls accumulate, so too does conformity. According to control theory, the more committed, attached, involved, and believing individuals are, the greater is their bond to society. Again, Hirschi's point is that no special strain between goals and means is necessarily required to produce delinquent behavior; all that is required is the elimination of the constraining elements of the social bond.

In each of the theories that we have considered thus far, values or beliefs play some role in causing delinquency. It is argued that the presence of success goals or values without the means to obtain them can produce deviant behavior, as can the absence of these goals or values in the first place. It is an emphasis on these values, and the role of the school and family in transmitting them, that ties the structural-functional theories together.

SYMBOLIC INTERACTIONISM AND DELINQUENCY

Symbolic-interactionist theories of delinquency are concerned less with values than with the way in which social meanings and definitions can help produce delinquent behavior. The assumption, of course, is that these meanings and definitions, these symbolic variations, affect behavior. Early versions of symbolic-interactionist theories focused on how adolescents acquired these meanings and definitions from others, especially peers; more recently, theorists have focused on the role of official control agencies, especially the police and courts, in imposing these meanings and definitions on adolescents. The significance of this difference in focus will become apparent as we consider the development of the symbolic-interactionist tradition.

Differential Association Theory. Edwin Sutherland (1939, 1949) anticipated an emphasis of the symbolic-interactionist perspective with his early use of the concept of *differential association*. This concept referred not only to associations among

people but also, and perhaps even more important, to associations among ideas. Sutherland's purpose was to develop a general theory that explained delinquency as well as adult criminality. He argued that people violate laws only when they define such behavior as acceptable and that there is an explicit connection between people and their ideas (that is, definitions). So, for example, delinquent behavior is "learned in association with those who define such behavior favorably and in isolation from those who define it unfavorably," and this behavior occurs when "the weight of the favorable definitions exceeds the weight of the unfavorable definitions."

Although Sutherland intended his theory to be general and explicitly to include the explanation of delinquency, his best-known applications of the theory were in his famous studies of professional theft and white-collar crime. Nonetheless, Sutherland's emphasis on white-collar illegality was important for the study of delinquency because it stressed the ubiquity of criminality, and, as we see next, it helped to mitigate delinquency theory's preoccupation with underclass delinquency.

Neutralization Theory. While most of the theories we have considered to this point portray the delinquent, especially the underclass delinquent, as markedly different from "the rest of us," Sykes and Matza (1957, 1961) follow Sutherland's lead in suggesting that the similarities actually outnumber the differences. Their argument is based in part on the observation that underclass delinquents, like white-collar criminals, usually exhibit guilt or shame when detected violating the law.

Sutherland had argued that individuals become white-collar criminals because they are immersed with their colleagues in a business ideology that defines illegal business practices as acceptable. Sykes and Matza (1957) argue that the delinquent, much like the white-collar criminal, drifts into a deviant lifestyle through a subtle process of justification. "We call these justifications of deviant behavior techniques of neutralization," they write, "and we believe these techniques make up a crucial component of Sutherland's definitions favorable to the violation of law" (p. 667).

Sykes and Matza list four of these *neutralization techniques*: denial of responsibility (e.g., blaming a bad upbringing), denial of injury (e.g., claiming that the victim deserved it), condemnation of

the condemners (e.g., calling their condemnation discriminatory), and an appeal to higher loyalties (e.g., citing loyalty to friends or family as the cause of the behavior). Sykes and Matza's point is that delinquency in the underclass, as elsewhere, is facilitated by this kind of thinking. A question lingered, however: Why are these delinquencies of the underclass more frequently made the subjects of official condemnation?

Labeling Theory. Franklin Tannenbaum (1938) anticipated a theoretical answer to this question. He pointed out that some aspects of juvenile delinquency—the play, adventure, and excitement—are a normal part of teenage street life and that, later in their lives, many nostalgically identify these activities as an important part of their adolescence. But others see such activities as a nuisance or as threatening, so they summon the police.

Tannenbaum's concern is that police intervention begins a process of change in the way the individuals and their activities are perceived. He suggests that there is a gradual shift from defining specific acts as evil to defining the individual as evil. Tannenbaum sees the individual's first contact with the law as the most consequential, referring to this event as a "dramatization of evil" that separates the child from his or her peers for specialized treatment. Tannenbaum goes on to argue that this dramatization may play a greater role in creating the criminal than any other experience. The problem is that individuals thus singled out may begin to think of themselves as the type of people who do such things—that is, as delinquents. From this viewpoint, efforts to reform or deter delinquent behavior create more problems than they solve. "The way out," Tannenbaum argues, "is through a refusal to dramatize the evil." He implies that the less said or done about delinquency the better.

Sociologists have expanded Tannenbaum's perspective into what is often called a labeling, or societal reactions, theory of delinquency and other kinds of deviance. For example, Lemert (1967) suggests the terms *primary deviance* and *secondary deviance* to distinguish between acts that occur before and after the societal response. Acts of primary deviance are those that precede a social or legal response. They may be incidental or even random aspects of an individual's general behavior. The important point is that these initial acts

have little impact on the individual's self-concept. Acts of secondary deviance, on the other hand, follow the societal response and involve a transformation of the individual's self-concept, "altering the psychic structure, producing specialized organization of social roles and self-regarding attitudes." From this point on, the individual takes on more and more of the "deviant" aspects of his or her new role (Becker 1963, 1964). The societal response has, from this viewpoint, succeeded only in confirming the individual in a deviant role; for example, by potentially making adolescent delinquents into adult criminals through the punitive reactions of the police, courts, and others.

In the end, symbolic interactionists do not insist that all or even most delinquent behavior is caused by officially imposed labels. Being labeled delinquent is thought, rather, to create special problems for the adolescents involved, often increasing the likelihood that this and related kinds of delinquent behavior will be repeated. The point is that not only the actor but also reactors participate in creating the meanings and definitions that generate delinquency. The symbolic interactionists note that poor are more likely than the rich to get caught up in this process. This point is further emphasized in conflict theories.

CONFLICT THEORY AND DELINQUENCY

The most distinctive features of conflict theories include attention to the role of power relations and economic contradictions in generating delinquency and reactions to it. For example, conflict theories have focused on the role of dominant societal groups in imposing legal labels on members of subordinate societal groups (Turk 1969). The fact that subcultural groups typically are also subordinate groups ties this work to earlier theoretical traditions discussed above.

An Early Group-Conflict Theory. George Vold (1958) was the first North American sociologist to write explicitly about a group-conflict theory of delinquency. He began with the assumption that criminality involves both human behavior (acts) and the judgments or definitions (laws, customs, or mores) of others as to whether specific behaviors are appropriate and acceptable or inappropriate and disreputable. Of the two components, Vold regarded judgments and definitions as more significant. His salient interest was in how groups

impose their value judgments by defining the behaviors of others as illegal.

Vold regarded delinquency as a "minority group" behavior. For example, he argues that "the juvenile gang . . . is nearly always a 'minority group', out of sympathy with and in more or less direct opposition to the rules and regulations of the dominant majority, that is, the established world of adult values and powers" (p. 211). In this struggle, the police are seen as representing and defending the values of the adult world, while the gang seeks the symbolic and material advantages not permitted it under the adult code. At root, Vold argues, the problem is one of intergenerational value conflict, with adults prevailing through their control of the legal process.

A Theory of Legal Bureaucracy. According to this viewpoint, determining which groups in society will experience more delinquency than others may be largely a matter of deciding which laws will be enforced. Chambliss and Seidman (1971) observe that in modern, complex, stratified societies such as our own, we assign the task of resolving such issues to bureaucratically structured agencies such as the police. The result is to mobilize what might be called the primary principle of legal bureaucracy. According to this principle, laws will be enforced when enforcement serves the interests of social control agencies and their officials; and laws will not be enforced when enforcement is likely to cause organizational strain. In other words, the primary principle of legal bureaucracy involves maximizing organizational gains while minimizing organizational strains.

Chambliss and Seidman conclude that a consequence of this principle is to bring into operation a "rule of law," whereby "discretion at every level . . . will be so exercised as to bring mainly those who are politically powerless (e.g., the poor) into the purview of the law" (p. 268). Theoretical work of this kind coincided with important research on the policing of juveniles (e.g., Reiss 1971). According to the conflict theorists, poor minority youth appear disproportionately in our delinquency statistics more because of class bias and police and court prejudice than because of actual behavioral differences.

Recent Structural Theories. Some recent theories of delinquency have combined conflict theory's structural focus on power relations with

etioloical questions about sources of delinquent behavior as well as reactions to it. Thus Spitzer (1975) begins the formulation of a Marxian theory of delinquency (and deviance more generally) with the observation, "We must not only ask why specific members of the underclass are selected for official processing, but also why they behave as they do" (p. 640).

One effort to answer behavioral questions with insights from conflict theory is an "integrated structural-Marxist theory" proposed by Colvin and Pauly (1983). This theory integrates elements of control theory and Marxian theory. The theory is comprehensive, and only some of its most striking features can be outlined here. These features include a Marxian focus on working-class parents' experiences of coerciveness in the workplace, which Colvin and Pauly suggest lead to coerciveness in parenting, including parental violence toward children. In turn, Colvin and Pauly argue that such children are more likely to be placed in coercive control structures at school and to enter into alliances with alienated peers. All of these experiences make delinquent behavior more likely, including the violent and instrumental kinds of delinquent behavior that may be precursors of adult criminality.

Power-control theory is another recent structural formulation (Hagan 1989) that attempts to explain large and persistent gender differences in delinquency by taking power relations into account. Power relations in the family are the starting point of this theory. The cornerstone of the theory is the observation that, especially in more patriarchal families, mothers more than fathers are involved in controlling daughters more than sons. A result of this intensified mother-daughter relationship is that daughters become less inclined to take what they perceive as greater risks of involvement in delinquency. Police and other processing agencies act on stereotypes that extend these gender differences in officially recorded delinquency. Power-control theory generally predicts that in more patriarchal families, sons will be subjected to less maternal control, develop stronger preferences for risk taking, be more delinquent, and more often be officially labeled for being so. More recently, this theory has been elaborated to emphasize that in less patriarchal families mothers may become more involved in the control of their

sons and this can reduce their sons' involvement in risk taking and delinquency (McCarthy and Hagan 1999).

These structural approaches illustrate an ongoing trend toward theoretical integration in this tradition and elsewhere in the study of delinquency (e.g., Hagan and McCarthy 1997; Messner et al. 1989; Sampson and Wilson 1995; Tittle 1995). These integrations involve theories that are often thought to be in apposition if not opposition to one another. Yet the trend toward integration in delinquency theory has been apparent for more than a decade, and it seems likely to continue.

TROUBLESOME QUESTIONS

Despite the richness of sociological theories of delinquency and the emerging sense of convergence among previously competing theoretical traditions, there is a new awareness that delinquency theories remain incomplete in their capacity to explain and sometimes even address basic micro- and macro-level questions. For example, a classic issue that persists despite its recognition is the question of why most delinquents discontinue their delinquency before or during their transition to adulthood. We know that most delinquents "age out" of delinquency, but we have not adequately explained why this happens (Hirschi and Gottfredson 1983). Our theories are much more attentive to why young people become delinquent than to why they stop being so.

A seemingly related but only more recently apparent question involves the decline since the early 1990s in the violent forms of delinquency, such as robbery and homicide, that we are best able to measure and monitor statistically over time. This trend is strikingly apparent as we head toward the millennium (see, e.g., Blumstein and Rosenfeld 1998). None of the prominent sociological theories of delinquency predicted or can easily account for this decline in violent delinquency. Again, our theories have focused more on increases in delinquency than on its decline. Sociological theories of delinquency confront new as well as continuing questions in the new century.

K

KINSHIP SYSTEMS AND FAMILY TYPES

Kinship systems are mechanisms that link conjugal families (and individuals not living in families) in ways that affect the integration of the general social structure and enhance the ability of the society to reproduce itself in an orderly fashion. Kinship performs these social functions in two ways. First, through relationships defined by blood ties and marriage, kinship systems make possible ready-made *contemporaneous networks* of social ties sustained during the lifetimes of related persons and, second, they enable the *temporal continuity* of identifiable family connections over generations, despite the limited lifespan of a family's members. Variations in norms governing the structure of contemporaneous networks and the modes of temporal continuity compose the basis for the typologies of kinship systems described in this article.

In conceptualizing connections between kinship systems and family types, social scientists have applied either of two approaches. Some have developed typologies from historical analyses (and evolutionary schemes) that depict the transition of Western societies from ancient or medieval origins to modern civilizations. Other social scientists construct typologies that cut across diverse historical periods. Each historical era then constitutes a unique medium in which the structural typologies are expressed.

MODERNITY, FAMILY PATTERNS, AND KINSHIP SYSTEMS

There are at least three ways to develop historical typologies related to kinship and family. One way is to hypothesize a linear historical progression, which includes a family type existing at the beginning point in time, a particular historical process that will act upon the family and kinship structures (e.g., urbanization or industrialization), and a logical outcome at the end of the process. A second approach builds upon the above approach by positing a transitional family type that emerges during the historical process and gives way in the final stages of the process to another family type. A third approach, which includes devising a family type based upon a configuration of attributes peculiar to a particular historical era (e.g., the Victorian family, the American colonial family), implies that any historical era represents a unique convergence of diverse factors.

Bipolar Typologies. By and large, sociologists have drawn a connection between kinship and family on the basis of a distinction between traditionalism and modernity. Generally, this distinction draws upon Henry Maine's ([1861] 1963) depiction of the transformation of social relations in early societies. Maine argued that social relations changed from those based on ascriptive status (deriving from birth) to relations created and sustained through voluntary contractual arrangements. Maine's theory has evoked a series of typologies that, in large measure, refine the status-contract distinction. For instance, an ideal type

developed by Ferdinand Toennies ([1887] 1957) has provided a backdrop for later typologies. The Toennies typology itself refers to a shift from *Gemeinschaft* (community) as a form of social organization based upon an existential will (*Wessenwille*), which is suited to feudalism and peasant society, to *Gesellschaft* (society) as a social form based upon rational will (*Kurwille*), which fits an urban environment under modern capitalism. Contemporary family typologies, in building upon Toennies's conceptual scheme, portray a weakening of kinship obligations and constraints.

One position, rooted in George P. Murdock's (1949) analysis of cross-cultural archives, has resulted in the main sequence theory of social change in kinship structure (Naroll 1970). Main sequence theory pertains to the way differential gender contributions to production of material resources affects the use of kindred as human resources/property. This theory holds that basic changes in kinship are initiated by a shift in the relative importance of men and women to the economic life of the society. First, there is a modification in the economic division of labor by gender. (For example, in hoe cultures, women tend to do the farming; when plows are introduced, men become the farmers.) Second, the shift in sexual division of labor generates a change in married couples' choices of residence, the major alternatives being near the husband's relatives (patrilocal), the wife's (matrilocal), or anywhere the couple desires (neolocal). (Plow cultures tend toward patrilocal residence.) Third, the change in choice of residential site affects the line of descent and inheritance favored in the kinship system: the husband's side (patrilineal), the wife's (matrilineal), or both sides (bilateral). (In line with the shift in residence, plow cultures show a greater inclination toward patrilinearity than do hoe cultures.) Fourth, the transfer to lineage affiliation generates a change in kinship terminology, particularly in ways that show tribal or clan membership, or, in modern societies, the dissolution of larger kinship structures. As applied to the emergence of modernity, main sequence theory predicts a continual emancipation from kinship constraints. An increase in the proportion of women in the labor force will produce a trend toward neolocal residence, which in turn will lead to increased emphasis upon bilaterality, weakening sibling ties and obligations to both

sides of the extended family, and in the long run to changes in kin terminology and identity [e.g., voluntarism in choice of surnames as an indicator of preference as to line(s) of descent].

In a variation of main sequence theory, urban sociologists such as Wirth (1956) and Burgess and associates (1963) wrote on the effects of transferring the economic base of societies from the land to urban centers. The theme of their work is to be found in the German proverb "Stadt Luft macht frei" ("city air makes one free"). For example, Burgess and associates described a progression from what they named the institutional family to the companionship family. In this conceptualization, the institutional family, embedded in a larger kinship group, is characterized by patriarchy, clearly defined division of household labor by sex, and high fertility. Its unity is derived mainly from external constraints—social mores, religious authority, fixity in location, position in the social structure, and the value of familism (i.e., values giving priority to the collective welfare of the family over that of individual members). Burgess and associates regarded the institutional family as an adaptation to relatively immobile, rural, agricultural societies and believed its way of life was fixed over time. By way of contrast, urban society, which is characterized by mobility, anonymity, and change, makes inoperative the social control mechanisms developed to maintain stable, rural societies. With the withering of these external controls on rural family life, Burgess, Locke, and Thomes proposed that the companionship family is bound together by internal forces—mutual affection, egalitarianism, a sense of belonging, common interests—and affords freedom from the demands of traditional family and kinship ties.

Unlike the urban sociologists, structural functionalists such as Talcott Parsons (1954) place considerable emphasis on the interaction of subsystems in the larger social system. In part, structural functionalists are concerned with economic and kinship factors in structuring nuclear family relationships. Parsons described American kinship as "a 'conjugal' system in that it is made up exclusively of interlocking conjugal families" (1954, p. 180) and is multilineal (i.e., bilateral) in descent. Parsons associates kinship solidarity with unilineal descent, that is, with a "structural bias in favor of

solidarity with the ascendant and descendant families in any one line of descent" (1954, p. 184). The absence of such bias in the American descent system, Parsons suggests, is in large measure responsible for "the structural isolation of the individual conjugal family" (i.e., its autonomy).

The importance Parsons attributes to unilinearity as a factor in facilitating strong dependence upon kin ties is exemplified by his highlighting two exceptions to the structural isolation of the conjugal family in America—the upper-class elements, whose status depends on the continuity of their patrilineages' solidarity, and the lower-class elements, in which there is "a strong tendency to instability of marriage and a 'mother-centered' type of family structure" (Parsons 1954, p. 185). However, Parsons regards the urban middle class as characterizing "the focal American type of kinship." Since in the middle class the residence of the conjugal family typically is neolocal, and the conjugal family is economically independent of "the family of orientation of either spouse," the role of the conjugal family in U.S. society can be, for theoretical purposes, understood as master of its own destiny, rid of the impediments of extended-family ties.

In reaction to those sociologists who see modernity as inimical to bonds of kinship, other social scientists (e.g., Adams 1968; Firth et al. 1969; Litwak 1985; Moge 1976; Shanas et al. 1968; Sussman 1959) turn their attention to the attenuated functions of kinship in contemporary society. Just as Goode (1963) notes a "fit" between the needs of modern capitalist society for a socially and geographically highly mobile population and the flexibility of the isolated conjugal family system, the revisionists indicate a similar fit between the existence of a highly mobile population and the presence of kin who give emergency aid and social support to relatives. The revisionists shift our attention away from constraints imposed by kinship loyalties and obligations and direct it instead to sources of services, goods, and emotional support that cannot readily be supplied by bureaucracies, markets, or other agencies. In his typology, Litwak (1960a, 1960b) distinguishes the isolated nuclear family (without kinship resources) from the traditional extended family (implying a hierarchy of authority), on the one hand, and from the

modified extended family (which consists of a network of related but autonomous nuclear families), on the other. Although the revisionists have not destroyed the foundation of the bipolar family typologies, they do focus on a previously neglected area of analysis.

Three-Stage Typologies. Some modernization typologies introduce a third, transitional stage between traditional and modern kinship and family structures. These typologies accept the position that initially there is an emancipation from traditional kinship constraints and obligations, but they also propose that at some point new values of modernity emerge to fill the vacuum left by the dissipation of the old kinship constraints. For example, building on the work of LePlay, Zimmerman and Frampton (1966) offer a scheme of transformation in which families change from a patriarchal form to a stem-family structure and thence to an unstable family type. Zimmerman and Frampton begin with the premise that each social organization derives its "essential character" from a triad of "imperishable institutions"—family, religion, and property. However, in their view, "familism is necessary in all complete social organization to a degree more imperative than the need for property" (1966, p. 14; 1947). Zimmerman and Frampton regard the patriarchal family as the most familistic form. The patriarchal type is rooted in idealistic religious values and is characterized by a common household of a patriarch and his married sons and their families, wherein the property is held in the name of the "house," with the father as trustee. They identify the patriarchal form as having been prevalent among agriculturists in the Orient, in rural Russia, and among Slavonic peasants.

With urbanization and industrialization, however, the unstable family becomes predominant. Zimmerman and Frampton associate the unstable family with materialism and individualism and the resulting atomization of social life. Individuals are "freed from all obligations toward their parents and relatives" (1966, p. 15), and the identity of each conjugal family as a social unit ends with the death of the parents and the dispersal of the children.

The stem family represents a transitional state between the patriarchal and unstable forms. The stem family extends branches into urban centers

while retaining its roots in the ancestral lands. As a result, the stem family provides a balance between the security of the traditional influences and resources of the “house” and the freedom and resources of the cities. (However, historical researchers yield less idyllic descriptions of the stem family than the Zimmerman and Frampton portrait. See Berkner 1972.)

A less romantic depiction of a transitional family type is drawn by Lawrence Stone (1975) in his typology of the English family’s movement from feudalism to modernity. Stone posits the existence of a dual historical process. He places the decline of the importance of kin ties in the context of the emergence of a powerful, centralized state, and he then regards the rise of the modern family as an ideological emergence accompanying the development of capitalism.

According to Stone’s typology, feudal England emphasized (1) kin-group responsibility for crimes and treasonable acts of members and (2) the institution of cousinship with its broad obligations. As political and economic power moved away from the traditional, landed elite to the state and the entrepreneurial class, the common law of the courts no longer recognized criminal and civil deviance as a kin-group responsibility, and cousinship lost its effectiveness. To fill the vacuum left by the decline of kinship as a factor in one’s destiny, the relatively denuded conjugal family had to take over the task of guiding the destiny for its members. Consequently, by the sixteenth century, as an intermediate step toward the modern family, there was a trend toward authoritarianism in husband-wife interaction, and governance in the conjugal family took the form of patriarchy.

Stone (1975, p. 15) suggests that it was not until the eighteenth century that the spread of individualism and utilitarianism gave rise to a more companionate and egalitarian family structure. This last family form has been designated by Alan Macfarlane (1986) as the Malthusian marriage system, in which (1) marriage is seen as ultimately the bride’s and groom’s concern rather than that of the kin group; (2) marital interaction is supposed to be primarily companionate; and (3) love is supposed to be a precursor of marriage. Functionally, the Malthusian system yields relatively fewer children—by choice—than earlier family forms.

The Problem of Structure in Modernity

Typologies. Typologies depicting historical transformations in family and kinship place much emphasis on the “fit” between the needs of modern industrial society and the presence of the conjugal family type (Litwak 1960a, 1960b; Parsons 1954). Despite this conjecture, Parsons (1954, p. 184) suggests that in Western society an “essentially open system” of kinship, with its “primary stress upon the conjugal family” and its lack of larger kin structures, has existed for centuries, long before the modern period. Like Macfarlane (1986), Parsons dates its establishment in late medieval times “when the kinship terminology of the European languages took shape.” Moreover, Goode’s (1963) analysis of family trends in eleven societies indicates that acceptance of modern, conjugal family ideology may precede economic and industrial development rather than come as a subsequent adaptation. Such findings cast doubt on the validity of the dichotomy between traditional societies and modernity as providing a theoretical basis for the typologies discussed above.

Parsons argues that (1) there is an incompatibility between corporate kinship and multilineal systems, and (2) in large measure, this incompatibility accounts for the prevalence of highly adaptable, structurally independent conjugal households in modern societies. However, findings by Davenport (1959), Mitchell (1963), Pehrson (1957), Peranio (1961), and others that corporate structures of kinship (such as clans) do exist in some multilineal kinship systems undercut Parsons’s argument that such structures are to be found only in unilineal systems. Nevertheless, if multilateral kinship systems can accommodate corporate structures, then they can also include other kinship elements that sustain loyalties to descent groups and facilitate segmentation of the society.

The Problem of Connecting Kinship and Family in Modernity Typologies.

Revisionists of the isolated conjugal family position have presented considerable evidence of residual elements of kinship ties in contemporary society. However, they do not adequately explain the connections between types of kinship systems and variation in performance of family functions in different parts of the social structure. Their main concern is with changes in kinship and family, changes that are consistent with the general loosening of tradition

in modern society. But their focus on emancipation from tradition diverts their attention from (1) the influence of emerging ethnic, religious, or class interests upon patterns of integration of family networks in the larger social structure and (2) the temporal dimensions of kinship, which go beyond living kin to departed ancestors and generations yet to come.

Additionally, given the fact that the family-kinship typologies described above have their roots in the distinction between tradition and modernity, they overlook those nonindustrial, primarily nonurban societies in which families approach the companionship model as well as those ethnic and religious segments of industrial, primarily urban societies where strong familistic tendencies persist. Except for Stone (1975) and Zimmerman and Frampton (1966), these typologies are based on the concept of emancipation from tradition, and they do not deal explicitly with the emergence of new family values (other than flexibility and freedom). Most of all, their emphasis on emancipation from the constraints of tradition precludes their explaining why cohesive forces of family and kinship may remain strong (or increase in strength) in the face of an economic and social environment that is hostile to stable family life. (Exceptions are Sennett 1970 and Harris and Rosser 1983.)

Critical Commentary on Historical Typologies.

Family typologies describing historical trends from one period of history to another are vulnerable to criticism of their teleological assumptions. Criticisms often involve (1) the definition of polar concepts and (2) the problem of inevitability.

(1) *Definition of polar concepts.* The definition of polar concepts depends upon the value commitments of the analyst. For example, those analysts who view trends in kinship and family as movement toward liberation from traditional constraints and from obstacles to personal independence define the original state as confining and generally unjust and the future state as enabling emancipation from these obsolete social structures.

Family-theorist Ernest Burgess and associates (1963) view the evolution of family structure as going “from institution to companionship”—from external community constraints upon family relations to voluntaristic unity that derives from affection, domestic peace, and common goals. Similarly, Marxists define the transition as being away

from family structures required to sustain an economic system based on unearned rewards of the dominant class and suppression of the laboring class. Their claim is that following the rise of future true communism, the dissolution of economic classes would liberate family life from the constraints and suffering imposed by economic position; for Frederick Engels ([1885] 1942), under true communism, family life would be liberated from economic demands, and, founded on personal bonds, families would endure only as long as these bonds lasted.

By way of contrast, analysts favoring traditional values define the trend in family life as a steady decay of family structure. Pitirim Sorokin (1937, vol. 4, p. 776), upon whose work Zimmerman and Frampton base their typology, notes that “the family as a sacred union of husband and wife, of parents and children, will continue to disintegrate [T]he home will become a mere overnight parking place mainly for sex-relationship.” From another perspective, the behaviorist John Watson (1927) predicted that “in fifty years [1977], unless there is some change, the tribal custom of marriage will no longer exist. Family standards have broken down . . . The mystery and beauty of marriage and the rearing of children has pretty well broken down.” In the Aldous Huxley’s science fiction novel *Brave New World* (1955), all functions now performed by families would be community undertakings, and the word “mother” would be regarded as obscene.

The distinction between typologies focusing on personal liberation and those portraying decay highlights the fact that each approach deals with partial realities. Liberation typologies tend to slight disruptive activities of emerging family structure (e.g., spouse abuse, child abuse, splitting into factions, isolation from resources of kin and family). Instead, they tend to associate these activities with traditional family structures. In the Soviet Union, family problems were generally attributed to survivals of the traditional pre-Revolution family forms. Decay typologies do the opposite. They tend to underestimate unifying elements and personal satisfactions associated with the emerging family types and to overestimate the chaos associated with these types.

(2) *Problem of inevitability.* Some typologies posit a straight-line progression from a beginning

state to an end state, while others at least imply a degree of indeterminacy in movement. For any particular typology, the degree of indeterminacy depends on the analyst's conception of history. For example, the Burgess institution-to-companionship family typology assumes there to be a major historical evolution from fairly isolated rural communities to societies with a high degree of industrialization; the family and kinship institutions evolve through a long series of adaptations to keep up with the industrialization of societies and a movement from a rural to an urban way of life. Similar typologies—like Toennies's *Gemeinschaft* to *Gesellschaft* ([1887] 1957) and Redfield's folk society to civilization (1947)—are based on comparable assumptions deriving from the dictum of Henry Maine, namely, that, as an overarching historical trend, the basis for social relations has been evolving from status to contract.

Despite the inevitability of trends implicit in the definition of polarities of family and kin structure in typologies of liberation (or decay), with the passage of time, definitions of polarities change. For example, analysts have redefined the concept of companionship as an end-state. In the 1940s, Burgess (1948; Burgess et al. 1963) regarded the future end-state as one in which the husband and wife (1) would be married without interference from family and community constraints, (2) would remain united through affection and common interests, (3) would maintain an equality in decision making and other aspects of family status, and (4) would orient their parenthood toward producing children with healthy personalities. But variations in family life included under the "companionship family" definition have been broadly expanded over time. By the end of the twentieth century, the end-state of the companionship family (as well as the unstable-family concept) has been redefined to include a diversity of household arrangements, such as (1) couples living together without formal marriage, (2) same-sex couples and their children (by adoption or by birth from previous or supplementary liaisons), and (3) voluntary single-parent households. Given these modifications in the concept of the companionship family, the very nature of the typology has been transformed. As a result, it is difficult to determine what family and kinship theorists will consider to be the evolutionary outcome twenty-five years from the present.

According to Murdoch's (1949) depiction of main sequence theory (described earlier), the changing pattern of employment has facilitated the widespread movement of women into broad sectors of occupations. This change has affected the composition of residences and, subsequently, will affect the descent structure and eventually kinship terminology. Evidence of this development can readily be seen. Around 1960, in an offhand comment during a lecture, Murdoch predicted that the control over wealth in America (1) would flow increasingly into the hands of women, (2) would at some point create shifts in household patterns, and (3) in the long run would produce a kinship structure dominated by women. Regardless of the accuracy of Murdoch's prediction, changes in practices pertaining to kinship are appearing in various ways: (1) Newspapers obituaries have routinely begun to include "life companions" (of either gender) in the list of related survivors; (2) public policy pertaining to health insurance coverage has been modified in some communities to include unmarried domestic partners; (3) in some countries (e.g., Russia, Israel), intestacy laws have been amended to include unrelated household residents; (4) the issue of legally recognizing same-sex marriages (or domestic partners) as a valid arrangement has emerged in a wide range of communities.

Unlike the theoretical inevitability of collectively rational adaptations assumed by evolutionary theorists, the typologies formulated by cyclical theorists lead away from regarding their end-states as inevitable. In their portrayal of historical processes, the cyclical theorists have the burden of explaining conditions for triggering reversals in historical cycles. These reversals imply that critical periods arise through cultural innovations and conflicts. The effects of novelty and conflict in these critical periods introduce an indeterminacy into the historical process. This indeterminacy brings to the foreground the problem of the inhibition of change: What introduces a new cycle, and what brings the cycle to a halt? For example, as discussed earlier, Zimmerman and Frampton (1947) see the history of the family as a series of repetitive cycles: a decay from corporate family forms (based on idealistic values) to unstable, chaotic families (based on materialistic values and individualism), followed by a regeneration of familism. Their

scheme of analysis explains the oscillations between various degrees of familism and individualism in terms of a conflict between maintaining an enduring, traditional social structure and attending to persistent personal yearnings. The idealism of religious or ascetic values facilitates social stability in corporate family settings. However, the stifling of personal aims and desires, without idealism, encourages the adoption of materialistic values and sensuality associated with the unstable family. Hence, there is no guarantee that an old cycle will end or that new ideals supporting familism will again emerge.

A TRANSHISTORICAL TYPOLOGY OF KINSHIP AND FAMILY SYSTEMS

For well over a millennium, church intellectuals have been aware of variations in marital selection and their implications for family structure and kinship ties as well as for social structure. Early in the fifth century, in his *De Civitate Dei (City of God)*, Saint Augustine of Hippo (1984, pp. 623–625) noted that in early biblical times demographic insufficiencies made it necessary for Jews to practice kinship endogamy. However, he proposed that marrying close relatives, and thereby creating multiple family ties with the same people, restricted the potential expanse of social circles that could be tied into a coherent community. Kinship endogamy tends to divide societies into segments. On the other hand, marrying persons from previously unrelated families would “serve to weld social life securely” by binding diverse peoples into an extensive web of relationships. Later, in the twelfth century, Gratian suggested that God commanded the Hebrews to select relatives as mates “because the salvation of man was realized in the pure Jewish race” but that the Christian faith, which could be readily spread through teaching, made kinship endogamy obsolete (Chodorow 1972, p. 74).

Gratian’s argument suggests that the differences between Judaic and Christian marriage systems have broad implications for contemporaneous functions of kinship as well as for temporal functions, connecting past and future generations. The discussion that follows presents a kinship and family typology derived ultimately from Augustine’s and Gratian’s depictions of marriage systems as well as from issues pertaining to descent.

This typology involves theoretical concerns drawn from sociology and anthropology.

Contemporaneous and Temporal Functions of Kinship Systems. Both marriage systems and descent rules affect the character of links between contemporaneous networks of families. A major controversy that at one time occupied many social anthropologists was whether marriage systems (i.e., marital alliances between groups) are more fundamental in generating forms of social organization than are descent rules or vice versa. At stake in the controversy was the issue of whether the social solidarity undergirding descent rules is more fundamental than the ideas of reciprocity and exchange involved in marriage systems. In the end, Africanists favored descent rules, while Asianists leaned toward marital alliances. In their assessment of the controversy, Buchler and Selby (1968) found evidence for the validity of both views.

However, despite the chicken-and-egg character of the controversy, the alliance–descent issue highlights the contradictory nature of kinship structure. This contradiction is depicted in the opposing views of structuralists such as Claude Lévi-Strauss (1963), who supports the alliance position, and functionalists such as Meyer Fortes (1969), who argues for the descent position.

Alliance theories of kinship systems identify the primary function of kinship as the integration of networks of related families into the contemporaneous social fabric. Alliance adherents begin with marriage as the central element in structuring the way kinship operates. To alliance theorists, the significance of marriage lies in the idea that marriage is essentially a mode of exchange whose primary reason for existence is to inhibit conflict in society. In their view, kin groups exist as organized entities to effect marital exchanges. According to Lévi-Strauss, the leading figure in alliance theory, “exchange in human society is a universal means of ensuring the interlocking of its constituent parts” (1963, p. 2). In unilineal systems, women are exchanged for equivalent valuable property, services, or both; in bilateral systems (which by their nature become multilateral in the long run), commitments to each other’s relatives are exchanged. In bilateral kinship, bride and groom are of presumably equivalent value. Thus, in general,

alliance theorists regard descent groupings primarily as a necessary ingredient for sustaining the marriage exchange system over the generations.

The descent theory of kinship systems rests on the assumption that the continued welfare of kindred over the generations is the primary function of kinship. In particular, Fortes regards "filiation"—being ascribed the status of a child of one's parents, with all the lifetime rights and obligations attached to that status (1969, p. 108)—as the "crucial relationships of intergenerational continuity and social reproduction" (pp. 255–256). He proposes that, as a concomitant of filiation, "the model relationship of kinship amity is fraternity, that is sibling unity, equality, and solidarity" (p. 241), and he provides a biblical example of the tie between David and Jonathan. But he also notes that "the Euro-American kinship institutions and values of Anglo-Saxon origin are imbued with the same notion of binding force of kinship amity" (p. 242), and he cites the mother–daughter relationship in England (in research findings by Young and Willmott 1957) as exemplifying that same moral code of diffuse but demanding reciprocal obligations.

On the one hand, alliance theory postulates that the basic drive in kinship organization is derived externally, from the kind of alliances appropriate to the structure of power in the community. Collectively, marital alliances create between families a network of links that integrate them in reference to overarching religious, economic, and political institutions. On the other hand, descent theory ascribes the bases of organization to internal demands, structural factors in the persistence of the kindred: rules governing residential location, division of labor and authority among members, and the various economic and political functions to be performed by the kinship system (Buchler and Selby 1968, p. 129).

Given the contradiction in the impulse for kinship organization, there is an apparent "impasse between the alliance and filiation point of view" (Buchler and Selby 1968, p. 141). What appears to be at issue is the depiction of the kinds of reciprocity norms that define the character of kinship. Descent theory presumes that an axiom of amity (i.e., prescriptive altruism or general reciprocity) is basic to the coherence of kin groups; alliance theory holds that balanced reciprocity

(i.e., the rightness of exchanges for overt self-interest, opportunistic individualism, or noumenal norms) is in the final analysis the glue that integrates families and kin groups into a coherent whole.

The contradiction is apparent in many ways. For example, in biblical references and religious writings, the Ten Commandments enjoin one to honor parents and, conversely, to "cleave" to one's spouse and maintain peace in the household. In terms of kinds of reciprocity, one commandment involves unconditional giving or honoring, while the other concerns maintaining domestic peace (implying fair give-and-take).

Similarly, contemporary writers on marriage generally find the concept of balanced reciprocity appropriate in describing the quality of husband–wife ties. For example, Walster and Walster (1978) report that marriages work best when both husband and wife (as well as lovers) believe that each is receiving a fair exchange for what he or she offers in the relationship. Moreover, in their review of research on the quality of marriage, Lewis and Spanier (1982) note the importance of the symmetry of exchange in establishing and maintaining strong marital ties. However, in the socialization of children and in the allocation of resources, the rule of amity (or prescriptive altruism) is supposed to prevail. For example, parents are ordinarily expected to make "sacrifices" for their children when necessary; to do otherwise is to be a "bad" parent. In the American court system, the general rule for the disposition of children in cases of divorce, child neglect or abuse, or adoption is that the court should base its decision on the welfare of the child rather than on the interests of the parents or other parties.

To some extent, the descent–marriage contradiction can be obscured by compartmentalizing marital, parental, and filial conduct and by dividing responsibilities of husband and wife. However, conflicts in norms for dealing with family members and kindred may occur for several reasons, but they occur principally because of scarcities of time and resources required to carry out duties and obligations in the face of a wide range of simultaneous and conflicting demands. Since the resulting dilemmas are widespread in the society, there is a need for a general rule. Because contradictory alliance and descent impulses are operative, each group is pushed to establish a coherent

kinship scheme that gives priority to one impulse over the other or at least establishes some form of compromise between them.

There is evidence that rules governing marital functions conflict with those pertaining to descent functions, paralleling the alliance–descent controversy in kinship systems. Where descent functions are given precedence in family organization, marital functions are subordinated (and vice versa). Examples of this inverse relationship are (1) if husband–wife unity is central, then the unity between siblings is peripheral (and the reverse), and (2) if marriage between close affines is forbidden, first-cousin marriage is permitted (and vice versa). These examples are discussed in the sections that follow.

Marital Unity Versus Unity of the Sibling Group. Comparisons between societies indicate that ties between siblings have an inverse relationship to husband–wife ties. Where descent is valued over alliance or marriage in kinship relations, brother–sister bonds are particularly close (Parsons 1954), while the husband–wife relationship is relatively distant. In such family systems (whether or not its therapeutic implications are true), parents are expected to remain together for the sake of the children, and this expectation expresses the priority of descent over marital ties. Conversely, in family systems where the marriage function is more valued, the husband–wife relationship is intense (e.g., the importance of the give-and-take of love and of companionship for marriage) and the brother–sister relationship is competitive, distant, or both and the incest taboo justifies their apartness (see Lopata 1973 on widows and their brothers). In societies where priority is given to marital bonds over descent ties, the presence of children is of less importance in dissolving an unhappy marriage, and there is greater ambiguity about what is best for the children. The mere fact that the strength of brother–sister ties and that of marital ties vary inversely in different societies lends support to the proposition that there is a contradiction in the family system between its marital functions and its descent functions.

Affines and Cousins in American Marriage Law. The opposition between marital and descent functions in the family is also illustrated by the inverse relationship in American law of marriages

considered to be incestuous: As a general tendency, states that forbid second marriages between a person and certain affines (such as that person's parents-in-law and sons- or daughters-in-law) allow first cousins to marry, while those that permit marriage between close affines forbid first-cousin marriage (Farber 1968). If the preferred function of marriage is to reinforce close consanguineous kinship ties, then this pattern of marital prohibitions signals a subordination of affinal bonds to those of consanguinity. Marrying into the family of the former spouse will not reinforce any of the other existing bonds of consanguinity. Consequently, although first-cousin marriage is to be permitted in order to reinforce intimate kinship ties, marriage with close affines should be avoided. However, if marriage is considered to be primarily a mechanism for creating new bonds between previously unrelated families, then a second marriage into the same family merely serves to maintain the affinal bonds initiated in the first marriage.

Social Structure and Kinship Systems. The presence of contradictory impulses in organizing kinship ties produces a predicament in establishing priorities between them. This contradiction evokes a question: Which circumstances lead some societies (and ethnic and religious subgroups) to give priority to descent and others to favor alliance assumptions in their kinship and family organization (Farber 1975)? In their analyses of the relationship between kinship organization and social structure, both Paige (1974) and Swanson (1969) distinguish between societies that feature the legitimacy of special interests—factionalism—in organizing social life and those that feature the importance of common interests—communalism—as an organizing theme.

Factions are a means for gathering forces and mobilizing members for conflict or competition with other factions. They emerge as a reaction to perceived danger to their well-being from other groups (cf. Douglas 1966). Factions emerge where either (1) special interest groups vie for superiority over other groups for access to power, wealth, or some other property, or (2) groups sense a danger to their continued autonomous existence as an ethnic or religious entity.

In kinship organization, the continual mobilization of family and kin results in the generation of

norms that are centripetal in nature, that is, they facilitate the pulling inward of human, symbolic, and material resources. This centripetal tendency permits each kin group to separate itself from competing groups in order to endure. As a result, centripetal kin groups favor norms strengthening descent relationships over norms facilitating new alliances with other groups through marriage. Insofar as descent-group norms are rooted in the axiom of amity, one would expect centripetal kinship organization to feature the norm of prescriptive altruism over balanced reciprocities in kinship and family relations (see Farber 1975).

Jewish family norms provide some insight into the relationship between centripetal kinship systems and the application of the axiom of amity. In its basic ideology and in the code of laws supporting that ideology, Judaism assigns a major significance to the concept of nurturance (Farber 1984). Since nurturance is a central feature of maternal giving, it can be regarded as a metaphor for the axiom of amity. *The Code of Jewish Law (Shulkhan Arukh)* offers numerous instances that signify the place of nurturance in Judaism (Ganzfried 1963). For example, the code sublimates feeding and eating into sacred, ritualistic acts. The act of eating is invested with holiness, to be enjoyed in abundance, particularly on feast days and the Sabbath. A connection is made in the code between providing food and giving gifts and charity. It proposes that festive occasions are also times for charity to the needy and for sending gifts. In addition to drawing a connection between food and charity, the code applies the metaphor of the parent-child relationship to charity giving and assigns a priority to family in its general concept of nurturance: First parents, then offspring, and “other kinsmen take precedence over strangers” (Ganzfried 1963, chap. 34). The injunction to nurture children involves an emphasis not only on food but on other aspects as well (for example, an exaggerated emphasis on elaborated linguistic codes for use in child rearing). Zena Smith Blau (1974) writes that “whatever Jewish mothers did for their children—and they did a great deal—was accompanied by a flow of language, consisting of rich, colorful expressive words and phrases” (p. 175). The aim of socialization is presumably to turn the child into a *Mensch*—to transform the child from a receiver of nurture to a giver of nurture (Zborowski and Herzog 1952). Hence, in traditional Judaism, the concept of

nurturance seems to tie together the kinship emphasis on descent and the axiom of amity in organizing family relationships.

If nurturing the next generation is a form of prescriptive altruism, this nurturing can also occur in symbolic form. Like the transmission of physical wealth and nurturing, the parents can also transmit a “symbolic estate” to the next generation. In a real sense, along with material resources, people inherit a collection of living and dead relatives connected to them by birth and/or marriage. These relatives constitute a trove of heroes and villains whose personal qualities, exploits, and ideas are remembered in socializing succeeding generations. This “symbolic estate” defines for individuals (1) a sense of belonging to an identifiable “family,” (2) role models to emulate (or disown), (3) a legitimation of one’s place in community and society (Farber 1971). Craig (1979) sees the symbolic estate as a vehicle for achieving personal and familial immortality. Implicitly, it is one’s duty in centripetally-oriented kinship systems to contribute to the symbolic estate by living an exemplary life (however this way of life is defined in particular historical circumstances).

To be operative as memorials (or reminders), the content of symbolic estates must have some bearing upon the personal identities (or destinies) of family members. In Judaism, historically this meant assessing the “quality” of one’s ancestry (*yachas*), however defined; this assessment was particularly important in eras of arranged marriages. However, Yerushalmi (1982) notes the general importance of collective memory for the endurance of Judaism. Its centrality is suggested by the appearance of the verb *zakhar* (to remember) “in the [Hebrew] Bible no less than one hundred sixty-nine times” (Yerushalmi 1982, p. 5). Moreover, numerous memorials have been incorporated into holy day observances (e.g., the retelling of the story of the Exodus annually at the family *seder* at Passover). Especially significant for sustaining symbolic estates among Jews is the ritualizing of the remembrance of dead relatives through (1) memorial prayer services (*yizkor*) on four major holy days, and (2) partly as a means to continue to honor one’s parents after their death, the recitation of the prayer for the dead (*kaddish*) on anniversaries of the death of each family members.

The concept of symbolic estates connects collective family memories—such as legends, myths, and moral ideas—to the continuity of “family” from one generation to the next. In her study of Genesis, Steinmetz (1991) applies the concept of “symbolic estates” to the succession from father to son of the obligation to ensure the realization of God’s command to found and then maintain a Jewish nation. She regards the entire structure of Genesis as resting upon the transfer of this ideal to worthy heirs in the family line. Her emphasis upon the transmission of “symbolic estates” is echoed in an investigation by Bendor (1996) of the social structure of ancient Israel. Bendor concludes that Israeli social stratification is derived to a large extent from the kinship ideology of familial perpetuity—rather than from the influence of economic factors upon kinship and family life. The findings on ancient Israel by Steinmetz and Bendor bear upon historical and contemporary studies of kinship and family. Examples are the research reports by Pina-Cabal (1997) on family legends in urban Portugal, Attias-Donfut (1997) on home-sharing in France, Hastrup (1982) on establishing Icelander ethnicity, and Weigert and Hastings (1977) on maintaining family archives of photographs, old records, letters, and other memorials. The focus in these studies is upon symbolic mechanisms for sustaining family continuity. (The discussion of centrifugal kinship systems in the next section will describe obstacles to the perpetuation of “symbolic estates.”)

As opposed to factionalism, communalism implies a situation in which special interests are subordinated to common concerns of diverse groups. In stateless societies, these common concerns may well emerge from economic interdependence or the presence of a common enemy. In societies with a centralized government, the state presumably symbolizes a concern for the common welfare of the populace. Other unifying concerns may exist as well, for example, the presence of a universal church (as opposed to competing sects and denominations), nationalism (as opposed to ethnic self-determination), a centralized bureaucracy or market (as opposed to regional competition for dominance), and so on. The common concerns would best be served if members of kin groups were to be dispersed by marriage to previously unrelated people living throughout the society. This dispersal would maximize the number

of diverse kin groups with which any family is connected, and it would thereby scatter kinship loyalties, obligations, and property as widely as possible. Consequently, this kind of kinship system, associated with communalism, can be identified as applying an outward pressure upon its constituents; it is centrifugal in nature.

In contrast to the centripetal system, the centrifugal system subordinates kinship ties to conjugal family ties and extends marital prohibitions widely in order to inhibit marriages that would merely reinforce existing consanguineous ties. According to the theory outlined above, in centrifugal kinship systems, in which marriage functions are given priority over descent functions, the appropriate norm for defining family interaction is balanced reciprocity—exchange rather than the axiom of amity.

In the United States, although the centrifugal kinship system appears in a wide range of socioeconomic, religious, and ethnic groups, it is found disproportionately at lower socioeconomic levels, where families seek improved integration into the larger society (Farber 1981).

The application of balanced exchange as a norm in family and kinship is exemplified in a study of poor families by Stack (1974). She describes the prevalence of “swapping” as a named, bartering norm governing both ties between kin and between family members in their struggle for survival. Stack notes that “reciprocal obligations last as long as both participants are mutually satisfied” and that they continue such exchange relationships as long as they can “draw upon the credit they accumulate with others through swapping” (p. 41). Indeed, according to Stack, “those actively involved in domestic networks swap goods and services on a daily, practically an hourly, basis” (p. 35). But this exchange does not constitute a playing out of the axiom of amity since “the obligation to repay carries kin and community sanctions” (p. 34) and it extends beyond family and kin to friends. Although swapping may involve some element of trust, it exists to ensure exchanges in the lean times that predictably recur in domestic networks that are too marginal in resources to be magnanimous. It pays to create numerous bartering arrangements rather than to accumulate obligations within a very small network of intimate kin. Thus, in its own way, swapping mimics the proliferation of

networks of previously unrelated families characteristic of centrifugal kinship systems.

In contrast to the importance of “symbolic estates” for facilitating the “immortality” of families in centripetal kinship systems, families in centrifugal systems are often characterized by a “legacy of silence.” This silence may signify the existence of shameful or immoral acts of relatives, or it may simply reflect an emphasis upon individualism in these families. In Germany after World War II, this “legacy of silence” functioned to erase the collective memory of parental activities and ideas they held during the Nazi era (Larney 1994, pp. 146–162). For victims of torture and displacement under the Nazi regime, the legacy of silence enabled them to wipe their degradation from memory (Bar-On 1989). In either case, whereas symbolic estates provide a vehicle for family continuity, the legacy of silence established a discontinuity.

The German experience may result in a single break in family continuity—to permit starting afresh. However, the institutionalization of the legacy of silence in centrifugal kinship systems perpetuates this discontinuity between generations of nuclear families. This legacy has been found to be prevalent in low socioeconomic-level families populating urban slums (Farber 1971). Families tend to exchange little information about one another; in fact what is hidden may permit closer ties between kin than the revelation of illicit or immoral acts. Then too, in families where welfare agencies and police intrude, silence serves to maintain the privacy of the household.

The tacit norm of collective forgetting in these centrifugal kinship systems places the onus for kinship unity upon mutual assistance, friendship, and availability of kin. Yet, in her study of kinship among poor racial and ethnic minorities, Roschelle (1997) found that degree of mutual assistance between families and extent of interaction among relatives depend largely upon availability of kin. Migrant families frequently are isolated in time of need and the legacy of silence may thereby be enhanced.

In a society marked by much internal migration and social mobility, there are many opportunities for a proliferation of centrifugal tendencies in kinship. Whether centrifugal systems actually emerge through mobility may depend upon a

variety of factors. Gullestad (1997) notes a shift in the meaning of kinship in urban Norway. She describes a social transformation from norms regarding “being of use” and social solidarity to self-realization and “finding oneself” (or “being oneself”), that is, from norms sustaining family continuity to norms fostering separation and discontinuity. She attributes this shift to “transformed modernity” involving “fundamental restructurings of home and neighborhood because women and children are not present in the same way or to the same extent as before” (Gullestad 1997, p. 210). Transformed modernity, as well as advances in reproductive technology, is identified also as a factor in the proliferation of diverse forms of kinship structure in contemporary society (Strathern 1992).

One can interpret the emergence of feminist movements as both stimulating and stimulated by the “transformed modernity” cited by Gullestad. For some forms of feminism, post-modern thought provides a rationale for denigrating traditional symbolic estates. Post-modern writings propose that the framing of “factual” and theoretical statements have an exclusionary element—that is, they mark a population segment for exclusion from free participation. These “factual” statements justify this exclusion. As “factual” statements, posing as objective discourses, these statements have a hidden core. This core reflects the special interests of those with the power to define “truth” for the society. (See Foucault [1971] 1996.) Certain feminists claim that the hidden core of meaning in statements justifying exclusion of women from full participation in society is to promote male dominance in social structure (Barnard 1993). The symbolic estates that facilitate the endurance of existing lines of descent are thus seen as supporting patriarchy. Consequently, they are regarded as an obstacle to the full participation of women in society. Yet, as women’s participation in economic and political spheres continues to expand, it is likely that symbolic estates will eventually be infused with a marked increase in content pertaining to exploits and interests of women.

Kinship-Map Typology. Although mapping of kinship ties cannot express all aspects of kinship relations, it can generate models expressing general orientations implicit in various patterns of kinship structure. Basically, genealogical maps of

consanguineal (“blood”) relationships merely locate positions in an ideal web of biological connections. Variations in mapping come into play when these maps are used to describe how one’s obligations and proscriptions vary in different kinship structures. Such obligations and proscriptions pertain to marriage, remarriage, birth and adoption, inheritance, relations between generations and genders, and so on.

One advantage of models of genealogical mapping is that these models express the logical connections between functions of kinship in a particular society and priorities assigned to different kin statuses. For instance, a kinship type with a prohibition to marry a first cousin generally has a different function in society as compared to one permitting such marriage. This pattern of marital prohibitions will likely be related to priorities in inheritance. For instance, in American state laws, permitting first-cousin marriage would be associated with giving a niece or nephew precedence over a grandparent in intestate inheritance (i.e., when there is no written will). The opposite will likely be true where first-cousin marriage is forbidden.

The relationship between genealogical mapping and functions of kinship has a long history in Western civilization. Atkins (1974) has explored a wide range of formulae for generating different patterns of priorities in mapping genealogical relationships. Implied in genealogical mapping is the principle that the smaller the number of links (by birth or marriage) between relatives, other things being equal, the greater is the degree of obligation between them. Thus, in such matters as succession to estates, when a choice is to be made among kin, genealogically close relatives are presumed to be given priority over more distantly related kin. However, since the various formulae differ in the patterns of priority among kin generated, choice of an appropriate pattern of mapping depends on the role of kinship in the particular society.

In general, three patterns of priority for mapping kin have been applied in the Western world (mainly in laws of intestacy and marriage). However, in practice, each society makes modifications in these patterns to fit its needs. Examples of these patterns occur in (1) Catholic canon law and the state of Georgia, (2) the civil code of the Twelve Tables of the Roman Republic and more recently in Napoleonic Code and Louisiana law, and (3) the

parentela orders in the Hebrew Bible and in abbreviated form in Israel, Germany, and various states (e.g., Arizona) (Farber 1981).

At one pole, the canon law of the Catholic Church stipulates that a function of the church is to create a unity that ties together diverse segments of its constituency in a web of extensive relationships (including family bonds). This aim implies that collateral ties between families are equal in importance to ties between ascendants and descendants (i.e., between generations). Under such conditions, ties between are extended outward in a centrifugal fashion. In laws governing marital prohibitions, marriage is discouraged within the second degree of distance of collateral kin (i.e., first cousins). In earlier generations, marital prohibitions in Canon Law were even more inclusive; for example, in thirteenth century, consanguineous marriages were prohibited within the fourth degree of relatedness.

In assigning distances from Ego in the canon law genealogical model (e.g., for priorities in inheritance), (1) all consanguineal members of Ego’s nuclear family (parents, siblings, and children) are one degree of distance from Ego, (2) relatives just outside the nuclear family are two degrees of distance (grandparents, aunts and uncles, first cousins, nieces and nephews, and grandchildren), and so on. The canon law model thereby expresses the general principle that neither line of descent nor collateral distance is given special emphasis—only degree of distance from one’s nuclear family is significant.

At the opposite pole, the parentela orders genealogical model places much emphasis upon line of descent (and among collateral relatives, the closeness of line of descent). Like the sociobiological ideal, the parentela orders model is oriented toward the survival of any given line of descent (or failing that, the next closest line of descent). This model expresses centripetal tendencies in kinship structure. In marriage law, collateral prohibitions are minimal, and marrying someone in the closest line of descent (first cousin) is preferred.

As the parentela orders model is applied to intestacy law, the centripetal principle is expressed in the Hebrew Bible in Numbers 27:8–11 and 36:7–9. In this model, priorities among relatives are allocated by line of descent: (1) Direct descendants of Ego are given first priority (children,

grandchildren, etc.); (2) if there are no direct descendants, those of Ego's parents are given next priority (siblings, nieces and nephews, etc.); (3) next in priority are descendants of Ego's grandparents (aunts and uncles, first cousins, etc.)—and so on. In theory, Ego's estate will be passed on to the closest survivor in the closest line of descent to Ego's.

Between the extremes of centrifugality of the canon law model and the centripetality of the parentela orders model stands the civil law model. This model gives somewhat more weight in assigning closeness in kinship distance to direct-line ascendants and descendants than to collateral relatives (i.e., those related to Ego through a common ancestor). In computing kinship distance from Ego, the civil law model counts generations between Ego and the common ancestor as well as generations between the other relative and the common ancestor; for direct-line relatives, only those generations between Ego and the other relative need be counted. Obviously, the nearer the common ancestor is to Ego, the closer is the collateral relative in genealogical distance (and vice versa). Thus, Ego's grandparent is closer genealogically than a niece or nephew; the reverse is true for parentela orders priorities, and both are equidistant from Ego in the canon law model.

Several social surveys have been undertaken to test empirically the above propositions about ways in which people's conceptions about priorities assigned to different relatives in kinship mapping are actually reflected in their lives—religious affiliation, socioeconomic status, minority status, and so on. In these surveys, the respondents were asked to choose priorities among kin (for which the kinship-map models differ) if they were to write a law to govern intestacy (i.e., where there is no written will). For ten pairs of relatives for whom the kinship models differed in assigning a priority, within each pair, the respondents were to select the relative they thought should have precedence (as a general rule). (Equal priority was one alternative.) Respondents were then classified according to the kinship model to which a majority of their choices conformed.

The first surveys were undertaken in the United States (Farber 1977, 1979). The results indicate that Jewish respondents do indeed tend to view priorities from the perspective of the parentela orders model, while Catholics tend to be

overrepresented in the canon law category. Of course, these are tendencies and not blanket findings covering all Jews or Catholics. For example, the degree to which a religious grouping adheres to scripture and/or ritual practices seems important in influencing kinship mapping. When religious branch was taken into account, responses of Jews who identified themselves as Conservative (a fairly traditional branch) tended to conform to the parentela orders model and none conformed to the canon law model, while those in the Reform category more often conformed to the canon law model than to the parentela orders model. Similarly, among Mormons whose marriage was sealed in the Temple, their responses were like those of the Conservative Jews, whereas those whose marriage was not sealed for time and eternity responded like Reform Jews. Moreover, neofundamentalist Protestants were the only other religious grouping overrepresented in the parentela orders category (Farber 1981, pp. 73–75).

Taken together, the above findings suggest that the parentela orders model tends to be prevalent in groupings where endurance of the particular religious community into the distant future may be problematic. The community would then be motivated to intensify its inward pull—its centripetal incentive—to keep succeeding generations within the fold.

In the course of one investigation (Farber 1981), a reanalysis of findings yielded a fourth kinship model. This model, whose computation is the reverse of the parentela orders model, emphasizes obligations to ancestors who have been responsible for preparing the groundwork for Ego's place in society. In the serendipitous model, Ego's direct ancestors are given priority over any descendants—first priority is given to parents, grandparents, and so on; the next set of priorities consists of Ego's children, then Ego's brothers and sisters, aunts and uncles, great-uncles and great-aunts, and so on; following these, Ego's grandchildren, nieces and nephews, first cousins, and on and on (Farber 1981, p. 50).

The serendipitous model was disproportionately prevalent in several sectors of respondents—nonminority Protestants, those in professional and managerial occupations and at higher income levels, and those persons with U.S.-born fathers. In

addition, persons who conformed to this model tended to come from smaller families (Farber 1981, p. 217) and expected to have fewer offspring than did other respondents (Farber 1981, p. 147). Since almost half the sample studied conformed to this model, it seemed appropriate to name it the Standard American model. The U.S. findings on the standard American model are consistent with Alexis de Tocqueville's observation made almost two centuries ago in *Democracy in America* ([1850] 1945), namely, that compared with Continental Europeans, Americans live in the present and show little interest in the perpetuation of family lines.

European data on the genealogical models throw further light on differences in the conception of kinship priorities between U.S. and Continental populations. An investigation in central Europe (Vienna, Bremen, and Cologne) shows parentela orders to be by far the most prevalent kinship model, especially among those families at upper socioeconomic levels (Baker 1991). By way of contrast, Baker's (1991) data from Dublin, Ireland, tend to be similar to the American findings: Jews display a strong tendency to conform to the parentela orders model, while Protestants and Catholics favor the standard American model (called by Baker the intercultural bourgeois model). Despite all the changes that have occurred over the generations, traditional perceptions of priorities in kinship claims still persist.

The typology of kinship maps (or collaterality models) is a heuristic for understanding an implicit theory of the workings of kinship structure. In itself, the typology is too simplistic to denote the complexity of norms and values and the operation of mechanisms involved. But these criticisms about the heuristic character of the types of collaterality models can be applied to all typologies used in kinship analysis. They are merely methodological tools for gaining insight into what is going on. To gain this insight, one forgoes the many nuances that give color to understanding the functioning of kinship.

Related Transhistorical Typologies. Variations on issues pertinent to the structural contradiction typology have been developed in other transhistorical schemes associated with the role of marriage and descent systems in organizing family and kinship

systems. For instance, Guichard (1977) distinguishes between Eastern/Islamic and Western/Christian kinship systems. According to his typology, in the Eastern system, (1) descent is patrilineal; (2) marital ties are weak, and polygyny and easy divorce are permitted; (3) close ties exist between kin related through male lineage groups; (4) strong preference is given to endogamy within patrilineages; and (5) the sexes are segregated and women are relatively secluded within the home. In contrast, in the Western system, (1) kinship is bilinear or bilateral/multilateral, with ties to the maternal family considered important and with an emphasis on affinal connections as well; (2) marital bonds are the dominant unifying feature in family and kinship, with monogamy as prescribed and with extended kin ties as weak; (3) kin ties are defined according to individual connections rather than by lineage groups, with an emphasis on the ascending line rather than the descending line and with little importance attached to lineal continuity or solidarity; (4) kinship exogamy is prescribed, with endogamy permitted primarily for economic reasons; and (5) interaction between the sexes occurs in a wide range of circumstances.

In his reaction to Guichard, Goody (1983) revives the anthropological controversy between alliance theory and descent theory. Goody criticizes Guichard for basing his typology on marital norms (i.e., the endogamy-exogamy distinction) and suggests that by not starting with descent factors (i.e., inheritance practices), Guichard has overlooked a more fundamental distinction—that between kinship systems in which property is passed from one generation to the next through both sexes (by means of inheritance and dowry) and those systems in which property is transmitted unisexually (usually through males). Goody contends that passing property down unisexually encourages the development of corporate kinship groups (e.g., African systems). However, the use of bilateral devolution discourages such corporate structures, and Goody places both Eastern and Western systems in Guichard's dichotomy in the bilateral category. He faults Guichard for overstating the existence of corporate structures in Eastern kinship and proposes that Guichard's Western type represents merely a later historical development away from its roots in the Eastern system. Goody sees the primary problem of explaining the character of family and kinship in Western society

as one of discerning how European societies shifted from preferred kinship endogamy (e.g., first-cousin marriage) to prescribed exogamy.

In his analysis of European kinship, Goody considers the changes introduced by the Christian (i.e., Roman Catholic) church from its beginnings to the late medieval period. He interprets the shift from kinship endogamy to exogamy mainly as a strategic move by the church to gain control over the lives of its members. As part of this effort, it had to wrest access to resources (especially productive land) from enduring control by family and kin. As a result, church laws evolved favoring those norms that might enhance allegiance to the church and weaken competition from the family and the state. In consequence, the church favored (1) the use of testation permitting bequests to the church; (2) the prescription of kinship exogamy as a means for inhibiting both the reinforcement of close kin ties and the passing down of resources exclusively within lineages; (3) the requirement of the consent of both bride and groom in marriage; (4) late marriage as a means for weakening family control over mate selection; (5) prohibition of divorce even for childless couples; and so on.

Goody seems to overstate his case in trying to interpret the shifts in kinship in ways that are consistent with his basic typology. For example, in giving primacy to inheritance patterns, Goody asserts that the ban on divorce in Roman Catholicism was devised primarily to encourage bequeathing estates to the church in case of childlessness. But, in fact, when there were no children, bequests usually were made “to brothers and sisters and to nieces and nephews” (Sheehan 1963, p. 75). Moreover, Goody’s explanation of the ban ignores the widespread practice of bequeathing a portion of one’s estate to the church even when one left a widow, children, or both. Sheehan (1963) reports that these bequests were made for the good of the soul: “Among the Anglo-Saxons, bequests to the parish church became so general that they were eventually required by law” (p. 292). This practice was not restricted to England. According to Sheehan, “Christians in the Mediterranean basin had developed the practice of bequeathing part of their estate in alms” (p. 303). Thus, church heirship in medieval Christian Europe was tied to repentance regardless of the existence of familial beneficiaries. Since church acquisition did not have to depend on bequests from childless couples, it is

unlikely that the ban on divorce derives primarily from the desire of the church for additional benefices.

In addition, Goody dismisses the intermittent presence of kinship endogamy in medieval Europe as opportunistic deviations from the moral injunctions of the church. Yet, as Duby (1977) indicates, in medieval Europe the ebb and flow in kinship endogamy was tied to the amount of emphasis given to strengthening lines of descent. For example, Duby notes that in northern France, from before the tenth century to about the middle of the eleventh century, there was little utilization of the concept of lineage and only vague awareness of genealogy and knowledge about ancestors. Prior to that time, even members of the aristocracy considered their family to consist of “a horizontal grouping” of neighbors and kin “whose bonds were as much the result of marriage alliances as of blood” (Duby 1977, p. 147). Then, beginning in the tenth century, there was a change in ideas and norms regarding kinship—a conscious strengthening of lineage by controlling marriage, which frequently took place between close relatives despite impediments in canon law (Canon Law Society 1983). To summarize, Goody’s argument is that medieval deviation from canon law consisted of opportunistic economic decisions and did not derive from a different set of norms. But Duby describes the coordination of kinship endogamy with the emerging notion of the legitimacy of lineage—a complex of ideas that requires a consensus among the kin in order to be effective. Hence, it appears that the change in marriage rules and the significance of lineage signaled more than ad hoc departures from church law.

There is still another reason for questioning Goody’s conclusions: Goody makes the point that through bequests the Catholic church became the largest landowner in Europe. In his focus on the growth of exogamy as a consequence of the devolution of estates to both sexes, he has overlooked the church’s own involvement as a major heir in the inheritance system. Particularly in the light of the church’s view that ties through faith are equivalent to blood ties, the church is identified with spiritual kinship (Goody 1983, pp. 194ff). However, if it is legitimate to consider the church as an heir on a par with familial heirs, the system becomes one of *trilateral* devolution—sons, daughters, *and* the church. In that case, the European

system differs markedly from the Eastern kinship system described by Guichard. Indeed, in contrast to Judaism and Islam, Christianity, at least until the end of the medieval period, saw family and kinship ties as *competitive* with church interests, and the strategies the church applied to weaken these ties altered both the marriage and the inheritance systems. The data imply that, despite their contradictory implications, the marriage, the alliance component, and the descent component should be addressed as equal factors in organizing family life. A task that remains is to integrate typologies of the emergence of modern kinship systems with transhistorical, structural typologies.

LABOR FORCE

Although labor-force concepts were originally designed to study economic activity and guide government policies, economic activities are a form of *social* behavior with numerous social determinants and consequences. Hence labor-force behavior has been the subject of a substantial body of sociological research.

MEASUREMENT

The U.S. Bureau of the Census developed the labor-force concept to measure the number of working-age people who were economically active during a particular time period—the calendar week preceding the sample interview (Cain 1979; U.S. Bureau of Labor Statistics 1982). It has two components: (1) *The employed*: those who, during the reference week, did any work at all as paid employees, were self-employed, or worked as unpaid family workers at least fifteen hours in a family-operated enterprise; included also are those who were employed but on vacation, home sick, etc. (2) *The unemployed*: those who were not employed during the reference week but who were available for work and had actively sought employment sometime within the preceding four-week period. All those who are neither employed nor unemployed

are defined as being out of the labor force and primarily include students, housewives, the retired, and the disabled. Since the size of the population affects the number of people who work, labor-force measures are usually expressed in ratio form. The *labor-force participation rate* is the percentage of the total working-age *population* that is in the labor force, while the *unemployment rate* is the percentage of the *labor force* that is unemployed. In order to compare particular subgroups in the population, analysts compute group-specific measures such as the percentage of all women versus men who are in the labor force or the percentage of black versus white labor-force members who are unemployed.

The Census Bureau developed the labor-force concepts during the Great Depression of the 1930s in response to the government's difficulty in charting the severity of unemployment during that crisis. Prior to 1940, measures of economic activity were collected only at the time of the decennial censuses, making it impossible to track business-cycle fluctuations in unemployment; for example, most of the Great Depression came between the 1930 and the 1940 censuses. Hence, in order to provide ongoing unemployment data, the Census Bureau initiated the monthly Current Population Survey in the 1940s.

A second problem was the ambiguity of the previously used measure of economic activity—the “gainful worker concept”—which was designed to ascertain individuals' *usual* occupation, if they had one, rather than whether they were actually working at any given time (Hauser 1949). In fact,

census enumerators were often specifically instructed to record an occupation, even if the individual was currently unemployed, thus *overstating* the number employed. On the other hand, some kinds of employment were often *underestimated* because people who considered their market work to be secondary to their other activities, such as taking care of the home and children or going to school, were less likely to report themselves as employed in response to a question on their usual occupation. Misreporting of this type is unlikely with the labor-force measure since most people will remember whether they had worked at all the previous week or, if not, whether they had been looking for a job. Information on occupation and on other important characteristics of their employment, such as hours worked, was then obtained separately in response to additional questions.

While labor-force concepts are relatively unambiguous measures of current economic activity, they too exhibit problems. One general concern is the adequacy of the unemployment measure. The extent of unemployment may be understated if persistently unemployed persons eventually give up trying and drop out of the labor force. The Census Bureau has therefore included additional questions to try to ascertain the number of such “discouraged workers” as well as to measure additional aspects of unemployment or underemployment (Cain 1979; Bregger and Haugen 1995). Clifford Clogg and Teresa Sullivan have extended this approach to address the larger question of “underemployment” (Sullivan 1978; Clogg and Sullivan 1983). They have developed and applied a variety of indicators of underemployment in order to achieve a more extensive assessment of the problem. In addition to the usual unemployment rate and estimates of discouraged workers, they use three other indicators—a measure of involuntary part-time work (due to economic factors); low work-related income relative to the poverty level, and a measure of the proportion of workers who are “overeducated” (“mismatched”) for the jobs they hold. The “adequately employed” are all those who are not underemployed in any one of these five categories. Their results indicate that underemployment is more common among the young and the old, and appears to have increased in recent years. While several of the indexes, particularly the mismatch measure, are somewhat

controversial (Keyfitz 1981), the work of Sullivan and Clogg represents an important innovation in the multidimensional measurement of underemployment.

A major characteristic of the labor-force concept is that it is a measure of *market-oriented* economic activities. People are considered employed only if they work for pay (or in the production of goods or services for sale). Yet there is a considerable amount of economic production for *home* consumption. Hence, labor-force status per se is an imperfect indicator of whether an individual is economically productive; for example, full-time homemakers are never counted as employed although they usually put in long hours producing goods and services for their families. However, if the market-oriented nature of the measure is kept in mind, this limitation is not too serious in a modern industrial society. Increases in married women’s labor-force participation can then be interpreted as indicating their growing participation in the *market* sector of the economy, usually in addition to their *home* productive activities, although working wives do less housework than nonworking wives (Vanek 1974; Berardo et al. 1987).

More serious problems arise in comparing societies at different levels of economic development (Moore 1953). Preindustrial subsistence economies produce few goods or services for a market. As societies develop economically, an increasing proportion of labor is sold in the marketplace, and the goods and services families consume are also increasingly purchased rather than home-produced. It is often difficult to undertake a meaningful comparison of labor force or unemployment rates among such different economies. The measurement of agricultural employment, especially that of women and youth, can be particularly problematic in countries with a large subsistence sector, and measurement inconsistencies are common (Dixon 1982). Moreover, *unemployment*, especially in rural areas, is often manifested as *underemployment*, and its extensiveness is difficult to determine.

Although best suited for examining whether people are currently economically active, labor force and employment status measures have also been invaluable in the analysis of more complex sociological and economic concepts because of

the ready availability of these data in time series. However, here it is important to recognize the ambiguities and limitations of such measures at the same time we exploit their utility. One example of this problem has to do with charting the extensiveness of changes in married women's economic role in the family; another concerns the measurement of life-course transitions such as the transition to work or to retirement. In the first case, the frequently reported time series of the changes in the average proportion of married women who were in the labor force in any given week each year, or even of the proportion who had worked at some time during a year, are valuable but also imperfect indicators of how extensively women's economic role has changed over time. For example, the proportion of married women with children under age 18 who were employed at some point during the year rose from 51 to 73 percent between 1970 and 1990. However, although the proportion who worked full-time, year-round had also increased considerably, it had only reached 34 percent by 1990; of women with children under age 6, only 28 percent had worked full-time year-round in 1990 (Bianchi 1995, p. 117). Hence, the commonly used time series of married women's labor-force status during as short a time period as a week will exaggerate the magnitude of the changes in wives' economic role in the family. And neither annual labor-force participation rates nor the weeks and hours worked during a whole year provide longitudinal data on the extensiveness of individual women's labor-market involvement over their adult life courses. Yet it is this sort of information that we would really like to have in assessing the changing nature of women's economic roles.

Although commonly used for this purpose, labor-force or employment status data also have their limitations as indicators of the timing of life-course transitions. The problem is that life-course transitions are not as clear-cut as the data make them appear (Oppenheimer and Kalmijn 1995; Oppenheimer et al. 1997). Students are increasingly likely to be working, at least part time, and young people go in and out of the labor force before they are able—or willing—to make a regular commitment to year-round full-time employment. Hence, the proportion of young people employed in any given week overstates whether they have completed the transition to work. Changes

in the proportion of *older* persons who are currently employed is also an ambiguous indicator because of a fair amount of labor-market turnover among this age group as well. Hence, some studies of retirement use information on when individuals start to receive pensions. However, older persons may be receiving private pensions and/or Social Security but still be working, if only part time; moreover, the retirement these pensions signify may not be entirely voluntary, complicating our interpretation of the phenomenon. So the goal of measuring when "permanent" withdrawal from work occurs can be quite elusive (Guillemard and Rein 1993; Henretta 1992).

DETERMINANTS AND CONSEQUENCES OF LABOR-FORCE CHANGES

The size and rate of growth of the labor force are dependent on three factors:

1. *The size and rate of population growth.* A large and/or rapidly growing population will produce a large and/or growing labor force.
2. *The propensity of the population to enter the labor force and how this varies among population subgroups.* Age and sex, and what these signify biologically and socially, are the major reasons for varying propensities. Infants and young children do not work, but, generally starting in adolescence, labor-force participation increases with age, peaking for those in their late thirties and early forties and starting an accelerating decline thereafter. Married women, particularly mothers of young children, have historically had lower labor-force participation rates than adult males, although this is much less so now than in the past (U.S. Bureau of the Census 1998, pp. 408–409).
3. *The composition of the population:* Since different population segments have different work propensities, the composition of the population will affect the overall proportions who are in the labor force. Sharp *short-run* fluctuations in the U.S. birthrate have led to corresponding variations in the relative size of the working-age population. Baby booms greatly increase

the number of new labor-force entrants after 16–18 years, while baby busts reduce this number. However, the overall *long-run* declines in U.S. fertility, combined with declines in mortality among the elderly, have increased the relative number of elderly in the population, an age group with low work propensities. On the other hand, foreign migration to the United States somewhat counteracts the effects of an aging population, since it has historically been disproportionately composed of young working-age adults, drawn to the United States by job opportunities.

One important long-term trend in labor-force participation in the United States has been the decline in the employment rate of young men, on the one hand, and of older men, on the other. In part, the decline for *younger* males has been due to more extended schooling, although this was somewhat offset by a rise in student employment (U.S. Bureau of Labor Statistics 1988). However, an additionally significant factor has been a decrease in the employment of moderately to less educated males, itself just one aspect of a trend in rising labor market inequality, encompassing declines in earnings as well as levels of employment (Burtless 1990; Levy 1998).

Another important long-term shift is the decline in the labor-force participation of older males, primarily due to the institution and spread of the social security system combined with the greater availability of disability benefits and private pensions. However, these declines have been observed not only for men aged 65 and older but also for men in their fifties and early sixties, although not to the same extent. Thus the labor-force participation rates for men aged 65–69 decreased from 64 percent in 1950 to 26 percent in 1990, but during these years the rates of men 60–64 and 55–59 also substantially declined, from 83 to 56 and from 90 to 80 percent, respectively (Gendell and Siegel 1992, p. 24). The increasing coverage of Social Security benefits for men retiring at age 65 and the institution of early retirement, at age 62, under the Social Security Act of 1962 has played the major role in the decreasing rates for those in their sixties. However, the declines for men in their fifties must be for other reasons. One important factor seems to be the growth of private pension

plans and employers' utilization of early retirement provisions to help downsize and restructure their firms (Guillemard and Rein 1993; Henretta 1992).

An important question is: How will the rapid rise in the older population affect the labor-force participation of older people? There is by no means an obvious answer to this question. For one thing, given the sensitivity of older persons' employment behavior to when Social Security is available, future changes in how old individuals must be in order to qualify for Social Security benefits will play an important role. Already the 1983 amendments to the Social Security Act have set in motion a rise in the age of entitlement to a full pension—from age 65 to 66 by 2009, and to 67 by 2027—and a higher rate of reduction will gradually be applied to pensions for those who retire earlier than 65. These changes in the law should operate to increase labor-force participation among the elderly. Other factors may also increase the employment of men in their fifties and sixties. Traditionally, the decline in employment over time has been disproportionately concentrated among the less educated who have fewer marketable skills and for whom the Social Security pension is relatively more attractive. However, with the rising educational attainment of the population, older adults in the twenty-first century might be expected to remain employed longer (Besl and Kale 1996). On the other hand, the state and structure of the economy is an important factor in the extent to which employers use private pension plans to encourage earlier retirement in periods of downturns or rapid structural change.

Probably the most substantial postwar change in employment behavior has been the enormous increase in married women's labor-force participation. While paid employment used to be generally limited to the period between school and marriage, since the 1940s married women's employment has become so prevalent that by 1997 between 66 and 76 percent of those in the 20–44 age groups were in the labor force. Moreover, 64 percent of married mothers of children under age 6 were also in the labor force (Oppenheimer 1970; U.S. Bureau of the Census 1998).

There are several reasons for this rapid rise in women's employment. One is that the bureaucratization of government and industry has raised the

demand for clerical workers; population growth, prosperity, and rising living standards have greatly expanded the consumption of services. This, in turn, raises the demand for sales workers and for those in the “helping” professions, such as teachers and social workers, as well as nurses and others in health-related occupations. All these are occupations that have been dominated by women workers for over a century. However, because the great majority of young, single, out-of-school women have worked throughout the twentieth century, the result of this increasing demand in the postwar period has been a strong and continuing demand for a previously underutilized source of female labor—married women (Oppenheimer 1970).

Married women have often had several major reasons for wanting to work—the need, early in marriage, to help set up a new household and perhaps to save money for a down payment on a house; the increasing importance of saving for children’s schooling; the couple’s aspiration to achieve a high level of living; and the desire for greater personal economic security and autonomy. Periodic rises in the cost of living and the stagnating or even declining economic position of many men since the 1970s have also increased the importance of having two earners in a family (Levy 1998).

The effects of changing labor-force behavior are not just limited to the economic realm; a number of sociologists (as well as economists) have argued that this behavior has also had an important impact on marriage and the family. Since the late 1960s the average age at marriage has risen substantially, after having first declined through most of the twentieth century; nonmarital cohabitation has become increasingly prevalent; and marital instability has accelerated its long-term upward trend after a sharp reversal in the early post-World War II period. However, the divorce rate appears to have stabilized recently. Two competing employment-related explanations for these trends are currently under debate. In one, the argument is that married women’s rapidly rising labor-force participation has increased their economic independence of males (Becker 1981; Espenshade 1985; Goldscheider and Waite 1986; Farley 1988; McLanahan and Casper 1995). The result, it is argued, is a decreasing desire on the part of women to remain in an unhappy marriage or even to marry at all. In addition, since women’s

traditional time- and energy-consuming familial roles of childbearing and childrearing compete with the pursuit of individual career goals, more women are either forgoing childbearing entirely or settling for one or two children at most.

While the women’s “independence” hypothesis appears plausible and the juxtaposition of time series data on marriage and family behavior with that of women’s labor-force participation appears to support it, this is largely because the time series utilized have typically been limited to the postwar period, the period during which married women’s employment was rising rapidly. The problem with these comparisons is that they use the family behavior of the early 1950s as the model of “traditional” family behavior against which to compare subsequent trends. However, the marriage and fertility behavior of the 1950s was by no means traditional (Cherlin 1992; Oppenheimer 1994). This was the baby boom era when, after a 150-year decline, the total fertility rate reversed itself and rose so much that, by the 1950s, it was back up to the level of 1900. Moreover, age at marriage had been decreasing throughout the twentieth century, at the same time that women’s employment was rising, so that the early postwar age at marriage was much younger than what was “traditional” before married women’s employment began its historic climb (Cherlin 1992; Oppenheimer 1994). In sum, the changes since the 1960s are more of a return to traditional patterns than a major departure from them. The independence hypothesis has also not held up to more recent micro-level empirical analyses using longitudinal data. For example, as summarized by Oppenheimer (1997), the evidence from several studies indicates that single women’s labor-market position tends to have little effect on marriage formation, but that what effect it does have is positive.

A characteristic of the women’s independence explanation of recent trends in family behavior is that it ignores the possible role of *men’s* changing economic position in these changes. Yet it is well known that marriage and family behavior are related to men’s employment characteristics (Cherlin 1979; Goldscheider and Waite 1986; Ross and Sawhill 1975; Teachman et al. 1987). Furthermore, there is a long demographic tradition, dating back to Malthus, which argues that changes in men’s economic position has an effect on marriage and fertility behavior. Supporting the view that these

changes might also be an important factor in the rise in both men's and women's age at marriage since the early 1970s is the well-documented finding that there has been a large absolute and relative decline in the labor-market position of young men with a high school education or less. In addition, there has been an increase in economic inequality within each educational group, including those with a college education (Levy 1998; Juhn et al. 1993). The reasons for these trends appear to be quite complex, and, to date, no general consensus has yet been reached regarding the relative importance of several proposed explanations. A variety of factors appear to be making a contribution. The globalization of manufacturing and the resulting competition from cheap semi-skilled labor in developing countries may be decreasing the demand for less skilled American workers, workers who previously were able to command relatively high wages in manufacturing; moreover, this same globalization has weakened the position of unions and hence their ability to protect such workers from an erosion in their job security and wages. All this has fostered the continued decline in the proportion of workers in manufacturing and the rapid rise in the proportion in service industries. However, the growth of service industries per se cannot be driving these changes because the growth in some service industries has increased the demand for more highly skilled labor while the expansion of other service industries has only resulted in a rising demand for low-wage unskilled labor, leaving the semiskilled in an increasingly poor position. Moreover, it does not appear that industrial restructuring alone can satisfactorily account for all or perhaps even most of these changes because, *within* industries, there is evidence of a sharp rise in the demand for more skilled labor pointing to an important role for technological change in both the manufacturing process and the production of services (Levy 1998; Meisenheimer 1998).

Whatever the reasons for the declining economic position of young, less educated males, recent research provides evidence that men in a poorer labor-market position do tend to delay marriage (Mare and Winship 1991; Lloyd and South 1996; Oppenheimer et al. 1997). Oppenheimer's work, in particular, has indicated that substantial inequalities in the length and difficulty of the career-entry process exist both within

and between race-schooling groups and lead to substantial differences in the marriage timing of young men.

This article has reviewed the history of labor-force measures as well as several important current issues in labor-force analysis. First, the study of the labor force reveals the changing significance of work in the lives of different segments of the population. Second, since economic behavior impacts on other social systems, such as the family and stratification systems, labor-force analysis will continue to be an essential field for sociological analysis.

VALERIE KINCADE OPPENHEIMER

LABOR MOVEMENTS AND UNIONS

Labor movements are collective activities by wage and salaried workers in market societies to improve their economic, social, and political status. The main manifestations of such movements are labor unions and political parties, but sometimes they include producer and consumer cooperatives; credit unions; newspapers; and educational, welfare, cultural, and recreational organizations. Labor movements and unions need sociological analysis because they are integral parts of two

major and related institutions of society, the economy and polity. Apart from bringing about changes in these institutions, they are the main vehicles for mobilizing the class interests of wage and salaried employees. No other social science discipline offers such a broad perspective of study.

Yet, in the United States since the inception of sociology, labor movements have received surprisingly little attention. From their founding up to 1999, three main journals—*The American Journal of Sociology*, *The American Sociological Review*, and *Social Forces*—together representing 219 years of publication, published only sixty-three articles whose titles mention labor movements, unions, or strikes. American sociological research on the topic has fluctuated with labor's fortunes. As union membership grew from 1940 to 1960, research expanded and then lagged, with falling membership in the 1970s. The more rapid decline of labor since 1980 has recently stimulated research on the causes.

The bulk of American labor research has been done by historians and labor economists. To be sure, sociologists have made contributions while working on other topics such as social stratification (e.g., working-class formation, income inequality), organizations (leadership turnover), race and gender (discrimination in unions), political sociology (party preferences of union members), case studies of industry (shop-floor life, the labor process), and social movements (Jenkins 1985). Combining these contributions with those of labor economists and historians, a sizable literature is now available (see the bibliography in Stern and Cornfield 1996). In Europe, the bulk of labor research has been done by sociologists and historians.

ORIGIN OF THE LABOR MOVEMENT

Labor movements and unions emerged with the rise of capitalism, the Industrial Revolution, and free labor markets in eighteenth-century Europe. Historians agree that labor unions did not evolve from medieval guilds, which were status groups of master-owners whose monopoly of skills was protected by public authorities. Journeymen, apprentices, and laborers had fewer or no privileges (Pirenne 1932; Lederer 1932). In early capitalism, factory workers created ad hoc organizations to withhold their labor from employers, to control production and job training, and to protect

wages and working conditions. Re-created with recurring crises, the organizations eventually became permanent (Jackson 1984). As product markets grew and spread, unions were forced to organize new locals in those markets to prevent wage competition among communities. The labor movement became larger, more institutionalized, and more diversified as it organized workers in different occupations, industries, and regions (Sturmthal 1974).

This fragmented response to threats forced labor leaders to press for a more united and centralized organization to respond to threats wherever and whenever they appeared. Invariably, some unions were reluctant to commit their resources for the welfare of a vague "movement." Failure to consider this persistent resistance has led many scholars to equate labor movement growth with the formation of the working class and with working-class politics. Although the two are related, their linkage varies enormously in different times and places. Where labor movements first emerged, they were not class movements, but efforts by a minority of skilled workers to protect their traditional privileges (Calhoun 1982). Even when unions expanded to include most workers, internal factions remained, based on skill, industry, status, and influence (Form 1985, p. 96). The emergence of class movements, on the other hand, involved complex processes of linking labor movements to other special interest groups and political parties (Katznelson and Zolberg 1986).

The character and strength of labor movements must be explained in the context of the societies in which they emerge, especially the ways they relate to distinctive traditions, economies, and political and governmental systems. Autonomous labor movements survive best in capitalist democratic industrial societies. To sustain free collective bargaining, labor, management, and government must exhibit considerable independence but not exert overwhelming power in the tripartite relationship. Where union membership is compulsory and universal, where unions are completely dominated by government and/or enterprise managers, unions lack the autonomy and strength to advance the special interests of workers. Paradoxically, where labor has total control over government and the economy, it lacks opposition and the attributes of free labor movements (Sturmthal 1968).

TYPES OF LABOR MOVEMENTS

Labor movements vary in structure and behavior according to their relationships to government and other institutions. Movements fall into roughly five types. In the independent type, as in the United States, labor is independent of all major institutions, especially parties, government, and religion. Although labor seeks political influence, it participates in a shifting multiclass coalition of a particular party. Corporate labor movements, as exhibited in Britain, Scandinavia, Germany, Italy, and France, are often formally incorporated into the political system, sometimes playing a dominant role in labor, religious, socialist, or social democratic parties. When such parties win electoral victories, labor participates in governmental bodies—cabinets, legislatures, and government agencies. In the third or party-dominant movement, sometimes found in developing societies with mixed economies, labor is part of a permanent ruling coalition—for instance, the Institutional Revolutionary Party of Mexico. Here labor loses some freedom to push for the special interests of workers because it is rarely strong enough to resist decisions of the coalition. In totalitarian fascist and communist regimes, labor movements are totally subordinate to the ruling party and exhibit the least independence. Finally, in enterprise labor movements, labor functions primarily in a consultative capacity at the enterprise level. Nationally, labor belongs to a loose federation of unions with weak links to major parties, organizations, and institutions.

In independent movements, labor seeks economic gains primarily by bargaining with management. In the political realm, it seeks governmental protection for the right to organize and bargain as well as protective legislation such as unemployment, old age, and medical insurance. In the corporate type, apart from bargaining with employers, labor makes gains through legislation that forces management to deal with labor in arriving at enterprise policies regarding job rights, the organization of work, investment and other decisions, as in codetermination in Germany and Scandinavia (Nutzinger and Backhaus 1980). Public ownership of certain industries (often mines, public utilities, and transportation) is also an option. Labor strength is highest in this type of movement. In the party-dominant movement, labor at best makes gains for a minority of organized workers,

stratifying the working class. Under totalitarian regimes, labor may be given certain functions, such as assigning housing or supervising cooperatives, but its ability to bargain with government and enterprise management is severely limited (Lane and O'Dell 1978). In enterprise unionism, organized workers may gain employment security and career rewards in exchange for loyalty to the enterprise. The unorganized are exposed to the vicissitudes of the market (Okochi et al. 1974).

AMERICAN EXCEPTIONALISM

Scholars have long tried to explain why the American labor movement has not developed into the sort of corporatist socialist movement found in other advanced industrial democracies (Sombart 1906). Most scholars agree that European societies, compared to the United States, have had longer and stronger links to past institutions. When landed aristocrats, business, military, and religious elites resisted worker participation in the political system, class-oriented parties appeared. In such class environments, labor unions developed or joined other parties to obtain voting rights for workers, government protection of unions, benefits unavailable through collective bargaining, and eventual public ownership of industries. In addition to supporting class parties, labor movements developed structures attuned to their interests—for example, an intellectual elite, cooperatives, newspapers, banks, schools, and recreational clubs. In response to socialist and communist movements, Catholics not only launched their own labor movements and parties, but also organized schools, hospitals, newspapers, and clubs to embrace workers in a harmonious class-inclusive environment (Knapp 1976). Rejecting “captured” socialist, communist, and religious labor movements, liberals sought to organize free or neutral unions and parties that appealed to some workers and middle-class adherents (Sturmthal 1968).

The labor movement in the United States faced a different environment. The absence of an agricultural aristocracy and traditional governmental, military, and religious elites dampened class sentiments. Early extension of suffrage to all adult males removed that objective as a rallying cry for labor parties. The rapid expansion of industry into new cities, high rates of internal migration and immigration, the separation of ethnic groups in

neighborhoods, and religious diversity slowed the formation of multiple working-class bonds. Moreover, an aggressive capitalist class, not bound by traditional obligations toward subordinates, fashioned laws and courts to protect property rights and suppress unions as conspiratorial monopolies (Dougherty 1941, pp. 635–677).

Even so, trade assemblies and craft unions emerged in several cities in the decade after the Civil War. In the 1880s, the Knights of Labor tried to organize unions that included all workers, even the white-collar and small businesses. This attempt lasted roughly a decade. Beginning in 1905, the militant International Workers of the World (IWW) organized workers of all skills to join unions and engage in political action to destroy capitalism (Dougherty 1941, pp. 317–349). The IWW too lasted a decade. For a few years, splintered socialist parties tried to support class-oriented unions. These efforts failed largely because the American political system places structural limitations on the development of third parties. The presidential system, decentralized state structures, constitutional barriers to the federal government making national economic policy, and the electoral college system favor a multiclass two-party system (Lipset 1977).

Weaknesses of class-oriented unions favored the American Federation of Labor (AFL), which successfully began to organize the skilled trades in 1891. The AFL concentrated on the skilled, because skilled workers dominated their trades and were capable of the sustained solidarity needed to win strikes. As an elite minority of the working class, the Federation focused largely on wage gains, better working conditions, and remained “neutral” in party politics. Yet, without legislative protection, union gains were periodically eroded by market downturns and antiunion employer drives. Thus, as a percentage of the labor force, the AFL experienced robust growth in the prosperous years before and during World War I. Membership declined rapidly in the depressions following the war; rose dramatically along with the formation of the Committee on Industrial Organizations just before and during World War II; declined slowly after the war for two decades; and then declined more rapidly in the economic recessions of the 1970s and 1980s, from which it has not recovered. That the decline was not more precipitous after World War II was due to the legislative protection

that labor received in the late 1930s under the Democratic administration’s New Deal.

POSSIBLE CONVERGENCE OF LABOR MOVEMENTS

A combination of events has tilted the American labor movement toward the European social democratic model and the latter toward the American. During the Great Depression in the United States, the Democratic Party came to power with the backing of urban-industrial and middle-class voters. The party quickly enacted legislation to increase labor’s purchasing power, reduce price competition in industry, protect union organizing, and restore economic order. The National Labor Relations Act (1935) gave unions legal protection to organize, and labor conducted a militant drive for members. The recruitment of many semiskilled workers into new unions organized by the Committee on Industrial Organization (CIO) of the AFL threatened the dominance of the skilled trades in the Federation, leading to a withdrawal of the CIO from the Federation. Yet, eager to protect and extend recent gains, the divided labor movement began to abandon its traditional nonpartisan political stand. After World War II, both labor movements created electoral organizations to support Democratic candidates and mobilize their members to vote. The two labor movements merged in 1955, as did their electoral arms, to form the Committee on Political Education (COPE), formally independent of the Democratic party, but essentially functioning as part of it.

This labor-party rapprochement, committed to a social security program and a welfare state, led some scholars to conclude that the American labor movement was no longer exceptional, because it had helped create a welfare state similar to that forged by the social democratic parties in Europe (Greenstone 1977). The claim is strained because neither American labor nor the major parties ever embraced a socialist framework (Marks 1989, Chap. 6). More important, American labor has never been formally incorporated into the party and government, nor has government passed laws giving labor consultative rights in work plant operations, both central features of European corporatist labor movements.

In Europe, experiments by labor-dominated governments to nationalize industries have met with limited success (Panitch 1976), and some parties have abandoned or severely curtailed nationalization programs. The matter has been and remains an issue within parties, with some unions strongly opposing it (Currie 1979). To obtain power or maintain it by democratic means, the parties found it necessary to obtain the support of middle-class employees who want the social security guarantees of a welfare state, but not nationalization of industry. To maintain a vigorous economy, social democratic parties have enacted pro-business policies, not unlike those of the Democratic Party in the United States. For example, pro-business legislation by the Clinton administration or free trade with Latin America opposed by labor. In short, conservative forces both in and outside social democratic parties have pushed European political economies toward the American model.

Where labor is part of a coalition of a permanent ruling party as in the Mexico or the former Yugoslavia, labor has sometimes shown independence and initiated strikes despite government opposition (Bronstein 1995). And even in Japan, some enterprise unions have abandoned traditional consensus policies and challenged management and government with strikes and political turmoil (Okochi et al. 1974; Kuruvilla et al. 1990). Korea has moved even farther in this direction (Deyo 1997).

If present trends continue, perhaps a slow convergence of labor movement structures will take place. Sufficient research is not available to uncover all the causes of this plausible trend, but several play a role. In totalitarian or enterprise labor movements, when governments or managements create organizations that resemble labor movements (unions, elections, bargaining sessions, and consultation), appearances may become realities during leadership crises, especially in face of turbulent external events. Thus, in Poland, during authority crises of the ruling party and the state in the late 1980s, unions began to assert control over working conditions, wage determination, and political choice (Martin 1997). With the help of clergy, intellectuals, farmers, and others, unions defied central authority and instigated a movement to bring about a democratic party and state.

These authority crises in the party-dominant, totalitarian, and enterprise labor movements often result from changes in their external environments. Top labor officials become acquainted with the independent and corporate types of movements while participating in international agencies like the International Labor Office of the United Nations. The ability of independent and corporate movements to gain visible economic and political rewards for their members has not escaped the notice of labor leaders of other types of movements. Thus, when they confront authority crises, they have a vision of the kind of changes that would help them.

More important, rising global trade and economic interdependence fosters convergence. For example, in the 1970s, Japanese and Korean auto manufacturers began to enlarge their share of the automobile markets of the United States and western Europe increasing their unemployment. While management and unions both called for tariff protection, Japanese and Korean and labor demanded and received pay increases (Deyo 1989). On making a partial recovery, American and European corporations, in pursuit of higher profits, began to outsource production in countries with lower wage rates—for example, Mexico and Brazil. Then, with limited success, American labor leaders pressed government to place tariffs on auto imports and urged labor leaders in the exporting countries to demand higher wages. However, international labor cooperation remains puny compared to growth of world trade.

TRENDS IN LABOR MOVEMENTS

In the advanced industrial capitalist democracies since the 1970s, the proportion of union members has declined in manufacturing and risen in the services and government. Some movements have shrunk rapidly, while others have remained relatively stable. Unions that had earlier won legal rights in the conduct of enterprise (codetermination, administering unemployment insurance, production planning, national bargaining) lost fewer members, for instance, corporate types of labor movements as found in Scandinavia and Germany rather than the independent type as in the United States.

In a study of eighteen advanced capitalist countries from 1970 to 1990, Western (1995) found

increasing dispersion in the rates of union decline, with the highest declines in countries with the lowest initial union density—such as the United States, Britain, and France. By 1990, the declines, wherever they occurred, were traced to unfavorable global economic conditions, decentralization of collective bargaining institutions, and electoral weakening of labor-oriented parties.

In the United States, the percentage of the labor force that was unionized shrank from 37 percent in 1945 to 14 percent in 1999. Union density in the private sector declined to one-tenth of the labor force, while public sector union density grew to over two-fifths. As unions were forced into a defensive position, strike rates declined precipitously. The causes of labor's decline are complex. The most common explanation, the shift from a manufacturing to a service economy, is inadequate. In a study of eleven capitalist democracies, Lipset (1986) found that union decline did not vary with manufacturing decline. Goldfield's study (1987) showed that after eliminating changes in the economy, industries, and occupations as possible causes, employer antiunion drives under Republican administrations tilted decisions of the National Labor Relations Board (NLRB) against organized labor. But Freeman and Medoff (1984) emphasized that white-collar unions grew rapidly despite employer resistance. Finally, some of the union decline is traced to labor's spending less money on organizing drives.

Undoubtedly, other factors were also involved in the decline, notably the outsourcing of manufacturing to other countries and the national conservative trend attending Republican electoral victories and consequent antilabor policies. Moreover, several new constituencies in the Democratic Party (blacks, women, educators, business) competed for party influence. Despite some Democratic electoral victories since 1992 and greater organizing efforts by the new AFL-CIO leadership, labor's slow downward trend has continued.

Labor movements trends in other parts of the world defy easy generalization. The best descriptions of their recent experiences appear in the *International Labour Review*. Clearly, free labor movements did not automatically emerge with the demise of totalitarian regimes in former soviet states. For example, in Poland, where the union-sponsored Solidarity Party gained governmental

control, unions almost ceased behaving like unions at the plant level, failing to bargain with management in support of the government's anti-inflation policy. In contrast, unions in the Czech Republic, by not participating in the Civic Forum which gained control of the government, bargained with government to win codetermination rights in industry and reduce unemployment (Ost 1997). In Romania, miners have episodically threatened violence against the government to win back-pay and wage increases. In other ex-soviet countries, especially Russia, the collapse of the economy virtually stalled the formation of a free labor movement.

In east Asia, union density has been declining recently not only in the industrializing tigers of Taiwan, Korea, Hong Kong, and Singapore but also in the more recent industrializing countries of Thailand, Indonesia, Malaysia, China, and Vietnam (Deyo 1997). Where unions and the working class have improved their positions, labor-market shortages, favorable government policies, and paternalism have been primarily responsible, rather than strong unions. Patriarchal and patrimonial regimes have excluded unions from decision making at the enterprise level or have weakened them when they appeared. Only in Korea, where industrial workers are rather homogeneous, are residentially concentrated, and have developed autonomous organization, have unions intermittently exhibited strong independence (Deyo 1989).

In Latin America, recent declines in autocratic regimes have encouraged the rise of autonomous labor movements. Yet, three factors that vary enormously by country are union autonomy from the state; the amount of collective bargaining; and dialogue among unions, the state, and management. Although some progress toward free-trade unionism has appeared in Argentina, Brazil, Mexico, and Chile, government pressure to achieve economic stability in the face of inflation, unemployment, poverty, and the legacy of autocratic military regimes has slowed basic changes in the tripartite relations of labor, state, and management (Bronstein 1995).

DEMOCRACY OR OLIGARCHY IN THE LABOR MOVEMENT

Even labor movements that are large, strong, and autonomous face constant problems. Unlike most

institutions, all labor movements claim to be democratic in ideology, structure, and behavior. Union officers are supposed to be leaders, not bosses, and, their primary task is to improve the well-being of membership. Sociologists have long pondered whether large and complex democratic organizations can escape becoming oligarchies with self-serving officers. The most famous proponent of this proposition was Roberto Michels (1911), who studied the history of the Socialist Party in pre-World War I Germany. He found that its officers had become a self-perpetuating elite who controlled communication with the membership, appointed their staff and successors, and pursued their self-interests, often oblivious of member needs and concerns.

Several case studies of unions have challenged Michels's thesis. Lipset, Trow, and Coleman (1956) found that the unique party system of the International Typographical Union fostered electoral competition, officer turnover, and membership involvement in union affairs. Edelman and Warner's (1979) study of fifty-one international unions revealed that officer turnover varied with constitutional provisions, such as frequency of elections, percentages of officers elected, and frequency of conventions. Cornfield (1989) found that substantial ethnic turnover among officers of the United Furniture Workers resulted from changes in the economy, the regional dispersal of the industry, political disputes among officers, ethnic tolerance of the membership, and a tradition of membership involvement in union affairs.

While most case studies of turnover among union leaders have focused on relatively small unions whose members exhibit rather homogeneous skills and earnings, the studies do not reveal the extent to which these conditions apply to the universe of unions. Marcus's study (1964) of all major unions in the country revealed that the larger and more heterogeneous the union, the slower the leadership turnover, the less frequently conventions were held, and the more decision making was concentrated in the officers.

Other dimensions of stratification within unions persist over their life histories. In a rare study, Bauman (1972) demonstrated that cleavages along skill lines persisted during the entire history of the British labor movement. At the beginning of the Industrial Revolution, skilled workers formed their

own societies. From 1850 to 1890, they formed craft unions that gained recognition. Between 1890 and 1924, they became an elite sector of the labor movement and maintained their status and influence in the large industrial unions. With the development of the Liberal and Labour parties, trade union leaders became subordinated to university-trained, middle-class intellectuals who dominated the parties, seats in Parliament, and high government positions. Herman Benson (1986) argued that this pattern also applies to the American labor movement, and Alain Touraine (1986) argued it is universal. In short, the rising size and organizational complexity of the labor movement are accompanied by increasing internal stratification and a less responsive bureaucracy, confirming Michels's original argument.

CONCLUSIONS

Although the future of the American labor movement is difficult to predict, the movement will surely survive and change. Michels argued that as movements become institutions, they lose the loyalty and commitment of the founding generations. Although economic gains always remain paramount goals of unions, money is not uppermost in the minds of members while they are working. Whatever changes take place in the economy or polity, workers live where they work. The historic union goal to improve working conditions erodes with the bureaucratization of enterprises and the labor movement. Therefore, improving the quality of work life must become a renewed priority of labor leaders, so as to invigorate member loyalty and commitment. This involves greater worker participation in the control of work organization, a challenge that management will surely resist, but union leaders must relentlessly pursue.

When labor was a larger constituency of the American Democratic Party, it had more influence in party affairs despite COPE's weak electoral organization. Form (1995) has shown that especially at the grass-roots level, COPE is severely fragmented along occupational and industrial lines; more important, union members are hardly aware of labor's political goals and electoral efforts. Understandably, Democratic Party elites have responded more to other, better-organized constituencies. Unless labor makes common cause with some of them in the workplace as well as in the political

arena, labor's party influence will continue to decline. Paradoxically, the more selflessly labor supports other constituencies, the more politically influential it will become. Labor's natural allies are African Americans, Hispanics, educators, women's movements, and environmentalists. The challenge of labor leaders is to convince their members to support this strategy.

Finally, like business, labor must become a worldwide movement. Self-interest requires labor movements in advanced capitalist economies to assist foreign labor movements in making economic, social, and political gains. This surely is the toughest assignment, but unless progress is made on this front, labor may continue to decline.

LABOR THEORY OF VALUE

See Marxist Sociology.

LATIN AMERICAN STUDIES

Sociological research on Latin American societies has focused on the understanding of the causes and consequences of different patterns of development. In the past decades, this research has been guided by the counterpoint between two different theoretical approaches and the findings

generated with their help. In the 1950s and 1960s, the field was dominated by what came to be known as the modernization approach. In the 1970s and 1980s, dependency and world-system theories became prevalent (Klaren and Bossert 1986; Valenzuela and Valenzuela 1978). Each of these paradigms spawned useful lines of research, but eventually they became unsatisfactory, either because some of their assumptions were inconsistent with the facts, or because they were incapable of encompassing important areas of social reality. The field is now ripe for a new conceptual framework, which could incorporate useful aspects of the previous ones. In the past few years, there has been a shift toward a state-centered approach, but it is still unclear whether it will develop into a synthetic paradigm.

THE REGION

The study of Latin American societies is complicated by the heterogeneous nature of the region. The nations that compose Latin America share some common traits, but they also have important differences.

Countries vary in terms of their economy and social structure, their ethnic composition, and their political institutions. The economic differentials are very substantial. The region includes Argentina and Uruguay, whose per capita gross national products (GNPs) are \$8,570 and \$6,020, respectively, higher than those of the Czech Republic and Hungary but lower than those of Portugal and Greece, the poorer countries in the European Union. At the other extreme, there are countries like Haiti and Honduras, with per capita gross national products (GNPs) of \$330 and \$700, respectively, which are comparable to those of the Central African Republic and the Congo, respectively (World Bank 1999). Social structures vary accordingly: About 90 percent of the Argentine and Uruguayan population is urban, but the percentages in Haiti and Guatemala are 35 percent and 44 percent (PNUD 1997); manufacturing accounts for about 20 to 25 percent of the GDP of Argentina, Brazil, and Mexico (about the same as in France, Germany, and Italy), but the proportion is only 3 percent in Bolivia and 9 percent in Panama, whose levels of industrialization are comparable to those of Cambodia and Bangladesh, respectively. Enrollment ratios in post-secondary

education vary from about 40 to 50 percent of the 20 to 24-year-olds in Argentina and Uruguay to about 8 to 9 percent in Honduras or Paraguay (World Bank 1992).

Latin American societies differ widely in their ethnic composition. The three basic components, Iberian settlers and other European immigrants, Indians, and blacks, are found in different proportions and mixes in different societies. Some are relatively homogeneous: most of the Argentine and Uruguayan populations are of European origin (the greater part are the product of transatlantic immigration at the turn of the century), and the population of Haiti is basically African. Other societies, like Mexico, Peru, and Guatemala, have maintained the colonial pattern of ethnic stratification, with mostly "white" elites ruling over largely Indian citizenries. Most of the population in Chile, Colombia, Venezuela, the Dominican Republic, El Salvador, and Honduras is the product of miscegenation. Brazil has a very heterogeneous population, with large contingents of all the ethnic groups and their different mixes (Ribeiro 1971; Lambert 1967).

With respect to their political institutions, countries in the region vary as well. Some, like Costa Rica, Chile, and Uruguay, have had long histories of constitutional rule (punctuated, by authoritarian episodes), while others, like Argentina, Brazil, and Peru, have wavered between instability and authoritarianism for much of the postwar period. All over the region, military dictatorships gave way to constitutional governments in the 1980s (O'Donnell and Schmitter 1986), and the 1990s has been the decade of democratic consolidation (Huntington 1991; Linz and Stepan 1996). The legitimacy and overall potential for institutionalization of these new governments vary according to the strength of liberal democratic traditions, the subordination of the state apparatus to the government, the vitality of the party system, and the dynamism of the economy. Authoritarian rule and state corporatism are still being dismantled in Mexico, and guerrillas operate in Colombia and Peru. Finally, Cuba is one of the few remaining state socialist polities in the world.

Nevertheless, there are economic, social, and political commonalities, besides the obvious cultural and religious ones. As far as the economy is concerned, and in spite of the variability noted

above, Latin American countries share four important traits. First, all these societies belong, in terms of their per capita product, to the low or lower-middle ranks in the world system. Second, all Latin American nations have basically been, and most still are, in spite of the considerable industrialization that took place in the most advanced countries, exporters of commodities and importers of manufacturing products. Third, industrialization, from the Depression of the 1930s up to the recent past, has been based on import-substitution policies. These policies have led to low growth rates, and even outright stagnation, once the domestic markets were saturated, a stage that the most advanced countries in the region reached in the 1970s and 1980s. Fourth, Latin American societies are highly dependent, in most instances because large segments of their economies are under the control of external actors (multinational corporations in particular), and in practically all cases because of their high levels of indebtedness to the advanced industrial countries.

There are many differences among Latin American social structures and political institutions, but all these societies except Haiti originated as Spanish and Portuguese colonies. The pillars of the original institutional matrix were the organization of the economy around the large agrarian property, a highly centralized political system in which representative features were weak, and a cultural system centered in the church, and in which the toleration of pluralism was extremely low (Lambert 1967; Veliz 1980). This institutional core disintegrated as a consequence of the economic and social changes of the nineteenth and twentieth centuries: New social actors were formed, and old ones were transformed by urbanization, industrialization, and the expansion of education, and also by the irruption of external economic, political, and cultural forces. Further, in some societies there were substantial changes in the composition of the population. However, the common origins still account for important similarities in the historical trajectories of the countries of the region.

In the realm of politics, commonalities are also evident in the post-independence period, especially after the Great Depression of the 1930s. At that time, liberal-democratic regimes, most of which had not integrated the lower classes into the political system, collapsed throughout the region.

In the following decades, most Latin American countries wavered between unstable democracy and nondemocratic forms of rule. South America has been especially prone to two of these: populist-corporatist regimes and bureaucratic military dictatorships (Malloy 1977; Pike and Stritch 1974; Stepan 1978; O'Donnell 1973, 1988). Many South American polities evolved cyclically in that period: populist-corporatist regimes (such as those headed by Juan Peron in Argentina and Getulio Vargas in Brazil) were frequent from World War II to the 1960s; military regimes and their coercive counterparts in society, guerrilla warfare and terrorism, predominated in the 1960s and 1970s (in Argentina, Brazil, Chile, Uruguay, and Peru); and democratization has swept the area in the 1980s.

MODERNIZATION THEORY

Modernization perspectives shared two core assumptions that distinguished them from dependency and world-system theories. The first was that the central variables for understanding the development of a society are internal to the society; the second, that development is an evolutionary process, whose main characteristics are common to all societies. These commonalities underlie different approaches, which can be classified in terms of the variables they have considered central for the analysis of development, because of their primary causal weight, and in terms of the nature of the evolutionary process societies were supposed to undergo.

A first approach, sometimes of Parsonian or anthropological inspiration, privileged the value system, or culture, as the basic part of society, in the sense that values were expected to determine the basic traits of the economy or the polity. Change in values or culture appeared then as a key dimension in the process of transition from "traditionality" to "modernity." Examples of this perspective are Seymour Martin Lipset's analysis of entrepreneurship in Latin America (1967) and Howard Wiarda's argument about the influence of the corporatist Iberian tradition on the political evolution of Latin American societies (1973).

The second approach was structural, in the sense that it viewed the social or economic structures as the determining part of society, and that it saw changes in these structures as the central

aspect of the process of development. The most elaborate versions of this perspective were inspired in Durkheim and in the most structural version of Parsonian theory: They regarded the degree of integration of society as the key characteristic of the social order and focused on the processes of differentiation and integration as the keys for the understanding of development, still conceptualized in terms of the "traditionality-modernity" continuum. Gino Germani's model of Latin American modernization in terms of the counterpoint between mobilization and integration is a good example of this perspective (1962, 1981; see also Kahl 1976). The typology of stages of economic development made popular by the influential Economic Commission for Latin America (ECLA) of the United Nations (Rodriguez 1980), shared these presuppositions.

These approaches spawned important types of sociological research in the 1950s and 1960s, but reality showed that the assumptions behind the evolutionary paradigm were problematic. Toward the end of the 1960s, it became clear that the predictions derived from the model of the traditionality-modernity continuum in relation to the social structure and the political system were inconsistent with the facts. In the social structure, the expansion of capitalist agriculture and the development of industry in societies with large peasantries did not lead to the dissolution of "traditional," or precapitalist, rural social relations. Its survival (Stavenhagen 1970; Cotler 1970) and the emergence of what came to be known as "dualistic," or structurally heterogeneous, societies meant that the patterns of social development of Latin America were not replicating those of the western European countries that were considered as the universally valid models of modernization.

Political processes in the 1960s and early 1970s were also paradoxical in relation to this theory: Lipset's thesis that liberal democracy was a correlate of development (as measured by variables such as income, urbanization, industrialization, and education) ([1960] 1981, pp. 27-63) seemed to be contradicted by the fact that it was precisely the most "modern" countries (Argentina, Uruguay, and Chile) that were the most prone to instability and authoritarianism. On the basis of this propensity, Guillermo O'Donnell (1973) argued that, in the peculiar situation of Latin American industrialization, countries of this type were

the most likely candidates for bureaucratic authoritarianism. This proposition was itself questioned from different perspectives (see Collier 1979), but the lack of correlation between development and democracy seemed nevertheless obvious at that time. Later, the wave of democratization that swept Latin America in the 1980s and the revolutions of 1989–1990 in eastern Europe would indicate that the relationship proposed by Lipset does exist, even though it does not seem to be linear.

DEPENDENCY AND WORLD-SYSTEM THEORIES

Approaches based on dependency and world-system theories were the contemporary elaboration of themes found in Marxism, the theory of imperialism in particular (Lenin 1968; Luxemburg 1968). They were based on two propositions that sharply contradicted the assumptions of modernization theory. The first was that internal characteristics of a society, such as its level of development or the nature of its political system, are determined by the society's position in the international system. The second assumption was a corollary of the first: Since the main causes of development are external, there is no reason to expect that all societies will follow the same evolutionary trajectory. On the contrary: The world system is organized into a more dynamic, developed, and powerful core, and a more passive, backward, and dependent periphery. Beyond these commonalities, there were differences between the dependency and world-system approaches.

Dependency theory, which in itself was a Latin American product, emphasized the radical distinction between core and periphery, and it took dependent societies as its unit of analysis. Its focus was on the mechanisms it claimed were responsible for the preservation of underdevelopment, the transfer of economic surplus to the center via trade and investment in particular (Cardoso and Faletto 1979; Frank 1969, 1972). Wallerstein's world-system approach (1974), on the other hand, singled out the world economy as the unit of analysis, and it explored the functions of different types of society (core, semiperiphery, and periphery) in that system.

These theories have generated, since the late 1960s, important pieces of research. Fernando H. Cardoso and Enzo Faletto's comparative analysis

of Latin American societies (1979) showed how different positions in the world economy generated different class structures and different patterns of development (see also Kahl 1976). Peter Evans (1979), in a study of Brazil, showed how the peculiarities of the country's development were shaped by the interaction among the state, foreign capital, and the domestic bourgeoisie. Gary Gereffi (1983) explored the consequences of dependency in a key industry. From a world-system perspective, Alejandro Portes and his colleagues (1981, 1985, 1989) conducted important studies of the labor flows in the world economy, and of the articulation between the formal and informal economies.

These approaches improved our understanding of Latin American development in two ways. First, by focusing on the effects of external factors and processes (those in the economy in particular, but the political and cultural ones as well), dependency and world-system perspectives corrected the assumption characteristic of modernization theory that societies could be studied in relative isolation. Second, since these theories constructed models of the world economy that were either pericentric (Doyle 1986), as in dependency theory; or that emphasized the analysis of peripheral and semiperipheral social structures alongside that of the core, as in world-system theory, they balanced the emphasis on core structures and processes characteristic of most preexisting studies of imperialism, which tended to ignore the institutions and dynamism of the periphery.

However, the basic tenets of dependency and world-system theories have also led in some cases (but not in the best research spawned by these perspectives) to simplistic assumptions, in particular to a tendency to consider internal structures and processes, especially the political and cultural ones, as transmission belts for external economic and political forces. The pendulum swung to the other extreme: from the neglect of external economic and political determinants of social change, characteristic of modernization theory, to a disregard for internal factors.

TOWARD A NEW PARADIGM

In the late 1980s the basic assumptions of dependency and world-system theories also became problematic. In the first place, research on the role of

the state in the development process led to its reconceptualization as an autonomous actor (see Evans et al. 1985; Evans 1995; and Waisman 1987 for a Latin American case). This challenged the conceptions characteristic of most approaches close to the Marxist tradition—dependency and world-system theories included—which tended to see the state, claims of “relative autonomy” notwithstanding, as basically an instrument of either domestic ruling classes or foreign forces. Second, there was a rediscovery of social movements in the region (a consequence that the redemocratization processes of the 1980s could not fail to produce). More often than in the past, agency came to be seen as relatively independent in relation to its structural and institutional context (see the essays in Eckstein [1989], for instance), a conceptualization that differs sharply from the structuralist assumption inherent in dependency and world-system perspectives. Finally, the proposition according to which the central determinants of the development of Latin American countries are external has also been challenged (Waisman 1987; Zeitlin 1984). In the 1990s there is a growing consensus, as there was in the 1970s, that existing paradigms do not encompass our current understanding of Latin American development.

A new theoretical synthesis should integrate the valid components of the modernization, dependency, and world-system approaches, and should also allow for the autonomy of the state and the role of agency. A point of departure should be the recognition of three facts. First, the division of the world into core, periphery, and semiperiphery is not sufficient to encompass the diversity of developmental situations and trajectories relevant for the study of the countries of Latin America. It is necessary to construct a typology of more specific kinds of peripheral societies (and of core societies as well: the core-periphery distinction is still too abstract), and to describe more systematically the structural “tracks” that have crystallized in the region at different stages of development of the world economy.

Second, the different developmental paths followed by Latin American societies have been determined by empirically variable constellations of external and internal processes, and of economic, political, and ideological-cognitive ones. Few propositions that privilege the causal role of specific factors are likely to be generally valid. Rather

than seeking propositions of this type, as modernization, dependency, and world-system approaches have tried to do, it would be more productive to map the specific bundles of factors that have influenced developmental outcomes in critical situations. Third, development is a discontinuous process (an instance of punctuated equilibrium, in Stephen D. Krasner’s [1984] words), but we lack a theory of the transition points, that is, of the crossroads where acceleration, stagnation, retrogression, and changes of developmental tracks have taken place. The Latin American experience indicates that these are the points in which major changes in the world system, such as depressions, wars, important technological developments, organizational changes in production or trade, and restructuring of the economic or military balance of power, have interacted with domestic processes economic, political, and cultural processes.

LATIN AMERICA IN THE PAST DECADE: THE DOUBLE TRANSFORMATION

In the past two decades, Latin America has been undergoing two simultaneous transformations: economic liberalization and democratization (Waisman 1998). The pervasive nature of these transitions is indicated by the fact that they have been independent of level of development and of political regime. Most countries in the region, from relatively underdeveloped Bolivia and Paraguay to relatively industrialized Brazil and Argentina, have moved from military rule to liberal democracy in the past decade. As for economic liberalization, it took place in authoritarian Argentina and also in democratic Argentina, in authoritarian Chile and also in democratic Chile, in state-corporatist Mexico, in social-democratic Venezuela and also in social-Christian Venezuela. Like the depressions of the 1870s or the 1930s, this is a critical juncture, a reshaping of domestic economic and political institutions, the regional manifestation of the processes of economic globalization and reconstitution of the world order following the collapse of communism.

Economic liberalization was the result of a constellation of internal and external determinants. In most cases, the former seem to be central, but in any case exogenous factors constituted a powerful set of incentives and constraints pushing countries toward the liberalization road. These

external causes can be classified into economic, political, and cultural.

The debt crisis of the 1980s was, for many Latin American countries, the central economic constraint (Felix 1990; Kahler 1986; Nelson 1990; Stallings and Kaufman 1989; Wesson 1988; Wionczek 1987). This crisis forced highly indebted countries to increase and diversify exports, which presupposed a higher rate of investment, and to reduce government spending. These objectives could have been sought with variable mixes of industrial policy ("picking the winners") and trade liberalization, but the policies of creditors and international lending agencies produced strong incentives for privatization, deregulation, and the opening up of the economy. Saying that the debt crisis has been in the 1980s both a powerful constraint and a substantial incentive for economic liberalization does not mean, of course, that the relationship between crisis and reform was necessary or sufficient. In fact, liberalization had begun in the 1960s and 1970s, as a consequence of perceived export opportunities, of export-oriented foreign investment, or of deliberate attempts by governments to overcome stagnating tendencies in the economy. The difference is that what had been a developmental option in previous decades had now become an imperious necessity.

As for political factors, the end of the Cold War facilitated not only political liberalization, which is more or less obvious, but also large-scale economic reform, especially in democratic settings. First, the collapse of communism led to the organizational and ideological disarmament of the radical left, and this rendered armed subversion less likely. Second, and more important, in the new international conditions the fear, be it realistic or paranoid, of exogenously induced revolution either weakened or disappeared. This fear, often unrealistic, was not only a central determinant of the exclusionary policies carried out by local elites and a reason for American and European support for authoritarian regimes, but it was also a constraint on elite behavior. During the Cold War, important segments of the state and political elites in many countries espoused the view that populist and protectionist economic policies were an antidote to communism, and many believed that the drastic social consequences of

the dismantling of autarkic capitalism would be a breeding ground for revolution (Waisman 1987).

Finally, the international demonstration effects received by the segments of Latin American societies most open to outside influences (economic and political elites, middle classes, and the intelligentsia) have favored, since the early 1980s, both economic and political liberalization. The economic success of capitalist economies and the crisis in the socialist ones, as well as the eastern European revolutions, have conferred an aura of empirical validity on two propositions: first, that capitalism and liberal democracy are both efficacious, while socialism as both an economic and a political formula is not; and second, that a capitalist economy and a democratic polity presuppose each other.

These external factors interacted with endogenous determinants. The most important of these was the realization, by state and political elites, but also by economic and intellectual ones, that autarkic capitalism had run its course, and caused in many countries stagnation or retrogression in the economy and instability and illegitimacy in the polity. It was simply no longer viable as an institutional model.

Autarkic capitalism was carried to its extreme in the countries of the Southern Cone: Argentina, Chile, and Uruguay. The long-term effects of radical import-substituting industrialization could only be stagnation, or at least stagnating tendencies, because industrialization was based on the transfer of resources from the internationally competitive export sector to a manufacturing sector shielded from the world by extraordinarily high levels of protection, both tariff and nontariff (outright prohibitions to import included). Advanced autarkic industrialization led to a situation in which most of the capital and labor in the society was committed to this captive domestic market. The outcome of this massive misallocation of resources could only be, in the long run, stagnation, and even retrogression.

Instability and illegitimacy were the long-term outcome of autarkic industrialization because this pattern of growth eventually produced an explosive combination: a stagnated economy and a society made up of highly mobilized and organized social forces, labor and the intelligentsia in particular. Stagnation led to the mobilization of large

segments of the lower classes and the intelligentsia. In some countries, such as those of the Southern Cone in the 1960s and 1970s, truly revolutionary situations, in the Leninist sense of the term, appeared. Eventually, they triggered, or justified, the establishment of authoritarian regimes.

The demise of autarkic capitalism was the result, as was the case with communism, of a revolution from above. In both situations, it was the elites who dismantled the existing regimes, after having reached the conclusion that the stagnation and illegitimacy experienced by their societies were the consequence of existing institutions, and that there was no solution to the economic and political crises within these institutions. In some cases, such as Argentina and Chile, this realization took place when radical import substitution had approached its limits, and produced not only stagnation but also a revolutionary regime in Chile, and guerrillas and food riots in Argentina. In other cases, such as Brazil, the switch is taking place before these consequences appear, largely as a consequence of the demonstration effects of other Latin American countries.

THE CONTRADICTION LOGICS OF ECONOMIC AND POLITICAL TRANSFORMATION

There are three possible sequences between economic and political liberalization (Bresser Pereira et al. 1993; Haggard and Kaufman 1995; Lijphart and Waisman 1997). To give them Latin American names, they would be the Chilean model, in which privatization, deregulation, and the opening up of the economy preceded democratization; the Venezuelan pattern, in which the liberalization of the economy takes place in the context of political institutions that have been in place for several decades; and finally the Argentine sequence, in which economic liberalization and the consolidation of democracy take place more or less at the same time. The three are fraught with dangers, but the third is the least favorable. The reason is that economic liberalization and the consolidation of democracy are governed by opposing social logics (Lijphart and Waisman 1997; Waisman 1998).

Privatization, deregulation, and the opening up of the economy are governed by the logic of differentiation. Their first impact on the society is

the increase of social differentiation in both the vertical and the horizontal senses: Polarization between rich and poor as a whole intensifies, and so does polarization between “winners” and “losers” within each social class, and also between sectors of the economy and regions of the country.

On the other hand, the consolidation of democracy is governed by the logic of mobilization. The political context of a new democracy renders the mobilization of those affected by economic liberalization more likely, due to the lowering of the costs of political action in relation to what was the case in the predemocratic period. Moreover, new democracies create incentives for political entrepreneurship, for in the new political conditions political and labor activists must secure and organize social and political bases. Economic liberalization presents them with an inventory of grievances that easily translates into a political agenda. Thus, both from below and from above, institutional factors are conducive to the articulation of movements of resistance to economic liberalization.

These two logics have the potential for inhibiting each other, and consequently for blocking or derailing economic liberalization, or the consolidation of democracy, or both. And yet, economic liberalization and the consolidation of democracy are occurring simultaneously in many Latin American countries, and so far no serious blockage or derailing has occurred as a consequence of the interaction between these processes. In several countries, there is an impressive consensus, involving state and economic elites, and even labor and some of the parties in the left and center that had supported state socialism or economic nationalism in the past.

The reason that, so far, the two opposing logics discussed above have not clashed lies in the operation of three “cushions” or moderating factors, which inhibit political mobilization. These can be classified into structural, institutional, and cognitive-ideological.

The structural cushion consists simply in the fact that economic liberalization itself weakens and destroys the power bases of the coalitions supporting the old regime (rent-seeking entrepreneurs and unions, and in some cases managers and workers in the public sector) and in general of those hurt by trade liberalization, privatization,

and deregulation. On the one hand, these processes of economic transformation generate insecurity and economic deprivation, and thus discontent. On the other, impoverishment and marginalization also reduce social groups' capacity for organization and mobilization in defense of their interests.

Business elites, both private and public, face the choice between recycling into competitive capitalists and dropping out from the elites. This group is usually differentiated, and its most entrepreneurial elements, and/or those endowed with large amounts of economic and social capital, usually join, or become, the elite in the open economy. Labor is also dualized: Workers in the competitive sectors of the economy, or in sectors insulated from foreign competition (e.g., those producing nontradeable goods) are likely to join the train of economic conversion, and to engage in bargaining-oriented unionism. Sectors weakened by deindustrialization, by the increase of unemployment, and in general by the growth of poverty, on the other hand, are more likely to develop confrontational forms of political action, but in the end their impact is likely to be modest, because of the factors discussed above. In many countries, the weakening of labor actually began before economic liberalization, for impoverishment and the growth of the labor reserve were manifestations of the crisis of the old regime itself.

In the second place, the clash between the two opposing logics discussed above has been inhibited by institutional change. The design or redesign of some of the basic economic and political institutions is in many cases a necessary component and in general an important contributing factor to successful transitions.

Finally, cognitive-ideological factors have both external and internal sources. As I argued above, economic nationalists as well as leftists have been affected by the collapse of communism (and also by the apparent success of the Thatcher-Reagan economic policies), and by a process of political learning, triggered by the experience of the economic and political consequences of the old regime. The cumulative effect of these cognitive processes has been not only the abandonment of autarkic capitalism, but also the acceptance of the liberal model, either under the form of active support, or because of ideological surrender produced by the exhaustion of alternatives.

Given this quasi-consensus, the negative consequences of the economic transformation are not conceptualized by large segments of economic, political, and intellectual elites as necessary or permanent attributes of the emerging institutional model, but to a large extent as the product of the failure of autarkic capitalism. And the new course is not perceived as a leap in the dark, but as a transition, whose undesirable side effects are in any case the inevitable and temporary cost of the only process that can ensure, in the long run, affluence and even a higher measure of equality of opportunity in the society. The most significant leftist and radical arguments, on the other hand, focus on the espousal of social democracy in opposition to the most radical forms of the market economy, often characterized as "Darwinian" or "savage" capitalism.

Both the strengthening of civil society and the enhancement of state capacity are necessary conditions not only for the consolidation of democracy but also for the success of the economic transformation.

The typical situation in the countries that are undergoing the double transformation is that the state is shrinking while its effectiveness remains questionable in many areas. At the same time, the corporatist apparatus that was characteristic of autarkic capitalism is being dismantled. Civil society has been weakened by the authoritarian experience, and by the increased social differentiation that follows economic liberalization. The consensus supporting the new course could erode unless the new model is institutionalized, something that cannot happen without a more effective state and a stronger civil society.

This is, thus, an inflection point in the relationship between state and society, a conjuncture that could be conceptualized both a danger and an opportunity. The danger resides in the fact that, in these conditions, the structural, institutional, and cognitive "cushions" discussed above could gradually lose their effectiveness. The social dislocation produced by economic liberalization would either increase the atomization of the society, and lead to mass anomie; or facilitate "praetorian" mobilization. The first outcome would entail a deterioration of the already modest quality of the new democracies, while the second would lead to disturbances. In both cases, the legitimacy of the

policies of economic transformation would fall precipitously. But this situation also represents and opportunity for social and political agency, whose goal would be the strengthening of civil society and the enhancement of state capacity.

CARLOS H. WAISMAN

LAW AND LEGAL SYSTEMS

The term *law* is surprisingly difficult to define. Perhaps the best-known definition within the sociology of law community is that of Max Weber: "An order will be called *law* if it is externally guaranteed by the probability that coercion (physical or psychological), to bring about conformity or avenge violation, will be applied by a *staff* of people holding themselves specially ready for that purpose" (1954, p. 5). Similar definitions include Donald Black's terse statement: "Law is governmental social control" (1976, p. 2). While these types of definitions have sometimes been attacked as employing a Westernized conception, appropriate for developed states but inappropriate for other societies, Hoebel advances a similar definition of law in all societies: "The really fundamental *sine qua non* of law in any society—primitive or civilized—is the legitimate use of physical coercion by a socially authorized agent" (1954, p. 26).

Definitions such as these are more interesting for what they exclude than for what they include. Weber and Hoebel each attempt to draw a line

where the boundary between law and something else is fuzziest. By including the term *legitimate*, Hoebel's definition is intended to distinguish law from the brute exercise of force. The leader of a criminal gang who forces people to give him money may be doing many things, but he is not enforcing the law. He is not a socially authorized agent, and his use of force is not legitimate. Legitimacy itself is a slippery concept, and disagreements about when it is present give rise to questions such as whether the Nazis governed under the rule of law.

The inclusion of coercion and specialized agents of enforcement in both Weber's and Hoebel's definitions is meant to distinguish law from customs or norms, the breach of which either is not sanctioned or is sanctioned only by members of the group against which the breach occurred. The internal rules (norms and customs) governing a family's life or an organization's life are not law unless they are reinstitutionalized, that is, unless they are "restated in such a way that they can be applied by an institution designed (or at very least, utilized) specifically for that purpose" (Bohannon 1965, p. 36). Some have rejected such definitions and argued that law consists of the regularized conduct and patterns of behavior in a community or society (Ehrlich 1936; Malinowski 1926). They fear that if the study of law is restricted to legal rules enforced by specialized legal staffs, it will exclude much of what legal anthropologists and legal sociologists may find interesting. Regularized conduct definitions in turn suffer from their inability to offer a clear boundary between legal norms and other norms in the society. However, they do capture the idea that there is law-stuff everywhere. Families and organizations do generate rules and do coerce or induce compliance. These groups constitute what Moore (1973) calls "semi-autonomous fields." Not only are the rules of these organizations interesting in their own right, the interaction of these rules and the state rules we call law helps to shape the fundamental choice between avoidance and compliance that is faced by all to whom rules are addressed.

The boundary maintenance functions of definitions such as those of Weber, Hoebel, and Bohannon undoubtedly have their place, but law's empire is so large that the border skirmishes occurring out on its frontiers have limited influence on our shared understanding of the words *law* and

legal system. Wherever it occurs, law is a body of rules that speak to how people should behave in society (substantive law) and how the legal system itself should proceed (adjective law). The volume and complexity of rules may be expected to parallel the size and complexity of the society of which they are a part. But broad categories of substantive law—tort law, property law, criminal law—apparently exist in all legal orders, as do the fundamentals of adjective law—procedure and evidence. The various definitions of "law" exist in an uneasy tension (Tamanaha 1997). This tension can serve us well if we follow Griffiths's advice (1984) and view "legalness" as a variable rather than thinking of "law" as a special, definable phenomenon. The complex body of substantive and adjective rules at different levels comprise a legal system.

LEGAL SYSTEMS

The comparative study of law might trace its roots to Aristotle's comparison of Greek city-state constitutions. A more recent example is Montesquieu, who, in *The Spirit of the Laws* ([1748] 1962), attempted to explain legal diversity in terms of various factors in the social setting. Interspersed between these efforts were comparisons of canon law with Roman law in Europe and with the common law in England. Despite these precursors, the modern study of comparative legal systems has become a topic of sustained academic interest only during the last 100 to 150 years.

The history of comparative law is set forth in a number of works, including Zweigert and Kotz (1987) and David and Brierley (1985). The present essay discusses a small part of this history, focusing on what Zweigert and Kotz call scientific or theoretical comparative law rather than legislative comparative law, in which foreign laws are examined and invoked in the process of drafting new nation-state laws.

Early theoretical efforts, exemplified by Maine's *Ancient Law* ([1861] 1963), adopted evolutionary theories of legal development. In Maine's famous formulation, legal systems, following changes in social arrangements, move from *status*, wherein one's rights and duties are determined by one's social niche (the law of feudalism), to *contract*, wherein one's rights and duties are determined by

oneself and the contracts one enters into (eventually the law of capitalism).

A second well-known developmental theory of changes in legal systems is that of Durkheim ([1893] 1964). A societal movement from mechanical to organic solidarity is accompanied by a movement from repressive law (law that punishes those who violate a shared moral understanding) to restitutive law (law that attempts to facilitate cooperation and to return people to a *status quo ante* when rule violations occur).

From the sociological point of view, perhaps the most important contributor to the early development of comparative law was that preeminent lawyer-social scientist, Max Weber. Weber's contribution was in three parts. First, he developed the device of an ideal type, a stylized construct that represents the perfect example of a phenomenon. The ideal type acts as a yardstick against which we might measure actual legal systems. Second, using ideal types, he provided a typology of legal systems classified by the formality and the rationality of their decision-making processes. Ideally, legal systems could be thought of as formal or substantive, rational or irrational. A legal system is formal to the extent that the norms it applies are intrinsic to the system itself. Substantive law, as the term was used earlier, should not be confused with the substantive dimension of Weber's typology. A legal system is substantive in Weber's sense to the extent that the source of the norms it applies is extrinsic to the legal system. For example, a legal system would be substantive if a court resolved disputes by reference to a religious rather than a legal code.

A legal system is rational if it yields results that are predictable from the facts of cases; that is, if case outcomes are determined by the reasoned analysis of action in light of a given set of norms. A legal system is irrational when outcomes are not predictable in this way. Basically, a legal system is rational to the extent that similar cases are decided similarly.

A formally irrational system exists when the legal order produces results unconstrained by reason. Classic examples are judgments following consultation with an oracle or trial by ordeal. Substantive irrationality exists when lawmakers and finders do not resort to some dominant general norms but, instead, act arbitrarily or decide

upon the basis of an emotional evaluation of a particular case. Weber apparently had in mind the justice dispensed by the Khadi, a Moslem judge who, at least as Weber saw him, sat in the marketplace and rendered judgment by making a free and idiosyncratic evaluation of the particular merits of each case.

A substantively rational legal system exists when lawmakers and finders follow a consistent set of principles derived from some source other than the legal system itself. Again, Weber thought that Moslem law tended toward this type insofar as it tried to implement the thoughts and commands of the Prophet.

Western legal systems, especially those of civil law countries such as France and Germany, most nearly approximate the formally rational ideal, a legal system where the generality of legal rules is high and where the legal rules are highly differentiated from other social norms.

The relationship between formal and substantive law is obviously more complex than can be reflected in these four Weberian types. For example, legal systems may be procedurally quite formal while incorporating substantive norms rooted in nonlegal institutions. Moreover, rational systems may incorporate potentially irrational components, as when the final judgment in a case is left to a lay jury. Nevertheless, as ideal types Weber's categories help to locate idealized Western law in a wider universe of possible legal systems.

The importance of Weber's categories, like those of Maine, resides in large part in his efforts to link types of rationality with different types of societies and different ways of organizing legal systems. Weber associated an irrational legal order with domination by a charismatic leader. Formal rationality, on the other hand, accompanies the rise of the bureaucratic style of organization. Weber regarded logically formal rationality as the most "advanced" kind of legal ordering and as particularly hospitable to the growth of the capitalist state.

Weber's third contribution to comparative legal studies was his insight that the nature of a society's legal system is shaped by the kinds of individuals who dominate it. On the European continent, in the absence of a powerful central

court, domination fell into the hands of the university law faculties who strove, through the promulgation and interpretation of authoritative texts, to create and understand the legal system as a general and autonomous set of rules. The common law in England, on the other hand, grew under the tutelage of a small elite judiciary and an accompanying centralized bar, more concerned with pronouncing rules for the settlement of disputes than with developing generalized rules of law (Weber 1954). In time, the differences in the legal systems created by these different sets of legal actors helped to spur interest in comparative legal systems.

Overall, Weber's contribution was part of a general movement away from comparing the legal codes of various societies and toward a comparison of the legal solutions that "are given to the same actual problems by the legal systems of different countries seen as a complete whole" (Zweigert and Kotz 1987, p. 60, quoting Ernst Rabel). From this perspective, legal systems confront similar problems, and if we examine the whole system we will uncover fundamental differences and similarities in their various solutions. The effort to uncover these similarities and differences has taken several different paths.

Macrocomparisons. One path has involved attempts to develop macrocomparisons of entire legal systems. This effort has resulted in a number of taxonomies of legal systems in which the laws of nations are grouped by what are commonly called "legal families." The criteria for classification and the ultimate categories of family types have varied from scholar to scholar. Among the factors that have been used are historical tradition, the sources of law, the conceptual structure of law, and the social objectives of law. Socialist writers have traditionally focused on the relationship of law to underlying economic relations and a society's history of class conflict (Szabo and Peteri 1977; Eorsi 1979), although more recent efforts paint a more complex picture that threatens some of the presumed differences between socialist and "capitalist" law (Sypnowich 1990). David (1950) and David and Brierley (1985) base their classification on ideology (resulting from philosophical, political, and economic factors) and legal technique. Zweigert and Kotz (1987, p. 69) base their classification on a multiple set of criteria they call the "style" of law. Legal style includes: historical background and

development, predominant modes of thought in legal matters (contrasting the use of abstract legal norms in civil law versus the narrow, reasoning by analogy typical of the common law), distinctive concepts (such as the trust in the common law and the abuse of right in civil law), the source of law (statutory or case law), and ideology (e.g., the ideology of socialist and Western legal families).

Given the wide variety of criteria used by various scholars, perhaps it is surprising that the resulting "families" tend to be quite similar. To provide but one example, Zweigert and Kotz (1987) divide the world into the following eight families: (1) Romanistic family (e.g., France); (2) Germanic family (e.g., Germany); (3) Nordic family (e.g., Sweden); (4) common law family (e.g., England); (5) socialist family (e.g., Soviet Union); (6) Far Eastern family (e.g., China); (7) Islamic systems; and (8) Hindu law. While some taxonomies may have fewer civil law divisions, this set of categories shares with many others a Eurocentric emphasis and a resulting inability to fit non-European legal systems easily into the taxonomy (see Ehrmann 1976; David and Brierley 1985), although the rise of non-Western societies such as Japan should help to redress this imbalance in time (see Institute of Comparative Law, Waseda University 1988).

The Eurocentric and Western emphasis is not simply a matter of greater particularity in describing differences between the legal traditions of Europe. It is also reflected in the concepts used to make distinctions. The categories of the various typologies are based primarily on a comparison of private law rather than on public or constitutional law and on substantive law rather than on adjective law. A different focus may lead to different family configurations. For example, American and German constitutional law are in some ways more similar to each other than to French or English constitutional law. The focus on private substantive law has the additional result that it overemphasizes legal doctrine while underemphasizing the degree to which legal systems are a product of the surrounding society. The consequence is to understate similarities in Western legal arrangements that may be captured by the idea of a legal culture.

One alternative designed to avoid this tendency is found in Merryman's concept of legal traditions (1969). Legal traditions are:

a set of deeply rooted, historically conditioned attitudes about the nature of law, about the role of law in the society and the polity, about the proper organization and operation of a legal system, and about the way law is or should be made, applied, studied, perfected, and taught. The legal tradition relates the legal system to the culture of which it is a partial expression. (Merryman 1969, p. 2)

From this perspective the Western legal tradition may be usefully compared to and contrasted with legal systems in other cultures (Barton et al. 1983).

A second alternative to the “legal families” approach is taxonomies that are not based on differences in substantive law. One recent example, closer to the Weberian heritage, is that of Damaska (1986). Like Weber, Damaska uses two dimensions to develop ideal-typical legal orders. The first dimension divides legal orders into activist and reactive systems of justice. Activist states attempt to use law to manage society, whereas reactive states attempt only to provide a legal framework for social interaction. At the heart of the image of law of the activist state is the state decree, spelling out programs, assigning tasks, and distributing welfare to citizens. At the heart of the reactive state are devices facilitating agreement, contracts, and pacts. While it might be thought that this dimension is designed primarily to distinguish capitalist and socialist legal orders, Damaska observes that not all types of socialist models follow the state socialism that has dominated the Soviet Union and eastern Europe. Yugoslavian self-management concepts speak to this reactive tradition in socialism. Likewise, capitalist societies exhibit considerable differences in their commitment to an activist state.

Damaska’s second dimension divides legal orders into hierarchical and coordinate systems of judicial organization. In the hierarchical ideal officials are professionals who are arranged in a strict hierarchy and who employ special, technical standards of decision making. The coordinate ideal describes a more amorphous machine in which legal functionaries are amateurs who are arranged in relationships of relatively equal authority and who do justice based on prevailing ethical, political, or religious norms. Weber’s vision of the Moslem Khadi applying substantive (religious) law would appear to describe this type of legal order.

There are other strong parallels between Damaska’s and Weber’s ideal types. Their categories are less obviously Eurocentric and, more important, employ a set of concepts that facilitate an understanding of ways in which the relationship between the state and society is mediated through law. Both analyses are inclined toward a functional approach. Rather than beginning with individual legal histories and doctrines and grouping them into families, this approach begins with a set of problems—how to mediate the relationship of the state and society and how to organize the structure of legal actors—and arranges legal systems according to how they address these problems.

Damaska’s distinction between the hierarchical and coordinate ideal and Weber’s distinction between formal and substantive rationality direct our attention to a central issue concerning law—the degree to which different legal systems are autonomous. Formalist theories of law posit a self-contained enterprise separate from the rest of society (Kelsen 1967), while most Marxist theories view law solely as an instrument of domination (Spitzer 1983).

More recent theoretical discussions of autonomy include those of the Critical Legal Studies Movement, Niklas Luhmann (1985), and Pierre Bourdieu (1987). Critical Legal Studies focuses on law’s indeterminacy and on the role of social forces and power relations as the actual determinants of legal outcomes (Kelman 1987). Luhmann’s theory, to the contrary, views the legal system as autopoietic. An *autopoietic system*, like a living organism, produces and reproduces its own elements by the interaction of its elements (Teubner 1988). Bourdieu offers a complex view of the autonomy of the “juridical field.” Legal system autonomy is the result of the constant resistance of the law to other forms of social practice. One way this is accomplished is by requiring those who wish to have their disputes resolved in court to surrender their ordinary understandings and experiences. Actions and actors brought into the legal system are dealt with only after they and their dispute are translated into a set of legal categories (e.g., debtor—unsecured creditor; lessor—lessee;). Western courts tend to treat as irrelevant and inappropriate those accounts that attempt to introduce the details of litigants’ social lives (Conley and O’Barr 1990).

Interest in the question of legal autonomy has been reinvigorated by the collapse of socialist regimes in central and eastern Europe. The legal systems in the formerly communist societies of central and eastern Europe enjoyed relatively less autonomy than their Western counterparts. For example, judges were sometimes told how to decide politically sensitive cases. Because the directive usually came via telephone, the practice acquired the pithy name “telephone law.” In the last decade much attention has been devoted to the question of how to establish the rule of law—that is, greater legal system autonomy—in Russia and eastern Europe (Hendley 1996). One would be wrong, however, to conclude that legal systems in capitalist societies enjoy complete autonomy. The intrusion of politics into the legal systems of these societies is more subtle but nevertheless substantial (Jacob et al. 1996). What is different is the way judicial field is structured: for example, the relative independence of the judiciary and the organization of the legal profession. These structures, as Bourdieu notes, make it easier for the legal system to resist penetration. Indeed, intrusion is not a one-way street. The “centrality of law” thesis argues that the legal system increasingly penetrates into other areas of modern society (Hunt 1993). Modern states have “more” law, larger state bureaucratic legal institutions, and growing numbers of legal professionals. Moreover, legal forms are exported to other spheres of life, as when the workplace becomes infused with due process requirements.

It should be clear by now that legal autonomy is a multifaceted phenomenon. Systems differ in their degree of judicial independence and judicial formalism, the extent to which their laws are status neutral, and whether those forced into the legal arena enjoy equal legal competence (Lempert 1987). One of the strengths of Weber’s and Damaska’s typologies is that they suggest dimensions along which legal system autonomy may vary. For example, systems that reflect Damaska’s hierarchical ideal will be more likely to exhibit some of the features of greater autonomy.

Microcomparisons. Microcomparisons of legal systems are concerned with the details of specific legal rules and institutions rather than with entire legal systems (Rheinstein 1968). The functional approach is even more pronounced at this

level. Scholars often begin with a specific social problem and seek to discover the various ways in which legal systems solve it, or they begin with a specific legal institution and examine how it operates in various systems. For example, Shapiro (1981) makes a comparative analysis of the court as an institution in common law, civil law, imperial Chinese, and Islamic legal systems.

The most valuable work done at this level has been that of legal anthropologists. By examining the dispute-processing activities of African, Latin American, and Asian legal tribunals, they have provided new insights into the connection between a society’s social relationships and the way in which it processes disputes. Ethnographies by Gluckman (1967), Gulliver (1963), Nader (1969), and others exposed a general pattern wherein tribunals confronted with disputes among individuals who are in multiplex and enduring relationships are more likely to widen the range of relevant evidence and to search for outcomes that allow flexibility, compromise, and integration. Tribunals confronted with disputes among individuals who are in one-dimensional and episodic relationships are more likely to narrow the range of relevant evidence and to provide binary outcomes in which one side clearly wins and the other loses.

Legal ethnographies have also supported the earlier observation based on macrocomparisons that the organization of courts and judges plays a role in determining styles of dispute processing. Fallers (1969), for instance, found that the Soga, a society in many ways very similar to the Barotse studied by Gluckman, tended to craft decisions that were narrower and that resulted in “legalistic” rulings. His explanation was that the “judiciary” in the two societies differed in at least one key respect. The Soga courts were more purely “judicial” bodies without administrative and executive functions. A specialized legal staff was more likely to issue narrower opinions. Moreover, because binary outcomes result in a judgment to be enforced against a losing party, the availability of a coercive judicial apparatus may facilitate this type of dispute resolution (Lempert and Sanders 1986).

Perhaps because of the seminal work by Llewellyn and Hoebel (1941) on the Cheyenne, the work of legal anthropologists, more than most macro approaches to the study of legal systems,

builds on the sociological jurisprudence and the legal realist traditions (Pound 1911–1912; Oliphant 1928; Llewellyn 1930; Arnold 1935). It is concerned with the law in action, with the actual experience of the legal staff and the disputants (Merry 1990). As a consequence, legal anthropology has had a substantial influence on the sociological study of disputing and what has come to be called alternative dispute resolution in Western societies (Greenhouse 1986; Abel 1981). Postmodern legal anthropology has grown increasingly preoccupied with the problem that confronts all comparativist work—understanding the effect of the observers' own backgrounds on the ways in which we distinguish legal systems (Comaroff and Comaroff 1992). Undoubtedly, however, the ethnographic tradition has provided rich detail to our understanding of the differences among legal systems.

Recently, anthropologists have come to appreciate the degree to which African and other consensual legal systems are themselves partly the outgrowth of colonial experience and of the distribution of power in society (Starr and Collier 1989). This observation underlines a more general point that has been noted by macro and micro scholars alike. Nearly all existing legal systems are, to a greater or lesser extent, externally imposed, and therefore all legal systems are layered (Watson 1974). In many societies layering occurs because of the existence of a federal system creating an internal hierarchy of rules, some of which are imposed from above. Layered legal systems also occur when nations such as Turkey (the Swiss code) or Japan (the German code) shop abroad and adopt the laws of another nation as the basic framework for substantial parts of their own legal system. In some situations the imposition is done wholesale and involuntarily, as when colonial powers impose a legal system. The result can be considerable social dislocation (Burman and Harrell-Bond 1979). In time, multiple layers may exist, as in Japan, where indigenous law has been overlaid by both the adopted German code and American constitutional law concepts imposed after World War II (Haley 1991).

In each of these situations a society's legal system is unlikely to fit easily within any of the legal families. For instance, a society may borrow another's substantive and adjective law for commercial

law purposes but retain the existing law of domestic relations. Frequently, such societies are said to have a "dual legal system." However, to the degree that this phrase describes a situation in which two equal systems stand side by side and rarely interact, it fails to capture the rich variety of hierarchical structures in layered systems. An important task for the students of legal systems is to understand the process by which individuals and groups use law at different levels and in so doing transform both.

At the uppermost layer of legal systems are legal arrangements that are multinational or transnational in scope. Within the European Economic Community, following the Treaty of Rome in 1957 and the Single European Act in 1987, the adoption or imposition of a multinational regime is proceeding rapidly. The process requires the harmonization of a large body of law including corporate, intellectual property, environmental, tax, products liability, banking, transportation, product regulation (e.g., food and pharmaceuticals), and antitrust law. Member states must conform their national laws to comply with community directives, inevitably leading to the homogenization of European law. This process, along with the substantial alterations in property and contract law accompanying the economic changes in the Soviet Union and eastern Europe, suggests that the differences among legal systems of European origin will diminish over the next few decades, especially differences among laws governing commercial and economic transactions.

Indeed, the existence of a global economic order promotes some similarities in all laws governing economic transactions. Islamic law has been compelled to create a number of legal devices and fictions designed to avoid direct confrontation with several teachings of the Koran, such as the prohibition against charging interest that would make participation in a modern economic order difficult (David and Brierley 1985, p. 469). The emerging global economy has also created a new layer of transnational legal actors who at once attempt to export their nationalist version of law and to create a set of transnational institutional arrangements that sometimes complement and sometimes are in opposition to national legal structures. For example, Dezalay and Garth (1996) describe the emergence of a cadre of international commercial

arbitrators and their creation of an international legal field with its own networks, hierarchical relationships, expertise, and rules.

A number of additional global issues also create pressures toward the creation of transnational legal arrangements. These include transnational crime; ethnic and racial conflict; world population and migration patterns; labor flows; and, perhaps most significant, environmental regulation. Common legal structures created to address these issues and demands that nation-state legal systems enact and enforce appropriate compliance mechanisms may lead to the rebirth of the ideal of international legal unification that was popular at the beginning of the century. As can be seen in the European example, such unification inevitably involves some imposition of law.

Because pressures to build a more complex body of transnational law coincide with the diminution of differences in Western legal systems, over the next few decades one of the most interesting issues in the study of legal systems will involve movements toward and resistance to a transnational legal order premised on the hegemony of Western legal systems and Western legal concepts. The ongoing task of comparative law is to understand the processes of borrowing, imposition, and resistance, both among nations and between levels of legal systems.

LAW AND SOCIETY

NOTE: Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.

The concepts of *law* and *society* refer to macrostructural phenomena. Is there a macro-oriented theory of law and society or a macro-sociolegal theory to guide this field? As an interdisciplinary endeavor, the sociology of law relies upon, or is influenced by, the intellectual assumptions and propositions of general sociology and legal theory. This article will therefore consider the relationship of this field to both parent disciplines.

RELATIONSHIP TO GENERAL SOCIOLOGY

It is no exaggeration to state that the field of sociology lacks a systematically developed and precise theory of society. Although interest in macro-sociological theory building has been in evidence for the past two decades, particularly among those concerned with comparative sociology (Eisenstadt and Curelaru 1977), no such theory has yet been developed in sufficient detail and precision to guide empirical research. This is not to deny the fact that such macrotheorists as Marx, Durkheim, Weber, and Parsons have exerted a pervasive influence on various specialties within sociology, including the relationship between law and society.

Marx. Marx conceived of law as a component of the “superstructure” of a capitalist society. As an epiphenomenon of the superstructure, it provides a rationale or ideology for preserving the existing class relations in a capitalist economy. Concepts of property and contract, for example, become instrumentalities for maintaining and reproducing class hegemony. In other words, legal concepts and doctrines reinforce the position of the ruling class and, at the same time, become the constituents of the “false consciousness” from which the working class suffers. Implicit in this theory of law as a weapon wielded by the state in a capitalist society against the working class is the assumption that if private property were abolished and a classless socialist society were ushered in, the state would “wither away” and, with it, law would “wither away” as well.

As usually formulated, the Marxian theory of law and society is not empirically verifiable. It does not follow, however, that this theory is devoid of any empirical implications. Questions can be raised—and have been raised—concerning class bias in the adjudication of civil and criminal cases, in the emergence of significant legal norms—for example, those regarding inheritance—and in the recurrent failure of agrarian reform laws. Likewise, it is possible to investigate a proposition counter to the Marxian thesis, namely, that the passage of laws in a capitalist state can potentially diminish the power of the ruling class vis-à-vis the working class. A case in point is the enactment of the National Labor Relations Act of 1935 in the United States, which institutionalized the rights of employees to unionize and to engage in collective bargaining with employers. Research questions

such as those cited above would test the validity of some propositions derivable from the Marxian theory of law and society.

Durkheim. Turning to Durkheim’s contribution to this field, one of necessity reverts to his *Division of Labor in Society* (1933), in which he argued that in societies characterized by “mechanical solidarity” there is a predominance of repressive laws, whereas in societies characterized by “organic solidarity” there is a predominance of restitutive laws. A number of social scientists have subjected Durkheim’s thesis to empirical tests and have found it wanting (Schwartz and Miller 1964). It is a testament, however, to the intriguing character of Durkheim’s thesis that it continues to evoke the interest of researchers (Baxi 1974; Schwartz 1974; Sheleff 1975). A more general formulation of Durkheim’s thesis would be that societies differing along various dimensions of societal development—of which the division of labor is but one—will exhibit systematic differences in their legal systems (Evan 1968).

In the course of developing his thesis that the division of labor is the principal source of social solidarity, Durkheim formulated his seminal idea of an “index” (Durkheim 1933, pp. 64–65). Apart from his fame as the “father of modern sociology,” Durkheim is the originator of the concept of an “index”, that is, an indirect and “external” measure of a complex dimension of social structure such as social solidarity. That he developed the concept of an index in connection with “juridical rules” and types of laws is of particular interest to sociologists of law and legal scholars. Under the circumstances, it is indeed surprising that to date, with few exceptions (Evan 1965, 1968, 1980; Merryman, Clark, and Friedman 1979; Lidz 1979), this facet of Durkheim’s work has been neglected. The concept of a “legal index” or a “legal indicator” merits systematic attention if we are to become more precise in our understanding of the role of law in social change.

Weber. In comparison with the work of Durkheim and Marx, Weber’s contributions to the sociology of law are appreciably more diverse and complex. Embedded in an intricate mosaic of ideal types and comparative and historical data on the emergence of legal rationality in Western civilization and on the role of law in the origins of capitalism (Weber 1950; Rheinstein 1954; Trubek

1972; Collins 1980), Weber's welter of legal conceptualizations poses a difficult challenge to the empirically oriented researcher. For example, his famous typology of lawmaking and lawfinding suggests possible research leads for comparative and historical analysis. Rheinstein, who edited and translated Weber's work on the sociology of law, lucidly summarizes his typology in the following manner:

1. *irrational, i.e., not guided by general rules*
 - a. *formal: guided by means which are beyond the control of reason (ordeal, oracle, etc.)*
 - b. *substantive: guided by reaction to the individual case*
2. *rational, i.e., guided by general rules*
 - a. *substantive: guided by the principles of an ideological system other than that of the law itself (ethics, religion, power, politics, etc.)*
 - b. *formal:*
 - (1) *extrinsically, i.e., ascribing significance to external acts observable by the senses*
 - (2) *logically, i.e., expressing its rules by the use of abstract concepts created by legal thought itself and conceived of as constituting a complete system.*

(Rheinstein 1954, p. 1)

Assuming that the meaning of each of these ideal type categories can be clarified and that legal indicators can be developed for each of the types, a comparative study could be undertaken to explore differences in lawmaking and in lawfinding of such major legal systems as common law, civil law, socialist law, and Moslem law. Equally challenging would be a study of long-term trends within each of these legal systems. The findings of such an inquiry would shed light on the occurrence of the evolutionary stages postulated by Weber.

The general development of law and procedure may be viewed as passing through the following stages: first, charismatic legal revelation through "law prophets"; second, empirical creation and finding of law by legal honoraries; . . . third, imposition of law by secular or theocratic powers; fourth and finally, systematic elaboration of law and professionalized administration of justice by persons who have received their legal training

in a learned and formally logical manner.
(Rheinstein 1954, p. 303)

Another significant thesis in Weber's corpus of writings on law is the innovative role he attributes to "legal honoraries" or "legal notables" (Bendix 1960). Is Weber's thesis more valid for civil law systems, with its heavy immersion in Roman law, than it is for common law, let alone for socialist law or Moslem law? Once again it would be necessary to develop appropriate legal indicators to measure the degree to which legal notables—lawyers, judges, and high-level civil servants—introduce new rules and new interpretations of existing legal norms in the course of administering justice.

Parsons. For decades, Parsons was the leading macrosociological theorist in the United States, making singular contributions to structural functionalism and to a general theory of action. Focusing on the action of social systems, Parsons developed a "four-function paradigm." According to Parsons, every society faces four subsystem problems: adaptation, goal attainment, integration, and pattern maintenance or latency (AGIL). The societal subsystems associated with these four functional problems are, respectively, the economy, the polity, law, and religion and education.

Following Weber, Parsons treats law as a rational-legal system consisting of a set of prescriptions, proscriptions, and permissions. The legal system, especially in highly differentiated modern societies, performs the functions of a "generalized mechanism of social control" (Parsons 1962). This function is performed vis-à-vis the economy, the polity, and pattern maintenance or latency. The net effect of the pervasive normative regulation is the integration of society. As Parsons puts it: "The legal system . . . broadly constitutes what is probably the single most important institutional key to understanding . . . problems of societal integration" (Parsons 1978, p. 52).

With his four-function paradigm, Parsons addresses the nexus between law and society with the aid of "generalized media of interchange." The economy in a developed and differentiated society uses the medium of money for transactions. Functionally analogous media of exchange operate in each of the other subsystems—power in the polity, value commitment in pattern maintenance, and influence in law.

Suggestive as Parsons's framework is for understanding interinstitutional relations, the generalized media of interchange have not, as yet, been operationalized so as to explain how the legal system interacts with other societal subsystems. In other words, since Parsons has not explicated specific linkages between the legal and nonlegal subsystems, it is difficult to discern what hypotheses can be tested against any body of data. Hence, a reasonable conclusion is that Parsons's macro-sociological theory, in its present form, is actually a metatheory.

The foregoing review of some sociological theories of law and society raises two common themes: (1) each of the theorists endeavored to comprehend the macrostructural relationships between law and other institutional systems of a society, and (2) if the hypotheses implicit in these theories are to be empirically tested, systematic attention would have to be devoted to the development of a body of legal indicators. The current generation of sociologists of law has yet to face up to the problems engendered by both of these themes.

RELATIONSHIP TO LEGAL THEORY

Is the relationship between the sociology of law and the field of legal theory any less problematic than it is with general sociology? On its face, the question should be answered in the affirmative because the sociologist of law must take some of the legal scholars' subjects as objects of inquiry. In actuality, because of the traditions of legal scholarship, legal scholars do not generally provide an analytical basis for sociological research. Legal scholarship tends to be preoccupied with legal rules, legal principles, and their application to a multitude of specific conflict situations. As a consequence, the scholarly literature—apart from being intellectually insular—is almost entirely verbal and idiographic, with virtually no interest in a *nomothetic*, let alone *quantitative*, analysis of legal phenomena. Furthermore, there is a high degree of specialization within legal scholarship such that most scholars tend to devote their entire careers to a particular body of law, be it labor law, criminal law, contract law, family law, and so forth, in their own country. Those scholars specializing in comparative law are inclined to study a particular specialty, for example, family law, by comparing case studies from two or more countries (Glendon

1975). Relatively few legal scholars seek to study the legal system of an entire society, such as the work of Hazard (1977) and Berman (1963) on the Soviet legal system. And fewer still have had the temerity to undertake systematic comparisons of total legal systems or families of legal systems, as exemplified in the work of David and Brierly (1968) and Wigmore (1928); and those who make no effort tolerate characteristics of total legal systems to the social-structural attributes of the societies in which they are embedded.

Surveying current legal theory, three distinct theoretical perspectives can be discerned: the theory of legal autonomy, critical legal studies, and autopoietic law. Each of these perspectives will be briefly reviewed and appraised for their implications for a theory of law and society.

Legal Autonomy. Traditional conceptions of the legal order and "sources of law" are based on two assumptions, the first being that the law is a "seamless web," a relatively "closed system." Whatever processes of change occur in the law are generated from within the legal system, not from without. In other words, processes of change are immanent or endogenous and are not externally induced. The second assumption is that the legal system is, by definition, autonomous from other systems or institutions of a society. Therefore, it is unnecessary to inquire into how the legal system interacts with other subsystems of a society or into what degree of autonomy a given legal system actually has from other societal subsystems.

Perhaps the most quintessential articulation of the theory of legal autonomy in recent years can be found in the work of Watson, a renowned legal historian and comparative law scholar. Watson has repeated his thesis of legal autonomy in a number of monographs and articles (Watson 1974, 1978, 1981, 1983, 1985, 1987). He contends that the growth and evolution of the law is determined largely by an autonomous legal tradition, which exists and operates outside the sphere of societal needs.

To a large extent law possesses a life and vitality of its own; that is, no extremely close, natural or inevitable relationship exists between law, legal structures, institutions and rules on the one hand and the needs and desires and political economy of the ruling elite

or of the members of the particular society on the other hand. If there was such a close relationship, legal rules, institutions and structures would transplant only with great difficulty, and their power of survival would be severely limited. (Watson 1978, pp. 314–315)

Law is largely autonomous and not shaped by societal needs; though legal institutions will not exist without corresponding social institutions, law evolves from the legal tradition. (Watson 1985, p. 119).

Unlike the Marxist view of law, Watson's is that the law does not advance the interests of the ruling class; instead, it reflects the "culture" of the legal elite. He bolsters his provocative thesis with a study of legal borrowing, which he refers to as "legal transplants" (1974). The fact that the individual statutes, legal doctrines, and entire codes have been borrowed by countries differing in cultural, political, economic, and other respects provides evidence, according to Watson, in support of his thesis of legal autonomy.

The concept of "legal transplant" has a naturalistic ring to it as though it occurs independent of any human agency. In point of fact, however, elites—legal and nonlegal—often act as "culture carriers" or intermediaries between societies involved in a legal transplant. Legal scholars who are associated with political elites may be instrumental in effecting a legal transplant. Moreover, many instances of legal borrowing involve the "imposition" of a foreign body of law by a colonial power (Burman and Harrell-Bond 1979). Hence, it is a mistake to describe and analyze the diffusion of law as if it were devoid of human agency. If human volition is involved, it is indeed questionable whether the borrowed legal elements do not perform a societal function—at the very least on behalf of the legal elite.

Critical Legal Studies. Unlike Watson's internalist focus on the legal system and its autonomous development, the critical legal studies (CLS) movement appears to pursue a dual strategy: externalist as well as internalist. CLS is externalist in its critique of the social order and of the values dominating judicial decision making. It is internalist in its fundamental critique of traditional jurisprudence and legal reasoning.

The CLS movement emerged in the late 1970s in American law schools. It brought together a diverse group of scholars with a left-of-center ideology concerned about inequality and injustice in American society. Although lacking any consensus regarding societal transformation, CLS scholars sought to identify the impact of society's dominant interests on the legal process and the impact of social and political values on legal decision making.

In his introduction to a volume of essays by CLS authors, David Kairys discusses the "basic elements" of the legal theory of this movement. Three of these elements are externalist in nature:

We place fundamental importance on democracy, by which we mean popular participation in the decisions that shape our society and affect our lives . . . We reject the common characterization of the law and the state as neutral, value-free arbiters, independent of and unaffected by social and economic relations, political forces, and cultural phenomena. The law's ultimate mechanism for control and enforcement is institutional violence, but it protects the dominant system of social and power relations against political and ideological as well as physical challenges. (Kairys 1982, pp. 3–5)

These three externalist principles of the CLS movement have a familiar ring to them; namely, they are reminiscent of criticisms leveled by Marxists and neo-Marxists against the legal order of capitalist societies.

By far the most distinctive contribution of the CLS movement has been its elaborate internalist critique of legal reasoning and legal process. As Kairys puts it:

We reject . . . the notion that a distinctly legal mode of reasoning or analysis characterizes the legal process or even exists . . . There is no legal reasoning in the sense of a legal methodology or process for reaching particular, correct results. There is a distinctly legal and quite elaborate system of discourse and body of knowledge, replete with its own language and conventions of argumentation, logic, and even manners. In some ways these aspects of the law are so distinct and all-embracing as to amount to a separate culture; and for many lawyers the courthouse, the law firm, the language, the

style, become a way of life. But in terms of a method or process for decision making—for determining correct rules, facts, or results—the law provides only a wide and conflicting variety of stylized rationalizations from which courts pick and choose. Social and political judgments about the substance, parties, and context of a case guide such choices, even when they are not the explicit or conscious basis of decision. (Kairys 1982, p. 3)

Not only do critical legal scholars reject the notion of legal reasoning, they also reject other idealized components constituting a “legal system,” in particular, that law is a body of doctrine, that the doctrine reflects a coherent view of relations between persons and the nature of society, and that social behavior reflects norms generated by the legal system (Trubek 1984, p. 577).

The general conclusion CLS writers draw from “unmasking” the legal system, “trashing” mainstream jurisprudence, and “deconstructing” legal scholarship (Barkan 1987) is that “law is simply politics by other means” (Kairys 1982, p. 17). Such a conclusion, on its face, does not hold out any promise for developing a new, let alone heuristic, approach to a theory of law and society. On the contrary, its antipositivism combined with its search for a transformative political agenda has prompted CLS writers to view with increasing skepticism the sociology of law and research into the relationship between law and society (Trubek and Esser 1989).

Autopoietic Law. Similar in some respects to Watson’s theory of legal autonomy, but fundamentally different from the theory of the CLS movement, autopoietic law claims to be a challenging new theory of law and society (Teubner 1988a). For the past few years several continental social theorists, who are also legal scholars, have enthusiastically developed and propagated the theory of autopoietic law. A complex cluster of ideas, this theory is derived from the work of two biologists, Maturana and Varela (Varela 1979; Maturana and Varela 1980).

In the course of their biological research, Maturana and Varela arrived at some methodological realizations that led them to generalize about the nature of living systems. Maturana coined the term *autopoiesis* to capture this new “scientific epistemology” (Maturana and Varela 1980, p. xvii).

“This was a word without a history, a word that could directly mean what takes place in the dynamics of the autonomy proper to living systems.” Conceptualizing living systems as machines, Maturana and Varela present the following rather complex and abstract definition:

Autopoietic machines are homeostatic machines. Their peculiarity, however, does not lie in this but in the fundamental variable which they maintain constant . . . an autopoietic machine continuously generates and specifies its own organization through its operation as a system of production of its own components, and does this in an endless turnover of components under conditions of continuous perturbations and compensation of perturbations. (Maturana and Varela 1980, pp. 78–79)

Another definition of autopoiesis is presented by Zeleny, one of the early advocates of this new theory:

An autopoietic system is a distinguishable complex of component-producing processes and their resulting components, bounded as an autonomous unity within its environment, and characterized by a particular kind of relation among its components, and component-producing processes: the components, through their interaction, recursively generate, maintain, and recover the same complex of processes which produced them. (Zeleny 1980, p. 4)

Clearly, these definitions and postulates are rather obscure and high-level generalizations that, from a general systems theory perspective (Bertalanffy 1968), are questionable. Especially suspect is the assertion that autopoietic systems do not have inputs and outputs. The authors introduce further complexity by postulating second- and third-order autopoietic systems, which occur when autopoietic systems interact with one another and, in turn, generate a new autopoietic system (Maturana and Varela 1980, pp. 107–111). Toward the end of their provocative monograph, Maturana and Varela raise the question of whether the dynamics of human societies are determined by the autopoiesis of its components. Failing to agree on the answer to this question, the authors postpone further discussion (Maturana and Varela 1980, p. 118). Zeleny, however, hastens to answer this question

and introduces the notion of “social autopoiesis” to convey that human societies are autopoietic (Zeleny 1980, p. 3).

Luhmann, an outstanding German theorist and jurist, has also gravitated to the theory of autopoiesis. According to Luhmann, “social systems can be regarded as special kinds of autopoietic systems” (1988b, p. 15). Influenced in part by Parsons and general systems theory, Luhmann applied some systems concepts in analyzing social structures (1982). In the conclusion to the second edition of his book *A Sociological Theory of Law* (1985), Luhmann briefly refers to new developments in general systems theory that warrant the application of autopoiesis to the legal system. Instead of maintaining the dichotomy between closed and open systems theory, articulated by Bertalanffy, Boulding, and Rapoport (Buckley 1968), Luhmann seeks to integrate the open and closed system perspectives. In the process he conceptualizes the legal system as self-referential, self-reproducing, “normatively closed,” and “cognitively open”—a theme he has pursued in a number of essays (1985, 1986, 1988c).

This formulation is, to say the least, ambiguous. Given normative closure, how does the learning of the system’s environmental changes, expectations, or demands get transmitted to the legal system? Further complicating the problem is Luhmann’s theory of a functionally differentiated modern society in which all subsystems—including the legal system—tend to be differentiated as self-referential systems, thereby reaching high levels of autonomy (Luhmann 1982). Although Luhmann has explicitly addressed the issue of integrating the closed and open system perspectives of general systems theory, it is by no means evident from his many publications how this is achieved.

Another prominent contributor to autopoietic law is the jurist and sociologist of law Gunther Teubner. In numerous publications, Teubner discusses the theory of autopoiesis and its implications for reflexive law, legal autonomy, and evolutionary theory (Teubner 1983a, 1983b, 1988a, 1988b). One essay, “Evolution of Autopoietic Law” (1988a), raises two general issues: the pre-requisites of autopoietic closure of a legal system, and legal evolution after a legal system achieves autopoietic

closure. With respect to the first issue, Teubner applies the concept of *hypercycle*, which he has borrowed from others but which he does not explicitly define. Another of his essays (Teubner 1988b) reveals how Teubner is using this concept. For Teubner, all self-referential systems involve, by definition, “circularity” or “recursivity” (1988b, p. 57). Legal systems are preeminently self-referential in the course of producing legal acts or legal decisions. However, if they are to achieve autopoietic autonomy their cyclically constituted system components must become interlinked in a “hypercycle,” “i.e., the additional cyclical linkage of cyclically constituted units” (Teubner 1988b, p. 55). The legal system components—as conceptualized by Teubner, “element, structure, process, identity boundary, environment, performance, function” (1988b, p. 55)—are general terms not readily susceptible to the construction of legal indicators.

The second question Teubner addresses, legal evolution after a legal system has attained autopoietic closure, poses a similar problem. The universal evolutionary functions of variation, selection, and retention manifest themselves in the form of legal mechanisms.

In the legal system, normative structures take over variation, institutional structures (especially procedures) take over selection and doctrinal structures take over retention.
(Teubner 1988a, p. 228)

Since Teubner subscribes to Luhmann’s theory of a functionally differentiated social system, with each subsystem undergoing autopoietic development, he confronts the problem of intersubsystem relations as regards evolution. This leads him to introduce the intriguing concept of *co-evolution*.

The environmental reference in evolution however is produced not in the direct, causal production of legal developments, but in processes of co-evolution. The thesis is as follows: In co-evolutionary processes it is not only the autopoiesis of the legal system which has a selective effect on the development of its own structures; the autopoiesis of other subsystems and that of society also affects—in any case in a much more mediatory and indirect way—the selection of legal changes. (Teubner 1988a, pp. 235–236)

Given the postulate of “autopoietic closure,” it is not clear by what mechanisms nonlegal subsystems of a society affect the evolution of the legal system and how they “co-evolve.” Once again, we confront the unsolved problem in the theory of autopoiesis of integrating the closed and open systems perspectives. Nevertheless, Teubner, with the help of the concept of co-evolution, has drawn our attention to a critical problem even if one remains skeptical of his proposition that “the historical relationship of ‘law and society’ must, in my view, be defined as a co-evolution of structurally coupled autopoietic systems” (Teubner 1988a, p. 218).

At least three additional questions about autopoietic law can be raised. Luhmann’s theory of a functionally differentiated society in which all subsystems are autopoietic raises anew Durkheim’s problem of social integration. The centrifugal forces in such a society would very likely threaten its viability. Such a societal theory implies a highly decentralized social system with a weak state and a passive legal system. Does Luhmann really think any modern society approximates his model of a functionally differentiated society?

A related problem is the implicit ethnocentrism of social scientists writing against the background of highly developed Western societies where law enjoys a substantial level of functional autonomy, which, however, is by no means equivalent to autopoietic closure. In developing societies and in socialist countries, many of which are developing societies as well, this is hardly the case. In these types of societies legal systems tend to be subordinated to political, economic, or military institutions. In other words, the legal systems are decidedly *allopoietic*. To characterize the subsystems of such societies as *autopoietic* is to distort social reality.

A third problem with the theory of autopoietic law is its reliance on the “positivity” of law. This fails to consider a secular legal trend of great import for the future of humankind, namely, the faltering efforts—initiated by Grotius in the seventeenth century—to develop a body of international law. By what mechanisms can autopoietic legal systems incorporate international legal norms? Because of the focus on “positivized” law untainted by political, religious, and other institutional values, autopoietic legal systems would have a

difficult time accommodating themselves to the growing corpus of international law.

Stimulating as is the development of the theory of legal autopoiesis, it does not appear to fulfill the requirements for a fruitful theory of law and society (Blankenburg 1983). In its present formulation, autopoietic law is a provocative metatheory. If any of its adherents succeed in deriving empirical propositions from this metatheory (Blankenburg 1983), subject them to an empirical test, and confirm them, they will be instrumental in bringing about a paradigm shift in the sociology of law.

The classical and contemporary theories of law and society, reviewed above, all fall short in providing precise and operational guidelines for uncovering the linkages over time between legal and nonlegal institutions in different societies. Thus, the search for a scientific macro sociolegal theory will continue. To further the search for such a theory, a social-structural model will now be outlined.

A SOCIAL-STRUCTURAL MODEL

A social-structural model begins with a theoretical amalgam of concepts from systems theory with Parsons’ four structural components of social systems: values, norms, roles, and collectivities (Parsons 1961, pp. 41–44; Evan 1975, pp. 387–388). Any subsystem or institution of a societal system, whether it be a legal system, a family system, an economic system, a religious system, or any other system, can be decomposed into four structural elements: values, norms, roles, and organizations. The first two elements relate to a cultural or normative level of analysis and the last two to a social-structural level of analysis. Interactions between two or more subsystems of a society are mediated by cultural as well as by social-structural elements. As Parsons has observed, law is a generalized mechanism for regulating behavior in the several subsystems of a society (Parsons 1962, p. 57). At the normative level of analysis, law entails a “double institutionalization” of the values and norms embedded in other subsystems of a society (Bohannan 1968). In performing this reinforcement function, law develops “cultural linkages” with other subsystems, thus contributing to the degree of normative integration that exists in a society. As disputes are adjudicated and new legal norms are enacted, a

value from one or more of the nonlegal subsystems is tapped. These values provide an implicit or explicit justification for legal decision making.

Parsons's constituents of social structure (values, norms, roles, and organizations) are nested elements, as in a Chinese box, with values incorporated in norms, both of these elements contained in roles, and all three elements constituting organizations. When values, norms, roles, and organizations are aggregated we have a new formulation, different from Parsons's AGIL paradigm, of the sociological concept of an institution. An institution of a society is composed of a configuration of values, norms, roles, and organizations. This definition is applicable to all social institutions, whether economic, political, religious, familial, educational, scientific, technological, or legal. In turn, the social structure of a society is a composite of these and other institutions.

Of fundamental importance to the field of the sociology of law is the question of how the legal institution is related to each of the nonlegal institutions. A preliminary answer to this question will be set forth in a model diagramming eight types of interactions or linkages between legal and nonlegal institutions (see Figure 1).

On the left-hand side of the diagram are a set of six nonlegal institutions, each of which is composed of values, norms, roles, and organizations. If the norms comprising the nonlegal institutions are sufficiently institutionalized, they can have a direct regulatory impact on legal personnel as well on the citizenry (interaction 4, "Single institutionalization"). On the other hand, according to Bohannan (1968), if the norms of the nonlegal institutions are not sufficiently strong to regulate the behavior of the citizenry, a process of "double institutionalization" (interaction 1) occurs whereby the legal system converts nonlegal institutional norms into legal norms. This effect can be seen in the rise in the Colonial period of "blue laws," which were needed to give legal reinforcement to the religious norms that held the Sabbath to be sacred (Evan 1980, pp. 517-518, 530-532). In addition, the legal system can introduce a norm that is not a component of any of the nonlegal institutions. In other words, the legal system can introduce an innovative norm (interaction 2) that does not have a counterpart in any of the nonlegal institutions (Bohannan 1968). An example of such

an innovation is "no-fault" divorce (Weitzman 1985; Jacob 1988).

The legal system's regulatory impact (interaction 3) may succeed or fail with legal personnel, with the citizenry, or with both. Depending on whether legal personnel faithfully implement the law, and the citizenry faithfully complies with the law, the effect on the legal system can be reinforcing (interaction 7) or subversive (interaction 5), and the effect on nonlegal institutions can be stabilizing (interaction 9) or destabilizing (interaction 6).

In systems-theoretic terms, the values of a society may be viewed as goal parameters in comparison with which the performance of a legal system may be objectively assessed. The inability of a legal system to develop "feedback loops" and "closed loop systems" to monitor and assess the efficacy of its outputs makes the legal system vulnerable to various types of failures. Instead of generating "negative feedback," that is, self-corrective measures, when legal personnel or rank-and-file citizens fail to comply with the law, the system generates detrimental "positive feedback" (Laszlo, Levine, and Milsum 1974).

CONCLUSION

What are some implications of this social-structural model? In the first place, the legal system is not viewed as only an immanently developing set of legal rules, principles, or doctrines insulated from other subsystems of society, as expressed by Watson and to some extent by Luhmann and Teubner. Second, the personnel of the legal system, whether judges, lawyers, prosecutors, or administrative agency officials, activate legal rules, principles, or doctrines in the course of performing their roles within the legal system. Third, formally organized collectivities, be they courts, legislatures, law-enforcement organizations, or administrative agencies, perform the various functions of a legal system. Fourth, in performing these functions, the formally organized collectivities comprising a legal system interact with individuals and organizations representing interests embedded in the nonlegal subsystems of a society. In other words, each of the society's institutions or subsystems—legal and nonlegal—has the same structural elements: values, norms, roles, and organizations.

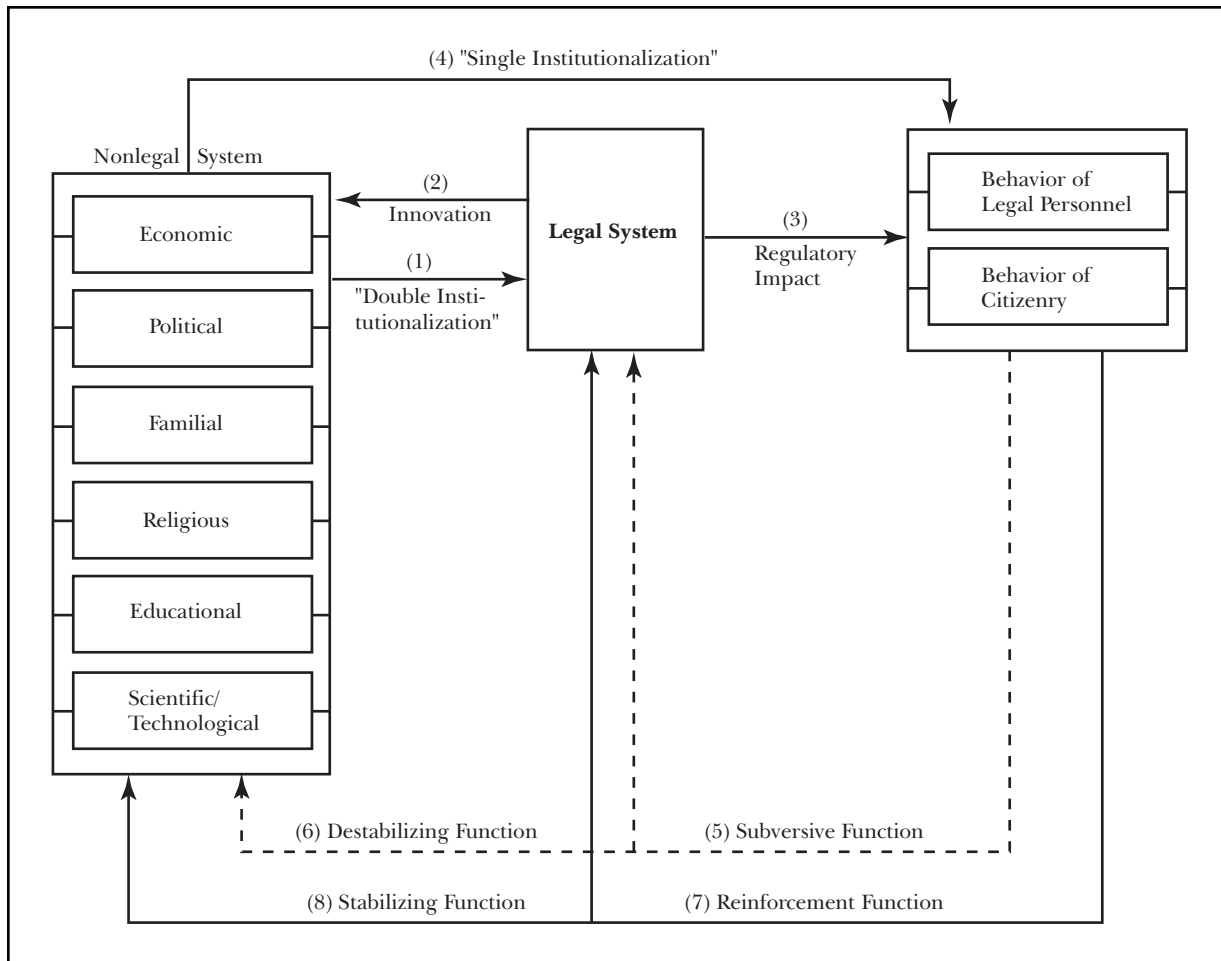

Figure 1

NOTE: A Social-Structural Model of the Interactions of Legal and Nonlegal Institutions

Interinstitutional interactions involve an effort at coupling these structural elements across institutional boundaries. A major challenge to the sociologists of law is to discover the diverse coupling or linkages—cultural and social-structural—between the legal system and the nonlegal systems in terms of the four constituent structural elements. Another challenge is to ascertain the impact of these linkages on the behavior of legal personnel and on the behavior of the citizenry, on the one hand, and to measure the impact of “double institutionalization” on societal goals, on the other.

A serendipitous outcome of this model is that it suggests a definition of law and society or the sociology of law, that is, that the sociology of law deals primarily with at least eight interactions or

linkages identified in Figure 1. Whether researchers accept this definition will be determined by its heuristic value, namely, whether it generates empirical research concerning the eight linkages.

LEADERSHIP

The concept of leadership has been the focus of research and discussion of scholars in a variety of

disciplines. Literary authors and philosophers provided the initial descriptions and guidance for leaders of their time. With the evolution of social sciences, scholars of political science, anthropology, sociology, psychology, and business have all explored the nature of leaders and the process of leadership. Although each of these various approaches did add a different perspective through the decades, there seem to be some who perceive a merging of disciplines in understanding leadership as we approach the close of the twentieth century. However, there are others who still maintain that leaders in different settings are fundamentally different.

As leadership is a vast field of research, only the most prevalent and unique approaches will be acknowledged in the following sections. Readers can find a more thorough review of leadership research and theories in texts such as Bass (1990), Chemers (1997), Chemers and Ayman (1993), and Dansereau and Yammarino (1998).

HISTORICAL REVIEW

The definition of leadership has varied across time and cultures. In ancient times, the focus was on kings and rulers, who received guidance from philosophers. In many civilizations around the world, authors have written essays on good and bad leadership. For example, Confucius and Mencius wrote essays on leaders' proper behavior during the end of the fourth century and the beginning of the fifth century B.C. in China. Aristotle's book, *The Politics*, describes the characteristics of the kings and kingship in ancient Greece (fourth century B.C.). In eleventh-century Iran, Unsuru'l-Ma'ali wrote *Qabus-Nameh* and Nezam Mulk Tussi wrote *Siyassat Nameh*, advising the kings of the time in effective governance. Machiavelli wrote *The Prince*, in Florence, Italy, during the sixteenth century, guiding European rulers in politics. Ibn-e-khaldun from Tunisia provided his observations and guidance to the ruling groups of North Africa in his famous book *Muqiddimah* in the fourteenth century.

From the end of the eighteenth century to the beginning of the twentieth century, during the evolution of industrialization, the concept of "leader" also came to include leaders of industry. Only a hundred and fifty years ago the first chief executive officer (CEO) appeared (Smoler 1999). Smoler

stated that the increased volume of economic activity required the increased efficiency and administrative coordination that gave rise to this kind of leadership. The twentieth century saw steep growth in the numbers of CEOs and of top executive management positions.

At the close of the twentieth century there is a debate on differentiating between leaders and managers, and between leadership and management (Kotter 1988). The saying that some leaders and managers both lead and manage, but most leaders do not manage and most managers do not lead, may make this distinction. A popular phrase that clarifies the relation between leader and managers is, "Good managers do things right and good leaders do the right thing."

At the beginning of the twentieth century, two schools of thought on leadership evolved (Ayman 1993; Bass 1990). In Britain, Thomas Carlyle (1907) presented the "great-man theory," and in Germany, Karl Marx (1906) explained leadership from a zeitgeist approach (i.e., as being in the spirit of the time). The great-man approach focuses on the unique characteristics of the individual as the basis for being a leader. In this approach there is a strong belief that some people have leadership qualities and some do not; thus the born-leader concept. In the zeitgeist approach, the assumption is that the situation provides the opportunity for the individual to become a leader. Thus, it is not the person but the circumstances or the waves of time that puts people in leadership positions. These two approaches have been the foundation of leadership research throughout the twentieth century.

As the end of the century is approaching, the fascination with leaders seems to be at an all-time high, based on the number of publications about and for leaders (Ayman 1997). Many of these publications are inspirational and guiding. The scholars of leadership maintain a steady effort to refine the conceptualization of leadership and enhance the methodologies used in the study of leadership.

The twentieth century was the beginning of scientific and systematic study of leadership. Many disciplines have contributed to this endeavor, such as political science, anthropology, sociology, social psychology, and, most recently, industrial and organizational psychology. Each discipline has explored this phenomenon uniquely, guided by its

own perspective and orientation. The psychologists' focus was initially influenced by the "great-man theory," whereas the sociologists and social psychologists were more interested in the situational perspective. As the investigations proceeded and the disciplines evolved, the interplay of these approaches and the complexity of leadership became apparent. The following sections will briefly review various approaches: the trait and behavior approaches, which evolved from the great-man theory; the situational approach, which evolved from the zeitgeist approach; and, finally, the contingency approach, which combined the two approaches. At the end of this article, some challenges facing leadership practice and research are delineated.

TRAIT APPROACH

The initial work on leadership was influenced by the *great-man theory*, which focuses on the characteristics of individuals in leadership situations. The primary focus of this approach is to compare the characteristics of those who are leaders and those who are not. The majority of trait research began in the early part of the twentieth century and declined somewhat in the late 1940s. In a majority of these studies, there seemed to be a search for one trait that best differentiated leaders from nonleaders. Stogdill (1948) reviewed studies in various settings and identified a list of traits that were most commonly studied to identify leaders. The traits that differentiated leaders from nonleaders included "sociability, initiative, persistence, knowing how to get things done, self-confidence, alertness to and insight into situations, cooperativeness, popularity, adaptability, verbal facility" (Bass 1990, p. 75). However, Stogdill (1948) concluded that research on leader's traits is inconclusive and that, depending on the situation, one trait may be more important than another.

Early industrial psychologists interested in selection maintained their focus on the trait approach. Therefore, primary pursuit of trait approach was by practitioners who were interested in selection and succession planning of managers in work settings. Later, Lord and colleagues (1986), with the assistance of meta-analytical techniques, reanalyzed past research by Stogdill (1948) and Mann (1959) and, across studies, identified certain

characteristics more associated with leaders than with nonleaders. The result of these studies was to identify intelligence, masculinity, and dominance as strongly related to leadership, whereas adaptability, introversion/extroversion, and conservatism had a weaker relationship. The adjustment and flexibility competency has received attention in recent years. In various studies, adaptability, as operationalized by the self-monitoring scale (Snyder 1979), has also been used to predict leader emergence and effectiveness with some degree of success (Zaccaro et al. 1991; Ayman and Chemers 1991). Hogan and colleagues (1994) revived interest in the trait approach by introducing a multitrait approach to the study of leaders. The traits included in the profile are known as the "big five" and consist of extroversion, emotional stability, openness, intellect, and surgency. In addition to the big five, there are also other measures (e.g., Myers Briggs) that are used to identify leader's profiles. However, results for predicting effective leaders from these traits are inconclusive. Overall, most of the trait research has focused on differentiating the characteristics of leaders from nonleaders, and on measuring leadership potential.

BEHAVIORAL APPROACH

The first known study focusing on leader behavior examined the differing effects of democratic, autocratic, and laissez-faire leadership behaviors (Lewin et al. 1939; Lippitt and White 1943). These studies were conducted with groups of Boy Scouts led by trained graduate students. The results of these studies showed that groups with democratic leaders had the best-satisfied members. Those with autocratic leaders demonstrated the highest level of task activity, but only when the leader was present. Starting in the 1950s, the interest of the U.S. scholar gravitated toward understanding the leader's behaviors and the relationship between these behaviors and effectiveness. Three main research centers concurrently studied leader behavior in small teams at Ohio State University, led by Stogdill and his associates; at the University of Michigan, led by Likert and his colleagues; and at Harvard, led by Bales and his collaborators. Although these studies were conducted in different work settings such as the military, education, insurance companies, car manufacturing, and laboratory settings, they all found the same results.

These results led to two categories of leader behavior. One category dealt with behaviors that establish and maintain relationships, commonly referred to as considerate, people-oriented, or socio-emotional behaviors. The second category focused on behaviors that get the task accomplished, commonly referred to as initiating-structure, production-oriented, or task-focused behaviors. Although many measures were designed to assess the leader's behaviors, the most prominent are three Ohio State measures: the Leader Behavior Description Questionnaire (LBDQ), the Subordinate Behavior Description, and the Leader Opinion Questionnaire (Cook et al. 1985).

The leadership behavior researchers in other countries identified two similar categories of structure and consideration, but also found some additional categories. Unlike the findings in the United States, the two behaviors in Iran were found to be intertwined, resulting in the concept of "benevolent paternalism," or the "father figure" leader (Ayman and Chemers 1983). In India, Sinha (1984) identified "nurturant-task" behavior as an addition to the two main behavioral categories. In Japan, Misumi (1985) introduced a measure that had behavioral categories similar to those in the U.S. findings, but the behaviors were assessed in context. He referred to this model as maintenance-production (MP) behaviors.

In the 1960s and 1970s, researchers investigated the relationship between these two categories of behaviors and various indexes of effectiveness (e.g., team satisfaction, performance, turnover, and grievance) in different work settings. Fisher and Edward's meta-analysis (1988) is among the studies that supported the overall effects of these two behaviors (cited in Bass 1990).

Since the middle of the 1980s, a paradigm shift in the study of leadership behavior emerged, which moved scholars from focusing on consideration and initiating structure behaviors, often referred to as "transactional leadership," to what is referred to as "transformational leadership" behavior. This movement started with the work of McGregor Burns (1978) and House (1977), and was further developed by two groups of scholars, Bass and Avolio (see Bass 1985); Avolio and Bass (1988) in the United States, and Conger and Kanungo (1987) in Canada. In this new approach,

the leader provided guidance to ensure that the work was done properly and that subordinates were happy, and also was responsible for developing a relationship with employees based on mutual trust. It was proposed that transformational leadership not only changes the subordinate, but is also evolutionary for the leader and the task. A recent meta-analysis has provided a promising review of the effects of transformational leadership behavior in a variety of settings (Lowe et al. 1996). Also, it was through these approaches that the emphasis on empowerment in leadership evolved (Conger and Kanungo 1988b). Empowering, coaching, and facilitating are behaviors that were not noted extensively in leadership literature until the middle of the 1980s. During this period many inspirational and guiding documents were presented by various authors (e.g., Kouzes and Posner 1987).

Three main categories of criticism have been directed at the behavioral approaches. The first, advanced by Korman (1966) and by Kerr and colleagues (1974), argued that situational factors moderate the relationship between leader's behavior and outcomes. In addition, Fisher and Edwards (1988) more recently reviewed the studies using LBDQ and outcome variables, and acknowledged that there is a need for studying moderators.

The second criticism is based on the fact that almost all leader behavior measures are based on perception of self or the perception of others (Ayman 1993). In the 1980s, a series of studies demonstrated that perceived behavior is contaminated with various factors that are not necessarily related to the leader's behavior (Lord and Maher 1991). In these studies it was demonstrated that people's memory of the behaviors that occurred can be affected by what they think of the leader (e.g., Larson 1982; Philips and Lord 1982). The implication of this criticism is critical in exploration of diversity and cross-cultural leadership, topics that will be discussed later.

The third criticism focused on the level of conceptualization and analysis. This criticism is based on the premise that leaders may treat different people differently. That is to say, is leadership a group-level phenomenon, dyadic, or is it in the eyes of the beholder? Recently, a multilevel approach has been investigated in relation to various

leader behavior paradigms (see Dansereau and Yammarino 1998).

SITUATION AND LEADERSHIP

In the 1950s, parallel to the development of leader behavioral studies, many scholars examined situational factors that gave rise to the identification of a leader without examining their characteristics. Some examined seating arrangement, or distance of the individuals (e.g., Bass et al. 1953; Howells and Becker 1962). The results of these studies demonstrated that individuals at the head of the table and who commanded more space were more often identified as the leader. Other studies examined communication patterns (Leavitt 1951) in the work team. The results demonstrated that those who have access to most of the information and are the center of the information flow are most often identified as leaders. The frequency of contribution to the team's goal achievement and verbal visibility was another contributor to the emergence of the leader (Bavelas et al. 1965). The position in the organization and assigned roles were also demonstrated to predict how a new leader behaved (Shartle 1951). That is, the best predictor of leadership behavior was the behavior of the leader's boss or predecessor. By the 1960s, there was some evidence that different tasks elicited different behaviors from the leaders (e.g., Morris and Hackman 1969).

In the 1980s, substitutes for leadership theory (Kerr and Jermier 1978; Howell et al. 1986) diverted the attention of leadership researchers again to the situation and provided a taxonomy for the role of the situation in leadership. This new approach categorized situations as neutralizers, enhancers, supplements, and substitutes (Schriesheim 1997). This approach has received mixed results, but the contribution of its taxonomy and methodological clarification has clarified the role of the situation in leadership research (Howell 1997).

In conclusion, the situational studies demonstrated that regardless of the leader's values, traits, or other characteristics, situational factors can influence the emergence of the leader and the behavior of the leader. Visibility and control of information are some of the necessary situational factors that assisted an individual being recognized as a leader. The more recent work on the

situation has further extended the role of the situation in leadership effectiveness.

LEADERSHIP EMERGENCE

Early situational research and trait approaches focused on leadership emergence. Most studies on leader behavior attended to the effectiveness of leaders and teams. Hollander's concept of idiosyncrasy credit (1958) examined the exchange that occurs in the work team and leader emergence process. This concept gave rise to a series of studies (e.g., Hollander 1978; Hollander and Julian 1970) that demonstrated that, in a team, the members who contribute to the team's goal achievement and are loyal to the values held by the team establish credibility or idiosyncrasy credits. These studies demonstrated that idiosyncrasy credits then could be spent as the individual took risks to lead the group. Hollander's work may be seen as the first work that brought leadership and the management of innovation and change close together.

Hollander's work also demonstrated that the exchange process in teams resulted in the emergence of the member with the highest credits as the team leader. Later, the work of Graen (1976) further expanded the nature of this exchange in the vertical-dyad linkage (VDL) model. In the VDL model, the leader and the subordinates establish their relationship by negotiating their roles. Therefore, in work groups, there are some members who form the core group and are closer to the leader. Also, there may be other members who stay on the periphery of the work group.

The results of the initial studies were criticized, and unfortunately this line of research was abandoned due to methodological limitations (Dansereau et al. 1975). However, the notion of exchange between the leader and his or her subordinates is still a fertile area of research, known as leader-member exchange theory (e.g., Graen and Uhl-bien 1995).

CONTINGENCY APPROACHES

Korman (1966) and Stogdill (1948) criticized past research on leader behavior and traits, and called for the study of leadership to be situation-based. In the early 1970s, two main categories of contingency approaches emerged, one based on the leader's trait and the other based on the leader's behavior.

The first scholar who operationalized the contingency approach to leadership and presented a trait-based model in this paradigm was Fred Fiedler. Several narrative reviews of the model have been written (see Ayman et al. 1998; Fiedler 1978). This model has been an impetus for many studies and some have criticized it over the years. However, several meta-analyses have provided some validating support on the thirty years of research (e.g., Strube and Garcia 1981; Peters et al. 1985).

The model is composed of three elements: one is the leader's motivational orientation, as measured by the "Least Preferred Coworker" scale; the second is the degree of leader's control and influence in a situation; and the third is the match between the situation and the leader's trait. In this model, three aspects of the situation were examined: leader-members relationship, task structure, and position power. The model's assumption is that leaders who are more focused on getting their job done than their relationship with people, do better than their counterparts in situations of high and low control and they are known to be in-match. Similarly, in situations of moderate control, those leaders with more focus on relationships will be more effective and are known as being in-match. When task oriented leaders are in moderate control condition and relationship oriented leaders are in high or low situational control conditions, they are referred to as being out-of-match (Ayman et al. 1995 and Ayman et al. 1998).

The strength of this model has been primarily in predicting team performance. More recently, subordinates' satisfaction and leader's experience of stress have also been included as outcomes examined by the model. Another strength of the model is that the information about the dependent variables and the independent variables are gathered from different sources. Leaders usually provide their motivational orientation by completing a quasi-projective test of Least Preferred Coworker. Sometimes the leader and other times the experimenter assessed the situation. A third party primarily has provided the assessments of the performance.

One area of potential improvement for the model is to include more than one trait. Recently, additional traits have been incorporated into the contingency model research. In 1993, Fiedler proposed the cognitive resource theory. This theory

included the leader's intelligence and experience and proposed that their contribution to the team's success may have contradictory effects depending on the stressfulness of the situation. Also, Ayman and Chemers (1991) included the leader's self-monitoring capability in their study, which was conducted with Mexican managers. Results showed that subordinates' work satisfaction was higher for out-of-match leaders who are high self-monitors than for those who were lower self-monitors. This may indicate that self-monitoring trait compensate for leaders who are out of match based on the contingency model of leadership effectiveness. However, the subordinates of in-match, high, self-monitoring leaders were not as satisfied with their work as the low self-monitoring in-match leaders. Therefore, self-monitoring seemed to only work for those who find themselves in situations that are not conducive to their internal state. As this is only one study, future work on these or other traits is warranted.

The contingency models of leader behavior examined the moderators that influence the relationship between leaders' behaviors and the outcome variables. As there are multiple leader behaviors and multiple ways that the situation can be conceptualized, many models have emerged. Two models have received substantial empirical attention (i.e., path goal theory [House 1971]) and the normative model of decision making [Vroom and Yetton 1973; Vroom and Jago 1974]). However, other models have made conceptual contributions, such as the multiple-influence model of leadership (Hunt 1991) and the multiple linkage model (Yukle 1989). These models' contributions have been in the development of taxonomy for situational factors and managerial behavior (see Chemers 1998). The behavior domains studied in this category of contingency models are managerial, supervisory, and decision-making behavior. However, most managers and leaders are also involved with managing interpersonal conflict, and this behavior domain has not received much attention by leadership researchers. In this section we will primarily review path goal theory and the decision-making model, and will acknowledge the relevance of conflict management to leadership.

Path goal theory (House 1971) was based on Vroom's expectancy model of motivation. Its proposition was that the leader as a supervisor needed to help the subordinates by clearing their path to goal

attainment. Therefore, the model predicted that the leader's behavior would be dependent on the situation, which was determined by the characteristics of the subordinates and the nature of their work. Therefore it predicted that subordinates with high ability were more satisfied and less stressed when their leaders were perceived as behaving considerately. Subordinates with complex tasks were more satisfied with leaders who were perceived as more directive. The model acknowledged four behavioral choices for the leaders: participative, supportive, directive, and achievement-focused. However, the majority of the research used Ohio State's measure of LBDQ-XII to define the leader's behavior as either considerate or structuring. In most of the studies, the descriptions of the situation, the subordinates' behavior, and the leader's behavior were assessed according to the subordinates' perceptions. Research on path goal theory received mixed results. In the majority of the studies either the subordinates' characteristics or their tasks were investigated. Also, the studies were primarily supportive, predicting subordinates' satisfaction but not their performance.

The decision-making model (Vroom and Yetton 1973; Vroom and Jago 1974) was mostly assessed from the leader's perspective. It provided the leader with choices of team decision-making strategies (e.g., very participative, partially participative, and very autocratic). The success of these choices depended on the situations. The model provided strategic questions that would help a leader determine the extent to which he or she should be participative or autocratic based on eight different criteria. These questions assessed the leader's knowledge and the subordinates' supportiveness in a given situation. The key finding was that subordinates who were part of the decision-making process were more satisfied, compared to those who were not part of this process.

Studies that have examined conflict management strategies of leaders are limited. The most commonly used measures are those by Rahim (1985) and by K. W. Thomas (1992). The two approaches identify five conflict management styles (competitive, withdrawing, accommodating, compromising, and collaborating) that represent the degree to which leaders are focused on themselves or the task, or the extent to which they are concerned about the subordinates' welfare.

In the same vein, the subordinates' choice of action with the leader was also examined. The situational factors studied so far have been the status of the actor in relationship to the target and the presence of an interpersonal conflict. The evidence seems to show that leaders have been perceived as using competitive and withdrawal strategies and subordinates tend to use more accommodating and compromising strategies. This line of research is new and requires more development. There is little evidence connecting choices of conflict management strategies to outcomes such as subordinate satisfaction or leader's influence or team performance.

Overall, the strength of behavioral approaches lies in their focus on the leader's behavior, which is assumed to present an aspect of the leadership process. These approaches are also sensitive to the moderating factor of situational elements; that is, they assume that not all successful or effective leaders behave the same way across situations. The behavioral approach provided some clarity in leadership process that allowed trainers to design training and development programs guiding leaders in how to behave.

These models have also faced challenges. First, the assessment of leader behavior and the situation in these models were dependent on the perception of the leader or the subordinates, thus susceptible to social cognitive influences, which will be briefly discussed in the next section. Second, most of these studies were based on a single source of information, that is, the same person who provided the predictors (e.g., the leader's behavior descriptions and the situation) also provided the assessment of the outcome and the moderator (i.e., situational factors). Finally, these models initially examined leadership only at a team level; thus assumed leaders treated everyone similarly. However, the criticism is that leader behavior may vary with each individual.

NEW TOPICS AND FUTURE DIRECTIONS

After a century of empirical research, there are theoretical and methodological issues that have drawn the attention of the leadership researchers, theorists, and practitioners alike. Theoretically, three issues that need to be explored are: (1) the role of social cognition in leadership, (2) the role

of diversity and multiculturalism in leadership, and (3) moving toward an integrative theory. From a methodological perspective, four issues need to be considered: single sources variance, level of conceptualization and analyses, a systematic conceptualization and measurement of the situation, and measurement of leadership effectiveness.

Many scholars have recognized the role of social cognition in leadership studies (e.g., Calder 1977; Martinko and Gardner 1987). Some have argued that leadership is a product of our imaginations (Miendl 1990), whereas others have respected the role of perception in the study of leadership (Ayman 1993; Lord and Maher 1991). From these discussions and the studies that have transpired, it has been substantiated that people have an image of a leader in "their mind's eye." This schema or the mental map does affect their perception and evaluation of leaders they meet (Larson 1982; Lord et al. 1978).

Research on diversity and multiculturalism in leadership has gained momentum in the later part of the century. Initially many studies in the United States focused on gender. This may have been partially due to sample availability. Studies have demonstrated that overall, in the United States and other cultures, across age and gender, the image of a leader is more similar to the image of a man than a woman (e.g., Ayman-Nolley et al. 1993; Schein et al. 1989, 1996). Although many meta-analyses have reflected that, across studies, men and women leaders' behavior differences are not very noticeable (Eagly and Johnson 1990), and that the differences that were found were mostly on task behaviors. However, the authors identified various moderators in determining a leader's gender and behavior relationship, such as self/subordinate rating, male-dominated setting, and role congenial position (Eagly and Johnson 1990). In measuring leader effectiveness across indexes such as overall satisfaction and performance, no gender difference was found. However, women leaders were favored more than men were when subordinates' satisfaction was measured, and men did better than women when performance was measured. In addition, the moderator of the gender role congeniality of the job was identified as a major predictor of this relationship. Therefore, it is possible that the dominant masculine image of a leader (i.e., more prevalent in traditional male-dominated roles) has been the major challenge of

women in breaking the glass ceiling (Morrison and Van Glinow 1990).

As leadership process is dependent on perception and social judgement, the saliency of the stimuli's characteristics is important in this process. Although most of the diversity studies on leadership have been on gender differences, other diversity indexes also need to be examined. In studying leaders who are diverse, it is critical that the superficial diversity elements (i.e., those that can be seen, such as sex and color) and the deep diversity elements (i.e., those that cannot be seen, such as traits and education) be considered separately (Harrison et al. 1998). For example, Korabik (1997) has presented evidence that women may perceive themselves differently based on their sex-role orientation. But observers perceive women mostly based on the feminine stereotypes.

In addition, the process of social interaction between leaders and subordinates involves the leader as the actor and others as observers who judge this leader. In this case, both the leader's characteristics and the characteristics of subordinates need to be considered. In gender studies already reviewed, the gender composition of the group has been shown to affect the selection of a man or a woman as the leader (Eagly and Karau 1991) and to impact on men and women leaders' evaluation (Eagly et al. 1995). Research has demonstrated that in mixed-gender teams, men are more often favored than women. So, in studying leaders of other cultures or ethnic groups, it is not sufficient to study their behavior or expectations with their own culture; rather, it is critical to examine their interaction with people from other cultures (Ayman 1997). For example, Thomas and Ravlin (1995) found that American autoworkers rated more negatively on the dimension of trust when Japanese managers behaved like American leaders, but perceived these Japanese managers as more similar and effective.

Recently, several researchers and scholars have conducted cross-paradigm studies and provided integrated models of leadership. In the last five years there have been studies that examined the relationship between traits and leader behavior, such as Myers-Briggs and transformational behavior (Roush and Atwater 1992) and Bem's sex-role inventory and transformational leadership (Hackman et al. 1992). There are also studies connecting

leader member exchange with transformational leadership (Basu and Green 1997). More efforts to connecting various leadership research approaches are warranted. Chemers (1997) has presented an integrative model of leadership enabling researchers to approach leadership research with a more comprehensive understanding in the future. That is, although each study may be limited in scope, using a model like that of Chemers can help place it in the universe of leadership research. Doing cross-theory studies of leadership will enhance the understanding of this complex phenomenon.

The methodological challenge facing leadership research may be categorized in three topics (i.e., single-source variance, level issues, and measurement of the situation and the effectiveness of the leader). Many models reviewed in this article were validated on a single source of information. In other words, the same person who provided the predictor (e.g., the leader's behavior description) also provided the criterion (e.g., satisfaction or performance). This can artificially inflate the relationships under investigation (Yukle and Van Fleet 1992). One solution that some have used is that one subordinate describes the leader's behavior and another provides the effectiveness measure (Avolio et al. 1991). Although this is a step in the right direction, still both the leader and the subordinates have a vested interest in the relationship and thus may provide a biased perception.

Level of conceptualization and analysis is another methodological challenge that recently became the focus of leadership researchers' attention (Dansereau et al. 1995). These authors propose that the level of variables used in leadership studies needs to consider whether it is assessing the phenomenon at an individual, a dyadic, a group, or an organizational level. Also, it is important to consider the level issues in design and analysis of a study. In some studies the measures and the analyses may stay in the same level or go across levels to examine a meso-level relationship. The gravity of this issue and the methodologies involved in this procedure are reflected in a two-volume book edited by Dansereau and Yammarino (1998). In these volumes, many leadership approaches and theories are examined with the multilevel question in mind. It is not necessary for all models to be validated at all levels. However, it is valuable to

understand the parameters of the various models in relation to the level issue.

The third challenge is the assessment of leadership situation and leadership effectiveness. Although in situational studies and in contingency models some element of the situation is operationalized, a more systematic, cohesive model for evaluating these variables across theories would assist the field's evolution. Fiedler and Chemers (Ayman and Romano 1998) have identified three elements in the situation that affect the leaders' perceived control (leader-member relation, task structure, and position power). These aspects of situational control parallel French and Raven's sources of power (Ayman et al. 1998). The relative degree of importance of these aspects of situation has been substantiated both in contingency model research (Fiedler 1978) and in sources-of-power research (Podsakoff and Schriesheim 1985). Also, Hunt (1991) identified different levels within the organization as another situational factor affecting leadership. What is important to remember is that the prominent models of leadership reviewed here were validated in various work settings and industries. These models have been able to explain leadership regardless of whether the person is a political leader, a hospital administrator, a factory manager, a retail manager, a school principal, or a military leader. Consequently, future work is needed on a framework for identifying elements and dimensions that are important to consider in leadership situations. For example, one dimension that has been identified is the leader's power base. What are others?

Leadership effectiveness (e.g., group performance, leader's performance, group cohesion, subordinate satisfaction, organizational commitment, employee turnover rate) has been measured by various indexes and by various sources such as self report, superiors, and subordinates. Some models were more effective in predicting leaders emergence than effectiveness. Others have been more successful in predicting the well-being and cohesion of the group, such as subordinate satisfaction, turnover in the group, and subordinates stress. Several have predicted group performance measures by subordinates' evaluation or a superiors' assessment, or have used performance criteria such as financial indexes, sales, or goals met (e.g., sport teams' scores). It is important to consider the

parameter of models and the measures used to assess leadership. Some models may be better in predicting one criterion than another.

In conclusion, some have said, "Leadership is paradoxical; popular thinking . . . emphasizes the importance of . . . leadership establishing excellent organizations, but many academic publications assert that leadership is consequential" (Day and Lord, in Hunt 1991, p. 1). However, as Fiedler said in a personal comment to the author: "This is a pretzel shape universe that requires a pretzel shape model." The complexity of the world and the challenges it presents may call for a different form of leadership from the one-person-focused leadership. Since the team approach is being used in many organizations, it may be that the future of leadership will also be a team leadership approach. Compared to many fields of science, study of leadership is very young. Although challenges are present and the phenomenon is nebulous, leaders would attest that there are some things going on that make things work, but they are hard to explain. Future researchers are charged to systematically overcome the challenges and to collectively gain control of understanding of leadership in a global dynamic environment.

LEGISLATION OF MORALITY

In *The Division of Labor in Society* ([1893] 1984), Emile Durkheim advanced the idea that the distinctive sociological feature of crime is society's reaction to it. Durkheim was writing at a time when Lombroso's view on the heritability of criminality dominated scientific and popular opinion. Science sought the etiology of crime in the biology of the criminal, in *atavism*—crime viewed as a reversion to primitive, ancestral characteristics.

From this perspective, the harmfulness of criminality was taken for granted. Given his more comparative and anthropological outlook, Durkheim rejected the idea that crime was condemned by society because of its harmful consequences or because the deviant act was in itself evil. For Durkheim, many things that attracted the severest reprimands of society were objectively quite harmless, such as the neglect of the food taboos or the neglect of religious observance. In his view, the major issue was the integrative function of law, not the individual sources of deviance. Indeed, in *Suicide* ([1897] 1951) he characterized individual acts of despair as expressions of social structural pathologies. He also noted that the integrative function of law extracted far more from the condemnation of the lower class thief than from the middle-class embezzler—even though the latter's financial gain was greater and the social consequences of his acts much more adverse. From these observations Durkheim concluded that the societal reactions to crime and deviance were not based on rational models of the incapacitation or deterrence of the offender. In contrast to such utilitarian thinking, the societal reaction to crime was marked by an impassioned moral condemnation. This common feeling of moral outrage was a mark of the collective consciousness of society, particularly in highly cohesive, simple, or "tribal" societies. The condemnation of crime exercised the collective outlook, and it reinforced the group's collective beliefs and values. In short, the criminal was a scapegoat, and if he did not exist in fact, given his functional importance, he could be invented.

With the advance of more competitive and technologically sophisticated societies, the division of labor resulted in a partitioning of the collective consciousness across various elements of society and resulted in the rise of legal codes with less appetite for vengeance and with a greater investment in the reconciliation of competing interests. Hence, for Durkheim, punitive criminal law was the hallmark of primitive societies, which enjoyed a "mechanical" division of labor (i.e., a homogeneity of work functions), while reconciliatory civil law characterized advanced societies with an "organic" division of labor (i.e., a diverse but mutually dependent specialization of tasks). The former societies were characterized by brutal executions, the latter by written contracts.

Other nineteenth-century authorities tackled the role of law in society. Marx and Engels shared Durkheim's insight that the thing that needed explaining was not why people break laws—the problem of criminology—but why people make laws—the problem of the sociology of law (Cain and Hunt 1979). In their view, law was primarily an instrument of control and a source of both mystification and legitimation. As the urban merchant classes expanded their private estates into the countryside, these classes employed laws to transform the existing common rights of the rural peasants to the harvest of the forest—to deer, fish, pasture, firewood, and so forth—into crimes of theft from private property (Thompson 1975). In addition, the rise of capitalist agriculture, which was associated with the international trade in wool, cleared the British and European common lands of subsistent peasant farmers. Under contract law, the disenfranchised peasants became independent juridical subjects, able to engage in agreements to sell their labor for wages in the cities, although the urban working classes, having been displaced from subsistence on rural estates, had little choice, aside from starvation, but to work in factories.

Durkheim's position on law as an expression of the collective consciousness and Marx and Engel's views on law as an instrument of control continue to exert influence on contemporary thinking about law and morality. Where Durkheim treated the law as an expression of general social consciousness, Marx and Engels viewed it as an expression of a class consciousness, although, to be fair, Durkheim's model of collective consciousness held for a sort of mythic primitive society—akin to Hobbes on the “natural” state of man confronting the war of all against all or akin to Veblen or Freud's primal horde. In each case, the ideal type was an imaginative, indeed a fictional, reconstruction of human origins. The division of consciousness by class would have been possible for Durkheim in advanced societies—even if it constituted a state that he classified in *The Division of Labor in Society* as “abnormal” and even if it was the sort of awareness he wanted to overcome through the “corporations” that cut across class divisions and that Durkheim speculated might form the political nucleus of a future society.

In North America, sociological theories about the legislation of morality took a distinctive turn with investigations of “moral panics,” “victimless

crimes,” and “moral entrepreneurs”—all of which figured importantly in the labeling theories of the 1960s. The studies investigated distinctively morally charged issues and stressed the influence of both social movements and the mass media in the construction of the criminal law. By way of example, Sutherland (1950) examined the role of “moral crusaders” in the context of the sexual psychopathy laws that were enacted in 1937 and thereafter in eleven northern states, California, and the District of Columbia. These laws provided for indefinite incarceration in hospitals for the criminally insane for anyone pronounced by a psychiatrist to be a sexual psychopath. Retrospectively, this diagnosis is not based on a discernible medical disease. In fact, many psychiatric categories are only labels for things we do not like. Nonetheless, a wide series of jurisdictions, with one eye to reforming sexual deviants, enacted laws based on this “disease.”

There was a threefold process underlying the creation of these laws. First, the laws were enacted after a state of fear and hysteria followed newspaper accounts of several sex crimes committed coincidentally in quick succession. In these states there was a rush to buy guns, guard dogs, and locks and chains, reflecting widespread evidence of public fears. Second, these fears were fueled by news coverage of related sex crimes in other areas and other times in history and of sex-related behaviors and morality (including questions regarding striptease) and by letters to newspaper editors and statements made by public figures. The third phase was the creation of committees to study “the facts” of the sex crimes and “the facts” of sexual psychopathology. These committees, though initially struck on the basis of collective terror, persisted long after the fear and news stories subsided. They resulted in a presentation of briefs to legislative bodies, particularly by a new class of medical experts—psychiatrists. The community hysteria was legitimated by the identification of the crimes as a form of disease by the psychiatric professionals. The legislatures responded to public fears by passing laws to control the offending parties, in this instance by making sexual psychopaths subject to incarceration under psychiatric supervision.

A second important illustration is the history of the American prohibition movement, reported in the classic sociological study by Joseph Gusfield—*Symbolic Crusade* (1963). From 1919 to 1933 an

amendment to the American Constitution outlawed the manufacture and sale of alcoholic beverages. The law was passed after decades of lobbying by members of the numerous “temperance movements,” who originated predominantly from fundamentalist Protestant stock, largely from rural areas, and initially from middle-class backgrounds. They were the upholders of the Protestant ethic and valued hard work, self-reliance, and sobriety.

Gusfield argues that as America industrialized during the nineteenth century, the traditional rural settlers experienced a loss of social status compared to the new urban classes and experienced a challenge to their traditional values as urban development introduced increasingly nontraditional immigrants. The temperance movements were a form of status politics designed to reaffirm the prestige of a lifestyle. In the early period (1825–1875) the temperance movements pursued their objective through education, persuasion, and the reform of social conditions that caused excessive drinking. With increasing urbanization and greater European immigration, however, the tactics changed from a policy of socialization to one of coercive reform. The temperance movement became a prohibition movement. And when conservative forces came to dominate the political scene in America following World War I, the value of sobriety was to be achieved coercively—by outlawing booze. In Canada prohibition was approved in a national plebiscite in 1898 and enabled by federal law in 1916. The federal law allowed provinces to implement their own legislation, and all but Quebec outlawed booze, although booze continued to be manufactured for export—usually illicitly to the United States—and was available in Canada by prescription in pharmacies. The Canadian experiment in forced temperance ended in the mid-1920s, and the United States repealed Prohibition in 1933.

Gusfield’s work is important for several reasons. It stressed the idea that legislation was “symbolic”—that it reflected the values of distinctive social groups and that such groups struggled to have their views insinuated into state legislation. Unlike Marx, who viewed political struggle as class politics, Gusfield stressed “status” politics—the advancement of group respectability or status by seeking to have the group values enshrined in law. Gusfield further implied that laws, particularly in the field of “victimless crimes,” were symbolic in another sense. Instrumentally, prohibition was a

terrible failure. It created huge markets for organized crime, and liquor consumption appears to have proceeded in spite of the law. Hence, the condemnation of insobriety was merely ritualistic (i.e., symbolic) because it did not extirpate drunkenness nor seriously inhibit liquor consumption. Similar arguments have been raised regarding the criminalization of narcotics, prostitution, and pornography—classical “victimless crimes,” the markets for which thrive on a demand that seems little impeded by legal proscription.

The labeling theories of the 1960s developed the Durkheimian emphasis on the importance of societal reaction to crime (Kitsuse 1962; Lemert 1967) and identified some of the processes by which conduct was successfully labeled as criminal or how it successfully evaded such a label (Becker 1963). Theorists explored the self-fulfilling prophecies of deviant labels and the role of stigma in stabilizing rejected identities (Goffman 1961, 1963). The role of moral entrepreneurs was identified; these Weberian charismatics personified the struggle against evil and expedited legal change by campaigning in the media on the dire consequences of everything from dance halls to crime comics to television violence and marijuana use. Research on societal reaction proliferated. Studies focused on the manufacture of mental illness (Scheff 1999; Szasz 1961, 1970), the creation of witchcraft as a form of labeling (Erikson 1966; Currie 1968), the selective policing and the resulting social construction of delinquents (Cicourel 1968), the political hysteria that underlay political show trials (O’Connor 1972), the role of hysterical stereotypes in the criminalization of narcotics (Cook 1969; Lindesmith 1965), and the mythification of the Hell’s Angels in the popular press (Thompson 1966).

The studies of this period had an insurgent flavor and a barely concealed contempt for legal structures and institutions that drew the line between conformity and deviance in an arbitrary fashion. This was particularly true in the context of legislation outlawing “victimless crimes.” John Stuart Mill had established the ideological pedigree of this critique when he suggested that the democratic state’s sole justification for limiting the freedom of an individual was that the person’s behavior was harmful to others. Legal critics in the 1960s and 1970s objected to the extension of the law to cover vices and immoral activities since the participants in these acts, it was argued, were autonomous

beings who had chosen them voluntarily and so were mischaracterized as either criminals or victims. The argument was that participants were not criminals since their behavior was not harmful to others, and they were not victims since their fates were chosen voluntarily (Schur 1965). Since these activities flowed from free choice in democratic states, how could they have been made unlawful? The answer lay in the fact that conservative forces led by moral entrepreneurs had stampeded democratic governments through wild allegations that the activities in question were so harmful that they struck at the very fabric of society and that however voluntary or self-inflicted the corruption, its control and eradication was justified for the sake of society itself. More recent studies have taken a different turn. Studies of the law-and-order campaigns associated with the resurgence of political conservatism have led sociologists to ask different sorts of questions.

Where Gusfield stressed that legislation might take on a symbolic aspect that reflects the interests of discrete social groups, recent work suggests that laws may *mystify* the social conditions that give rise to them and consequently may result in social control that is sought for altogether different reasons than the ones identified in the legislation. Taylor (1982) argues that many crime waves, moral panics, and anticrime campaigns are orchestrated in response to basic social conflicts and shifting economic realities and that they function to misdirect our attention away from social contradictions. Three noted British investigations lend support to this view. Hall and colleagues (1978) argue that the moral panic in British papers over street mugging in the early 1970s that resulted in calls for tougher jail sentences and more law and order in England mystified a basic structural shift in employment patterns that occurred during attempts to dismantle the British welfare state. In the late 1960s and early 1970s there was a conservative political movement in both America and Great Britain to curb state investments in public welfare—to “down-size” governments and to privatize public institutions. There was a certain amount of conscious political resistance in the labor movement and in socialist political quarters. However, the control culture succeeded in redefining the political resistance into an issue of individual lawlessness that required tougher policing, particularly of those persons who experienced the greatest amount of

social dislocation as a result of fiscal restraint—poor youth, minority groups, and immigrants. The reports of street “muggings” imparted to England the imagery of lawlessness from the American ghetto, creating the impression that there were dramatic increases in street crime, that the crimes were disturbingly “un-British,” and that they were symptomatic of a wider threat to Great Britain’s collective security as witnessed by violence in industrial disputes (fights at picket lines) and misconduct among soccer fans.

Having defined the problem as individual lawlessness, the conservative solution of more law and order, greater investment in policing, longer jail sentences, and so forth, occluded the problem of youthful unemployment that *resulted* from conservative fiscal policies and that contributed to theft and other petty rackets in the first place. In this interpretation, moral panics have a material foundation in everyday experience, but where the earlier labeling theorists viewed the panics as *causes* of legal change, the British theorists suggest that panic was the *result* of social change. Sensationalism over crime in the popular media legitimates the introduction of coercive legislation that frequently suspends normal democratic liberties and replaces parsimonious forms of control with more punitive measures. In the case reported by Hall and colleagues (1978), penalties for petty street crimes increased dramatically as the public, the judiciary, and the politicians were treated to hysterical excesses in the popular press of violent youth running amok.

A similar structural argument is advanced by Stanley Cohen in *Folk Devils and Moral Panics* (1972). This study examines the role of the media in the re-creation of the “mods” and “rockers.” There have been a series of distinct trends in youth culture in both America and Great Britain over the last four or five decades—the zoot suiters, the Teddy Boys, the beats, the skin heads and punks, the soccer hooligans, and the motorcycle rebels—all of whom expressed antiauthoritarianism and youthful rebellion. What seems to have set off the postwar youth cultures was society’s relative affluence, which created conditions for distinctive consumption patterns supporting unique fashion styles, musical tastes, and recreational opportunities. The mods and rockers were motorcycle-riding youth groups who appeared in the British seaside resorts

in the middle 1960s. As Hunter Thompson discovered in his study (1966) of the California Hell's Angels, the British newspapers made a feast of the mods' antics, typically exaggerating and reporting spuriously on their activities. Cohen (1972) stresses that the function of the news hysteria was to create a kind of rogue's gallery of folk devils—vivid, even fearsome images that registered collective fears about the youth, their mobility, and their independence, which served as collective reminders of what youth should not be.

In this approach, moral panics are an ongoing, recurrent, and predictable aspect of the popular culture. From this perspective, they are not considered the handiwork of individual moralists who may or may not decide for personal reasons to pursue a moral campaign. Moral panics are orchestrated when individuals feel compelled by their sense of the collective consciousness to repair a breach in the ideological fabric of society. Typically, either such persons are affiliated with institutions that have a longstanding investment in moral control—church organizations, community groups, political parties, and so forth—or they occupy roles as self-appointed arbiters in democratic societies—academic experts, professional journalists, and publishers.

Also, moral panics and the legislative changes they engender track important shifts in social structure fairly closely. This is the conclusion of Pearson's *Hooligan: A History of Respectable Fears* (1983). Pearson reports that the current "public" appetite for law and order, for stiffer justice, and for a return to the past are recurrent themes in Western history. The historical perspective suggests that the feelings that, from the perspective of crime and delinquency, things are at an unprecedented nadir, that the present conduct of society compares poorly with the way things were in a previous golden age, that the family is falling apart, and that the popular entertainments of the lower classes are criminogenic, are recurrent in every major period of British history from the 1750s to the present. Over time, the rhetoric of decline has an uncanny similarity. Pearson's point is that crime fears or moral panics occur when the legitimacy of state control over the working class is somehow challenged or brought into question. In the nineteenth century the British working class was only partially integrated into the political process. Consequently, their consent to government—which

was dominated by the propertied classes—was usually testy. In the 1840s in particular, there is an apprehension in philanthropical writings about the working-class "dodgers," bold, independent delinquents viewed as potential revolutionaries who might fuel the Chartist movement and overthrow the private ownership of property. In this context, philanthropists prescribed education and policing to create internal restraints in the interest of protecting property.

From this perspective, class tensions were misinterpreted in the public press and by middle-class politicians as "rising crime and delinquency," and the middle-class solutions were recurrently more "law and order" on the one hand and education on the other—that is, more police repression and control, a return to birching, a removal of the un-British elements of the population, a repudiation of meretricious American culture, and a return to the tranquility of the golden age when people knew their place.

It is difficult to give an overall assessment of how the processes of legislating morality discovered in the labeling period in America can be integrated with the class conflict approaches stressed in the recent British studies. Certainly, there is no reason to believe that the class antagonisms that characterize British society are as developed in North America, nor that these would be a monolithic source of legal change. On the other hand, there is also no reason that the search for systematic sources of moral panics as effects of social change could not be undertaken in North American studies. Since the early 1980s it has become clear that the preoccupation with abortion, pornography, the funding of acquired immunodeficiency syndrome (AIDS) research, gay bashing, and the Equal Rights Amendment in U.S. public discourses is related to important trends in family composition and female labor force participation. For the tradition minded, the suppression of access to abortion, pornography, and the Equal Rights Amendment (ERA) as well as lethargy in dealing with AIDS, all seem to be an attempt to turn the clock back toward patriarchal families. For more progressive feminists, access to abortion on demand, suppression of degrading pornography, and the confrontation of the epidemics of sexual and physical violence against women and children are essential ideological matters for the insurance

of greater female social and economic advancement. In both cases, the public imagery of epidemics of fetal massacres on the one hand, and epidemics of incest and female abuse on the other, are not the products of idiosyncratic moral campaigns but arise in the context of profound social structural transformations—suggesting the need to develop a convergence of theories of symbolic interests and structural shifts that have developed independently to date.

As we enter the new millennium in American politics, it is clear that the contemporary issues in moral discourse are distinct from the earlier focus on the criminalization of things such as drugs and alcohol. Political observers have coined the term “culture war” to characterize the attempt of the “Moral Majority” of Christian right-wing politicians to topple “the moral decline of the nation” and to substitute “moral sanity” in the form of widespread laws consistent with their religious beliefs (Scatamburlo 1998). Despite the dominance in the U.S. House of Representatives and the Senate by leading proponents of “born-again” politics over the past decade (Shupe and Stacey 1982), the New Right has effectively capitulated and virtually despaired of incorporating its views into American public and personal life (CBS 1999). Its proponents have failed repeatedly to achieve significant change. Specifically, they have failed to reintroduce prayer into the public school system—at the very time when American schools were racked by senseless shootings by disgruntled students. They have failed to curb the use of abortion as a method of birth control, failed to oust a philandering president despite a relentless investigation by a special prosecutor, and failed to curb the spread of sexual explicitness and capricious violence in everything from video games to Hollywood movies in spite of the fear that a great deal of youthful violence appears to be copied from mass media images. Further, they have failed to protect the hegemonic status of the traditional, heterosexual family and its access to spousal benefits from incursions by lesbian and gay lobbyists. They have made headway in downsizing the welfare state, but this has been achieved to varying degrees throughout the Western democracies without the same moral agenda.

The other side of the culture war has been associated with the rise of “identity politics”—a

growth in social movements among *racial minorities*, women, and sexual minorities during the past two decades. In an attempt to recenter knowledge and power on the basis of experiences overlooked by male, Eurocentric, and heterosexual perspectives, claims have sometimes been made that gynocentric, Afrocentric, and gay voices have epistemological and moral standpoints that are superior to those which have traditionally overshadowed them (Seidman 1994, p. 234). Though such claims are extravagant, they signal cultural conflicts over basic moral and social questions and foster power politics resulting from the emancipation of racial minorities, women, and gays and lesbians. This explains in part the Moral Majority’s sense of crisis, its backlash against political correctness, and its desire to return to the previous equilibrium. Schlesinger argues that the crisis is further fueled by the feeling that the common presuppositions that are required for democracy are imperiled by the spread of “strident multiculturalism,” radical ethnocentrism, and the undermining of the very possibility of a common American identity (Schlesinger 1998). The matter is only intensified by the shifting racial composition of America. Maharidge’s *The Coming White Minority* (1996) documents the apprehension among white Californians about becoming a minority group in their “own” state, a trend true of America as a whole in the larger global perspective. The social processes are not unlike those identified by Gusfield in the analysis of the temperance movement, suggesting that the social forces explaining the cultural conflicts are not unfamiliar to students of moral panic. What is less well acknowledged, and what might be important to keep in mind for resolution of what is regrettably labeled the “culture war” is the following. From the start, the Moral Majority campaign tended to be exclusionary and fundamentalist (Snowball 1991). Democracy requires coalitions and a broad basis of mutual support. When politicians in a democracy take their policies from religion, moral condemnation overshadows political dialogue. Political decisions are not arrived at through compromise and mutual dependence but through faith. Given these tendencies, “average citizens” have failed to assent to the moral absolutes required by politics based on religious righteousness, and the movement appears to have run its course (Weyrich 1999). Whether the culture war is amenable to an alternative, more inclusive, multicultural resolution remains to be seen.

LEISURE

Since 1930 the sociology of leisure in North America and Europe has not developed in a linear or cumulative fashion. Rather, research agendas, the

accepted premises for research and theory, and the “common wisdom” of the field have been revised and challenged. Change did not come in one great overturning, but in a sequence of revisions. A dialectical model seems to be most appropriate to follow the sequence. Through the 1950s, there was an accepted consensus as to both issues and premises. This common wisdom was eroded as well as challenged by new research. The “revised consensus” expanded agendas for both research and theory without completely overturning earlier developments.

Since 1985, a more critical antithesis with multiple sources has emerged to subject the second consensus to a more thoroughgoing revision. The sources of this antithesis have included conflict or neo-Marxist theory, gender-focused critiques, non-Western perspectives, and various poststructural analytical approaches. Critiques are associated with concepts such as hegemony and power, commodification, cultural and social fragmentation, gender and patriarchal structures, imperialism, world views, symbol systems, ideologies, and existential action. Now a central question concerns the kind of synthesis that will be developed in the ongoing process.

The dialectical sequence provides a dynamic framework for a review of central areas in the study of leisure. Although many issues and lines of research can be identified, four have consistently been most salient. In a highly abbreviated form, we will summarize the dialectics of theory and research in relation to (1) work and time, (2) family and community, (3) aging and the life course, and (4) the nature of leisure.

WORK AND TIME

Leisure and Work Domains. When sociologists turned their attention to leisure in the 1960s, three perspectives were adopted. The first, based on earlier community studies, approached leisure as a dimension of the social organization of the community (Lundberg, Komarovsky, and McInerney 1934; Dumazedier 1967). The second, exemplified by David Riesman and initiated at the University of Chicago, viewed leisure as social action that created its own worlds of meaning. The third, the one that came to shape domain assumption and research agendas, emerged from the sociology of work. Its fundamental premise was that economic

institutions are central to the society and economic roles the primary determinants of other roles. Especially leisure was assumed to be secondary and derivative. As a consequence, various models of determination by work were proposed that modeled leisure as similar to work (“spillover” or identity), contrasting (compensation), or separate (Wilensky 1960; Parker 1971). The bias, however, was clearly toward some kind of determination rather than segmentation.

As research proceeded, the “long arm of the job” was found to be both shorter and less powerful than expected as only limited, modest, and sometimes inconsistent relationships were found between leisure styles and occupational level and type (Wilson 1980). In a fuller perspective, on the other hand, it was evident that economic roles are determinative of the social context of adult lives—schedules, control of resources, autonomy, and other basic conditions (Blauner 1964). Leisure is part of the reward structure of a social system with differential access to resources based largely on socioeconomic position.

A second revision of the common wisdom concerned time available for leisure. The long-term reduction in the average workweek from as high as eighty hours in the early days of the industrial revolution to about forty hours in the post-World War II period along with the five-day workweek and paid vacations for many workers had led to an unquestioned assurance that more and more leisure time would be the product of increased economic productivity. In the 1970s, however, the declining rate of the decrease moving toward stability produced a revised consensus suggesting segmented time scarcity and a variety of social timetables. Most recently, analysis of labor statistics indicates that workers in high-pressure occupations and some services may have average workweeks much longer than forty hours (Schor 1991) even though time-diary research identifies a small overall increase in time for leisure (Robinson and Godbey 1997). Considerable attention has also been given to those impacted by the time scarcities of those, mostly women, with multiple work, household, and caregiving roles.

A next challenge to the early common wisdom was a recognition of leisure as a dimension of life with its own meaning and integrity. Leisure is more than leftover and derivative. It has its own

place in the rhythm and flow of life. First, leisure came to be defined more as activity than as empty time. Among the themes emerging were relative freedom of choice, distinction from the obligations of other roles, and the variety of meanings and aims that might be sought in such activity. Just as important as the revised definition, however, was the identification of leisure as something more than a derivation of work. Social life could not be divided into a work versus leisure dichotomy, but consisted of multiple sets of intersecting roles. Leisure, although it has a particular relationship with the bonding of family and other immediate communities (Cheek and Burch 1976), had multiple contexts, connections, and meanings (Kelly 1981).

The Challenge of Critical Theory. The domain assumptions of functional sociology have been challenged by critical analyses with roots in neo-Marxist cultural studies (Clarke and Critcher 1986; Rojek 1985), historical study that focuses on power and the struggles of the working class, and social construction approaches that take into account the interpretive symbolic activity of social actors (Rojek 1995).

The central theme of the critical challenge is social control by ruling elites. Leisure is seen as a critical element in the hegemony of ruling elites in a capitalist society. In order to assure compliance in the routinized "Fordist" workplace, the political arena, and the marketplace, leisure has emerged as central to the capitalist reward and control system. Leisure is, from this critical perspective, a market-mediated instrument that binds workers to the production process and to roles that support the reproduction of the capital-dominated social system. Leisure is defined as a commodity that must be earned and is indissolubly connected to what can be purchased and possessed.

A number of themes are gathered in this critique. The power to enforce compliance is masked behind an ideology in which "freedom" comes to be defined as purchasing power in the marketplace of leisure. Such "commodity fetishism" (Marx 1970) of attachment to things defines life and leisure in terms of possessions. Leisure, then, becomes "commodified" as the consumption of marketed goods and services, entertainment in contrast with commitment to involving,

challenging, and developmental activity (Kelly and Freysinger 1999). Social status is symbolized by leisure display (Veblen 1899). Absorption in mass media, especially low-cost and easy-access television (Robinson and Godbey 1997), legitimates consumption-oriented values and worldviews (Habermas 1975). What appear to be varying styles of leisure reflect the profoundly different conditions of work, family, and leisure assigned by class, gender, and race (Clarke and Critcher 1986).

A Prospective Synthesis. The fundamental presupposition of any sociology of leisure is that leisure is a thoroughly social phenomenon. It is a part of the culture and a product of the social system. Leisure is not separate and secondary, but embedded in the institutional structures, social times, and power allocations of the society. In a complex social system, both individual self-determination and institutional control differ by economic and social position. Leisure is not segmented, but woven into the system. Out of the current dialectic between the consensus and the critique, a number of issues call for attention.

The first agenda is to move beyond ideologies to examine the lived conditions of poor, excluded, and disinherited children, women, and men. Their struggles for life in the present, and their struggles for a future, are reflected in what they do to express themselves, create community, fill ordinary hours and days, and seek new possibilities.

The second issue is to identify the ways in which economic roles provide contexts, resources, limitations, and orientations for the rest of life—family and community as well as leisure. In a "post-Fordist" global economy with a loss of linear work careers and fragmented cultural schemes, the question is not the simple determination of life and leisure by work, but how determinative definitions of both the self and society are learned in a power-differentiated social context.

The third issue is meanings. Purchasing is not necessarily commodification and owning is not fetishism. What are the commitments, symbols, meanings, self-definitions, and worldviews that are the cognitive context of decisions and actions? What are the meanings and outcomes of leisure-related spending, media use, packaged entertainment and travel, and images of pleasure? Possession may be a way of life or an instrument of

activity. Does leisure reflect a culture of possession? Or is there a deep paradox between alienation and creation that permeates the entire society?

The fourth issue revolves around time. It is necessary to discard misleading models about average workweeks and the "more or less leisure" argument. Rather, what are the actual patterns and varieties of time structure and allocation? How do these patterns and possibilities vary by economic role, gender, life course, family conditions, ethnicity and race, location, and other placement factors? Time remains a basic resource for leisure action, one that not only varies widely but is one index of the possibility of self-determination.

FAMILY AND COMMUNITY

Leisure as a Context for Family Bonding. If leisure is not just activity determined by and complementary to work, then is there some other critical relationship to the social system? The evident connection is to family and other immediate communities (Roberts 1970). Most leisure is in or around the home. The most common leisure companions are family and other close friends and intimates.

The basis of the first common wisdom was the series of community studies beginning in the 1930s (Lundberg, Komarovsky, and McInerney 1934; Lynd and Lynd 1956). Leisure was found to be a web of ordinary activity, mostly social interaction and tied to the institutions of the community from the family outward to status-based organizations. From this perspective, the later work of Cheek and Burch (1976) argued that the primary function of leisure is to provide a context for social bonding, especially that of family and ethnic community.

An anomaly in family leisure began a revision to the first consensus. The family context was reaffirmed and the centrality of the family to leisure supported (Kelly 1983). Despite the traditional focus on freedom as the primary defining theme of leisure, activity with major components of obligation was found to be most important to most adults. The major theme was that leisure was closely tied to central roles, not separate from them.

Leisure, then, is bound to both the roles and the developmental requirements of life (Rapoport and Rapoport 1976). In fact, from this perspective it may be quite central to life, not residual or

secondary at all. It is a primary setting for social bonding and expression as well as for human development. The implied issue, on the other hand, is the consequences for the nature of freedom and choice in leisure. No activity embedded in primary role relationships can ever be free of accompanying obligations and responsibilities (Kelly 1987a, chap. 6). Leisure might be more central but is also less pure and simple.

Power and Self-determination in Leisure Roles. First, there is the challenge posed by changing family patterns now that an unbroken marriage and family through the life course has become a minority probability. The most radical response and antithesis, however, begins with the suggestion that leisure, like other areas of life, has roles. That is, the expectations and power differentials that characterize family, work, and community roles are found in leisure as well. Currently the most salient source of this challenging antithesis is the focus on gender, especially from a feminist perspective (Henderson et al. 1996).

The critique calls for sociologists to go beneath the leisure rhetoric of freedom and self-expression to the realities of lives with limited power of self-determination. From this perspective, the history of the culture is characterized by male domination of women in profound and multifaceted ways that permeate every aspect of life (Deem 1986). Women have been repressed in where they are permitted to go and what they are allowed to do in leisure. Men have had the power to sexualize social contexts to objectify women and their bodies. Physical power and even violence have rendered many leisure times and places unsafe for women.

Even in the home, women's leisure is fundamentally different from that of men. It is usually women who are expected to do the work that makes "family leisure" possible. It is the "hidden work" of women that offers relative freedom to much of the leisure of men and children. Women both enable men's leisure and are leisure for men.

What, then, is the meaning of freedom and self-determination for any subordinate population segment? What about the poor, the racially and ethnically excluded, those cut off from opportunity in abandoned urban areas, and even many of the old? Again, many potential leisure venues in the inner city are unsafe, especially for children and

the old. The resources of time, money, access, and autonomy are evidently unevenly distributed in any society.

In this antithesis, the connections of leisure to nonwork roles and resources, especially family and community, and the positive evaluation of how leisure contributes to development through the life course are brought up against a critical model of society. Leisure may indeed be indissolubly tied to family and community, but in ways that reflect social divisions and dominations as well as expressive action.

Leisure's Immediate Context: a New Agenda. Leisure takes place in its small worlds, but also in the larger scale of the society. Further, its actualization is in the midst of real life. Research may be based on premises of systemic integration and the benefits of leisure as well as challenged by critiques reflecting ideologies of subjugation and alienation. A new agenda for research, however informed, should be directed toward the actual lived conditions of decisions and actions, relationships and roles. In such an agenda related to community and family, several themes are highlighted by critiques of the common wisdom:

First, the realities of leisure as a struggle for action and self-determination in the midst of acute differences in power and access to resources will receive more attention. Especially gender, race, and poverty will reconstitute research strategies and frames past the easy assumptions that leisure is equally free and beneficial for all. The realities of family instability and crisis as well as of community divisions and conflicts will be taken into account as the immediate communities of leisure are reformulated.

Second, underlying the new agenda is the theme of differential power, not only power to command resources but to determine the course of one's life and what is required of others. In the action of leisure, there is both a relative openness for action and modes of repression that stimulate submission and resistance.

Third, the pervasiveness of sexuality, gender roles, and sexual orientation throughout life in society will gain greater prominence in leisure sociology. One set of issues revolves around sexuality and related emotions to leisure. Simple models of explanation based solely on rational action

will be recognized as inadequate. Also, gender will be seen as negotiated identity and power of self-determination rather than a simple dichotomized category.

Fourth, the danger of leisure's becoming increasingly privatized, bound only to immediate communities and the small worlds of personal life construction, is a perspective that runs counter to the functional view of leisure as a context for social bonding. There may be a negative side to a focus on the family basis of leisure activity and meanings. As technologies increasingly make the home a center of varied entertainment, leisure could become more and more cut off from larger communities.

In general, leisure is surely not peripheral to the central concerns and relationships of life. That, however, does not lead simply to bonding without domination, to development without alienation, or to intimacy without conflict.

AGING AND THE LIFE COURSE

Continuity and Change in the Life Course. The earliest common wisdom was simply that age indexed many kinds of leisure engagement. In a simple model, age was even referred to as a cause of decreased rates of participation. It was assumed that something decremental happened to people as they aged. The rates of decline varied according to activity: rapid for sports, especially team sports; more gradual for travel and community involvement. Attention given to those in their later years, generally their sixties and seventies but sometimes their fifties as well, suggested that such "disengagement" might even be functional. Perhaps older people needed to consolidate their activity and recognize their limitations.

The revised common wisdom began by recasting age as an index of multiple related changes rather than an independent variable. Further, the revised framework became the life course rather than linear age (Neugarten 1968). A number of themes emerged:

First, in the Kansas City study of adult life, normative disengagement was replaced with activity (Havighurst 1961). Instead of making a necessary or desirable withdrawal from activity, older people were found to revise their patterns and commitments in ways that fit their later life roles

and opportunities. Leisure was conceptualized as multidimensional in meaning as well as in forms. More recently, this approach has led to a discovery of the “active old,” those before and in retirement who adopt lifestyles of engagement in a variety of leisure activities and relationships. Further, such engagement has been consistently found to be a major factor in life satisfaction (Cutler and Hendricks 1990).

Second, the model of inevitable decrement was challenged by research that failed to measure high correlations between age and functional ability. Rather, a model of aging that stressed *continuity* rather than loss and change was applied to leisure as well as other aspects of life (Atchley 1989). A return to earlier socialization studies provided a base for a revised model that identified lines of commitment rather than age-graded discontinuity. Especially the “core” of daily accessible activity and interaction remains central to time allocation through the life course (Kelly 1983).

Third, the life course also provided a perspective in which intersecting work, leisure, and family roles and opportunities were related to developmental changes (Rapoport and Rapoport 1976). Leisure is not a list of activities dwindling with age, but a social environment in which many critical issues of life may be worked out. Developing sexual identity for teens, expressing intimacy for those exploring and consolidating family commitments, reconstituting social contexts after midlife disruptions, and ensuring social integration in later years are all central requirements of the life course that are developed in leisure. Not only interests, but also significant identities are often found in leisure as well as in family and work (Gordon, Gaitz, and Scott 1976).

In the revised consensus, then, the life course with its interwoven work, family, and community roles was accepted as a valuable framework for analyzing both the continuities and the changes of leisure. Leisure was seen as tied not only to role sequences but also to developmental preoccupations. The life course was found to incorporate revisions and reorientations rather than being simply an inevitable downhill slide measured by participation rates in selected recreation pursuits.

An Integrated View of Life . . . and Leisure. The regular and predictable transitions of the life-course model, however, seem to gloss over many

of the realities of contemporary life. A majority of adults in their middle or later years have experienced at least one disrupting trauma in health, work, or the family that has required a fundamental reconstituting of roles and orientations (Kelly 1987b). Further, conditions are not the same for all persons in a social system. Race, gender, class, and ethnicity designate different life chances.

In this perspective of continuity and change in a metaphor of life as journey, a number of issues call for attention. First, salient differences in life conditions are more than variations in starting points for the journey. Rather, deprivation and denial are cumulative in ways that affect every dimension of life. Second, individuals come to define themselves in the actual circumstances of life, not in an abstracted concept. Identities, the concepts of the self that are central to what we believe is possible and probable in our lives, are developed in the realities of the life course. Third, the structures of the society, including access to institutional power, provide forceful contexts of opportunity and denial that shape both direction and resources for the journey.

In this revised life-course approach, leisure remains as a significant dimension, tied to family, work, education, community, and other elements of life. Changes in one may affect all the others. Leisure, then, is distinct from the product orientation of work and the intimate bonding of the family, and yet is connected to both.

Leisure and the Life Course: New Agendas.

From the perspective of the life course, research focusing on leisure now requires several revised issues. Among the most significant are:

First, leisure is woven through the life course. It is existential in a developmental sense. That is, leisure is action that involves *becoming*, action in which the actor becomes something more than before. For example, leisure is central to changing early socialization in the increased activity scheduling, electronic entertainment and interaction, and professional supervision of upper- and middle-class children. It is the main context for exploring sexuality and romance for teens and young adults.

Second, the developmental orientation of some leisure is highlighted by this perspective that recognizes lines of action as well as singular events and episodes. What has been termed “serious

leisure” by Robert Stebbins (1979) is activity in which there is considerable personal investment in skills and often in equipment and organization. Such investment places serious leisure in a central position in identity formation and expression. Leisure identities may provide continuity through the transitions and traumas of the life course. Yet, how women and men define themselves and take action toward redefinition has been a subject of speculation more than research.

Third, what is the place of leisure in the schema of life investments and commitments? Further, how do those investments differ according to the life conditions of men and women as they make their way through the shifting expectations and possibilities of the life course? Xavier Gallier (1988) presents a model of the life course that emphasizes disruptions rather than linear progress. In an irregular life journey, work, family, and leisure may rise and fall both in salience and in the “chunks” of time they are allocated. He proposes that education, production, and leisure become themes woven through life rather than discrete sequential periods.

THE NATURE OF LEISURE

As already suggested, perspectives on the nature of leisure have changed in the modern period of scholarly attention from the 1930s to now. The change is not self-contained, but reflects shifts in theoretical paradigms as well as drawing from other disciplines, especially social psychology.

Leisure as Free Time and Meaning. Despite repeated references to Greek roots and especially Aristotle, the first accepted operational definition of leisure was that of time. Leisure did not require that all other role obligations be completed, but that the use of the time be more by choice than by requirement. How choice was to be measured was seldom addressed. Concurrently, international “time-budget” research quantified leisure as one type of activity that could be identified by its form (Szalai 1974). Leisure was assumed to be clearly distinguished from work, required maintenance, and family responsibilities.

The first consensus, although persisting in many research designs, did not endure long without amendment. To begin with, it was obvious that any activity might be required, an extension of

work or other roles. Further, even such simple terms as “choice” and “discretionary” implied that the actor’s definition of the situation might be crucial.

In the 1970s, the field claimed more attention from psychologists, who focused on attitudes rather than activities. Leisure was said to be defined by attitudes or a “state of mind” that included elements such as perceived freedom, intrinsic motivation, and a concentration on the experience rather than external ends (Neulinger 1974). Attention was directed toward meanings, but wholly in the actor rather than in definitions of the social context. Such psychological approaches were one salient influence on sociologists, who added at least three dimensions to the earlier time- and activity-known to common definitions.

First, in the 1950s, the Kansas City research (Havighurst 1961) along with the community studies tied leisure to social roles. The satisfactions anticipated in an activity involved meanings and relationships brought to the action context as well as what occurred in the time frame.

Second, the immediate experience might be the critical focus for leisure, but it occurs in particular environments that involve social learning, acquired skills and orientations (Csikszentmihalyi 1981), and interaction with components imported from other role relationships (Cheek and Burch 1976). Freedom is perceived, or not, in actual circumstances.

Third, although the dimension of freedom recurs in the literature, studies of experiences and activity engagements found that leisure seldom is monodimensional. The meanings, outcomes, motivations, and experiences themselves are multifaceted (Havighurst 1961; Kelly 1981).

Leisure, then, in the revised approaches is a more complex phenomenon than either the earlier sociologists or the psychologists proposed. In fact, the consensus broke down under the weight of multiple approaches that ranged from individualistic psychology to functional sociology, from presumably self-evident quantities of time to interpretive self-definitions and lines of action, and from discrete self-presentations (Goffman 1967) to actions embedded in life-course role sequences (Rapoport and Rapoport 1976).

Revolt against the Abstract. Antithetical themes came from several directions.

First, which is fundamental to accounting for life in society, the interpretive acts of the individual or the social context in which the action takes place (Giddens 1979)? Further, since the forms and symbols by which action is directed are learned and reinforced in the society, can action be prior to the context? The nature of leisure, then, is neither an acontextual nor a determined social role. Rather, it is actualized in processual action. And this process has continuities that extend beyond the immediate to personal development and the creation of significant communities (Kelly 1981).

Second, a number of critical analysts have raised questions about the positive cast usually given to leisure. Such positive approaches seem to presuppose resources, options, perspectives, and self-determination that are in fact unequally distributed in societies (Clarke and Critcher 1986). Do the unemployed and the poor have enough resources for discretion and choice to be meaningful concepts? Do histories of subjugation and life-defining limits for women in male-dominated societies make assumptions of self-determining action a sham? Such opportunity differences are most substantive in a market system of buying, renting, or otherwise acquiring resources. The real contexts of leisure are not voids of time and space, but are extensions of the structures of the society and ideologies of the culture. There is clearly an "other side" to leisure that includes many kinds of activity with destructive potential such as gambling, substance use, and sexual exploitation. There are also negative elements in other activities such as physical violence and racial stereotyping in sport, sexual violence in socializing, and even turning driving into a contest endangering others. All social forms of exploitation and exclusion are found in leisure (Rojek 1995; Kelly and Freysinger 1999).

Third, a consequence of this distorted and constricted context of leisure is alienation. Leisure is not entirely free, creative, authentic, and community-building activity. It may also be, perhaps at the same time, stultifying and alienating. It may separate rather than unite, narrow rather than expand, and entrap rather than free. It may, in short, be negative as well as positive. It is not a rarified ideal or a perfect experience. It is real life,

often struggle and conflict as well as development and expression.

The dialectic between expression and oppression that characterizes the rest of life in society is the reality of leisure as well. Being role-based in a stratified society means being limited, directed, and excluded. The contexts of any experience, however free and exhilarating, are the real culture and social system. The multiple meanings of leisure include separation as well as community, determination as well as creation, and routine as well as expression. The former simplicity of leisure as essentially a "good thing" becomes alloyed by situating it in the real society with all its forces, pressures, and conflicts.

Leisure as a Dimension of Life. The question, then, is what does such extension and critique do to any conceptualization of the nature of leisure? Leisure encompasses both the existential and the social. It has myriad forms, locales, social settings, and outcomes. Leisure is neither separated from social roles nor wholly determined by them. Leisure has developed amid conflict as well as social development, in division as well as integration, with control as well as freedom. It may involve acquiescence as well as resistance, alienation as well as authenticity, and preoccupation with self as well as commitment to community. Leisure, then, is multidimensional and cannot be characterized by any single or simple element.

A further issue is whether leisure is really a domain of life at all. Is leisure clearly distinguished from work, family, community, church, and school: or is it a dimension of action and interaction within them all? In the Preparation period, leisure is a social space for the exploration and development of sexual identities as well as working out the issues of peer identification and independence from parents and the past. It also stresses the theme of expression that is central to developing a sense of selfhood, of personal identity among emerging social roles. In the Establishment period, leisure adds the dimension of bonding to intimate others, especially in the formation and consolidation of the family. In the Third Age, leisure has meanings tied to both integration with significant other persons and maintenance of a sense of ability when some work and community roles are lost (Kelly 1987b). Leisure, then, might

be conceptualized as being woven into the intersecting role sequences of the life course rather than being a segregated realm of activity. Productivity is not limited to work, nor bonding to the family, nor learning and development to education, nor expression to leisure. Production, bonding and community, learning and development, and relative freedom and self-authenticating experience may all be found in any domain of life.

Yet there must also be distinguishing elements of leisure or it disappears into the ongoing round of life. Further, those elements should be significant in relation to central issues of life such as production and work, love and community, sexuality and gender, learning and development, emotion and involvement. Leisure should connect with the lived conditions of ordinary life rather than being an esoteric and precious idea to be actualized only in rare and elite conditions.

Leisure, then, may be more a dimension than a domain, more a theme than an identifiable realm (Kelly 1987a). That dimension is characterized by three elements: First, it is action in the inclusive sense of doing something, of being an intentioned and deliberate act. Such action is existential in producing an outcome with meaning to the actor. Second, this action is focused on the experience more than on the result. It is done primarily because of what occurs in the defined time and space. Third, leisure as a dimension of life is characterized by freedom more than by necessity. It is not required by any role, coercive power, or repressive ideology. Leisure is not detached from its social and cultural contexts, but is a dimension of relatively self-determined action within such contexts. Its meaning is not in its products as much as in the experience, not in its forms as much as in its expression.

The Sociology of Leisure in the Future. Leisure sociology, then, is not a closed book or a finalized product. Rather, central issues are currently being raised that promise to reform the field in its premises as well as conclusions. No common wisdom will go unchallenged, no consensus remain unchanged, and no theoretical formulation be above conflict. Yet, every challenge, every conflict, and every developing synthesis provides a new basis for at least one conclusion: Leisure is a significant dimension of life that calls for both disciplined and innovative attention. From this

perspective, a number of issues are likely to receive greater attention in the new century (Kelly and Freysinger 1999):

The first issue is the ascendancy of the market sector as the primary leisure resource provider, with an estimated 97 percent of total spending. In a global economy, leisure including tourism is attracting more investment capital with a significant bias toward upscale markets, big-ticket toys, sport as business and spectacle, and entertainment with multiple entrance fees. This bias combined with media images of a commodified "good life" may underlie trends away from skill-based physical activity and "serious" leisure with high time costs. Is there a fundamental conflict between developmental and consumptive leisure?

The second issue is the emergence of a global culture. The dominant direction of the dispersal is currently from the West through the mass media. However, as communication links and business and cultural contacts become more common, both the concepts and the practices of leisure in the West will become more affected by other cultures.

Third, a focus on gender is leading away from male-oriented "reasoned action" modes of leisure decisions and toward the significance of emotions and especially sexuality. Since all social interaction is gendered and most has deep dimensions of sexuality, leisure will be understood more as a multidimensional process rather than a singular choice. Leisure, then, is both contextual and contested.

Fourth, leisure becomes more a part of "ordinary life" rather than segregated activities with special designations. In a more fragmented social milieu, elements of leisure may be located in almost any social context. Further, if work itself loses familiar continuities, then leisure may become more central to identities and persistent lines of meaning as individuals seek to make sense of their lives.

Fifth, there will likely be concerns over many negative aspects of leisure. Will easy entertainment lessen personal investments in challenging leisure? Will available and affordable electronics damage the social fabric of associations and intimate relationships? Will leisure increasingly become privatized at the cost of community exploitative of the poor and powerless? Will leisure become

spectacular rather than engaging, violent rather than sharing, destructive of natural environments, and divisive rather than integrating?

The basic questions, of course, are those of the kind of society that is emerging and the kind of people who will live in it. It is clear, whatever is ahead, that leisure will be a significant dimension in a variety of forms and contexts.

LEVELS OF ANALYSIS

Determining the level of analysis is usually straightforward, but whether to, or how to, draw inferences from one level of analysis to another is a difficult problem for which there is no general solution. The cases used as the units in an analysis determine the level of analysis. These cases may be quite varied, for example, countries, political parties, advertisements, families, or individuals. Thus, analysis may occur at the individual level, family level, advertisement level, and so forth.

The types of variables used at any one level of analysis, however, may be quite different. As an example, in studying the determinants of individuals' attitudes toward public education, the individuals (the units of analysis) may be described in terms of their sex and race (measures of individual properties), whether they attended a public or private college, and the region of the country in which they reside (measures of the collectives to which they belong). The analysis in this example is at the individual level because the cases used are individuals who are described in terms of individual properties and the properties of the collectives to which they belong.

This article focuses on (1) the types of variables used to describe the properties of collectives and members and the use of these variables at different levels of analysis; (2) problems that arise when using relationships at one level of analysis to make inferences about relationships at another level of analysis; (3) a brief discussion of a statistical model that explicates these problems; (4) some useful data analytic techniques to use when data at two or more levels of analysis are available, and (5)

proposed solutions or partial solutions to the problem of cross level inference when data at only a single level of analysis are available.

TYPES OF VARIABLES USED TO DESCRIBE COLLECTIVES AND MEMBERS

Lazarsfeld and Menzel (1969) propose a typology of the kinds of properties (variables) that describe "collectives" and "members." For example, in discussing the properties of collectives, Lazarsfeld and Menzel distinguish between analytical, structural, and global properties.

Analytical properties are obtained by performing some mathematical operation upon some property of each *single* member. These properties are typically referred to as aggregate variables. Examples are the percentage of blacks in cities, the sex ratio for different counties, and the Gini Index as a measure of inequality of incomes in organizations.

Structural properties of collectives are obtained by performing some operation on data about the relations of each member to some or all of the others. Such measures are common in network analysis. Friendship density, for example, could be defined as the relative number of pairs of members of a collective who are directly connected by friendship ties. Since the total number of potential ties in a group with N members is $N(N-1)/2$, one measure of density is the total number of ties divided by this number.

Global properties of collectives do not use information about the properties of individual members either singly or in relationship to one another. Having a democratic or nondemocratic form of government is a global property of collectives. Being a private rather than a public school is a global property of a school. The proportion of gross national product (GNP) spent on education is a global property of countries.

Thus, variables that describe collectives can be based on summary data concerning single members of those collectives, the relationships of members to other members, or some global characteristic of the collective itself. Turning to variables that describe the properties of members of collectives, there are four major types: absolute, relational, comparative, and contextual.

Absolute properties are obtained without making use either of information about the characteristics of the collective or of information about the relationships of the member being described to other members. Thus, sex, level of education, and income are absolute properties of individuals.

Relational properties of members are computed from information about the substantive relationships between them and other members. For example, the number of friends an individual has at school or the number of family members is a property of the individual based on other members in the collective.

Comparative properties characterize a member by a comparison between his or her value on some (absolute or relational) property and the distribution of this property over the entire collective to which the person belongs. A person's class rank and birth order are comparative properties.

Contextual properties describe members by a property of the collective to which they belong. For example, being from a densely populated census tract or a school with a certain percentage of nonwhite students is a contextual property describing the context in which the member acts. Contextual properties are characteristics of collectives that are applied to members.

Contextual variables remind us that the level of analysis is determined by the cases used as the units of analysis, not by the level of the phenomena described by a particular variable. Thus, all the variables that describe a collective may be used at the individual level of analysis as well as those that describe individual properties; for example, a person's attitude may be predicted on the basis of the percentage of blacks in the person's school (contextual/analytic), whether or not the school is private or public (contextual/global), the density of friendships at the school (contextual/structural), the person's sex (absolute), his or her class standing (comparative), and the number of friendship choices he or she receives (relational).

INFERENCES FROM ONE LEVEL TO ANOTHER

The section above describes abstractly two different levels of analysis, the collective (or aggregate) and the member (or individual). Sociologists typically distinguish levels concretely depending on

the units of analysis; for example, the units may be schools, advertisements, children's stories, or riots. To make inferences from relationships discovered at one level of analysis to relationships at another level is not logically valid, and sociologists have labeled such inferences "fallacies." Still, at times one may be able to argue for the reasonableness of such inferences. These arguments may be based on statistical considerations (Achen and Shively 1995; Duncan and Davis 1953; Goodman 1953, 1959; King 1997) or on rationales that closely tie relationships at one level with those at another (Durkheim [1897] 1966; Dornbusch and Hickman 1959).

Disaggregative fallacies (often called ecological fallacies) are the classic case of cross level fallacies. Robinson (1950) brought them to the attention of sociologists. He cites two cases of cross level inferences, both of which involve making inferences about relationships at the individual level based on relationships discovered at the aggregate level. Robinson noted that the Pearson product moment correlation between the percent black and the percent illiterate in 1930 for the Census Bureau's nine geographical divisions was 0.95 and for states it was 0.77, while the correlation (measured by phi) on the individual level between being illiterate or not and being black or not was only 0.20. The relationship between percent illiterate and percent foreign-born was negative for regions and states (-0.62 and -0.53, respectively), while the relationship between being illiterate and being foreign-born at the individual level was positive (0.12).

Robinson demonstrated that relationships at one level of analysis do not have to be the same as those at another level. To assume that they must be the same or even that they must be quite similar is a logical fallacy.

Aggregative fallacies occur in the opposite direction, that is, when one assumes that relationships existing at the individual level must exist at the aggregate level. Robinson's results show that the positive relationship between being foreign born and being illiterate at the individual level may not be mirrored at the state level.

Universal fallacies (Alker 1969) occur when researchers assume that relationships based on the total population must be true for subsamples of the whole. It may be true, for example, that the

relationship between population density and the crime rates of cities for all cities in the United States is not the same for southern cities or for cities with a population of over one million. Here, the fallacy is to assume that a relationship based on the total population must hold for selected subpopulations.

Similarly, one might commit a *selective fallacy* (Alker 1969) by assuming that relationships based on a particular sample of cities must hold for all cities. If the selected cities are a random sample of cities, this is a problem of statistical inference, but if they are selected on some other basis (e.g., size), then making inferences to all cities is a selective fallacy.

Cross-modality fallacies occur when the inference is from one distinct type of unit to another distinct type of unit. A cross-modality fallacy occurs when trends in advertisement content are used to make inferences about trends in the attitudes of individuals, or designs on pottery are used to infer the level of need for achievement in different cultures. (Aggregative and disaggregative fallacies are cross-modality fallacies because groups and individuals are distinct units. But these fallacies have traditionally been classified separately.)

Cross-sectional fallacies occur when one makes inferences from cross-sectional relationships (relationships based on units of analysis from a single point in time) to longitudinal relationships. For example, if unemployment rates and crime rates are positively related at the city level, this fallacy is committed by inferring that increases over time in the unemployment rate are related to increases in the crime rate over time.

Longitudinal fallacies occur when one makes inferences from longitudinal relationships (relationships based on units of analysis across time units) to cross-sectional ones, that is inferring from a relationship between unemployment rates and crime rates over time to the relationship between these rates over units such as cities, counties, or states at a given point in time.

In all of their varied manifestations, cross-level inferences are not logically valid inferences (Skyrms 1975). That is, relationships on one level of analysis are not necessarily the same as those on another level. They may not even be similar. In the final section of this article, however, we note that data at

one level of analysis may serve as evidence for relationships at another level of analysis even if they do not strictly imply such a relationship.

**STATISTICAL ANALYSIS OF
DISAGGREGATIVE AND AGGREGATIVE
INFERENCES**

This section presents the results of a mathematical demonstration of why disaggregative and aggregative inferences are fallacies, that is, why results at the aggregate level are not necessarily mirrored at the individual level. The derivation of this model is not shown here but may be found in several sources (Duncan et al. 1961; Alker 1969; Hannan 1971; and Robinson 1950). Readers who prefer can skip to the next section without loss of continuity.

The individual level or total correlation (r^t_{xy}) between two variables (X and Y) can be written as a function of the correlation between group means (the aggregate level correlation: r^b_{xy}), the correlation of individual scores within groups (a weighted average of the correlations within each of the groups: r^w_{xy}), and the correlation ratios for the two variables, X and Y . The correlation ratio is the ratio of the variance between groups (the variance of the group means: V^b_x) to the total variance (variance of the individual scores: V^t_x). Thus, the individual level or total correlation can be written

$$r^t_{xy} = r^w_{xy} \sqrt{1 - \left(\frac{V^b_x}{V^t_x}\right)^2} \sqrt{1 - \left(\frac{V^b_y}{V^t_y}\right)^2} + r^b_{xy} \left(\frac{V^b_x}{V^t_x}\right) \left(\frac{V^b_y}{V^t_y}\right) \tag{1}$$

Similarly, the individual level regression coefficient can be written as a function of the within-group regression coefficient, the group level (between group) regression coefficient, and the correlation ratio for variable X (equation 2):

$$b^t_{yx} = b^w_{yx} + \left(\frac{V^b_x}{V^t_x}\right)^2 (b^b_{yx} - b^w_{yx}) \tag{2}$$

It is a simple algebraic exercise to derive formulas for r^b_{xy} and b^b_{yx} (the aggregate level correlation and regression coefficients) in terms of correlation ratios, and correlation and regression coefficients at other levels.

These formulas clearly demonstrate why one cannot use the ecological or group level correlation or regression coefficients to estimate individual level relationships: The individual level relationships are a function of group level relationships, within-group level relationships, and correlation ratios. This approach can be extended to include other levels of analysis, for example, individuals on one level, counties on another, states on another, and time as yet another level (see, e.g., Alker 1969; Duncan et al. 1961).

SEPARATING AGGREGATE LEVEL AND INDIVIDUAL LEVEL EFFECTS

Obtaining data at the different levels of analysis solves the problem of inferring relationships from one level to another. Researchers in this situation know the relationship at both levels for their data. Such data also provide additional information about the relationships at different levels of analysis.

O'Brien (1998) shows that when individual level data are aggregated to create summary measures at the aggregate level (e.g., means or rates for aggregates), then it is possible to estimate the reliability of the aggregate level measures. Further, when two or more of the aggregate level measures are based on samples of the same respondents within each aggregate, correlated errors between aggregate level measures are likely to occur. This correlated error can be measured and the aggregate level relationships can be corrected for this spurious correlation as well as for unreliability in the aggregate level measures.

In some situations one may want to argue that the best measures of individual level "effects" (in a causal sense) are provided by analyses at the individual level that include as predictors relevant individual properties and the properties of the collective to which the individuals belong (contextual variables). Estimates of these individual level relationships are then "controlled" for group level effects (Alwin and Otto 1977).

Since the relationship between group level means may reflect nothing more than the relationship between variables at the individual level, it has been suggested that the best estimate of group level "effects" compares the regression coefficient for the group means and for the individual scores. Lincoln and Zeitz (1980) show how this may be

done in a single regression equation while at the same time controlling for other relevant variables. For both of these techniques to work, some stringent assumptions must be met, including assumptions of no measurement error in the independent variables and of a common within-group regression coefficient. Most importantly, these techniques depend upon having data from different levels of analysis.

The introduction of Hierarchical Linear Models (HLM) provides a flexible method for examining the relationship of individual level variables to group level variables (Bryk and Raudenbush 1992). These models allow for the relationships between individual level variables to vary within different groups and for differences between these relationships to be predicted by group level characteristics. It might be the case, for example, that the relationship between socioeconomic standing and student achievement differs depending upon class size and whether the school is private or public. These models allow for the prediction of different relationships for different individuals based on group level characteristics. These models may be extended to several levels of analysis in which members are nested within collectives.

SOLUTIONS TO THE PROBLEM OF INFERENCES FROM ONE LEVEL TO ANOTHER

Even when data at only one level of analysis are available, cross level inferences can be and often are made by sociologists. There is no absolute stricture against making such inferences, but when researchers make them, they need to do so with some awareness of their limitations.

While both Duncan and Davis (1953) and Goodman (1953, 1959) maintain that it is generally inappropriate to use aggregate level (ecological) relationships to make inferences about individual level relationships, they each propose strategies that set bounds on the possible relationships that could exist at one level of analysis given relationships that exist at the other. The bounds are designed for use with aggregated data (analytic measures), and in some circumstances these techniques are useful.

Goodman (1953, 1959) suggested a technique called "ecological regression," which became the

most widely used method for making inferences from aggregate level data to individual level relationships when group level variables are “analytical properties of collectives.” Goodman’s method has been extended by a number of authors and summarized in the work of Achen and Shiveley (1995). King (1997) has proposed a statistical “solution to the problem of ecological inference,” but the success of that solution is controversial (Freedman et al. 1998).

“Theory” may also allow one to make cross level inferences. For example, Dornbusch and Hickman (1959) tested Riesman et al.’s contention (1950) that other-directedness in individuals declined in the United States during the first half of the twentieth century. They obviously could not interview individuals throughout the first half of the century, so they turned to advertisements in a women’s magazine (*Ladies Home Journal*, 1890–1956) to examine whether these ads increasingly used themes of other-directedness. Their units of analysis were advertisements, but they explicitly stated that they wanted to make inferences about changes in the other-directedness of individuals. Is this justified? The answer is no, on strictly logical grounds, and this constitutes a cross-modality fallacy. Certainly changes in the contents of advertisements do not demonstrate changes in individuals’ personalities. But Dornbusch and Hickman (1959) convincingly argue that advertisements (in this case) are likely to reflect aspects of other-directedness in the targets of the advertisements (individuals). They recognize the need for other tests of this hypothesis, using other types of data.

Perhaps the classic case in sociology of an analysis built on the ecological fallacy is Emile Durkheim’s analysis of suicide ([1897] 1966). One factor that Durkheim sees as “protecting” individuals from suicide is social integration. When individuals are married, have children, are members of a church that provides a high degree of social integration (e.g., Catholic rather than Protestant), or live at a time when their countries are in crisis (e.g., a war or electoral crisis), they are seen as more integrated into social, religious, and political society and less likely to commit suicide. Much of the data available to Durkheim did not allow an analysis on the individual level. There was no “suicide registry” with detailed data on the sex, religion, family status, and so forth of those committing suicide. There were, however, census data

on the proportion of Catholics, the proportion married, and the average family size in different regions. Other sources could be used to ascertain the rate of suicide for different regions. Using these data, Durkheim showed that Catholic countries had lower suicide rates than Protestant countries, and that, France and Germany, Catholic cantons exhibited lower suicide rates than Protestant cantons. Further, departments in France with larger average family sizes had lower suicide rates, and the suicide rate was lower during the months of electoral crises in France than during comparable months of the previous or following year. He combined this evidence with other evidence dealing with individuals (e.g., suicide rates for married versus unmarried men), and it was all consistent with his theory of suicide and social integration.

One could dismiss these aggregate level relationships by arguing that perhaps in Protestant countries those of other religions kill themselves at such a high rate that the suicide rates are higher in Protestant countries than in Catholic countries (and similarly in Protestant cantons in France and Germany). Isn’t it possible that in departments with relatively small average family sizes there is a tendency for those in large-size families to kill themselves relatively more often? This would create a relationship at the aggregate level (department level) in which smaller average family size is associated with higher rates of suicide. It is possible, because relationships at one level of analysis are not necessarily mirrored at another level of analysis. But Durkheim’s results are not easily dismissed.

Strict logic does not justify cross level inferences. But strict logic is not the only rational way to justify inferences. If a series of diverse relationships that are predicted to hold at the individual level are found at the aggregate level, they do not prove that the same relationships would be found at the individual level, but they are not irrelevant. It is incumbent on the critic of a study such as Durkheim’s to give a series of alternative explanations explaining why the relationships at the aggregate level should differ from those at the individual level. If the alternative explanations are not very convincing or parsimonious, researchers are likely to find Durkheim’s evidence persuasive. To the extent that social scientists are convinced that a set of advertisements is designed to appeal to motivations in their target population, that the target

population of the magazine in which the advertisements appears represents the population of interest, and so on, they will find Dornbusch and Hickman's cross level inference persuasive. That a relationship at one level of analysis does not imply a relationship at another level of analysis does not mean that it cannot be used, along with other evidence, to help infer a relationship at another level of analysis.

Persuasion is a matter of degree and is subject to change. Sociologists would want to examine additional studies based on, for instance, other populations, modalities, and periods. These data might strengthen cross level inferences.

ROBERT M. O'BRIEN

LIBERALISM/CONSERVATISM

NOTE: *Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.*

"Is (or was) Blank a liberal?" The precise reply to this question inevitably begins with a throat-clearing preface such as, "It all depends on the period you have in mind—and the place. Are you speaking of someone in nineteenth-century England, the United States during the Franklin Roosevelt New Deal days, contemporary Great Britain, continental Europe, or contemporary U.S.A.?"

For Americans nurtured on the "liberal" tradition of Franklin Delano Roosevelt and the Democratic party, the significance of the *L* word was quite clear. The private business establishment,

left to its own devices, had brought about the economic collapse of 1929. "Rugged individualism" had demonstrated its inadequacies even for many rugged individualists themselves. Almost two-thirds of a century after that collapse, the Great American Depression still retains the power to evoke terrifying memories of mass unemployment, bank failures, small business bankruptcies, soup kitchens, and popular ditties like "Brother can you spare a dime?" These were all nostalgic but chilling reminiscences of the desolation to which "nonliberal," or "conservative," social, economic, and political policies had led. There seems to persist an enormous reluctance to release this era and its memories to the historians as just another noteworthy episode in American history like the War of 1812 or the Panic of 1873.

For other Americans, some of whom matured perhaps too rapidly during the late 1960s and whose memories were filled with visions of the war in Vietnam, the battles for Civil Rights, and the turmoil in urban ghettos, things were much less clear. Stalwarts of liberalism like Hubert Humphrey (senator, vice president, and unsuccessful Democratic candidate for President) seemed to become part of the very establishment toward which hostility was directed. Government, instead of representing a liberating force, increasingly was seen as the source of existing difficulties. Liberalism, for many, was no longer the solution; it had become part of the problem.

Liberalism has often been identified with the struggle to free individuals from the confining embraces of other persons, institutions, or even habitual ways of behaving. It is seen by its advocates as a liberating orientation. Thoughts that, in various times and places, have been called liberal, all seem to have as their common denominator this fundamental notion of freedom for individual human beings.

It was during the period between the Reformation and the French Revolution that a new social class emerged. Political control by a landowning aristocracy was challenged by this new class whose power lay only in the control of movable capital. It consisted of such people as bankers, traders, and manufacturers. Science began to replace religion as the source of ultimate authority; contract replaced status as the legal foundation of society. The ideas of individual initiative and individual

control became the basis for a new philosophy: liberalism (Laski 1962, p. 11).

Liberalism began as the champion of freedom and the foe of privilege derived from inherited class position. But freedom was not fought for on behalf of everyone in society. The constituency of liberalism consisted of those who had property to defend. Its supporters sought to limit the range of political authority and tried to develop a system of fundamental rights not subject to invasion by the state (Laski 1962, p. 13). Most of the population (e.g., factory and agricultural workers) were not initially included in the concerns of liberalism. But redefinitions of governmental concerns and authority inevitably had consequences for all members of society. Thoughtful economists and others soon realized this.

Thus, from the perspective of the closing years of twentieth-century America, it is easy to forget that classical economists like Adam Smith and David Ricardo, far from being simply reflex ideologists for the business establishment, were deeply concerned about liberty for individuals and saw their classical economic doctrines as the best way to insure it. In this sense, many contemporary Americans could legitimately view them as representatives of the liberal, rather than the conservative, genre. The *free enterprise* game was originally a liberal game.

For many participants in this great game of free enterprise, it became increasingly more obvious that the game was "fixed," that somehow participants did not emerge with either their liberty or their pocketbooks intact. To insure even a modicum of freedom and liberty for individuals, it became necessary to provide them with a helping hand from a source outside the marketplace. This source, a powerful and beneficent outsider, the national government, could help monitor the rules and to some extent the play of the economic game. It *could* provide, for heavy losers or potential losers, social benefits in the form of such consolations as unemployment insurance, old age pensions, insured bank accounts, and coordinated measures to combat environmental pollution. It *could* help protect consumers from the harmful effects of adulterated food and drug products; it *could* protect workers from the hazards of unregulated workplaces. In short, the liberal ethos in twentieth-century America incorporated as one of its tenets

reliance on government action to protect the liberty of individuals.

The conservative ethos, on the other hand, during the same period has been characterized by a hands-off posture with respect to many aspects of government policy. This constitutes a fascinating reversal of traditional conservatism. The shades of Edmund Burke and other historical conservative spirits might well cringe at the characterization of their philosophy as “less government.”

For some observers, this liberal-conservative contrast seems to be based on different psychological sets, or frames, of mind. Thus, we have been told that liberals are more hospitable to change, more willing to reexamine institutions and established practices in the light of new problems and needs. From this perspective, conservatives are those who appeal to the experience of the past but do not learn from it. Liberals are presented as being less reverent of the status quo, more venturesome in the realm of ideas, and much more optimistic about the possibilities available through exploration and discovery (Girvetz 1966).

Willingness to change becomes meaningful only when viewed against the nature of the status quo. When “liberal” governments adopt measures to provide for persons who are aged, ill, unemployed, or handicapped (as they have in some Scandinavian countries), to be “liberal” may mean to *retain* the status quo. To eliminate the measures—to engage in change—may be precisely what Western conservatives might demand.

For many observers of the dramatic events occurring at the end of the 1980s and in the early 1990s in Eastern Europe, members of communist parties who struggled to maintain their power in government were labeled “conservatives.” Those fighting for *free enterprise* and other capitalist-like changes were called “liberal reformers.” Communists for many years had been viewed by Western conservatives as the ultimate enemy; liberals were characteristically referred to by many of these conservatives as thinly disguised “Reds.” In a dramatic and even comic reversal, dedicated Stalinists were now described as “conservatives.”

At one time or another a wide variety of ideas have been called conservative. There have been efforts, however, to reduce the essence of these ideas to a limited number of more or less well

defined notions. Clinton Rossiter and Russell Kirk, two ardent defenders of the conservative faith, once prepared a summary that received widespread approval. Although not all conservatives would necessarily agree with everything appearing in their summary, “it would be exceedingly difficult to find a conservative who did not agree with a good deal of what Professors Kirk and Rossiter impute to their tradition” (Witonski 1971, pp. 34–35).

The imputation begins with an assumption about the more or less immutable character of human nature. Behind the curtain of civilized behavior there exists, in human beings, wickedness, unreason, and an urge to engage in violence. In addition, a great deal of emphasis is placed upon the conviction that people are not naturally equal in most qualities of mind, body, and spirit. Liberty is more important than social equality. This leads to the conclusion that society must always have its classes. It is futile to level or eliminate them. Accordingly, societies will always require ruling aristocracies; efforts to have majority rule will lead to errors and potential tyranny.

Human beings, this conservative ethos insists, are not born with rights. These are earned as a result of duties performed. Service, effort, obedience, cultivation of virtue and self-restraint are the price of rights. Of primary importance to liberty, order, and progress, is the institution of private property. Inherited institutions, values, symbols, and rituals are indispensable and even sacred. Human reason is subject to error and severely limited; the surest guide to wisdom and virtue is historical experience.

Beyond this, fundamental to conservatism is the belief that all political problems are fundamentally religious in nature. Narrow rationality cannot, in itself, satisfy human needs. Both society and conscience are ruled by divine intent. Conservatives, it is asserted, have an affection for the traditional life; others (presumably liberals) favor narrow uniformity, egalitarianism, and pursuit of utilitarian goals. The only true equality is moral equality; civilized society requires orders and classes. Property and freedom are inseparable. If property is separated from private possession, liberty disappears.

This basic conservative creed goes on to say that human beings have anarchic impulses and are governed more by emotion than by reason. It

therefore becomes necessary to place controls on human appetite. The correct method of accomplishing this is through tradition and sound “prejudice.”

Finally, the proper instrument for social change is Providence. Some change is necessary from time to time to conserve society. It is like the perpetual renewal of the human body. But this change must always be accomplished slowly and with an awareness of the direction in which Providence is moving social forces (Witonski 1971, pp. 32–34).

Undergirding the entire structure of this conservative doctrine is a more or less explicit version of the *chain of being*. This metaphor is designed to express the enormous extent, variety, order, and unity of “God’s Creation.” The chain stretches from the foot of God’s throne to the meanest of inanimate objects. Every speck of creation is a link in this chain, and every link except those at the two extremities is simultaneously bigger and smaller than another; there can be no gap (Tillyard 1959). The classic examination of the history of this idea was written by Arthur S. Lovejoy (1960).

Every category of things excels at *something*. Plants are higher than stones, but stones are stronger and more durable. Animals (“Beasts”) are above plants, but plants can assimilate nourishment better. Human beings are above beasts but inferior to them in physical energy and desires.

All this suggests a sort of interdependency among all objects and living creatures. Central to the idea of the chain is the concept that every object, animal or person, is part of an all-encompassing whole. Basic to the metaphor is an implicit, if not always explicit, view of the universe as an organism (strong traces of this continue to be found in some formulations of contemporary systems theory).

Pushed to its logical conclusion, this suggests that all creatures and objects are equally important. Every existing part of the cosmic organism might well be seen as necessary (perhaps in some unknown way) for the survival of the whole. This, in turn implies that, although they do different things, all human beings, for example, are equally necessary. This logic could lead to dangerous subversive doctrines about social equality. Another feature was required to make the chain-of-being notion acceptable to those searching for reasons

to justify existing inequalities in human societies. This was found in the *primacy doctrine*, the idea that, within each category of objects and creatures, there is one above the others, a *primate*. The eagle is first among birds; the whale or dolphin, among “fishes”; the rose, among flowers; the fire, among elements; the lion or elephant, among beasts; and, naturally, the emperor, among men (Tillyard 1959, pp. 29–30).

More recently, the distinguished conservative sociologist Robert Nisbet has insisted that conservatism is simply one of three major political ideologies of the eighteenth and nineteenth centuries. The other two are *liberalism* and *socialism*. Interestingly, an ideology for him, in addition to having a “reasonably” coherent body of ideas, has a *power base* that makes possible a victory for the body of ideas. It extends over a period of time and has “major” advocates or spokespersons as well as a “respectable” degree of institutionalization and charismatic figures. For conservatism, these figures would include people like Edmund Burke, Benjamin Disraeli, and Winston Churchill. Liberals have their own counterparts to these. The philosophical substance of conservatism dates from 1790 with the publication of Edmund Burke’s *Reflections on the Revolution in France* (Nisbet 1986; Burke 1855).

There is a fascinating contradiction to be found in conservative doctrine. Methodologically, Nisbet offers it as a champion of historical method. This he approves of as an alternative to the liberal utilitarianism of Jeremy Bentham that is “soulless,” “mechanical,” and even “inhuman.” Bentham’s doctrine idolizes pure reason, but human beings require a different mode of thought, one based on feelings, emotions, and long experience, as well as on pure logic.

In attacking liberal utilitarianism, Nisbet is attacking a doctrine essentially abandoned by twentieth-century American liberals. Sociologist L. T. Hobhouse must be credited with having made the most serious effort to reformulate liberal doctrine.

Utilitarianism, as fashioned by Jeremy Bentham and his followers, was the visible core of nineteenth-century liberalism. It has been defined as “nothing but an attempt to apply the principles of Newton to the affairs of politics and morals” (Halevy 1972, p. 6). The principle of utility, the notion that

every possible action of human beings is either taken or not depending upon whether it is seen as resulting in either pleasure or pain, was the basis for an “objective science” of behavior modeled on the physical sciences. As such, in common with other alleged sciences, it was perhaps congenitally soulless, somewhat mechanical, and potentially inhuman. Using a “rational” (but not empirically derived) model, it announced that, by pursuing his or her own pleasure and avoiding pain, each person would maximize happiness for everyone. Society was simply a collection of separate individuals operating in their individual self-interests. Government action, or “interference,” constituted a disservice to these individuals and should be rejected on “scientific” grounds.

Hobhouse took issue with this view but modestly presented John Stuart Mill as the transition figure between the old and new liberalisms. Mill, reared on Benthamite doctrine, continually brought it into contact with fresh experience and new trains of thought. As a result, Mill is, “the easiest person in the world to convict of inconsistency, incompleteness, and lack of rounded system. Hence also his work will survive the death of many consistent, complete, and perfectly rounded systems” (Hobhouse 1964, p. 58).

Hobhouse noted that, although the life of society is, ultimately, the life of individuals as they act upon each other, the lives of individuals would be quite different if they were separated from society. He stressed the fact that collective social action does not necessarily involve coercion or restraint. The state is simply one of many forms of human association, a form to which individuals owe much more of their personal security and freedom than most people recognize. “The value of a site in London,” he pointed out, “is something due essentially to London, not to the landlord. More accurately, a part of it is due to London, a part to the British empire, a part, perhaps we should say, to Western civilization” (Hobhouse 1964, p. 100). “Democracy,” he tells us, “is not founded merely on the right or the private interest of the individual. . . It is founded equally on the function of the individual as a member of the community” (Hobhouse 1964, p. 116).

In sum, Hobhouse helped provide a theoretic basis for a twentieth-century liberalism severed

from the constricted framework of its origins and aimed at the liberation of *all* members of society. It continues to be very much concerned with feelings, emotions, and historical experience. Twentieth-century *conservatism* assumed the mantle of rigid utilitarianism shorn of its humanistic aspirations.

The contradictions in conservative doctrine become even more apparent when the matter of prejudice is considered. As Nisbet explains it, prejudice has its own intrinsic wisdom anterior to intellect. It can be readily applied in emergencies and does not leave one indecisive at the moment of decision. It sums up in an individual mind tradition’s authority and wisdom (Nisbet 1986, p. 29).

This seems to epitomize the “mechanical” thought attributed to utilitarian or enlightenment liberals. Prejudice, in these terms, is, in effect, a mode of preprogrammed decision making. It insists upon shackling the human mind when confronted with new or unforeseen situations. It demands that such situations be dealt with through the use of what may well be outdated modes of thought, with strategies that were perhaps once useful but have lost their relevance. It denies a role for human creativity.

It is but a step from this doctrine to the prejudice castigated by civil rights activists and others. We meet a man whose skin is black or yellow; we meet a woman whose features tell us she is Jewish. We have preprogrammed responses to each of these, based on the “wisdom” of tradition, informing us that they, in various ways, are inferior creatures who must be dealt with accordingly.

The feudal origins of conservative doctrine are seen most clearly in its adamant stand on the issue of inheritance and property. Not only does it fight all efforts to loosen property from family groups by means of taxation, it fights all other efforts to redistribute wealth, ranging from special entitlements to affirmative action programs. It insists upon the indestructibility of existing hierarchical structures in society, seeing all efforts to modify them as attacks on cultural and psychological diversity.

Further complicating the distinction between liberalism and conservatism has been what some might refer to as a fringe movement within conservatism, called *neoconservatism*.

One explanation for the emergence of this phenomenon begins by noting that in the mid-1960s American universities, as well as literature and art in general, had become increasingly radicalized. Some cold war liberals, others who were uncomfortable with black power politics, and some critics of the counterculture disengaged themselves from liberalism. Prominent names in this group include Irving Kristol, Norman Podhoretz, and sociologists Seymour Martin Lipset, Nathan Glazer, Daniel Bell, and James Coleman. Some of these continue to reject the label but “it is as though by some invisible hand their writings and lectures gave help to the conservative cause when it was needed” (Nisbet 1986, p. 101).

Periodicals most strongly identified with neoconservatism are *The Public Interest* and *Commentary*. Neoconservatives have had close ties with the Scaife, Smith Richardson, John M. Olin, and other foundations. They have appeared as resident scholars and trustees of think tanks like the Hoover Institution, The Heritage Foundation, and the American Enterprise Institute (Gottfried and Fleming 1988, p. 73).

Unlike more traditional conservatives, neoconservatives are not irrevocably opposed to some possible versions of a welfare state. They do not depend upon historical methodology; on the contrary, they seem to show a marked preference for quantification.

Thus, the difference between contemporary liberalism and conservatism is apparently not to be found in issues of methodology, personality, or individual items of public policy. Yet there seems to remain an ineradicable core of difference. Ultimately this must be sought in the structure of material interests on the one hand and values on the other.

Historically, conservative doctrine was formulated as an intellectual defense of feudal property rights against the onslaughts of an emerging, business-oriented, industrializing bourgeoisie. Liberalism, with its early defense of individualism, championed the enemies of conservative doctrine and properly (from its perspective) fought against dominance by a central governing authority. Subsequently (as in the case of New Deal liberalism), it discovered that the logic of unhampered individualism led to serious economic difficulties for large

numbers of the population. Experiments with varieties of the welfare state since the days of Bismarck probably can all be traced in considerable measure to the fear of more drastic consequences that might follow any effort to persist in an uncontrolled laissez-faire economy.

In the contemporary world complexity has become compounded. It has probably always been the case that some people refuse to act in accordance with their own more or less self-evident material interests. These days, however, the arts of propaganda and advertising have been raised to a level of effective applied science. It is difficult for many to recognize exactly where their own self-interest lies. Beyond this, numerous techniques have been developed with the practical effect of inducing many to adopt positions in marked contrast to their own existing material interests. Government-sponsored lotteries hold out the hope of dramatic changes in class position. Tales of fabulous profits to be made in real estate or the stock market induce many to identify with the interests toward which they aspire rather than with those they hold and are likely to retain.

This is not the only source of confusion. Although many intellectuals, as well as others, having “made it,” subsequently become concerned with the maintenance of an order that has been good to them (Coser 1977), there are many others who, despite coming from very well-to-do backgrounds, maintain values consistent with economic deprivation. There are indeed generous souls as well as villains to be found among adherents of both liberalism and conservatism.

The shape of values is by no means always coterminous with the shape of existing material interests. Labels like liberalism and conservatism are uncertain predictors of specific actions, as are existing material interests. A variety of social forms, or structures, can be used to serve either selfish or communally oriented values. It is these values that are ultimately more reliable auguries.

In recent years there have been efforts to develop more useful theoretical frameworks for conceptualizing value configurations and more empirically based social policy alternatives. For example, Amitai Etzioni has elaborated an “I-We” paradigm as a substitute for both “unfettered” individualism and organismic views of society (Etzioni 1988). S. M. Miller and his colleagues

eschew the *liberal* label in favor of *progressive*, a term less saddled with conflicting conceptual baggage. They have provided an agenda for social policy issues requiring considerable rethinking by those unwilling to accept either contemporary conservative and neoconservative doctrine or traditional socialist formulations (Ansara and Miller 1986).

It is clear that serious linguistic difficulties serve to exacerbate the problem of distinguishing clearly between liberalism and conservatism. Each term tends to represent a generic symbol for a range of widely diversified issues, values, and interests. Surrogate expressions are used extensively in popular speech to convey either finer shades of meaning or degrees of opprobrium.

For conservatives these expressions may include “right-wing crazies,” “extreme right,” “right-wing,” “supply-siders,” “libertarians,” “filthy rich,” “Republicans,” and others. In contemporary America, portions of the conservative spectrum voice strong opinions not only on economic issues but also on such “social” issues as pornography, abortion, and affirmative action, although opinion on these issues is by no means unanimous. Traditional conservatism would, of course, back state-supported cultural standards in speech, art, literature, and entertainment. Nineteenth-century liberalism would oppose these in the name of individual “rights.” Is abortion a woman’s “right” or is it an “offense” against society? Many conservatives might define it as an offense; others might well define it as a right—a traditional liberal position.

Among liberals, surrogate expressions in use include “Red,” “parlor-pink,” “left-liberal,” “bleeding heart,” “tax and spender,” “Democrat,” and “Progressive.” The liberal spectrum tends to support rights of women to have abortions or, more generally, to maintain control over their own bodies. It opposes abrogation of rights of self-expression through pornography legislation, censorship, or other efforts to monitor art, literature, theatre, and other communication vehicles. On the other hand, American liberals favor limitations on the asserted “rights” of corporations or individual business persons to discriminate in employment, housing, and other areas on the basis of skin color, age, religion, or physical disability—property rights that many conservatives insist are inviolable.

As one might expect, survey researchers have made and continue to make strong efforts to detect empirical differences between persons who are called or who call themselves liberal or conservative. Data from a variety of survey research studies indicate that, despite the existence of important philosophical differences between liberals and conservatives, changing social and economic conditions have at times compelled them to alter their positions on certain economic, social, and political issues without altering their underlying philosophies (McCloskey and Zaller 1984, p. 191). In general, these studies seem to confirm stereotypical images of both liberals and conservatives.

Liberals show a marked preference for social progress and human betterment, especially for the poor and powerless. Some believe personal happiness and success depend heavily upon institutional arrangements. Most liberals are “inveterate reformers”; they continually look for ways to improve the human condition by remodeling social, economic, and political institutions. Underlying this pursuit of change, social reform, and benevolence is faith in the potential perfectability of human beings and their capacity to manage their own affairs in a responsible and reasoned fashion.

Conservatives have a different notion of what constitutes the good society and how it can be achieved. Survey research data show that they have a more pessimistic view of human nature and its perfectability. They feel that people need strong leaders, firm laws and institutions, and strict moral codes to keep their appetites under control. Firm adherence to conventional norms and practices is essential for human well-being. They believe that those who fail in life must bear primary responsibility for its consequences. They are far less likely than liberals to support movements that have as their objectives the eradication of poverty, the better treatment of oppressed minorities, or the alleviation of social distress generally. They maintain that these movements, by disrupting existing institutions, do more harm than good (McCloskey and Zaller 1984, pp. 190–191).

Conventional public opinion polling techniques encounter increasing difficulties in this area. Thus, one study examined a hypothesized inverse relationship between socioeconomic status and conservatism on a wide range of so-called social issues.

(Many observers felt that, during the 1970s and 1980s, as well as during the late 1960s, the main support for liberal and left political parties in the United States and other Western industrialized countries came from youthful members of the upper or middle strata.) It found that, in practice, many issues defied a neat separation of interests and values or of economic versus social arenas. Many social issues such as environmental protection, nuclear power, defense spending, and race or gender problems have an economic dimension, to the extent that they influence opportunities for jobs or profits. Conversely, government domestic spending, a classic economic issue, may have a social dimension if it is seen as involving welfare or aid to minorities. No consistent relationship between socioeconomic status and conservatism was found, with one exception. Liberalism on social issues tends to increase with education, but even here the relationship varies considerably from issue to issue. The authors suggest that lack of a consistent relationship reflects both the diversity of social issues and the fuzziness of the social/economic distinction (Himmelstein and McCrae 1988).

Another study examined what appeared to be an anomaly in this area. It postulated that high socioeconomic status remains one of the best predictors of Republican party support and conservative attitudes in the United States, that Republicans are wealthier, more educated, and hold higher status jobs than Democrats and independents. Jewish liberalism, however, confounds this general relationship. American Jews are generally wealthier, better educated, and hold higher status jobs than average Americans but continue to be the most liberal white ethnic group in the United States (Lerner, Nagai, and Rothman 1989, p. 330).

The emergence of a small cadre of Jewish neoconservative intellectuals has raised questions about Jewish liberalism. A sample of Jewish elites was compared with their Gentile counterparts. The study found that Jewish elites continue to be more liberal. Despite a plethora of competing explanations, the study concludes that Jewish liberalism is a product of a family tradition of liberalism that developed in response to European conditions. Specifically, the authors suggest that the Jewish elites inherited a tradition of responding in particular ways to felt marginality. This raises the

question as to whether a realignment might occur when this cohort of American Jews loses its prominence and is replaced by a cohort with different patterns of socialization. In a concluding footnote, the authors raise the open question of whether events in the Middle East and the emergence in the Democratic party of an increasingly powerful African-American presence less supportive of Israel can transform the liberalism of American Jews (Lerner, Nagai, and Rothman 1989).

A study of public opinion on nuclear power concludes that assessing public opinion through responses to survey questions with fixed categories presents serious difficulties. It compares these difficulties with those arising from the effort to “impose elite dichotomies such as ‘liberal’ and ‘conservative’ on a mass public whose beliefs are not organized by such dimensions” (Gamson and Modigliani 1989, p. 36).

Perhaps the more general difficulty is not to be found solely in the insufficiency of measuring instruments but in the increasingly more truncated vistas of the “mass publics.” Fundamental philosophical positions and value orientations seem to have become increasingly more obscured by the exigencies of short-range decision making.

In societies where immediate job opportunities, social pressures, and short-range profits have serious implications not only for the quality of life but also for existence itself, it is scarcely surprising to find that many public issues and even individual values are filtered through the prisms of short-run individual economic concerns and ethnic identification. Manipulating perceptions of vital interests through sophisticated media technology does much to resolve the recurrent riddle, “Is Blank a liberal—or a conservative?”

ROBERT BOGUSLAW

LIBRARY RESOURCES AND SERVICES FOR SOCIOLOGY

INTRODUCTION

Libraries have a long history of providing access to the resources sociologists and other social scientists have needed and used, and to the literature they produce. In addition, libraries have established a strong tradition of providing reference and instructional services. Although the recent and pervasive growth in information technology has led to major changes in the way these resources and services are provided, libraries will continue to serve an important function to the discipline. Knowing how libraries are organized and how they work, what research tools and services are available, and how to use these tools and services effectively can help researchers at various levels to be more efficient and productive.

AN OVERVIEW OF ACADEMIC LIBRARIES

Many of the thousands of academic libraries in the United States and other parts of the world support sociological course work and research, and researchers near major urban centers can also obtain important materials and substantial research help from some of the larger nonacademic public and research libraries. However, each library's ability to provide these kinds of support is affected greatly by the size of its budget, collections, and staff.

At the larger end of the size continuum, libraries can be quite complex organizationally, although most users will be aware of only the parts and functions of direct relevance to them. In the United States, libraries are organized so that users can use them effectively on their own, identifying what is needed through a public catalog and an open

“stacks” area. Almost all users have contact with staff members at a circulation desk, who check out books and sometimes periodicals to them. These staff members also help users locate items they may not be able to find on their own and help make resources available by enforcing loan periods, recalling books from other users, setting up reserve reading rooms for heavily used materials assigned for course readings, and so on. Academic libraries also typically organize their journals into periodical reading rooms or stack areas, and may provide related support services there. Interlibrary loan departments provide access to resources owned by other libraries.

Almost all libraries provide reference service in a variety of ways, and often in different settings. The role of the reference librarian typically extends far beyond the answering of informational questions, and may include providing individualized help in using electronic or complex print resources, or organizing a literature search, as well as speaking to classes about major disciplinary research tools and strategies. Reference librarians often have special areas of subject expertise and may perform liaison or collection development work with academic departments for book and journal purchasing. Where this is the case, graduate students may find it helpful to get to know the librarian responsible for sociology. College and university libraries will generally also have special sections or departments for government publications. Because these resources can be quite specialized, and access to them complex, staff help can be especially important.

Regardless of size, most academic libraries must deal with a variety of interrelated budgetary and technological pressures. For the last several years and for a variety of reasons, the costs of providing periodicals and other serials have been rising more rapidly than other indicators of inflation. (Ketcham–Van Orsdel and Born 1998). This trend has resulted both in a larger share of budgets being devoted to serials and in an ongoing need to evaluate and sometimes cancel subscriptions to journals. At the same time, there has been very rapid growth in book title production in the United States (Bosch 1998), with the result that libraries typically buy a decreasing share of the domestic books published in most disciplines. Economic pressures and increased book production abroad

have also made it more difficult for research libraries to buy as large a share of foreign language books and journals as in the past. Accordingly, libraries rely increasingly on cooperative buying and resource sharing. Paradoxically, library users may now actually have better access to some resources than in the past when locally owned resources were relied on more exclusively.

Key developments in information technology such as the CD-ROM and the World Wide Web, have also introduced new options for delivering information. On-line catalogs with sophisticated search features and other functionality have quickly replaced card catalogs. In addition, many periodical indexes and abstracts and the text of key journals are also now available online. These services make it possible for researchers to locate information quickly and easily—even from their homes or offices—but they almost always cost substantially more to purchase and support than do comparable print resources. Together, these factors make for a complex, rapidly changing environment for academic libraries and their users.

LIBRARIES AND THE LITERATURE OF SOCIOLOGY

Because of sociology’s great topical and methodological diversity, it is difficult to characterize its literature. This diversity is well represented in the hundreds of articles in this encyclopedia, and in recent discussions of sociology’s most influential books (Clawson and Zussman 1998; Gans 1998; Marwell 1998; Sullivan 1994). Sociologists rely on and use a range of publications and information sources for their research, including books, journals, statistical publications and data sets, and governmental and other specialized reports (Zabel 1996; Shapiro 1985). Of these, the most important outlets for sociological writings have been books and scholarly journals, which appear to assume somewhat greater or lesser importance for different research communities. Some have suggested, for example, that there are two fairly distinct research cultures in sociology—one a “book sociology” that relies on, values, and publishes primarily in books, and the other an “article sociology” that relies on and publishes in scholarly journals. To some extent article sociology may be more characteristic of the scientific end of the discipline,

and book sociology more characteristic of its humanistic, historical, ethnographic, and theoretical emphases and traditions (Sullivan 1994).

The sociological journal literature is quite extensive. Of the 5965 items judged significant enough to be included in the 1996 volume of the *International Bibliography of Sociology*, roughly three-quarters were periodical articles, and even more articles are indexed annually in *Sociological Abstracts*. According to the 1998–1999 *Ulrich's International Periodicals Directory*, several hundred periodicals relevant to the field are published worldwide, although this count includes newsletters and other less substantial publications. Hargens (1991) estimated that roughly 250 of these might be characterized as research journals publishing original reports of relevant research findings. Lists of the more prominent or important titles have ranged in size from a couple of dozen (Sociology Writing Group 1998) to sixty or so (Katz and Katz 1997; Aby 1997), to well over a hundred (Bart and Frankel 1986). As in many other disciplines, a handful of journals (primarily the *American Journal of Sociology*, *American Sociological Review*, and *Social Forces*) are widely regarded as the most prestigious and/or influential. However, it appears that publication of important research is less likely to be concentrated in these few journals than in some other disciplines, and use of and reliance on review serials like the *Annual Review of Sociology* is relatively low (Hargens 1991). As in other disciplines, articles submitted to journals in sociology are typically refereed, or subjected to critical evaluation by peers who thus serve an important gatekeeping function (Mullins 1977; Osburn 1984; Simon 1994).

Many journals are now available electronically as part of larger full-text services to which libraries subscribe, and archives of the journals published by the American Sociological Association are now available electronically via the World Wide Web through the innovative JSTOR program (Guthrie and Lougee 1997; see also <http://www.jstor.org/>). In addition, a few sociological journals are available exclusively via the Web, and there has been much recent speculation that journal publishing may soon undergo fundamental change in response to the Web's interactive possibilities. As in the field of physics, for example, articles in other disciplines may commonly circulate on the Web

prior to formal publication. The statistical data on which an article is based may also be linked to the Web version of the article for further analysis—which may have special significance for sociology.

As noted earlier, books are also important to the discipline and annual production numbers at least in the thousands. The 1996 volume of the *International Bibliography of Sociology*, mentioned earlier, listed about 1,300 titles from around the world, but this number did not include textbooks or popular titles. A broader count of relevant titles published or distributed in the United States that same year put the figure at 4,186 (Bosch 1998), up more than 50 percent from 1989. As with journals, hardly any library can build a comprehensive book collection, and libraries select on the basis of relevance to local emphases, user requests, judgments of quality, cost, and other factors. Often book vendor “approval programs,” which match published books with formalized interest profiles, are relied on, since they can supply new books quickly and efficiently. Standard book review publications like *Choice* (aimed at undergraduate libraries) and *Contemporary Sociology* (a publication mainly for sociologists) may also be systematically utilized for selection, but they lack the space to be comprehensive. (During 1997, for example, *Choice* reviewed only 216 of the available titles, and *Contemporary Sociology* roughly 500.) At this writing relatively few newly published books or monographs are being made available electronically, but this seems likely to change in the near future.

There are a variety of other outlets for sociological research in addition to books and journal articles, and sociologists use many other sources of information in their research. For example, those sociologists who work for government agencies often write formal reports, which may be published by the agency. Statistical reports of various kinds that are of interest to sociologists (the U.S. Census being a prime example) are often also published in printed form by government agencies and distributed to academic libraries. These data are also increasingly being made available via the Web. A few academic libraries also pay for and coordinate their institutions' memberships in the Interuniversity Consortium for Political and Social Research (ICPSR), and make the associated survey data and codebooks available, although it is more typical for other campus agencies to do so.

And, of course, the dissertations written by doctoral students are typically acquired and cataloged by their institution's libraries, and sold through Bell and Howell Information and Learning in Ann Arbor, Michigan.

The published literature in sociology can also be seen as part of a broader professional communication system which includes less formal interchanges like presentation of papers at regional and national conferences (Osburn 1984). Developments in information technology have fostered the growth of such "invisible colleges"—especially in sociology, where computers have long been important tools. Sociologists have, for many years, made use of data analysis packages the Statistical Package for the Social Sciences (SPSS) and now quite commonly have their own personal computers with word processing software and connections to the Internet. As a result, formerly disparate activities like data analysis, writing, and publishing have begun to merge (Anderson 1998). E-mail listserv discussion groups, and the ease with which writings can be posted to the World Wide Web have fostered efficient communication among sociologists sharing research interests, and seem to hold considerable promise for the discipline (Bainbridge 1995). Libraries participate in and help foster these developments in a variety of ways. For example, many libraries participate in the JSTOR program, subscribe to full text services, and provide their users with on-line access to journal indexes like *Sociological Abstracts* and the *Social Sciences Citation Index*. Many also support the development of exclusively electronic journals by directing users to them through their on-line catalogs and Web pages.

GENERAL STRATEGIES FOR LITERATURE SEARCHING IN SOCIOLOGY

It is difficult to provide good general strategies for location information in sociology for a variety of reasons. As noted, any number of topics and approaches may be pursued, and a large number of journals and other sources may contain important articles or other information. In addition, a doctoral student "terrified by the literature" in anticipation of preliminary exam questions (Becker 1986) will need to use different research strategies than will an undergraduate student writing the

typical library term paper. Rapid changes in information technology make it even harder to suggest tactics that will be valid five years from now. It is also useful to remember that, although librarians tend to view literature searching as something of a structured and rationalized activity, it can and should often take place in a more open, informal, serendipitous, or even mysterious way—especially in the early stages of a research project. Nevertheless, being alert to the following issues and suggestions can help make literature searching more effective and more efficient. Users are urged to consult their local library staff for additional advice and guidance, and for current information on local resources.

1. *Overview or summarizing tools.* Although sociologists tend not to use or rely on review serials like the *Annual Review of Sociology*, these can often prove helpful by summarizing and evaluating the main themes of recent research and setting them in a broader context. A similar function is played by subject encyclopedias like this one, by disciplinary handbooks (such as Smelser 1988; Smelser and Swedberg 1994; Gilbert et al. 1998), and to some extent by sociology textbooks. Some summarizing sources like these can be found in general and specialized reference books and guides (Aby 1997; Balay 1996; Wertheimer 1986; Zabel 1996). In addition, searches of electronic databases can sometimes be limited to "review articles."
2. *Differences in indexing terminology.* Periodical indexes and library catalogs quite often use a defined list of subject terms, which may vary from those commonly used in an area of literature, by a community of scholars, or by an individual student trying to describe a topic. Successful use of these tools often requires matching an idea to indexing terminology. This can save time by helping to eliminate irrelevant citations.
3. *Techniques for searching electronic resources.* The scholarly communication system in all disciplines seems destined to be tied increasingly to developments in information technology, and researchers will need to understand how to interact with and

use electronic tools effectively. Although most users now know that rough “keyword” searching can give them relevant citations, it is also important to know how to use “Boolean operators,” such as AND, OR, and NOT to combine and manipulate terms (Sociology Writing Group 1998) and to incorporate subject indexing terms into a search strategy.

4. *Evaluation of sources.* The gatekeeping role played by peer reviewers of journal articles helps guarantee that an article has passed a test of quality or adherence to accepted research norms. This is less apt to be the case with other information sources—especially those found on Web pages or via Web search engines. It is consequently useful to develop a generally skeptical outlook on information sources, and to evaluate such sources on the basis of such things as credibility of origin, scope and coverage, currency, and reputation (Sociology Writing Group 1998).
5. *Library collections as a linked system.* Since it seems unlikely that the financial constraints facing academic libraries will ease in the foreseeable future, libraries will continue their efforts to share resources efficiently. As a result, library users should assume that the collections available to them extend far beyond what their local libraries own. Graduate students and faculty, especially, will need to be aware of how their libraries are making these broader resources available and how long it will take to obtain publications from elsewhere.

LOCATING PERIODICAL LITERATURE

The most important tools for locating relevant periodical articles are known by librarians as abstracting and indexing services, because they abstract (or summarize) articles and index them (apply subject terms to them) according to a vocabulary developed for the purpose. These tools are frequently available in both printed and electronic form, and the electronic versions offer powerful searching capabilities and other features such as links to the full text of articles. The most important for researchers in sociology are the *Social*

Sciences Index (and some competing products), *Sociological Abstracts*, and *Social Sciences Citation Index*.

The *Social Sciences Index* and several competing products are important because they provide students with relatively easy access to a more manageable subset of the available literature than do the other two main tools. Because even smaller academic libraries will tend to subscribe to the majority of periodicals indexed in them, they are especially helpful for beginning students. For many years the printed *Social Sciences Index* was the primary general tool for social science researchers. It has gradually grown in coverage and now indexes roughly four hundred important social science journals, including about fifty titles in sociology, and is available in a few different electronic versions with abstracts and the full text of some of the indexed articles. Articles are carefully indexed according to subject, with “see” and “see also” references pointing users to other relevant subjects.

Within the last several years a few companies like EBSCO, the Gale Group, and Bell and Howell have offered some other, more general periodical indexes aimed at the college or undergraduate library market which cover largely the same range of social science literature. Although the sociology journals indexed are fairly similar, these products do differ in their indexing and abstracting practices, how far back their indexing and full text coverage extends, which titles are provided in full text, and in their search capabilities and limitations.

In contrast to these general sources, *Sociological Abstracts* covers the sociological literature much more comprehensively. Since this source is so fundamental to literature searching in sociology, it is worth quoting the publisher’s description at length:

Sociological Abstracts provides access to the world’s literature in sociology and related disciplines, both theoretical and applied. The database includes abstracts of journal articles selected from over 2,500 journals, abstracts of conference papers presented at various sociological association meetings, relevant dissertation listings from *Dissertation Abstracts International*, enhanced bibliographic citations of book reviews, and abstracts of selected sociology books published in *Sociological Abstracts* (SA) and *Social*

Planning/Policy and Development Abstracts (SOPODA) since 1974.

Approximately 2,500 journals in thirty different languages from about fifty-five countries are scanned for inclusion, covering sociological topics in fields such as anthropology, economics, education, medicine, community development, philosophy, demography, political science, and social psychology. Journals published by sociological associations, groups, faculties, and institutes, and periodicals containing the term "sociology" in their titles, are abstracted fully, irrespective of language or country of publication. Noncore journals are screened for articles by sociologists and/or articles of immediate interest or relevance to sociologists.

The abstracts provided are typically lengthy and detailed, and articles are indexed by author and a sufficient number of indexing terms from the *Thesaurus of Sociological Index Terms* to describe their content. The *Thesaurus* has been developed over time with sociological concepts and terminology in mind, and this tool—which may be integrated into an electronic version of the publication—is a key to making searching more efficient and effective. As shown by the following sample entry for the term "Satisfaction," the *Thesaurus* indicates what subject terms are available for searching, and what relationships they have with one another.

Satisfaction

DC D740400

SN A context-dependent term for an individual's positive assessment of self or circumstances. Select a more specific entry or coordinate with other terms.

HN Formerly (1963–1985) DC 403350

UF Fulfillment (1969–1985)

BT Attitudes

NT Community Satisfaction
Job Satisfaction
Life Satisfaction
Marital Satisfaction

RT Discontent
Emotions
Happiness
Improvement

Needs
Quality
Self Esteem

The most important codes shown in this example are as follows. **SN** stands for a "scope note," or definition of the term. **BT** indicates that the "broader term" of "Attitudes" can be used. **NT** stands for "narrower" or more specific terms, and **RT** for "related terms." **UF** means that "Satisfaction" is "used for" Fulfillment (in other words, fulfillment is not used as a subject term). (For a complete discussion of the codes and their meaning and use, consult the *Thesaurus*.)

Users of both the printed and electronic versions of *Sociological Abstracts* would be able to find abstract entries using these terms. The printed index refers users to an abstract number, which is then looked up in another part of the volume to actually locate the abstract, whereas the electronic version would provide a set of abstracts that could be reviewed and printed out. The following example was found on line by searching for "Life Satisfaction" as a subject term using a version of Sociological Abstracts produced by Silver Platter Information in Norwood, Massachusetts.

TI: Marital Status, Gender, and Perception of Well-Being
AU: Mookherjee,-Harsha-N.
IN: Dept Sociology Tennessee Technological U, Cookeville 38505
SO: Journal-of-Social-Psychology; 1997, 137, 1, Feb, 95-105.
IS: 0022-4545
CO: JSPSAG
DT: aja Abstract-of-Journal-Article
LA: English
CP: United-States
PY: 1997
AB: Draws on data from the combined 1982-1991 National Opinion Research Center's General Social Surveys (total N = 12,168 adults) to reexamine relationships among marital status, gender, & perception of well-being. ANOVA revealed that marriage significantly enhances perception of well-being for both men & women, though in general, women express more satisfaction than men. Well-being perceptions were significantly affected by

race & financial status, regardless of marital status. 3 Tables, 44 References.

Adapted from the source document

DEM: *Marital-Status (D491150); *Well-Being (D916500); *Sex-Differences (D758100); *Single-Persons (D771900); *Life-Satisfaction (D463800)

DES: United-States-of-America (D890700)

SH: social psychology; personality & social roles (individual traits, social identity, adjustment, conformism, & deviance) (0312)

The “DEM” label in this entry stands for “major descriptors”, and indicates that the main topics of this article are Marital Status, Well-Being, Sex-Differences, Single-Persons, and Life-Satisfaction. The “DES” label stands for “minor descriptors,” and shows that although the article has been indexed under “United-States-of-America,” this is not an important focus.

As noted earlier, a key technique in using this and other electronic indexes is combining terms using Boolean operators to make searching more precise and to limit the amount of material that must be reviewed. In this case, this article and other entries could have been found by searching for the subject terms “Life Satisfaction” AND “Sex Differences.” A slightly more complex search strategy or statement might have been to search for “Life Satisfaction OR Well-Being” AND “Marital Status OR Single Persons.” This kind of search statement can be made as elaborate as necessary to the situation. It is also possible to limit search results by date, language, journal, and type of publication (such as book review, journal article, or conference paper), and to search on virtually any combination of words found in the article title and abstract entry. It is, of course, impossible or impractical to do so with the printed publication. Because of its comprehensiveness, many users of *Sociological Abstracts* will need to adjust their search strategies to exclude conference papers and dissertations (which are often difficult to obtain) and foreign language publications.

The *Social Sciences Citation Index (SSCI)* does not cover journals in sociology quite as extensively as *Sociological Abstracts*, but it covers journals in other social science disciplines more completely than the latter, and much more comprehensively

than does the *Social Sciences Index*. In 1997, for example, the *SSCI* indexed 1,725 journals “completely,” including 92 titles in sociology, and indexed another 1,371 on a selective basis. During that year, 72,665 articles and another 39,412 book reviews in all social science disciplines were indexed. Unlike *Sociological Abstracts*, abstracts have only recently begun to be provided in *SSCI* (in the electronic versions only), and articles are not indexed according to a fixed indexing vocabulary. Instead, heavy reliance is made in the print version on words from the titles of articles. Articles are also indexed by author, of course, although the publisher uses only authors’ first and middle initials, rather than their full names, which can occasionally cause confusion.

What is uniquely valuable about this source is that it enables users to search “by citation,” or to locate articles that have cited an earlier author or article. Eugene Garfield, the founder of the Institute for Scientific Information, which publishes *SSCI*, described the idea behind citation indexes as follows:

The concept of citation indexing is simple. Almost all the papers, notes, reviews, corrections, and correspondence published in scientific journals contain citations. These cite—generally by title, author, and where and when published—documents that support, provide precedent for, illustrate or elaborate on what the author has to say. Citations are the formal, explicit linkages between papers that have particular points in common. A citation index is built around these linkages. It lists publications that have been cited and identifies the sources of the citations. Anyone conducting a literature search can find from one to dozens of additional papers on a subject just by knowing one that has been cited. And every paper that is found provides a list of new citations with which to continue the search. (Garfield 1979, p. 1)

Books as well as journal articles in sociology can be, and often are, cited by the journal articles indexed in *SSCI* (Sullivan 1994) and the ability to search on cited references may provide a large number of additional “access points” for locating an article. The article on marital status that was used as the sample record from *Sociological Abstracts*, for example, cited forty-four earlier articles

and studies. Users of *SSCI* could search on any of those citations and locate the article that way.

One difficulty with performing citation searches lies in knowing when it will be useful to do so. In sociology, although it is possible to perform citation searches on the handful of authors in the recognized pantheon (i.e., Marx, Durkheim, Weber, and some others), such an approach will often result in far too many references with only tenuous subject relationships to one another. It may consequently be necessary to combine a result set from a citation search with some other group of search terms. Where citation searching seems most useful in sociology is when tracing a methodological article, or in other somewhat narrow circumstances. To do a citation search for a journal article—using either the printed *SSCI* or its electronic counterpart—requires that a researcher know the author's name and initials, and preferably the volume, volume number, year, and page of the publication. For example, Clifford Clogg and Gerhard Arminger's 1993 article titled "On Strategy for Methodological Analysis" from the publication *Sociological Methodology* (vol. 23, pp. 57-74) is listed in *SSCI* as:

CLOGG CC SOCIOL
METHODOL 23 57 1993

By searching the printed or electronic versions of *SSCI* under this entry, it would be possible to find other articles which cited this article. It would also be possible to look at the list of sources cited by Clogg and Arminger and find other articles which have cited them. As with *Sociological Abstracts*, the electronic version of *SSCI* makes for far more efficient searching—especially of citations. Another interesting use to which citation searching is often put is comparing faculty members' research productivity—especially for promotion and tenure consideration. This procedure is controversial for a variety of reasons—especially when comparing faculty members from different disciplines, which may not share the same publication and citation patterns.

Depending on the particular topic being researched, and the depth with which the search must be carried out, a number of other tools in neighboring or related fields may prove useful, including *Anthropological Literature*, *EconLit*, *Popline*, *Psychological Abstracts/PsycInfo*, and *Social Work Abstracts*. In addition, researchers may be able to avail

themselves of journal article "alerting" services, such as *Uncover Reveal*, which automatically sends the tables of contents of specified journals and article citations containing specified keywords to users via e-mail. Although some of the electronic versions of the indexes discussed also provide linkages to a local library's journal holdings information or to on-line full text, accurately determining which articles are available locally still typically requires a separate step.

LOCATING BOOKS, JOURNALS, AND OTHER RESOURCES IN LIBRARIES

As noted earlier, most libraries now provide on-line versions of their catalogs. Unlike card catalogs, on-line catalogs can be searched via keyword, and with Boolean operators or combinations. They may also provide direct links to electronic resources on the World Wide Web, as well as the circulation status of a book. In addition, many now permit users to view lists of the books they have checked out and to reserve items checked out to other users. Despite these and other less visible changes, books are catalogued in much the same way they have been for years: by author, title, and subject. Few college students will be unaware that books can be searched by author and title, but they may also mistakenly assume that a journal article can be found by its author or title in a library catalog. Instead, the title of the journal must be searched, and then the specific volume and page located on the shelf within that journal.

Although many students will also realize that books can be located by subject, few will understand how the subject heading system works. The system used for this in most academic libraries was developed at the Library of Congress in Washington, D.C., and the headings themselves are called Library of Congress Subject Headings (LCSH). These headings are published in multivolume sets by the same name, which now closely resemble database thesauri like the *Thesaurus of Sociological Index Terms*. They can be used in the same way to find relevant subject headings for searching. For example, the entry for "Satisfaction" in the 1997 edition of LCSH looks like this:

Satisfaction
BT Self
RT Self-realization
NT Consumer satisfaction

Contentment	HQ-HT	Social Groups
Housing—Resident satisfaction	HQ	Family, Marriage, Woman
Job satisfaction	HS	Societies: Secret, Benevolent, etc., Clubs
Libraries—User satisfaction	HT	Communities, Classes, Races
Office buildings—Tenant satisfaction	HV	Social Pathology. Social and Public Welfare; Criminology
Patient satisfaction		
Public housing—Resident satisfaction		
Rental housing—Resident satisfaction		
— Religious aspects		
— — Buddhism, [Christianity, etc.]		

Like the entry from the *Thesaurus*, this shows the availability of Broader (BT), Related (RT), and Narrower (NT) terms. Unlike terms from the *Thesaurus*, though, *LCSH* lists a large number of terms that are subdivisions of more general terms. In other words, if a researcher were to look under “Libraries” as a subject term, she or he might find books listed under many subdivisions, including “User satisfaction.” This is also true of subject headings that are more directly related to sociology. For example, the term “Sociology” can be subdivided by a country or other geographic term, or by such terms as “—Methodology”, “—Philosophy,” or “—Statistical methods.” Subject headings can also be modified by adding a comma and an adjective to a term. For instance, “Sociology, Islamic” would be used instead of “Islamic Sociology.” Although it is not necessary to thoroughly understand this system, it is useful to realize that it exists, and that some help from library staff in identifying useful subject headings may be needed. As with other databases, noticing what subject headings have been applied to relevant, known books may be a good start, and may lead to the finding of other important books.

Most academic libraries now also physically organize their book and journal collections using another system developed at the Library of Congress: its call number scheme. Unlike the Dewey Decimal system that is commonly used in school and public libraries, Library of Congress call numbers start with one or two letters. For example, sociology and economics have both been assigned the letter H, to which a second letter is added for a further breakdown. For sociology, the primary classes are:

SOCIOLOGY

7HM	General Works, Theory
HN	Social History and Conditions; Social Problems, Social Reform

Numbers make these breakdowns more specific. For example, before extensive changes were introduced recently, the numbers between HM 1 and HM 299 were used for topics in sociology. Under the revised scheme, HM numbers 401 and higher will be used instead, which will allow a finer topical breakdown and arrangement. For example, under the old scheme the numbers from HM 251 to HM 299 were assigned to various topics in Social Psychology, such as:

HM	251	General
	255	Instinct in social psychology
	261	Public Opinion
	263	Publicity. Propaganda.

A particular book in general social psychology would have been assigned the subject call number HM 251, to which additional combinations of letters, numbers and possibly dates designating the author or work would be applied. For example, the 1998 edition of the *Handbook of Social Psychology* was assigned the number HM 251 H224 1998, where H224 represents the title, and 1998 the edition. Under the revised system, books in social psychology will receive numbers HM 1000 and above, and the same *Handbook* cataloged under it might have the call number HM 1033 H34 1998. This will obviously and unfortunately cause books on similar topics but classed under the older and newer systems to be separated on library shelves. Again, it is not necessary to fully understand the call number system, but having a general sense of how it works can make locating books a little easier.

Many researchers will also need to develop an understanding of the kinds of materials that may be available in a given library but not listed in its catalog. The single largest category of such material, in most cases, consists of government publications or documents—especially those things published by the U.S. federal government, but also by state and local governments, the governments of other countries, and the United Nations or other international agencies. Because there are so many

of these publications and documents, very few libraries can provide thorough and complete coverage of them. As a result, other indexes and similar sources are often necessary. For the federal government publications of the United States, the primary tool is the *Monthly Catalog of United States Government Publications*, although there are a number of other supplementary sources available. For example, the *American Statistics Index* provides very detailed indexing coverage of federal statistical publications. Both of these tools were originally published in paper, but are now available both in electronic versions. Access to publications of U.S. state governments and those of other countries are also unlikely to be catalogued, and other tools may be needed.

TIMOTHY D. JEWELL

LIFE COURSE, THE

INTRODUCTION

The study of lives represents an enduring interest of sociology and the social sciences, reflecting important societal changes and their human consequences. Most notably, developments after World War II called for new ways of thinking about

people, society, and their connection. In the United States, pioneering longitudinal studies of children born in the 1920s became studies of adults as the children grew up, thereby raising questions about the course they followed to the adult years and beyond. The changing age composition of society assigned greater significance to problems of aging and their relation to people's lives. Insights regarding old age directed inquiry to earlier phases of life and to the process by which life patterns are shaped by a changing society.

This essay presents the life course as a theoretical orientation for the study of individual lives, human development, and aging. In concept, the life course refers to a pattern of age-graded events and social roles that is embedded in social structures and subject to historical change. These structures vary from family relations and friendships at the micro level to age-graded work organizations and government policies at the macro level. Life-course theory defines a common domain of inquiry with a framework that guides research in terms of problem identification and formulation, variable selection and rationales, and strategies of design and analysis. Beginning in the 1960s, this theoretical orientation has diffused across substantive domains and disciplinary boundaries in the social and behavioral science.

It has uniquely forged a conceptual bridge between developmental processes, the life course, and ongoing changes in society, one based on the premise that age places people in the social structure and in particular birth cohorts. To understand this conceptual bridge, it is useful to distinguish among three levels of the life course and their interplay over a person's life: (1) *institutionalized pathways* in society, as established by state policies, education, the workplace, and so on; (2) the *individual life course* that is formed by the individual's choices and constraints, frequently in terms of a career or trajectory; and (3) the *developmental or aging trajectory of the individual*, defined, for example, by intellectual functioning or self-confidence.

Each of these levels are illustrated by Spilerman (1977) in terms of work. He used the concept of "career line" to refer to pathways that are defined by the aggregated work histories of individuals. Career lines are patterned by industry structures and the labor market. A person's work life is one

part of the individual life course, and it varies by the career requirements of firm and marketplace. At the psychological level, changes in work life have consequences for personal feelings of efficacy (Bandura 1997).

In this essay, I first take up concepts that have been used interchangeably—the life course, life cycle, life history, and life span. Then I turn to the emergence of life-course theory since the 1960s and its paradigmatic principles.

CLARIFICATION OF CONCEPTS

A number of concepts have been applied interchangeably to lives (life course, life cycle, life history, and life span), but each makes a distinctive contribution that deserves notice in mapping this domain (Elder 1998). The *concept of life course* is defined by trajectories that extend across the life span, such as family or work; and by short-term changes or transitions, such as entering and leaving school, acquiring a full-time job, and the first marriage. Each life-course transition is embedded in a trajectory that gives it specific form and meaning. Thus, work transitions are core elements of a work-life trajectory; and births are key markers along a parental trajectory. Multiple marriages and divorces are elements of a marital trajectory.

Multiple roles of this kind become interlocking trajectories over time. These linked trajectories may define the life course of a parent and her child. Goode (1960) argues that an individual's set of relationships at any point in time is both "unique and overdemanding," requiring strategies that minimize demands by rescheduling transitions (such as entry into work, the birth of a second child), where possible. The synchronization of role demands may entail a spreading out of commitments or obligations, as in the transition to adulthood or in the family formation years. Among dual-earner couples, the timing of retirement has become a synchronization issue in working out an appropriate action for each partner and their relationship (O'Rand et al. 1991). The synchronization of lives is central to life-course planning in families.

Major transitions in the life course typically involve multiple life changes, from entry into the diverse roles of adulthood (Modell 1989) to later-life changes in work, residence, and family (Hareven 1978; Kohli 1986). These transitions may also

entail a sequence of phases or choice points. The transition to unwed motherhood thus involves premarital sexual experience followed by decisions not to have an abortion, not to give the child up for adoption, and not to marry the father. Causal influences vary across choice points. Early transitions can have developmental consequences by affecting subsequent transitions, even after many years and decades have passed. They do so through behavioral consequences that set in motion cumulative disadvantages or advantages, with radiating implications for other aspects of life (Furstenberg et al. 1987). For example, early teenage childbearing may curtail education and work-life prospects.

The social meanings of age give structure to the life course through age norms, sanctions, and age-graded relationships. In theory, a normative concept of social time specifies an appropriate time or age for marriage, childbearing, and retirement (Neugarten and Datan 1973). This concept also provides a guideline on the meaning of career advancement, whether accelerated or lagging relative to one's age. Empirical findings are beginning to cumulate on event timing, sequences, and durations, although the knowledge base is thin on causal mechanisms (Shanahan in press). Beyond these social distinctions, age has historical significance for the life course as it locates people in historical context according to birth cohorts.

Family connections invariably place the life course in a broader matrix of kinship relationships, one that extends beyond the boundaries of the immediate family to in-laws, grandparents, uncles, aunts, and cousins (Rossi and Rossi 1990). Within the life course of each generation, unexpected and involuntary events occur through life changes in related generations. Thus, a thirty-year old woman becomes a grandmother when her adolescent daughter has a first baby. People lose their status as grandchildren when their grandparents pass away, and their roles as sons or daughters when their parents die. They become the oldest generation in the family. Ties to family members are part of the normative regulation of life-course decisions.

The *life-cycle concept* is frequently used to describe a sequence of life events from birth to death, though its more precise meaning refers to an intergenerational sequence of parenthood stages over the life course, from the birth of the

children to their own departure from home and childbearing (O'Rand and Krecker 1990). This sequence, it should be noted, refers to a reproductive process in human populations. Within a life cycle of generational succession, newborns are socialized to maturity, give birth to the next generation, grow old, and die. The cycle is repeated from one generation to the next, though only within the framework of a population. Some people do not have children and consequently are not part of an intergenerational life cycle.

The life cycle is commonly known in terms of a family cycle, a set of ordered stages of parenthood defined primarily by variations in family composition and size (Hill 1970). Major transition points include marriage, birth of the first and the last child, the children's transitions in school, departure of the eldest and the youngest child from the home, and marital dissolution through death of one spouse. The stages are not defined in terms of age, as a rule, and typically follow a preferred script of a marriage that bears children and survives to old age, an increasingly rare specimen in view of the divorce rate. The life-cycle concept tells us about the sequence of family events, but it does not indicate how closely spaced the events are or when the sequence began in a woman's life, whether in adolescence or in the late thirties. A rapid sequence of births produces a different family process from that of widely dispersed births. The life stage of the mother also has relevance to the meaning of a birth sequence. Moreover, some women do not bear children.

Life history commonly refers to a lifetime chronology of events and activities that typically and variably combines data records on education, work life, family, and residence. A life history may also include information on physical health, social identity change, and emotional well-being. These records may be generated by obtaining information from archival materials or from interviews with a respondent. Some interviews are prospective and focus on the present; others are retrospective and enable the investigator to obtain information that was not collected in the past (Giele and Elder 1998). The accuracy of these reports of the past depends on the type of information requested. Subjective states in the past cannot be recovered accurately in retrospective reports. They are interpreted in terms of the present.

A retrospective life history or calendar is based on an age-event matrix (Freedman et al. 1988; Caspi et al. 1996). It records the age (year and month) at which transitions occur in each activity domain, and thus depicts an unfolding life course in ways uniquely suited to event-history analyses (Mayer and Tuma 1990) and to the assessment of time-varying causal influences. The advantages and disadvantages of retrospective life histories and prospective reports are discussed by Scott and Alwin (1998). In developing societies especially, retrospective life calendars are typically the only sources of information on prior life experience.

The term "life history" also refers to a self-reported narration of life, as in Thomas and Znaniecki's famous life history of Wladek, a Polish peasant, in *The Polish Peasant in Europe and America* (1918–1920). Narrative accounts are frequently recorded on tape and then transcribed. Another common approach assigns the interviewer a more active editorial role in actually putting together a life history. In *American Lives* (1993), Clausen interviewed six adults in their later years and prepared life histories, which the respondents later reviewed for accuracy. He has written about this method in two essays (1995, 1998) that discuss the difference between life stories and life histories.

This qualitative approach to life histories is increasingly considered one part of a multimethod approach to the study of lives. In their pathbreaking longitudinal study of juvenile delinquents, Laub and Sampson (1998) show how the qualitative life histories provide critical insight, when combined with quantitative data, on events that turned men's lives around toward productive work and good citizenship. Events that are turning points change the direction of lives, they are often "course corrections." Examples include marriage, military service, and higher education.

Life span specifies the temporal scope of inquiry and specialization, as in life-span psychology or sociology. A life-span study extends across a substantial period of life and generally links behavior in two or more life stages. Instead of limiting research to social and developmental processes within a specific life stage, such as adolescence or the middle years, a life-span design favors studies of antecedents and consequences. Sociologists tend to focus on the social life course, in which "life stage" refers to either socially defined positions,

such as the age of young adulthood, or to analytically defined positions, such as the career stage of men or women at age forty (i.e., where they are in their career at this age). Thus, men who differ in age when they encounter work-life misfortune occupy different life stages at the time.

Developmental stages and trajectories are the focus of life-span developmental psychology. Examples of a stage theory include Erik Erikson's (1963) psychosocial stages, such as the stage of generativity in the later years. Life-span developmental psychology gained coherence and visibility through a series of conferences at the University of West Virginia beginning in the late 1960s (Baltes and Reese 1984). The approach is defined by a concern with the description and explanation of age-related biological and behavioral changes from birth to death.

All the above concepts have a place in studies of the life course. Contemporary inquiry extends across the life span and frequently draws upon the life records and life cycles of successive generations. The life course takes the form of a multidimensional and intergenerational concept: a dynamic life pattern of interlocking trajectories and transitions, such as work, marriage, and being parents. Within this context, misfortune and opportunities are intergenerational as well as personal life events. Failed marriages and work lives can lead adult offspring back to the parental household and alter the parents's life plans for their later years (Goldscheider and Goldscheider 1993). Conversely, parents' economic setbacks and marital dissolution may impede their children's transition to adulthood by postponing higher education and marriage. Each generation is bound to fateful decisions and events in the other's life course.

THE EMERGENCE OF LIFE-COURSE THEORY

When pioneering investigators followed children born before 1930 into their adult years, they encountered major limitations in conventional approaches to human development, including those associated with a child-based model. Three such limitations and their challenges, in particular, played a major role in the genesis of life course theory and appropriate methods (Elder 1998):

1. To formulate concepts that apply to development and aging across the life span as a replacement for child-based, growth-oriented accounts.
2. To conceptualize how human lives are socially organized and evolve over time.
3. To relate lives to an ever-changing society, with emphasis on the linking processes and mechanisms and the developmental effects of changing circumstances.

Responses to the first challenge in the 1970s led to the formulation of more life-span concepts of development and aging (Baltes and Baltes, 1990; Baltes et al. 1998), especially with the field of life-span developmental psychology. Life-span development is conceived as a life-long adaptational process. Some processes are discontinuous and innovative, while others are continuous and cumulative. Biological resources tend to decline over the life span, whereas cultural resources may increase, as in the growth of wisdom. Theorists stress the lifelong interaction of person and social context, the relative plasticity and agency of the aging organism, and the multidirectionality of life-span development (Lerner 1991). Psychologist Paul Baltes at the Berlin Max Planck Institute is a leading figure in the programmatic effort to study development and aging across the life span.

This emergence of life-span thinking on human development and aging occurred with little attention to a well-established "relationship" view of human lives. Dating back to the nineteenth century, social scientists have viewed the individual's life pattern in terms of multiple role sequences and their transitions (Cain 1964; Kertzer and Keith 1984). Changes in social roles, such as from dependency to marriage and parenthood, represent changes in social stage across the life cycle. Commitments to a line of action arise from obligations to significant others. Stable relationships ensure a measure of personal stability, just as entry into such relationships can stabilize a person's life and minimize involvement in unconventional and illegal activities (Robins 1966). A change in relationships may produce a turning point, a redirection of the life course.

Life-cycle theory helped to contextualize people's lives by emphasizing the social dynamic of "linked lives." These connections extend across the generations and across people's lives through

convoys of friends and relatives—others who remain part of their social network as they age (Kahn and Antonucci 1980). One of the earliest proponents of a life-cycle view of lives was sociologist William I. Thomas. With Florian Znaniecki, he used life-record data to study the emigration of Polish peasants to European and American cities around the turn of the century (1918–1920). The societies they left and entered presented contrasting “lines of genesis” or role sequences for individual lives.

For many decades, the life cycle perspective offered a valuable way of thinking about the social patterning of lives, though insensitive to age, time, and historical context. During the 1960s, the life-cycle approach began to converge with new understandings of age to draw upon the virtues of each tradition; of *linked lives* across the life span and generations, and of *temporality* through an age-graded sequence of events and social roles, embedded in a changing world. The emerging theory of the life course was informed as well by life-span concepts of human development.

Three discoveries of variation in lives were based on this new understanding of age, and together they gave rise to life-course thinking. First, studies in the 1960s began to identify substantial *variation in age patterns* across lives: Contrary to established views (Eisenstadt 1956), people of the same age varied in the pace and sequencing of transitions in their lives. During the late 1950s and early 1960s, Bernice Neugarten (1968) developed a research program that featured normative timetables and individual deviations from such expectations. Ever since this pioneering work and the growth of social demography, the study of differential timing and order among events has been one of the most active domains in life-course study. However, we still know little about age expectations in large populations.

Second, *social relations and kinship* especially emerged as a primary source of variation and regulation of life trajectories. Lives are lived interdependently among members of family and kin. The most significant integration of age and relationship distinctions is found in *Of Human Bonding* (Rossi and Rossi 1990). Using a three-generation sample in the Boston region, the study investigates the interlocking nature of the life

course within family systems, with particular focus on the relationship between individual aging and kin-defined relationships across the life span.

Third, the new work on aging made visible the role of *historical variation* as a source of life variations. Studies of social change and life patterns had been conducted up to the 1960s as if they had little in common, an assumption effectively challenged by Norman Ryder’s concept of the interaction of individual lives and history (1965). Ryder proposed the term “cohort” as a concept for studying the life course—the age at which the person enters the system. With its life-stage principle, Ryder’s essay provided a useful point of departure for understanding the interaction between social change and the life patterns of birth cohorts. The impact of a historical event on the life course reflects the life or career stage at which the change was experienced. The publication of *Aging and Society* (Riley et al. 1972) strengthened this sensitivity to the historical setting of lives through membership in a particular birth cohort.

The three streams of life-course theory (social relations–life cycle, age, and life-span concepts of development) came together in a study of children who were born in the early 1920s, grew up in the Great Depression, and then entered service roles in World War II. In *Children of the Great Depression* (Elder, [1974] 1999), the study began with ideas from the relationship tradition, such as generation and social roles, and soon turned to the analytic meanings of age for ways of linking family and individual experience to historical change, and for identifying trajectories across the life course. The study tested Ryder’s life-stage principle by comparing the effects of drastic income loss during the Great Depression on the family and individual experience of the Oakland study members with that of a younger cohort born toward the end of the 1920s (Elder et al. 1984). Consistent with the life-stage hypothesis, the younger boys in particular were more adversely influenced by family hardship, when compared to the older boys. But similar effects were not observed among the girls.

By the 1990s, the life course had become a general theoretical framework for the study of lives, human development, and aging in a changing society. This advance is coupled with the continued growth of longitudinal studies and the

emergence of new methodologies for the collection and analysis of life history data (Giele and Elder 1998; Mayer and Tuma 1990).

PARADIGMATIC PRINCIPLES

Life course theory is organized around paradigmatic principles that guide inquiry on issues of problem identification, model formulation, and research design. Four principles are primary: 1) the interplay of human lives and development with changing times and places; 2) the social timing of lives; 3) the interdependence of lives; and 4) human agency in choice-making and actions (Elder 1998).

1. *The life course of individuals is embedded in and shaped by the historical times and places they experience over their lifetime.*

When societies are undergoing rapid change, different birth years expose individuals to historical worlds with different opportunity systems, cultures, and structural constraints. Historical influences on life trajectories take the form of a cohort effect when social change differentiates the life course of successive cohorts, such as older and younger men before the World War II. History also takes the form of a period effect when the impact of social change is relatively uniform across successive birth cohorts. Birth year and cohort membership locate people in relation to historical change, such as the economic recession of 1982–83, but they do not indicate actual exposure to the change or the process by which historical influences are expressed. Direct study of such change and its influences is essential for identifying explanatory mechanisms.

Life stage informs such mechanisms; people of unlike age and those who occupy different roles are differentially exposed to and influenced by particular types of social change. Four other components of an explanatory mechanism (for linking social change to lives) are worth noting (Elder 1998, pp. 959–61). One linking factor is defined by *social imperatives*, the behavioral demands or requirements of new situations. The more

demanding the situation, the more individual behavior is constrained to meet role expectations. Studies of worklives by Kohn and Schooler (1983) suggest that the establishment of a new set of occupational and workplace imperatives can alter how workers think and function. A second factor involves the dynamics of a *control cycle*. A loss of personal control occurs when people enter a new world and this sets in motion efforts to regain this control. These efforts may entail new choices that construct a different direction in life, a different life course. Historical influences are often expressed through a network of relationships. *Interdependent lives* are thus a linking factor in the explanatory analysis. The last factor involves *accentuation*. When a social transition heightens a prominent attribute that people bring to the new role or situation, the process accentuates the effect of the change. Our understanding of such change is enhanced by the *principle of timing in lives*.

2. *The developmental impact of a life transition or event is contingent on when it occurs in a person's life.*

This principle subsumes the concept of life stage; social change affects the individual according to when the exposure occurred over the life course. Recruitment into the military illustrates this point (Sampson and Laub 1996). Mobilization immediately after high school occurs before marriage and worklife obligations, and during World War II, entry into the service at this time was less disruptive than it was for males who entered in their late twenties or thirties. Studies of veterans from World War II indicate that late entry into the armed forces significantly increased the risk of divorce, worklife disruption, and an accelerated pattern of physical health decline (Elder and Chan 1999). By comparison, early entry provided access to educational and job opportunities without the costs of life disruption.

Across the life course, Neugarten's (1996) emphasis on the consequences of timing variations has been followed by

extensive research on differential timing patterns, from marriage and births to retirement (Shanahan in press). The impact of a life event, such as a personal loss, depends in part on when the event occurs. But to fully assess this impact, we must consider also the *principle of linked lives*.

3. *Lives are lived interdependently and social and historical influences are expressed through this network of shared relationships.*

Social relationships represent a vehicle for transmitting and amplifying the effects of stressful change, as in families under economic stress. For example, Depression hardship tended to increase the explosiveness of fathers who were inclined toward irritability before the crisis (Elder et al. 1986). And the more explosive they became under stress, the more adversely it affected the quality of marriage and effectiveness as a parent. Unstable family relations (marital, parent-child) became mutually reinforcing dynamics across the life course and generations. These dynamics tended to persist from one generation to the next through a process of individual continuity and intergenerational transmission.

Linked lives tend to transmit the life course implications of an ill-timed event in a person's life. One of the clearest examples of this phenomenon comes from a study of female lineages in Los Angeles (Burton and Bengtson 1985). The birth of a child to the teenage daughter of a young mother created a large disparity between age and kinship status, between being young and facing the prospects of grandparental obligations. Four out of five mothers of young mothers actually refused to accept these new child-care obligations, shifting the burden up the generational ladder to the great-grandmother, who in many cases was carrying a heavy load. By comparison, the women who became grandmothers in their late forties or so were eager for the new role; in this lineage, a daughter's timely transition to motherhood set in motion her mother's timely transition to grandmotherhood. In

both cases, the *principle of human agency* addresses the process by which lives and life courses are socially constructed.

4. *Individuals construct their own life course through the choices and actions they have taken within the constraints and opportunities of history and social circumstances.*

Human agency has been a central theme in the study of biographies. Lives are influenced by social structures and cultures, but human agency can shape lives through the choices that are made under such conditions. In Clausen's *American Lives* (1993), the central question is not how social systems made a difference in the life course, but why people made certain choices and thereby constructed their own life course. Clausen focused on the primary role of planful competence in late adolescence, that competent young people who think about the future with a sense of efficacy are more effective in making sound choices and in implementing them. This study found substantial support for this hypothesis in the lives of men in particular from adolescence to the retirement age of 65. However, longitudinal research (Shanahan et al. 1997) shows that planful competence makes a difference only when opportunities are available. Planful competence was not expressed in education or occupational career among men who entered the labor market in the depressed 1930s.

The emergence of life course theory and methods can be viewed as a response to pressing questions in the 1960s. The rapidly developing field of human development and aging needed a conceptual framework for thinking about the patterning of human lives in changing societies and its consequences. As life course theory addressed issue of this kind, it gained prominence as a theoretical orientation among fields of gerontology, criminology, social history, medical studies, developmental science, education, and social stratification. Noting such developments, Colby (Giele and Elder 1998, pp. x), refers to this approach as "one of the

most important achievements of social science in the second half of the 20th century." Only time will tell about the accuracy of this appraisal. In the meantime, the field of life course studies continues to flourish.

LIFE CYCLE

The *life cycle* is the socially defined, age-related sequence of stages individuals pass through beginning with birth and ending with death. Underlying the life cycle is the recognition that humans are biological organisms that are born, mature, and die. As with other biological organisms, reproduction is a key feature of human maturation, ensuring the persistence of the species.

FORMS OF THE LIFE CYCLE

In very simple societies, the life cycle may consist simply of two stages—infant and adult. Once infant survivorship is reasonably certain (typically by about age 6) young persons participate in adult work life, doing jobs that are suitable to their physical strength or as apprentices learning more complex skills. Work continues until death. But such a simple definition of the life cycle rarely endures the complexities attendant on reproduction. Among women, physical maturation separates childhood from the age when childbearing is possible. For men, marriage entails responsibility for supporting a family and guaranteeing their safety, something that typically must await completion of puberty and the achievement of economic viability. Even in societies with a low life expectancy, some adults survive to the point at which they are no longer able to work.

These examples illustrate how individual *social roles* (such as work or having a child) define a human life cycle that is more complex than the biological minimum. These roles are almost always defined as age related, and typically are also different for men and women. The concept of age-appropriate roles enables societies to regulate or prohibit behavior that is occurring “too early.” These societies also use the concept of age appropriateness to move individuals along in their maturation process, urging the adoption of a social role before it is “too late.”

Age. In most societies, chronological age is a handy proxy for maturity, with particular age groups assigned certain responsibilities and rights. In some societies (such as in postwar Japan) the age appropriateness of the sequence of social roles is rigorously defined by cultural values and enforced by

social institutions (such as schools or labor markets) which impose strict age rules on entry, promotion, and exit. In African age-set societies the system is even more rigid: Groups of persons born during contiguous years are defined as members of a particular age group (age set). These age sets experience together the transition from one life cycle stage to the next, under community traditions that specify the formal requirements and ceremonies necessary to move from one set of social roles to another. Typically this process is one of considerable dispute—the moving up of one age set causes all members of the society to move to the next life-cycle stage so that one group will have to give up preferred adult roles for old age.

Age Stratification and Cohort Succession.

Individual childbearing and the aging of individuals ready to assume new age-appropriate roles drive the societal process of age stratification and cohort succession (Riley 1985). The more complex the society, the more social roles that need to be filled. Most such roles in the society are gender linked and age stratified (defined as age appropriate and differing markedly from age to age). The use of chronological age rather than maturational capacity to construct the age-stratification system mandates that individuals as they age will move from one age stratum to the next, with an implicit societal mandate of assuming new roles. The birth of persons in contiguous years (what demographers call a “birth cohort”) reinforces the dynamic of the age-stratification system by producing new role entrants who can only be accommodated by the movement of all age strata to the next life-cycle stage. In the United States we can see this system at work in age-graded schooling: When one group achieves high school graduation, the remaining students are promoted from one grade to the next. This opens entry-level spaces for a new cohort to begin school. Universities develop a variety of incentives to get elderly faculty to retire so that newly trained and presumably more innovative faculty can be hired.

The Life Cycle in Social Science. To summarize, the lives of humans from birth to death are organized as socially defined, age-related sequence of stages individuals pass through over their lifetime. These stages are inherently age related, with individuals maturing from one life-cycle stage to the next. Reproduction is a key feature of human maturation, distinguishing the roles of men and

women and linked to the age-related biological capacity to bear children. An ongoing flow of new births ensures the persistence of human populations. Accommodating these new members of society also drives the dynamic of life-cycle change by necessitating the movement of earlier cohorts to more mature positions in the age-stratification system. This process of cohort succession is, in turn, a major source of societal innovation and change, as new cohorts take a fresh look at the content and form of the age strata they have just reached. In this way, the life-cycle concept links individual aging, the organization of roles in society, reproduction, and societal innovation and change.

CONTRIBUTIONS OF THE LIFE CYCLE

The life cycle has proved to be a powerful and flexible tool for the analysis and explanation of human lives, used by researchers from a number of different disciplines. Anthropologists have focused on the process of socialization by which one age stratum is taught to succeed the next over the life cycle, linking social roles to the cultural system of beliefs and values. Age-set societies have been intensively described because of the very visible structure of age stratification and the explicit group-level patterns of life-cycle stages. Rites of passage are the symbolic counterparts of age-set transitions from one age stratum to the next, marking the personal change and announcing it to the entire community.

Developmental psychologists have used the life cycle as an organizing principle for specifying the steps in human development. The process of aging drives this principle, which is defined and structured by social organizations and individual roles. A prominent example is Erikson's eight stages of life (1968). In this model, psychosocial stages are identified, consisting of times in which opportunities for success and the risk of failure are present. For example, the young adult stage is marked by the capacity for intimacy versus isolation, and integration, while a choice between wisdom and despair marks old age. The passage from one of the eight life stages to the next is regarded as a *turning point* that is fraught with vulnerability and heightened potential.

The life cycle forced gerontologists to recognize that the study of old age in isolation from the

prior life cycle is not viable. The economic resources, health, knowledge, and family situations of the elderly result from the cumulating of life-cycle experiences. These same factors influence the chronological age at which people take on characteristics of the aged. Gerontology as a field has expanded to encompass the dynamics of life-cycle transitions. Immediately noteworthy when one adopts this aging approach is the fact that persons currently reaching old age have prior life-cycle experiences that may better prepare them for becoming old than did prior cohorts. The sociological interest in aging motivates gerontologists to attend to both the lifelong process of aging and potentially dramatic intercohort changes in successive cohorts of the aged.

Life Cycle Squeeze. Economists have relied on the life cycle and the gendered division of labor to study household and family economics. Wages follow a curvilinear pattern over the life cycle: Young workers receive the lowest wages; wages increase over the life cycle, peaking at midlife; while workers older than 55 tend to experience stability or even a decline in earnings. Women's earnings show much less of an age profile, both because young women frequently interrupt or reduce labor-force involvement when children are born, and because women's jobs are less likely to take the form of careers in which progression upward from one job to the next occurs.

This life-cycle pattern of earnings does not always match family income needs. Early in the life cycle, children are net consumers of income. As societies require a more educated population, youth and adolescents also become net income consumers. While this has long-term payoff for the society and for new cohorts of workers, it increases the costs and reduces the economic value of children to families. These costs most often occur when workers are at the low point in their earnings. Later in the life cycle, earnings are higher but the cost of a college education and assisting children in getting started also may be high. At the same time, elderly parents may become a social and financial obligation for children, leading to the powerful concept of the "life-cycle squeeze."

Cohorts facing this new mix of obligations with the traditional earnings profile have acted to reduce desynchronies in the stages of the life cycle.

Credit mechanisms (for example, long-term mortgages, home equity loans to pay for college education) smooth income and costs over the lifetime. The intercohort upgrading of the situations of the elderly in the United States means that parents become dependent on their adult children at an older age. The government has intervened to bear much of the cost of the elderly. Life-cycle pressures have also resulted in intercohort changes in the content of the life cycle of men and women—delays in marriage and first birth, a reduction in family size, the shift to two-earner families, and increases in divorce.

Sociologists have devoted considerable attention to the cohort-level study of life-cycle transitions. Turning points imply inevitability and potential crisis. Sociologists study the form of the transition (for example, cohabitation or marriage), whether or not a transition occurs (for example, parenthood), and the average age and variability in age of a transition across individuals of the same cohort. This approach recognizes (building on the idea of an age-stratification system) that a variety of transitions are crosscutting (for example, work and marriage, birth of a first child and marriage).

The Life Cycle in Demographic Models. It is the educational, labor-force, and family outcomes that interest demographers. The study of family life has proceeded with the measurement of marriage and then the progression to first birth, second birth, and so forth (taking into account both the number and the timing of births). A special tool called *parity progression analysis* has enabled demographers to identify turning points in fertility decisions, and how these have changed across cohorts. This approach to the study of demographic life-cycle stages, along with the recognition that fertility is inherently a biological process, has led demographers to develop population models of fertility that take into account marriage patterns, the level of marital fertility, and birth limitation. The life-cycle model also has informed research on age patterns of migration, and its regularities across time and place.

The life-cycle perspective has produced a variety of unexpected results. The American baby boom of the late 1940s and the 1950s was largely due to the temporal coincidence of childbearing by successive cohorts, rather than to a dramatic increase in family size. During the baby boom,

women 35 and older made up childbearing that had been delayed by the Great Depression and World War II. Women reaching adulthood during the baby boom years responded to favorable economic conditions for young families by having their first child at a younger age and having subsequent children more quickly.

Family Life Cycle. Family sociologists made a great leap in developing the family life cycle as a variant form of the life cycle (Glick 1965). The family life cycle is unusual in that it focuses on family formation and childbearing, ignoring such linked transitions as completion of schooling and work. The family life cycle stretched the life-cycle model to incorporate role changes associated with the transitions of other individuals. (For example, a husband makes the transition to marriage at the same time as the wife. Only when all children grow up and leave the home does the family experience an “empty nest.”) The family life cycle became a predominant research paradigm in family studies.

The family life cycle can be a useful analytic tool for understanding the succession of family roles in populations in which families predominate over individual interests. The family life-cycle model works only for those populations in which marriage precedes childbearing, the ages of each are specified within a narrow time band, and marriages do not end (by widowhood or divorce) before the last child leaves home.

None of these assumptions are even approximately satisfied for the United States. First births often precede marriage (among blacks this is the typical pattern). Many couples postpone childbearing within marriage, and as many as one-fifth remain voluntarily childless. Over half of all first marriages end within twenty years. Remarriage often follows. This degree of inconstancy in household membership begs the question of how to define the family whose life cycle is being described, and followed over time. The family life cycle is now widely regarded as a useless conceptual tool because it utterly fails to capture the realities of contemporary family life.

LIFE CYCLE AND LIFE COURSE

The life cycle defines pathways for individuals as they age from birth to death, specifying usual expectations about the sequence and timing of

roles (for example, a first birth when married and at age 18 or older). Empirical research that uses the life cycle to analyze the lives of population *cohorts* typically find that these life-cycle stages, as socially defined and demarcated, follow expected patterns.

Research on the transitions of *individuals* over their lifetime has demonstrated the essential incorrectness of this supposition. For many individuals, childbearing precedes marriage, parenthood occurs when the parents are not yet economically self-sufficient, and adult children return to their parental household after they have assumed (and sometimes failed at) adult family and economic roles. This has caused researchers to consider whether new life-cycle patterns are emerging, or whether a group of individuals is somehow “deviant” from the established life cycle.

Clearly there have been marked intercohort changes in the life cycle, reflecting the varying opportunity structures of time periods and cultural change. For example, the availability of the GI Bill for college education and interruptions in education associated with wartime military service allowed many men to marry and have children before they finished school and became economically established. In recent cohorts of young women there is a decreasing emphasis on the necessity of marrying before having a child, and, on the part of all adults, a greater readiness to assist rather than condemn single mothers.

An even greater source of departure from the population life-cycle model is the large number of persons in each cohort who never make a transition to a given life-cycle stage (e.g., those not marrying or not becoming parents), who retreat from a given life-cycle stage to an earlier stage (e.g., fathers who divorce and abandon their families, and retired persons who return to work), and who are not part of the typical life cycle (e.g., the severely disabled, persons who die before reaching old age). These features of the life cycle vary by such primary sociological variables as social class origin, education, race and ethnic group, and place of residence.

Among Americans the seeming conformity of cohorts to the life-cycle patterns masks the overwhelming number and frequency of individual departures. In this situation the life cycle seems to be a far less useful analytic device. Social scientists

have adopted in its place the more sophisticated and flexible “life-course” perspective. The life course sees individual lives as a series of trajectories (such as family or career) that are socially recognized and defined. Age is significant in the life-course approach because it is an indicator of biological aging and locates individuals in historical context through birth cohorts. The social meaning of age helps define life-course pathways (recognized routes of trajectories) through age norms and sanctions, and social timetables for the occurrence and order of events. Transitions (leaving home, getting a job, marrying) define trajectories. Interlocking transitions and their trajectories lead to multiple roles that define the individual life course from birth to death.

Because of the emphasis on variations in trajectories across individuals, every individual life course has the potential to be unique. Much of the population-level research with the life-course model has focused on transitions—the proportion of cohorts making a transition, average age at transitions, and the range of ages at which cohorts typically make these transitions. The life cycle gives analytic meaning to these life-course transitions by providing a standard against which to measure how transitions vary across cohorts and differ among key population groups within cohorts.

Causal analyses of the life course are usually done at the individual level, typically with a class of statistical methods called “event history” or “hazards” models. These statistical methods enable investigators to examine empirical data on individual transitions, modeling the age-graded pattern of transitions from one social role to another and identifying “heterogeneity” (sources of variation in transitions at the individual level).

The Necessity for Life Cycle in Studies of the Life Course. This points to a dilemma for social scientists—the very life-cycle model that the life-course approach undermines provides the essential theoretical framework that gives meaning to individual behaviors. Because social scientists are part of the societies they study, they also carry in their own heads models of the life cycle—what should be done when it should be done, and what denotes success or failure. The life-course perspective on pathways that define typical trajectories and the social meanings of age capture the essence of a life-cycle model. The apparent tension between the

life-cycle and life-course conceptualizations is perhaps overdrawn.

The life-cycle model retains many valuable features that are typically missing from life-course studies. Life-course transitions focus on individuals at particular times during their lives (adolescents becoming adults, older workers becoming disabled or retired). While past experiences and current opportunities are often included in life-course models, the life-course perspective has not lent itself well to viewing transitions at particular ages in the context of the lifelong process of aging, an idea that is innate in the life-cycle approach. Economic research, which is theoretically driven and uses a life-cycle model, has been most successful at integrating findings from transitions at a given age into the lifetimes of individuals.

With such an approach it is also possible to simulate the effects of changes in transition rates (resulting from heterogeneity in rates and changes in population composition) on cohort-life cycle behaviors. The life-course perspective typically views cohorts as proxies for age-specific experiences with the social structure; the life-cycle model brings a necessary emphasis on intercohort change as a method of social innovation.

The life-course approach emphasizes variability in transitions and trajectories to such an extent that many social scientists have neglected regularities and consistencies in behaviors, and the advantages they may entail. There is a great deal of research on adolescent mothers but relatively little research on why married women have children. There is more interest in unemployment and poverty than in the advantages of paid employment and career lines. While children of welfare mothers disproportionately go on to become welfare mothers themselves (the subject of much research), the overwhelming majority grow up to be free of welfare dependence (a subject about which we know very little). Nor do we have a strong explanation of the reasons persons marry. The life-cycle approach draws attention to these questions of social organization, and the matching of individual behaviors to necessary social roles.

FUTURE OF LIFE CYCLE

The life cycle thus remains a viable and valuable conceptual tool for studying human lives. In much

of the developing world, transitions and trajectories are sufficiently universal and age regulated that the life-cycle model remains a highly useful tool for social science. In societies where such regularities are no longer the norm, the life-course approach is the more appropriate. To be meaningful, the life course must be interpreted in light of the life cycle—the underlying beliefs about the shape and timing of the life stages to understand the social meanings of age, identify alternative pathways for life trajectories, draw attention to the strong regularities in transition behaviors and linkages, and direct attention to intercohort stability and change. The concept of the life cycle thus will continue to be a valuable and necessary tool for the social sciences.

DENNIS P. HOGAN

LIFE EXPECTANCY

Life expectancy (or the expectation of life) is the average length of life remaining to be lived by a

population at a given age. It is computed in the process of building a life table and can be computed for any age in the life table. Life expectancy at birth is the most commonly presented value because this measure provides a succinct indicator of mortality that reflects mortality conditions across the age range and is unaffected by the age structure of the actual population and thus can be compared across populations. The symbol used to represent life expectancy is e_x where x represents an exact age.

LIFE EXPECTANCY IN THE UNITED STATES

In 1996, life expectancy at birth, e_0 , in the United States was 76.1 years; at age 65, e_{65} was 17.5 years; and at age 85, e_{85} was 6.1 years (Anderson 1998). These figures can be interpreted to mean that if a baby born in 1996 were exposed to the mortality conditions existing at each age of the life span in 1996, the baby with an average length life would live 76.1 years.

PERIOD AND COHORT VALUES OF LIFE EXPECTANCY

The 1996 U.S. life table is a period life table, based on cross-sectional data collected over a year; thus, this life table indicates the mortality experience of a hypothetical cohort. No actual cohort ever experiences the mortality in a period or cross-sectional life table; rather, the table indicates mortality conditions if the mortality levels of each age group at the period of time used as a reference were experienced by the hypothetical cohort. Because mortality has been falling over time, period life tables for a cohort's year of birth have indicated an average expected length of life that is lower than that actually achieved by the cohort. For instance, in 1900 the cross-sectional life table for the United States showed life expectations of 46 for males and 49 for females. On the basis of their actual experience up through the age of 80, the 1900 birth cohort had an average length of life of 52 years for males and 58 years for females (Faber and Wade 1983).

Generation or cohort life tables, like the one mentioned above, based on the experience of an actual cohort are sometimes constructed. These

indicate the average length of life actually lived after specific ages for a real cohort. The major difficulty faced in building cohort life tables is obtaining population and death data for a cohort from birth until the last survivors have died—over a 100-year period.

A mistaken notion held by many people is that life expectancy at birth is a good indicator of the age at which an older individual will die. This notion has undoubtedly led to some poor planning for old age because a person who has already reached older adulthood on average will die at an age that exceeds life expectancy at birth by a significant amount. As mentioned above, expectation of life in 1996 was 17.5 years for 65-year-olds, 11.1 for 75-year-olds, and 6.1 for 85-year-olds. With this number of years remaining to be lived on average, 65-year-olds should expect to live to 83 on average. Those who live to 75 should expect to live to 86, and those who live to 85 can expect to live to 91 on average. While expectation of life decreases as age increases, the expected age at death increases for those who survive.

CHANGES IN LIFE EXPECTANCY OVER TIME

As noted above, life expectancy has been increasing over time. This has probably been going on since some time in the last half of the nineteenth century, although reliable data for large sections of the country are not available to track the increase before 1900. In 1900, life expectancy at birth for both sexes was 47.3 years (U.S. Bureau of the Census 1975). This indicates an increase in life expectancy between 1900 and 1996 of 28.8 years. Most of this increase in life expectancy since 1900 is due to declines in mortality among infants and children. These mortality declines were primarily due to the diminishing force of infectious and parasitic diseases which were the most important causes of death among children.

Because life expectancy was low in the past, people often hold the mistaken notion that very few people ever reached old age under high mortality conditions. Yin and Shine (1985) have demonstrated that this mistaken notion was so prevalent that it was commonly incorporated into gerontology textbooks. The fact is that even under conditions of low life expectancy, once childhood

is survived, the chances of living to old age are quite high. This is indicated by the fact that life expectancy at the older years has not increased over time nearly as much as life expectancy at birth. For instance, while life expectancy at birth for white males has increased almost 26 years since 1900, from 48.2 to 73.9 years, life expectancy for white males at age 40 has increased almost 9 years between 1900 and 1996, from 27.7 years to 36.4 years; at age 70, the increase for males has been just over 3 1/2 years, from 9.0 to 12.6 (Anderson 1998).

It should be noted, however, that in the past three decades the pace of improvement in life expectancy at the oldest ages has increased. In 1970 expectation of life for white males at age 70 was 10.5 years, indicating an improvement of 1.5 years in the 70 years between 1900 and 1970. Between 1970 and 1998, the increase was 2 years—significantly greater than the improvement during the first seven decades of the century. This reflects the new era of mortality decline in which decreases in mortality are due to decreased mortality from chronic conditions and are concentrated among the old.

A number of authors have studied the relationships between changes in age-specific mortality and life expectancy. Vaupel (1986) concludes that a reduction in the force of mortality of 1 percent at all ages would not produce as much gain in life expectancy today as it did in 1900. This is because we have already made so much progress in lowering infant and child mortality, the ages that have the greatest effect on life expectancy. Vaupel also shows that as mortality moves to lower levels, more progress is made in increasing life expectancy from mortality declines at older ages rather than at younger ages. At the level of mortality now experienced in the United States, much of the future increase in life expectancy will come from mortality declines occurring at ages over 65. This is true because of the prior success in reducing mortality at earlier ages to such low levels.

CALCULATION OF LIFE EXPECTANCY WITHIN THE LIFE TABLE

These observations about changes in life expectancy should make clear that life expectancy at birth is heavily weighted by mortality conditions at the

youngest ages. A brief explanation of the life table and how life expectancy is calculated demonstrates why this is the case.

The life table is a statistical model that provides a comprehensive description of the mortality level of a population. Life table measures are particularly valuable because they are succinct indicators of mortality that reflect mortality conditions across the age range, are unaffected by the age structure of the actual population, and thus can be compared across populations. Life table measures can also be used to describe the characteristics of the stationary population that would result from an unchanging schedule of age-specific mortality rates in a closed population with a constant number of births.

There are a number of functions that appear in most life tables and for which conventional notation is widely recognized: q_x , l_x , d_x , L_x , T_x , and e_x . Each of these measures provides information useful in describing some aspect of the mortality conditions and/or characteristics of the stationary population. The definitions and interpretations of the life table functions follow below. In order to clarify the interpretation of the abridged life table functions, the life table for the U.S. population for 1996 is used as an example (Table 1).

${}_nq_x$ is the probability of dying between exact age x and $x + n$. As shown in Table 1, the probability of dying in the first year of life is 0.00732. This is higher than at subsequent ages until age 60 to 65, when the probability of death is 0.06649.

l_x is the number of survivors reaching exact age x out of the original life table population. The size of the original life table population, the radix or l_0 , is usually assumed to be 100,000; however, this is a convention and other values can be used. Mortality conditions in 1996 were such that out of 100,000 births, 99,268 would reach age 1. This column of the life table can be used to compute how many people who reach a given age will survive to a later age. For instance, among the 80,870 people who reach age 65, 33,629 people or 42 percent will reach age 85 with mortality conditions as shown in Table 1.

${}_nd_x$ is the number of deaths in the life table population between exact age x and $x + n$.

LIFE EXPECTANCY

Abridged Life Table: United States, 1996

Age Interval	Proportion Dying	Of 100,000 Born Alive		Stationary Population		Average Remaining Lifetime
Period of Life between Two Exact Ages Stated in Years	Proportion of Persons Alive at Beginning of Age Interval Dying during Interval	Number Living at Beginning of Age Interval	Number Dying during Age Interval	In the Age Interval	In This and All Subsequent Age Intervals	Average Number of Years of Life Remaining at Beginning of Age Interval
(1) X to $X+n$	(2) ${}_nq_x$	(3) l_x	(4) ${}_nd_x$	(5) ${}_nL_x$	(6) T_x	(7) e_x

Table 1

SOURCE: R. N. Anderson 1988 *United States Abridged Life Tables, 1996. National Vital Statistics Reports: From the Centers for Disease Control and Prevention, National Center for Health Statistics, National Vital Statistics System* 47(13):5. Hyattsville, Md.: National Center for Health Statistics.

In the sample life table, 732 of the 100,000 births would die between ages 0 and 1 and 7,814 would die between ages 65 and 70.

${}_nL_x$ is the total number of years lived by the life table population between exact age x and $x + n$. Between birth and age 1, the life table population represented in Table 1 would live 99,370 years. This column also can be interpreted as the number of people in the stationary population at each year of age.

T_x is the total number of years lived after exact age x by the life table population surviving to age x , or the number of people in the stationary population age x and older. The 100,000 entrants to the life table in Table 1 would live a total of 7,611,825

years, and the 80,870 who reach age 65 would live a total of 1,416,873 more years.

e_x is the expectation of life at exact age x or the average length of life remaining to be lived for the life table population which survives to exact age x . e_x is computed from the T_x and l_x columns of the life table: $e_x = T_x/l_x$. As indicated earlier, at birth, the life table population in Table 1 has a life expectancy of 76.1 years.

DIFFERENTIALS IN LIFE EXPECTANCY

There are large differentials in life expectancy among demographic and socioeconomic groups in the United States. Males have lower life expectancies than females throughout the age

range. Males' lower chances for a longer life are thought to result from a combination of biological differences and lifestyle factors. In 1996, e_0 was 73.1 for males and 79.1 for females (Anderson 1998). By age 50, the difference is narrowed to 4.3 years, with a life expectancy of 27.2 for men and 31.5 for women. At age 85, men can expect to live another 5.4 years, while women can expect to live 6.4 years.

There is also a significant difference in life expectancy between whites and African Americans in the United States. This is assumed to result primarily from the difference in socioeconomic status and accompanying life circumstances that exist between African Americans and whites in the United States. In 1996, life expectancy at birth was 76.8 for whites and only 70.2 for blacks. At age 65, white life expectancy was 17.6 years; while for blacks of that age, it was 15.8 years. At the oldest ages, a crossover in mortality rates by race has been observed in the past. After the age of crossover, African-American mortality rates are lower than white mortality rates. In 1987 this was true at ages above 83. In the past, this crossover has shown up repeatedly in comparisons of African-American and white mortality in the United States and has been attributed to the "survival of the fittest" among the black population (Manton and Stallard 1981). Recently, however, doubt has been raised as to whether the crossover is real or is a statistical artifact resulting from age misstatement by older African Americans in both the census and vital records of deaths (Coale and Kisker 1986; Elo and Preston 1994; Preston et al. 1996). Interestingly, Hispanics appear to have life expectancy values that are higher than non-Hispanic whites (Anderson et al. 1997).

INTERNATIONAL DIFFERENCES

In general, the life expectancy of a country is related to its level of socioeconomic development. Most countries that are classified as "more developed" have higher levels of life expectancy at birth than most of the countries classified as "developing"; however, within each of these groups of countries there is quite a bit of variability in life expectancy. While the United States has a high level of life expectancy compared to that of the developing countries of the world, the United States ranks quite low in life expectancy among

developed countries and relative to its income level. A recent United Nations listing of the developed countries by level of life expectancy at birth ranks U.S. males as nineteenth and U.S. females as fourteenth (United Nations 1997). The countries with higher life expectancy for women include Japan and the Scandinavian countries. For men, most European countries including some in southern Europe have higher life expectancies at birth than the United States. The low ranking of the United States is attributed, in part, to the inequities in mortality among subgroups of the population, especially the high level among African Americans, and also to the high level of violent deaths. In recent years Japan has become the world leader in life expectancy at birth with values of e_0 of 76.4 for men and 82.9 for women in 1995 (Ministry of Health and Welfare, Japan 1999). These values exceed 1996 U.S. values by 3.3 years for men and 3.8 years for women. The success of the Japanese in raising their levels of life expectancy has been due to large declines in mortality from cerebrovascular disease and maintenance of low levels of heart disease relative to other developed countries (Yanagishita and Guralnik 1988).

RELATED CONCEPTS

There are some other concepts that are related to life expectancy and are sometimes confused with life expectancy. One is "life span." The *life span* of a species is the age to which the longest-lived members survive. The life span of humans is thought to be approximately 115 years; however, Madame Jeanne Calment, whose age was well documented, died in 1997 at the age of 122. Current thinking is that while life expectancy has increased dramatically over the last century, the life span of humans has not changed over time; however, this does not mean it will never change. If discoveries are made in the future that enable us to retard the aging process, it may be possible to lengthen the human life span in the future.

"Life endurancy" is a related concept that, like life expectancy, is computed from the life table. This is the age at which a specified proportion of the life table entry cohort is still alive. For instance, in 1990 the age at which 0.1, or 10 percent, of the life table population remained alive was 90 years for men and 96 years for women. Life endurancy has been increasing over time and is

expected to continue to change with changes in survival rates. In 1900 the 10 percent survival age was 81 and 82 for men and women, respectively (Faber and Wade 1983).

Finally, "healthy or active life expectancy" is a subset of total life expectancy. Total life expectancy at any age is the sum of two parts: healthy life expectancy and unhealthy life expectancy. While the concept of health life expectancy was introduced in the 1960s (Sanders 1964) and developed in the 1970s (Sullivan 1971a, 1971b), it has only become widely adapted by governments and international organizations in the 1990s.

Interest in healthy life expectancy has grown recently as people have recognized that gains in total life expectancy today may not mean the same thing as in the past. Past gains in life expectancy came about largely because fewer people died of infectious diseases, either because they did not get the diseases or they received treatment that prevented death. People thus saved from death were generally free of the disease. Under these circumstances gains in life expectancy were accompanied by better health in the population surviving. Now, with gains in life expectancy being made because of declining death rates from chronic diseases especially among the old, it is not clear that the surviving population is a healthier population. This is because generally there is no cure for the chronic diseases, and for many their onset has not yet been prevented. People may be saved from death but they live with disease. This is the basis for questioning whether the additions to life expectancy are healthy or unhealthy years.

Crimmins and colleagues (1997) estimated that healthy life expectancy or disability-free life expectancy at birth in the United States in 1990 was 58.8 years for men and 63.9 years for women. The difference between blacks and whites in disability-free life expectancy at birth was even greater than the difference in total life expectancy. In 1990 black disability-free life expectancy for males at age 20 was 37.9 years while that for whites was 45.8 years (Hayward and Heron 1999). Studies that addressed the issue of changes in healthy life expectancy for the 1970 and 1980 period generally found that when *healthy life* was defined as nondisabled life, active life expectancy had not increased (Wilkins and Adams 1983; Crimmins et al. 1989). More recent studies have found increases in active

life expectancy (Crimmins et al. 1997; Robine and Mormiche 1994).

Healthy life expectancy can be defined in many ways. Examples include average length of life free from a disability that causes a person to alter his or her normal activity; average length of life free of dependency on others for the performance of basic activities necessary to living, such as eating, bathing, and getting in and out of bed; and average length of life without disease (Bebbington 1988; Colvez et al. 1986; Crimmins et al. 1997; Crimmins et al. 1994; Rogers et al. 1989). Some measures of healthy life combine multiple indicators of health using weights; for instance, the U.S. National Center for Health Statistics measure combines self-assessed health and disability in its indicator of healthy life (Erickson et al. 1995).

There are multiple methodological approaches to estimating health expectancy. Most can be described under one of two headings: the Sullivan method or the multistate method (Sullivan 1971a; Schoen 1988). Microsimulation techniques have also been employed recently (Laditka and Wolf 1998).

LIFE HISTORIES AND NARRATIVES

The life history approach to social research and theory subsumes several methodological techniques and types of data. These include case studies, interviews, use of documents (letters, diaries, archival records), oral histories, and various kinds of narratives. The popularity of this approach has waxed and waned since the early 1900s. It was used extensively in the 1920s and 1930s and was identified with the Chicago sociology of W. I. Thomas, Robert Park, Clifford Shaw, and others. The succeeding generation of sociology witnessed the solidification of quantitative measurement techniques coupled with survey data collection, and the increased use of those approaches paralleled a relative decline in life history research. In the 1970s, however, there began a resurgence of interest in life history research not only in the United States but in Europe. The work of some sociologists, such as Howard S. Becker and Anselm Strauss, has maintained the early Chicago tradition, while newer generations of scholars—such as Norman Denzin and Michal McCall (United States), Ken Plummer (England), Daniel Bertaux (France), and Fritz Schütze (Germany)—have augmented life history research. This resurgence has been accompanied by the creation of Research Committee 38 (Biography and Society) of the International Sociological

Association in the late 1970s and has included a broadened interdisciplinary base through the incorporation of narrative theory and methods from other disciplines. In this broadened use there has been a transition from using the approach as purely a methodological device to using it as method, theory, and substance. It is this transition that frames this article.

The main assumptions of this approach are that the actions of individuals and groups are simultaneously emergent and structured and that individual and group perspectives must be included in the data used for analysis. Accordingly, any materials that reveal those perspectives can and should be regarded as essential to the empirical study of human social life. Life history materials, as described above (see Denzin 1989b, chap. 8; Plummer 1983, chap. 2; Gottschalk et al. 1945), contain first-, second-, and third-order accounts of past actions, as well as plans and expectations regarding future actions. Those materials will reveal significant information concerning the author's (writer and speaker) meanings. Invariably, these materials pertain also to the processual character of social life, and thus there is a major emphasis on temporal properties such as sequence, duration, and tempo. These assumptions and emphases have been characteristic of the vast majority of life history studies.

The first major empirical study in American sociology that systematically combined explicit theory and method was Thomas and Znaniecki's *The Polish Peasant in Europe and America* (1918–1920). The purpose of these researchers was to investigate Polish immigrants in America, especially their problems in adjusting to American urban life. The researchers used their famous attitude-value scheme as an explanatory framework. In this scheme, *attitudes* referred to individual subjective meanings and *values* to objective societal conditions. Thomas and Znaniecki proposed a set of causal explanations based on how the relations of attitudes and values were interpreted by individuals and groups. In their five-volume, 2,200-page work, they presented almost 800 pages of life history data in support of their conclusions and generalizations. The data included newspaper articles, letters to family members, records from courts and social work agencies, and a 300-page biography of one person that was presented as a representative case (Blumer 1939).

This research, which the Social Science Research Council in 1938 voted as the most outstanding in sociology to that date, depended solely on life history data. Because of its systematic incorporation of theory and method, it stimulated and became an exemplar for a long series of similar studies. These included research on race relations, delinquency, housing, mass media, migration, occupations, and other issues centered primarily in the areas of ethnic and urban studies (Bulmer 1984). The emphasis during this period was on the contributions of life history methods to sociology as an empirical and scientific discipline. Accordingly, researchers using this approach focused on methodological problems such as reliability, validity, hypothesis formation, and the making of generalizations, although comparatively less concern was given to sampling (Gottschalk et al. 1945). Reflecting the major issue of pre-World War II sociological work, the focus was on the adequacy of this approach for discovering lawlike behavior or empirically valid generalizations. The emphasis, in short, was on the approach as a research tool.

The developments in this approach since the early 1970s, perhaps stimulated in part by increased interest in historical sociology and in part by the articulation of insoluble problems in statistical approaches, have been more interdisciplinary, international, and sophisticated than the early works (McCall and Wittner 1990; Jones 1983; Roth 1987). It is increasingly recognized that all social science data, whether represented in discursive or numeric form, are interpretations (Denzin 1989a; Gephart 1988). This recognition is one of the central tenets of the narrative approach to social research (Fisher 1987; Reed 1989; Richardson 1990; Maines 1993), which makes the ontological claim that human beings are inherently storytellers. This shift in emphasis concerning the subject matter of sociology, in which human behavior is conceptualized as significantly communicative and narrative in nature, is precisely what has reframed the utility and potential of the life history approach.

Current uses of life history research display considerable variation as well as more precise conceptual distinctions. Terms such as *life story*, *biography*, *discourse*, *history*, *oral history*, *personal experience narratives*, *collective narratives*, and *sagas* are now distinguished from one another (Denzin 1989b, pp. 184–187), and frameworks for linking types of verbal accounts to types of generalizations

have been developed (Sperber 1985, pp. 9–34). Moreover, these developments have occurred within and across different theoretical approaches and disciplines.

It is now common to regard life histories as a legitimate form of data in which currency is established through the propositions contained in narrative theory. Some of the uses found in contemporary work include the following. Schütze (1983) has developed what he calls the narrative interview. This approach focuses on establishing event sequences across the life course on the basis of interview data. These sequences are derived from detailed analyses of biographical materials, with special attention to the structural factors that have shaped the person's life. Analytical summaries are developed and, through analytical inductive procedures, are compared to subsequently developed summaries. The goal is to produce theoretical interpretations centering on various analytical interests such as life course transitions, career models, or natural histories. Riemann and Schütze (1991) provide a substantive application of this method in the area of chronic illness.

Bertaux (1981; Bertaux and Kohli 1984) has long been an advocate of life history research and was the primary organizer of the Biography and Society Section of the International Sociological Association. He has conducted a number of projects that have goals similar to those of Schütze. His collaborative research on social movements (1990), for example, used life history data from members of students movements in the United States, England, Ireland, Italy, West Germany, and France. There he shows the application of the method in large-scale comparative research projects. The epistemological approach was not to gather data on lived, biographical experiences of the activists but to analyze those data in collective, generic terms. That is, his strategy was to focus on similarities rather than differences across nations and to ground empirically theoretical statements about, for example, processes of commitment to social-movement ideologies. The contention of this research is that biographical and life history data from ordinary people will reveal those similarities and thus make contributions to cross-national research.

Dolby-Stahl (1989), a folklorist, has developed a variation of the life history approach. She calls it

literary folkloristics, and it focuses on personal narrative data. She uses reader response theory to develop an interpretive method for studying the interdependence of personal narratives (stories) and collective narratives (e.g., ethnic group folklore). Her procedures entail locating the respondent (storyteller) in large collectivities (e.g., single parents), identifying salient themes (e.g., day care), and connecting personal to collective narratives (e.g., the respondent's accounts of day care and media or community accounts). The assumption of this approach is that personal and collective narratives are inherently connected, and thus a personal story is always in some way a collective story. Further, the assumption that the researcher in varying ways is part of the collective story requires facing the interpretive nature of data collection. In this respect, the researcher draws on her own shared cultural experiences to analyze the life history or narrative data provided by the respondent. These procedures locate the life history approach squarely in interpretive social theory, in which credible interpretation is the goal as opposed to, say, producing explanations justified by measures of reliability and validity.

Similarly, Denzin (1989a) has developed an interpretive approach that draws conceptually from postmodernism and phenomenology, and methodologically from Clifford Geertz's advocacy of thick description. He calls his method *interpretive biography*, and it is designed to study the turning points of problematic situations in which people find themselves during transition periods. Data include documents, obituaries, life histories, and personal experience stories, with the emphasis on how such information is read and used. The basic question he asks concerns how people live and give meaning to their lives, and how meaning is represented in written, narrative, and oral forms. His approach thus addresses an enduring problem in sociology, which C. Wright Mills located at the intersection of biography and history, as well as the newer problem articulated by interpretive theories regarding the interpretations of texts, cultural forms, and personal acts.

Most of the developments in the 1990s continue to be flamed largely under the rubric of narrative inquiry, signified by the 1991 inception of the *Journal of Narrative and Life History*. These recent lines of work can be organized loosely into four categories. First, there have been a considerable

increase in substantive studies. Ezzy (1998) joins a rather large number of scholars (e.g., Angrosino 1995) studying narrative identity, which Orbuch (1997) moves more generically into the arena of accounts. Gubrium (1993) uses narrative data in his examination of quality of life among nursing home residents. Plummer (1995) uses similar data to study sexuality. Maines and Bridger (1992) studied the narrative character of land-use decisions. Randall (1999) has studied the narrative aspects of intelligence. Eheart and Power (1995) assess processes of success and failure in families with adopted children. Maines (1999) has provided data about how racial attitudes about justice are embedded in larger narrative structures. TenHouten (1999) has used life history interviews in a comparative analysis of temporality among Australian aborigines and Europeans.

These substantive topics overlap with the second line of work pertaining to historical sociology. Barry Schwartz (1996, 1997) has rekindled sociological interest in collective memory to show how historical processes contribute to changing cultural representations (see also Wertsch and O'Conner 1994). Another strand of work has pertained to causal analysis. Abbott (1992) articulated his version as *narrative positivism* which focuses on the properties of events and sequence to move quantitative sociology from the study of variables to the study of actual events. Griffin (1993) uses data on lynchings to propose a similar approach, utilizing computer-assisted event structure analysis that focuses directly on temporality. Gotham and Staples (1996) follow these studies with a theoretical analysis of narrative in the relations of agency and social structure, as does Berger (1995) in his analysis of Jewish Holocaust survivors. Mahoney (1999) addresses nominal, ordinal, and narrative dimensions of causal analysis, noting that "narrative analysis has the obvious strength of allowing the analyst to show sensitivity to detail, process, conjuncture, and causal complexity" (p. 1168).

The third area concerns methods of data collection and analysis. Holstein and Gubrium (1995) treat the interview as a social encounter that itself constructs the data gathered. In these encounters, respondents are regarded as narrators who tell the story of their "own past attitudes, feelings, and behaviors" (p. 32). McMahan and Rogers (1994) likewise present oral history interviewing as an interactive, negotiated process. They synthesize a

large amount of materials about potential biases, and make concrete suggestions for developing skills to deal with them. On the other hand, Lieblich and associates (1998) present a model for analyzing life story data. Their model is composed of two continua: holistic versus categorical (whether a life story is taken as a whole or dissected into parts or categories) and content versus form (analysis of the substance or structure of life story accounts). This model is suggested as useful for guiding analyses for varying purposes. Mishler (1995) also addresses the diversity of narrative inquiry, and proposes a typology of narrative analyses. These include modes of analysis that focus on (1) the correspondence between temporal sequences of actual events and their textual representation, (2) how types of stories acquire structure and coherence, and (3) the content and function of stories. This typology organizes a large literature on narrative, and serves as a heuristic for discerning similarities and differences in analytical approaches and purposes. Finally, Atkinson (1998) describes procedures for the life story interview, whose "product is entirely a first-person narrative, with the researcher removed as much as possible from the text" (p. 2). These procedures would encourage respondents to see and tell their lives as a whole, and Atkinson has developed a growing archival data base of over 300 documents suitable for various analytical purposes.

The life story interview merges with the fourth line of work, which focuses on biographies and autobiographies. Smith (1994) provides an excellent overview of biographical methods. He begins with Charles Darwin's biography and brings the reader to contemporary issues that cut across various disciplines in the human sciences. In doing so, he emphasizes that biographical analysis remains an unfinished project that is filled with both conflict and creativity. Inside that space of conflict and creativity rests the new genre of *auto-ethnography*, or literally the study of oneself. Bochner and Ellis (1992) provide one of the more interesting instances of this approach. Each author was involved in the same first-time event. Wanting to fully explore the meaning of that event, they first wrote extensive personal accounts of it. Second, they shared those accounts with one another and with friends; and third, they wrote a joint account from the standpoint of their relationship. Through these procedures, they were able to preserve their own

biographical perspectives on the event as well as depicting its intersubjective, consensual meanings.

The auto-ethnography stimulates attention to writing as a way of knowing, which is an issue widely discussed in the last decade among narrative scholars. Richardson (1994) discusses an array of issues pertaining to writing as inquiry, and then provides a detailed autobiographical account of how context affects writing (Richardson 1997). Her account includes her family, academic departments, networks of colleagues, and students, and shows how her relationships and experiences with these people were part and parcel of how and what she wrote as a professional sociologist. Her writing, she shows, was intimately tied to constructions of knowledge.

While Richardson and others illustrate what Polkinghorne (1988) has termed "narrative knowing" Diane Bjorklund (1998) treats autobiographies as sociological subject matter. She analyzed a sample of the 11,000 American autobiographies written from 1800 to 1980 to provide a historical analysis of representations of the self. She shows how social conventions and vocabularies for describing oneself have changed through four discernible eras of American history. By taking autobiographies seriously, this analysis powerfully locates the "texts" of personhood in cultural and social structural contexts.

Scholars working in the area of life history research accept that all social science data are made up of human interpretations and that nearly all such data are reconstructions or representations of past events and experiences. Because of its development of techniques for gathering, coding, and analyzing explicitly reconstructive data, the life history approach is suitable for studying not only the subjective phases of social life but the historical and structural aspects as well. It can be used for a wide variety of topics and purposes, ranging from research on the trajectories of personal biographies to organizational functioning to migration patterns. It invariably leads to development of theories emphasizing social processes. Recent scholarship on narrative has shown three dominant and related trends. The first, which represents an extension of the life history research of the 1920s, pertains to the linking of collective and personal narratives. The second, a departure from the earlier work, recognizes scholars as active

narrators themselves and thus creators of narrative knowing. The third trend is the broad appeal of this area of work. It is found in all disciplines of the human sciences, it uses a wide variety of theoretical approaches, and it incorporates the array of analytical methods typical of sociological work found among American and European scholars.

LIFE TABLES

See Demography; Life Expectancy.

LIFESTYLES AND HEALTH

Lifestyles are a major determinant of who shall live and who shall die (Fuchs 1974; McKinlay and Marceau 1999). Mechanic (1978, p. 164) argues that the concept of lifestyles refers to a diverse set of variables, including nutrition, housing, health attitudes and beliefs, risk-taking behavior, health behavior and habits, and preventive health behavior.

CONFIRMING THE LINK BETWEEN LIFESTYLES AND HEALTH

Establishing the causal linkage between lifestyles and health is not a simple task. Variables included in lifestyles interact with each other (Mechanic 1978), making it difficult to adjust for confounding variables such as race and ethnicity, gender, social class, and psychological distress.

In addition, there are problems in specifying the nature of the etiological relationship between lifestyles and disease. Not every person who engages in an unhealthy lifestyle will die prematurely. For example, some heavy smokers do not develop lung cancer. Genetic predisposition, comorbidities, other health habits, and access to adequate medical care are factors that may intervene in the relationship between host and disease. For certain conditions, it may be complicated to determine the precise role of risky lifestyle behaviors in the development of disease.

The most convincing models of the relationship between lifestyles and health are those built on triangulated evidence from animal, clinical, and epidemiological studies. As an example, consider the link between tobacco use and cancer. In controlled randomized trials using animal subjects that are genetically the same, the experimental group of animals is exposed to tobacco smoke while the control group is not. If the experimental group has a higher incidence of cancer than the control group, the study provides evidence to link tobacco smoke to cancer. Another strategy to link lifestyle behavior to health involves clinical studies with human subjects. Lung tissue of smokers is compared with lung tissue of nonsmokers. If more smokers than nonsmokers have cancerous cells in the lung tissue, this provides additional data to confirm that smoking causes lung cancer. A final strategy uses epidemiological methods. In prospective studies, separate groups of smokers and nonsmokers are followed over time to ascertain the risk of developing cancer within each group. All else being equal, if smokers develop more cases of cancer, the causal relationship between smoking and cancer is confirmed.

With these methodological issues in mind, four selected behaviors are used below to illustrate how lifestyles impact on health: tobacco use, alcohol consumption, diet, and sexual behavior and injection-related practices that increase the risk of acquiring the human immunodeficiency virus (HIV). For each behavior, extensive animal, clinical, and epidemiological data exist to support the causal relationship between each agent and disease. Gender differences in these behaviors are used to illustrate how lifestyles vary across social groups. Men are more likely to engage in these risky behaviors compared to women; this helps explain why women live longer than men do (Croese 1997). Finally, examples of successful efforts to change risky life-style behaviors are provided.

TOBACCO USE

Tobacco use has been defined as the most important single preventable cause of death and disease in society. Smoking causes an average of 430,700 deaths per year in the United States. One in every five deaths is smoking related (Centers for Disease Control and Prevention 1997a).

Careful epidemiological studies have determined that tobacco use increases the risks for heart disease, lung cancer, emphysema, and other lung diseases. Smoking during pregnancy increases the risk for premature births, complications of pregnancy, low-birthweight infants, stillbirths, and infant mortality. Fetuses exposed to smoke in utero and young infants exposed to secondhand smoke are at increased risk for sudden infant death syndrome, poor lung development, asthma, and respiratory infections (Centers for Disease Control and Prevention 1997b; Environmental Protection Agency 1992; Floyd et al. 1993). Secondhand smoke is also associated with adult illnesses (Centers for Disease Control and Prevention 1997a). Increased risks for lung cancer and heart disease are reported for nonsmokers who live with smokers.

Age-adjusted rates indicate that 27 percent of men smoked in 1995, compared to 23 percent of women (National Center for Health Statistics 1998). The gender gap used to be wider. In 1965, men were 1.5 times more likely to smoke than women were. Today, the gender difference is only 17 percent. The decline in cigarette smoking has been greater among men. While the prevalence of smoking among men dropped by almost half from 1965 to 1995, the rate for women dropped by only one-third. Traditionally, smoking by women was not condoned, but over time these attitudes have changed. As a result, the smoking rates for men and women are nearly the same. This translates into a 400 percent increase in deaths from lung cancer among women between 1960 and 1990 (Centers for Disease Control and Prevention 1997a).

Various prevention efforts have reduced the prevalence of smoking in the United States. Smokefree workplaces are the norm rather than the exception. Warning labels appear on cigarette packages, and billboards advertising cigarettes are banned. Community-based public education campaigns and worksite programs have been successful in smoking reduction (COMMIT Research Group 1995).

ALCOHOL

The National Institute on Alcohol Abuse and Alcoholism (NIAAA 1997) estimates that alcohol use is

responsible for 100,000 deaths in year in this country. About 44 percent of the motor vehicle fatalities in 1994 were alcohol related (National Highway Traffic Safety Administration 1994). Alcohol use is frequently implicated in accidental injuries and deaths from falls, drowning, interpersonal and family violence, occupational hazards, and fires (NIAAA 1997).

From 10 to 20 percent of heavy drinkers develop cirrhosis of the liver, which was the tenth leading cause of death in the United States in 1996 (DeBakey et al. 1995; National Center for Health Statistics 1998). The liver is the primary site of alcohol metabolism, and drinkers are at risk for other forms of liver disease, including alcoholic hepatitis and cancer.

Heavy alcohol use causes loss in heart muscle contractile function, arrhythmias, degenerative disease of the heart muscle, and heart enlargement, and also increases the risk for hypertension and stroke. Alcohol is implicated in esophageal, breast, and colorectal cancer, and it may increase the risk for other types of cancer as well. NIAAA concludes, "The range of medical consequences of alcohol abuse is both immense and complex—virtually no part of the body is spared the effects of excessive alcohol consumption" (1990, p. 127).

Alcohol also functions as a teratogen, producing defects in the human fetus in utero. The possible effects of alcohol on the fetus include gross morphological defects as well as cognitive and behavioral dysfunctions. Alcohol ingestion during pregnancy causes a variety of birth defects, including fetal alcohol syndrome, alcohol-related birth defects, and alcohol-related neurodevelopmental disorder. Fetal alcohol syndrome is the most severe consequence of the mother's heavy drinking during pregnancy and is characterized by craniofacial anomalies, mental retardation, central nervous system dysfunction, and growth retardation. Fetal alcohol syndrome is one of the leading causes of preventable birth defects (Stratton et al. 1996).

Men are more likely to drink alcohol than women are. Twenty-two percent of men are lifetime abstainers from alcohol, versus 45 percent of women. About 56 percent of men are current drinkers, compared to 34 percent of women. Heavy drinking is gender related. Almost 12 percent of

men average more than fourteen alcoholic drinks per week, compared to less than 4 percent of women (NIAAA 1998).

Various prevention efforts are directed toward decreasing alcohol consumption. The alcohol beverage warning label, implemented in 1989, warns drinkers about birth defects, drunk driving, operating machinery, and health problems; however, its impact has been modest. Other alcohol prevention programs have been implemented, including dram shop liability (servers are legally responsible for damage or injury caused by drunk patrons), training servers of alcohol to avoid selling to intoxicated persons and to minors, lowering the allowable blood alcohol concentration levels for drivers, changing the availability of alcohol, enforcing impaired driving laws, and designating one person in a car as the nondrinking driver. These community intervention programs have reduced alcohol-related traffic deaths significantly (NIAAA 1997).

DIET

Dietary factors have been linked to mortality from cardiovascular disease (heart disease and stroke) and cancer; these diseases are the leading causes of death in the United States. Diet affects four of the major risk factors for cardiovascular disease: hypertension, obesity, diabetes, and high cholesterol. Obesity, as well as diets high in saturated fats, trans fatty acids, and cholesterol, raise blood cholesterol concentration and blood pressure, thus increasing the risk for coronary heart disease and stroke. Diets low in saturated fats but high in fiber and some omega-3 fatty acids (found in walnuts, certain oils [fish, canola, soybean], and green leafy vegetables) lower the risk for heart disease (Hu et al. 1997; Ascherio et al. 1996).

Diet also affects cancer risk. While the link between dietary intake and breast cancer is controversial, there is evidence that a diet high in saturated fat plays an etiological role (Kolonel 1997; Hankin 1993). High fat intake increases the risk for prostate cancer, lung cancer, and colorectal cancer (Kolonel 1997). On the other hand, diets high in fruits, vegetables, and fiber lower the probability of developing various types of cancer, including breast, colorectal, stomach, and lung (Ziegler 1991; Hankin 1993).

Gender differences in diet and obesity exist. For example, women are more likely to be overweight compared to men (39 percent versus 36 percent). Among the poor, the gender gap is larger: 46 percent of poor women versus 31 percent of poor men suffer from obesity (National Center for Health Statistics 1998). Despite this increased risk for obesity, women consume healthier food than men do. While men consume more meat, saturated fat, and high-calorie foods, women eat more fruits, vegetables, whole grains, and lower-calorie foods (Croese 1997). Successful programs have been developed to encourage healthier eating habits for men and women, including interventions in worksites and families (Sorensen et al. 1999). The public has responded to these efforts, as evidenced by a 4 percent drop in blood cholesterol levels from 1978 to 1990 (National Heart, Lung, and Blood Institute 1996).

SEXUAL AND INJECTION-RELATED PRACTICES

The human immunodeficiency virus (HIV) causes acquired immune deficiency syndrome (AIDS), the eighth leading cause of death in the United States in 1996 (Peters et al. 1998). HIV is transmitted through blood products, bodily fluids, and breast milk. Transmission of HIV can be prevented by the use of safe sexual practices and sterile needles.

There are clear gender differences in the way AIDS is contracted, and the infection rate among women has been rising. Forty-eight percent of AIDS patients acquire the disease through male homosexual contact. Another 10 percent of AIDS cases appear in men who have sexual relations with a male or female partner and also use intravenous drugs. Almost 26 percent become ill solely through infected needles, and 6 percent through heterosexual contact that was not related to intravenous drug use. Among women, the most common route of infection is intravenous drug use (by herself or her partner), 60 percent or unprotected sex with an infected partner, 22 percent (Centers for Disease Control and Prevention 1998a).

While some HIV prevention programs promote abstention from sex and cessation of drug injecting, most programs define harm reduction

as the goal (Kelly 1999). This policy promotes using condoms correctly on a consistent basis, having sex with uninfected partners, and cleaning needles with bleach or exchanging contaminated syringes for sterile ones.

Programs designed to decrease (1) the rate of unprotected anal sex among men who have sex with men and (2) the proportion of men having unprotected sex with multiple male partners contributed to the reduction in AIDS cases among homosexuals during the 1980s and early 1990s. However, 1997 data suggest that unprotected anal sex among gay men and unprotected sex with multiple partners is increasing, especially among younger gay men (Centers for Disease Control and Prevention 1999).

The second major mode of HIV transmission, especially among women, is by infected needles. Syringe exchange programs or the use of bleach to clean syringes prevent the spread of HIV among injecting-drug users. The number of syringe exchange programs has grown rapidly; 17.5 million needles were exchanged in 100 programs in 1997 (Centers for Disease Control and Prevention 1998b). Other communities have distributed bleach kits that reduce the spread of HIV (CDC AIDS Community Demonstration Projects Research Group 1999).

DISCUSSION

Four examples were selected to illustrate the role of lifestyles and health. There are other lifestyles that are related to health, which are beyond the scope of this article. For example, stressful lifestyles have been linked to mental illness, gastrointestinal illness, and heart disease. Regular use of seatbelts reduces the likelihood of death or injury in automobile accidents. Proper dental hygiene decreases the rate of dental caries. Childhood immunizations prevent measles, mumps, and polio.

When discussing lifestyles and health, several unresolved issues remain. First, the role of lifestyles in health is still evolving. As Becker (1993) argues, what is said to be bad for us one day may be determined to be good for us the next (and vice versa). For example, while researchers have documented the deleterious effects of alcohol on health, there is some recent evidence that red wine consumption may lower cholesterol levels (NIAAA 1997).

Second, there is continuing debate about the pros and cons of changing an individual's lifestyle versus changing the social milieu (Kelly 1999). Should we invest in programs designed to encourage an individual to stop smoking? Is it better to develop strategies that change societal norms about the acceptability of smoking? Should we do both?

Third, policy makers note that healthy lifestyle programs must be tailored to the individual, the subgroup (gender, age, race or ethnicity, and social class) and the particular community at risk (Kelly 1999). Thus, designing successful interventions to alter lifestyles is challenging.

Finally, it must be emphasized that while a healthy lifestyle may be a necessary condition for longevity; it is not a sufficient condition. Many variables interact with lifestyles to protect against disease and death. For example, evidence is mounting that genetic predispositions are very important in the etiology of certain diseases. Thus, the models predicting who shall live and who shall die involve complicated interactions of lifestyles, preventive health behavior, genetic risk, sociodemographic characteristics, and so on. Nonetheless, individuals who abstain from smoking and injecting drugs, drink alcohol in moderation, reduce the intake of saturated fat and cholesterol, and use safe sex practices have a better chance of survival than those who eat and drink excessively and do not follow recommended safe sex practices.

LITERATURE AND SOCIETY

Interest in the relationship between literature and society is hardly a new phenomenon. We still read and refer to the ancient Greeks in this regard. In *The Republic*, for example, Plato presages both Mme. de Staël's treatise of 1800, which was the first to discuss cross-national differences in literature, and later notions of literary reflection with his idea of imitation. What is new, however, is the relative legitimacy of the study of literature within the discipline of sociology. This is due both to the increasing interest in culture in sociology after years of marginalization (Calhoun 1989) and to the increasing influence of cultural studies on sociology and throughout the academy.

A broader interest in and acceptance of cultural sociology has meant that the types of research questions and methods common to sociological studies of literature are now more widely accepted within the field. Sociology has extended its methodological boundaries in response to both attacks on the dominance of positivism and the rising power of alternative stances suggested by postmodernism. At the same time, changes in the goals, and sometimes the methods, of studying literature sociologically have moved the area closer to what is still the mainstream of the discipline. Thus the sociology of literature has benefited from a twofold movement in which (1) sociology as a discipline has become more interested in and accepting of research questions pertaining to meaning (cf. Wuthnow 1987, however, for a particularly strong attack on meaning from within the culture camp) and employing qualitative methods; and (2) the sociology of literature has evolved in the direction of more mainstream sociological areas through the merging of quantitative with qualitative methods and of empirical with hermeneutic research questions.

TRADITIONAL APPROACHES

As recently as 1993, Wendy Griswold maintained that the sociology of literature was a "nonfield" and "like an amoeba . . . lack[ing] firm structure" (1993, p. 455). Certainly the sociology of literature has been a marginal area in the discipline of sociology. As such, it has generally failed to attract the kind of career-long commitments common to

more central areas of the discipline. Many scholars writing on the sociology of literature see the area as a sideline and produce only a single book or article on the subject. This has exacerbated the lack of structure in the development of the field. Even so, it is surprising just how much sociological research has been done on literature and on literature's relationship to social patterns and processes.

Reflection Theory. Traditionally, the central perspective for sociologists studying literature has been the use of literature as information about society. To a much lesser degree, traditional work has focused on the effect of literature in shaping and creating social action. The former approach, the idea that literature can be "read" as information about social behavior and values, is generally referred to as *reflection theory*. Literary texts have been variously described as reflecting the "economics, family relationships, climate and landscapes, attitudes, morals, races, social classes, political events, wars, [and] religion" of the society that produced the texts (Albrecht 1954, p. 426). Most people are familiar with an at least implicit reflection perspective from journalistic social commentary. For instance, when *Time* magazine put the star of the television show *Ally McBeal* on its cover, asking "Is Feminism Dead?" (1998), it assumed that a television show could be read as information on Americans' values and understanding of feminism.

Unfortunately, "reflection" is a metaphor, not a theory. The basic idea behind reflection, that the social context of a cultural work affects the cultural work, is obvious and fundamental to a sociological study of literature. But the metaphor of reflection is misleading. Reflection assumes a simple mimetic theory of literature in which literary works transparently and unproblematically document the social world for the reader. In fact, however, literature is a construct of language; its experience is symbolic and mediating rather than direct. Literary realism in particular "effaces its own status as a sign" (Eagleton 1983, p. 136; see also Candido [1995, p. 149] on the "liberty" of even naturalist authors). Literature draws on the social world, but it does so selectively, magnifying some aspects of reality, misspecifying others, and ignoring most (Desan et al. 1989). The reflection metaphor assumes a single and stable meaning for literary texts. Anyone who has ever argued about what a book "really" meant knows what researchers have worked hard to demonstrate—textual meaning is contingent,

created by active readers with their own expectations and life experiences that act in concert with inherent textual features to produce variable meanings (Jauss 1982; Radway 1984; Griswold 1987).

Despite repeated demonstrations of reflection's myriad failings (e.g., Noble 1976; Griswold 1994; Corse 1997), the idea of literature as a mirror of society still seems a fundamental way of thinking about why sociologists—and indeed many other people as well—are interested in literature. A relatively crude reflection approach remains common for teaching sociology department courses on literature, and also in certain types of journal articles whose main interest is not the sociology of literature *per se*, but the illumination of some sociological theory or observation through literary “evidence” (e.g., Corbett's article [1994] advocating the use of novels featuring probation officers to teach courses on the sociology of occupations, or the continuing stream of articles examining gender portrayals in children's literature [e.g., Grauerholz and Pescosolido 1989]). Convincing research arguing for literary evidence of social patterns now requires the careful specification of how and why certain social patterns are incorporated in literature while others are not (e.g., Lamont 1995), thorough attention to comparative data across either place or time (e.g., Long 1985), and a detailed consideration of the processes that transform the social into the literary (e.g., Corse 1997).

Structural Reflection. A more sophisticated but still problematic type of reflection argues that it is the form or structure of literary works rather than their content that incorporates the social: “successful works . . . are those in which the form exemplifies the nature of the social phenomenon that furnishes the matter of the fiction” (Candido 1995, p. xiii). The “humanist” Marxist Georg Lukács is perhaps the seminal figure in the development of a Marxist literary sociology. Marxism is the only one of the three major strands of classical theory to have generated a significant body of work on literature. Lukács (1971) argued that it is not the content of literary works but the categories of thought within them that reflect the author's social world.

Goldmann (1964, 1970), Lukács's most prominent student and the one most influential for American sociology, proposed the concept of a

homologous relationship between the inherent structure of literary works and the key structures of the social context of the author. Goldmann justified his focus on the canonical works he studied by arguing that lesser works fail to achieve the necessary clarity of structure that allows the sociologist to see the homologies present in works by, for example, Racine and Pascal (1964). In the 1960s Louis Althusser challenged the preeminence of Lukács's tradition through, in part, his emphasis on the autonomy of literature. Thus Goldmann's work, though it was influential at the time of its publication, has been eclipsed as newer theories have made more problematic the notion that literature embodies a single meaning that is reducible to an expression of class consciousness.

The High Culture/Popular Culture Divide.

Traditionally in the United States sociologists have left the study of high culture to specialists in literature, art, and music. This attitude was partially a product of sociologists' discomfort with aesthetic evaluation. Popular culture, on the other hand, was seen as simply unworthy of attention or study. To the extent that sociologists did consider literature, they tended to focus on high-culture literature, in part because of the largely Marxist orientation of many early sociologists of literature. Marxist thought defines literature as part of the ideological superstructure within which the literatures of elites are the ruling ideas since culture serves to legitimate the interests of the ruling class.

The tendency to concentrate on high-culture literature was intensified by the Frankfurt School, which understood “mass” culture as a destructive force, imposed on a passive audience by the machinery of a capitalist culture “industry” (e.g., Horkheimer and Adorno 1972). Lowenthal's ([1961] 1968) analysis of popular magazine biography, for example, stressed the increasing focus on leisure-time consumption over production and on personality over business and political achievement, as the private lives of movie stars and sports figures came to dominate magazine biographies. This approach highlighted the passivity and docility of audiences, tying mass culture to the increasing apathy of the public. Thus this work saw literature both as a reflection of changing social patterns and as a force shaping those patterns. Although researchers now rarely use the term “mass” culture, the Frankfurt School's critique continues to inform much of current cultural sociology, although

often it does so on an implicit level as researchers react either positively or negatively to this understanding of popular culture.

One response to the critique of mass culture was articulated by the scholars of the Birmingham School. This line of research shared earlier understandings of culture as a resource for the powerful, but focused in large part on the potential for active participation on the part of cultural receivers. Work in the Birmingham School tradition drew heavily on feminist approaches and demonstrated how “mass” audiences of popular cultural forms might engage in resistance, undermining earlier arguments of cultural hegemony and of passive cultural “dopes” (e.g., Hall et al. 1980; Hebdige 1979). This interest in resistance and the meaning-making activity of readers remains an important line of research, particularly for studies of popular culture (e.g., Radway 1984). The continued relevance of the distinction between high and popular culture, however, is now under debate, as some charge that the hierarchical dichotomy is no longer the most powerful conceptualization of cultural differences (e.g., Crane 1992; DiMaggio 1987).

Sociology through Literature. A final type of traditional sociological interest in literature also stems from an implicit reflectionist approach. This type of work sees literature as exemplary of sociological concepts and theories or uses literature simply as a type of data like any other. While Coser’s (1972) anthology exemplifies the former tradition, the recent ASA publication *Teaching Sociology with Fiction* demonstrates the persistence of the genre. Examples of the latter are altogether too numerous, including, for example, an article testing recent Afrocentric and feminist claims of differing epistemological stances across genders and races by coding differences in the grounding of knowledge in novels for adolescent readers (Clark and Morris 1995). Such work ignores ignoring the mediated nature of literary “reality.” These discussions, although common, are not properly part of the sociology of literature.

SOCIOLOGICAL ADVANCES

The 1980s saw the institutionalization of sociological studies of cultural objects and processes as most prominently indicated by the establishment

of the Culture Section of the American Sociological Association (ASA)—now one of the largest sections of the ASA with over one thousand members. This groundswell of interest in culture did not produce an equally large increase in interest in the sociology of literature, but it certainly created a more favorable climate for such work, as well as reenergizing research within the field.

Wendy Griswold is the key figure in the contemporary sociological study of literature in the United States. Her early research (1981, 1983, 1987) set the stage for a new synthesis that both takes seriously the issue of literary meaning and recognizes the importance of extratextual variables, while deploying the empirical data demanded by much of the discipline. By balancing these often-competing claims, Griswold allows for a study of literature that is sociological in the deepest sense of the word. Her concern for what she has called a “provisional, provincial positivism” (1990, p. 1580) has legitimated the sociology of literature to other sociologists and has articulated to nonsociologists the unique power of literary sociology. By publishing repeatedly in *American Journal of Sociology* and in *American Sociological Review*, Griswold made the sociology of literature visible to an extent previously unknown.

Griswold’s work (1981) began with a critique of reflection theory’s exclusive focus on “deep” meaning, demonstrating the importance of production variables such as copyright legislation for explaining the diversity of books available in a market. A second project (1983, 1986) investigated the determinants of cultural revival, arguing that Elizabethan plays are revived most frequently when the social conditions of the day resonate with those the plays originally addressed. In 1987, Griswold published the results of a third project centrally located in the new reception of culture approach. This innovative work used published reviews as data on reception, thus allowing Griswold (1987) to address reception across time and across three very diverse audiences—an impossible strategy in the first instance and a prohibitively expensive strategy in the second when using interviews to gather data on audience interpretation. The 1990s saw Griswold (1992) beginning a large-scale project on the literary world of Nigeria, a project that returned Griswold to her initial interest in nationalism and literature among other concerns.

Griswold's impact on the sociology of literature has been powerful because she has systematically developed a methodological approach to studying literature and other cultural products and because her substantive research integrates a concern for meaning and the unique properties inherent in literary texts with an equal interest in social context, in the actors, institutions, and social behaviors surrounding texts.

Griswold's concern for the integration of literary content with social context is shared by many. Janet Wolff, although she works primarily in visual arts rather than literature, has repeatedly challenged sociological students of culture to take content and aesthetics seriously, allying these concerns with their traditional specialty in social context and history (e.g., 1992; see also Becker in Candido 1995, p. xi). Priscilla Parkhurst Clark/Ferguson (e.g., 1987) has written extensively on the literary culture of France, combining a study of specific works and authors with detailed analyses of literary institutions and social processes, in addition to her normative writings on improving the sociology of literature (1982). Corse (1995, 1997) combines a detailed reading of three types of American and Canadian novels with a historical consideration of the two nations' canon development and a survey of the respective publishing industries to create a full picture of cross-national literary patterns and the explanation thereof. These works draw upon several important new approaches developed in the last twenty years.

The Production of Culture. The production of culture approach was the earliest of the new paradigms reinvigorating the study of culture in sociology. It stemmed from the growing interest of several prominent organizational sociologists in the sociology of culture (e.g., Hirsch 1972; Peterson 1976). These scholars made the now obvious insight that cultural objects are produced and distributed within a particular set of organizational and institutional arrangements, and that these arrangements mediate between author and audience and influence both the range of cultural products available and their content. Such arguments stand in stark contrast to earlier nonsociological conceptions of artistic production that featured artists as romantic loners and inspired geniuses with few ties to the social world. Art, in this view, is the product of a single artist and the content of

artistic works and the range of works available are explained by individual artistic vision. Becker's influential *Art Worlds* (1982) effectively refuted such individualistic conceptions of cultural producers, at least in sociological research. Researchers in the production of culture tradition have showed conclusively that even the most antisocial artistic hermits work within an art world that provides the artistic conventions that allow readers to decode the work. Artists are free to modify or even reject these conventions, but the conventions are a crucial component of the work's context. Art worlds also provide the materials, support personnel, and payment systems artists rely upon to create their works.

The social organization of the literary world and the publishing industry became obvious focuses for sociological investigations, from the production-of-culture approach. Walter W. Powell initiated a major research project with his dissertation, which was followed by his work on *Books: The Culture and Commerce of Publishing* (Cosser et al. 1982) and *Getting into Print* (Powell 1985). This stream of research demonstrates how production variables, such as the degree of competition in the publishing industry, the web of social interactions underlying decisions about publication, and the fundamental embeddedness of publishing in particular historical and social circumstances, affect the diversity of books available to the public.

Peterson (1985) outlines six production factors constraining the publishing industry. Berezin (1991) demonstrates how the Italian fascist regime under Mussolini shaped the theatre through bureaucratic production. Long (1986) situates the concern with economic concentration in the publishing industry in a historical perspective, and argues that a simple relationship between concentration and "massification" is insufficient for understanding contemporary publishing. Similarly, although as part of larger projects, Radway (1984), Long (1985), and Corse (1997) analyze the publishing industry and its changes as a backdrop for an understanding of particular literary characteristics. Radway traces the rise of mass-market paperbacks and the marketing of formulaic fiction to help explain the success of the romance genre (1984; chapter 1). Long (1985; chapter 2) acknowledges the importance of post World War II changes in the publishing houses and authorial demographics

in her analysis of the changing visions of success enshrined in best-selling novels, although she grants primary explanatory power to changes in the broader social context. Corse (1997, chapter 6) provides a cross-national study of Canada and the United States, arguing that the publishing industry in the latter dominates the former because of market size and population density. Canada's publishing industry has become largely a distributive arm of the American publishing industry, despite governmental subsidies and other attempts to bolster Canadian publishing. The result is that American novels dominate the Canadian market (Corse 1997, pp. 145–154).

One important focus of production approaches is gender. Tuchman (1989) analyzes the movement of male authors into the previously female-dominated field of British novel publishing during the late 1800s as the field became increasingly remunerative. Rogers (1991), in her ambitious attempt at establishing a phenomenology of literary sociology, notes the gendered construction of both writers and readers. Rosengren's (1983) network analysis of authorial references in book reviewing demonstrates, among other suggestive findings, the persistence of the literary system's underrepresentation of female authors.

Reception Theory and the Focus on Audience. A second fundamental shift in the sociology of literature occurred as sociologists became familiar with the work of German reception theorists. Reception theory, and several other strains of similar work, shifted scholarly attention to the interaction of text and reader. The central figures in Germany in the late 1960s and 1970s were Hans Robert Jauss and Wolfgang Iser. In *Toward an Aesthetic of Reception* (1982) Jauss presents his main argument: that literature can be understood only as a dialectical process of production and reception in which equal weight is given to the text and the reader. Iser's (1978) central focus is the act of reading itself.

Janice Radway's (1984) seminal *Reading the Romance* introduced reception theory with its central interest in audience interpretation to many American sociologists, as well as to many scholars in related fields. To those already familiar with the work of reception theorists, Radway's work powerfully demonstrated the potential of reception approaches for the sociology of literature. Radway's

interviews with "ordinary" readers of genre romance novels (1984) uncovered multiple interpretations, instances of resistance, and fundamental insights into literary use and gender in a genre previously scorned as unworthy of serious scholarly attention.

Reception theory has generated a fruitful line of research in the sociology of literature. Long (1987) has examined women's reading groups and their acceptance or rejection of traditional cultural authority in the selection and interpretation of book choices. Howard and Allen (1990) compare the interpretations made by male and female readers of two short stories in an attempt to understand how gender affects reception. Although they find few interpretive differences based solely on gender, they find numerous differences based on "life experience" and argue that gender affects interpretation indirectly through the "pervasive gender-markings of social context" (1990, p. 549). DeVault (1990) compares professional readings to her own reading of a Nadine Gordimer novel to demonstrate both the collective and the gendered nature of reception. Lichterman (1992) interviewed readers of self-help books to understand how such books are used as what he describes as a "thin culture" that helps readers with their personal lives without requiring any deep personal commitment to the book's advice.

Griswold (1987) innovatively applied the reception perspective to a study of the cross-national range of published reviews of a single author, generating another fruitful line of research. Bayma and Fine (1996) analyze 1950s reviews of Vladimir Nabokov's *Lolita* to demonstrate how cultural stereotypes of the time constructed reviewers' understandings of the novel's protagonist. Corse and Griffin (1997) analyze the history of reception of Zora Neale Hurston's *Their Eyes Were Watching God*, analyzing the different positionings of the novel over time and detailing how various "interpretive strategies" available to critics construct the novel as more or less powerful.

Stratification. One final area of growth centers on the relationship between cultural products and stratification systems. Perhaps the central figure is Pierre Bourdieu (1984, 1993), whose analyses of class-based differences in taste, concepts of cultural capital and habitus, and examination of

the distinction between the fields of “restricted” and “large-scale” production have profoundly affected sociological thinking. Bourdieu (1984) has demonstrated how constructed differences in capacities for aesthetic judgment help reproduce the class structure. This fundamentally affects the conditions under which types of culture are produced, interpreted, and evaluated (1993). Bourdieu’s theoretical insights have inspired many researchers, although few work in literary sociology directly. For example, Corse (1997) examined the use of high-culture literature in elite programs of nation building, Halle (1992) investigated class variations in the display of artistic genres in the home, and DiMaggio and Mohr (1985) correlated cultural capital and marital selection. Cultural consumption and use are also stratified across categories other than class, for example, gender, race, and ethnicity. These categories have received even less attention than class in the sociology of literature, although some work has been done in gender (e.g., Simonds and Rothman 1992; Wolff 1990; Radway 1984).

Bourdieu, among others, has also highlighted the need for sociological understanding of aesthetic evaluation as a social process and for a recognition of the contested nature of the cultural authority manifested in aesthetic judgments (e.g., DiMaggio 1991). Although this is not a new point (e.g., Noble 1976), sociology is finally coming to terms with literary evaluations and the codified hierarchy of value as objects of sociological attention (Lamont 1987; Corse and Griffin 1997; Corse 1997).

International Approaches. Obviously much of the material discussed so far is international, primarily European, in origin. European social theory has always been part of American sociology—the “fathers” of sociology are, after all, European—but there are cycles of more and less cross-fertilization. Historically, European sociologists certainly evinced greater interest in the sociology of literature than did their American counterparts; an example is the ongoing series of articles in *The British Journal of Sociology* debating the state of literary sociology (e.g., Noble 1976). The reasons for European sociology’s greater interest in the sociology of literature are several: the relatively greater influence of Marxist and neo-Marxist traditions; methodological differences that legitimate

qualitative and hermeneutic traditions; and the tighter link between sociology and the humanities compared to the “science-envy” and concomitant embrace of positivism characterizing much of American sociology.

These historical differences have at least residual remains. Marxist and hermeneutic approaches and methods more reminiscent of the humanities are still more prevalent in Europe. For example, there is greater acceptance of work looking at a single novel, an approach rarely seen in American sociology (e.g., Wahlforss’s 1989 discussion of the success of a best-selling Finnish love story). Differences have decreased, however, primarily from the American embrace of European theories and methods rather than from the opposite movement.

One important group in the sociology of literature also proves a major exception to the historic differences in method between American and European sociologies of literature. The Marketing and Sociology of Books Group at Tilburg University in the Netherlands specializes in an institutional approach to understanding “the functioning of literary and cultural institutions . . . [and] the various aspects of consumer behavior towards books and literary magazines” (Verdaasdonk and van Rees 1991, p. 421; see also, for example, Janssen 1997). The group includes Cees van Rees, editor of the journal *Poetics*, which lives up to its subtitle—*Journal of Empirical Research on Literature, the Media and the Arts*. The International Association for the Empirical Study of Literature (IGEL) sponsors an annual conference concentrating on such work (see Ibsch et al. 1995).

BROADER IMPLICATIONS

The sociology of literature has implications for wider social issues. In the debate over the opening of the canon—the question of what should be considered “great literature” and therefore required in school—people on both sides assume that reading X is different in some important way than reading Y. If not, it wouldn’t matter what was taught. Sociology of literature illuminates the process of canon formation helping to explain why certain books are canonized rather than others (Corse 1997; Corse and Griffin 1997); it sheds analytic light on processes of cultural authority

detailing who gets cultural power and how (DiMaggio 1991); and it elucidates the meaning-making activities of readers, showing what different audiences draw from particular texts (Griswold 1987). Sociological studies can help explain why people read, what they make of their reading, and how reading affects their lives. The relevance of literary sociology to the canon debates and its foundational arguments regarding the importance of extraliterary processes and structures can be seen in the increasing interest scholars outside sociology are showing in sociological variables and studies of literature (e.g., Tompkins 1985; Lauter 1991).

Similarly, many of the same questions of interest to sociologists of literature inform debates on media effects, debates such as whether watching cartoon violence causes children to act violently. This debate—and similar ones about the danger of rap music lyrics or the value of reading William Bennett's *Book of Virtues* rather than cyberpunk or social fears about Internet chat rooms—centers on the core question of what effect art and culture have on their audiences. Radway (1984), for example, asks whether reading romance novels teaches women to expect fulfillment only through patriarchal marriage—and demonstrates that the answer is a qualified yes. Corse (1997) argues that reading canonical novels is used to help construct national identities and feelings of solidarity among disparate readers. Griswold (1992) shows how the “village novel” establishes a powerful yet historically suspect sense of Nigerian identity. The question of the effect of reading—and the related question of literary use—is central to a complete sociology of literature. Although recent developments have moved us closer to answers, these are the key questions the sociology of literature needs to answer in the future.

LONG-TERM CARE

Long-term care (LTC) includes the full range of health, personal care, and social services provided at home and in the community for a continuing period to adults who lack or have lost the capacity to care fully for themselves and remain independent (Dearborn Financial Publishing 1997). A narrower but fairly common view is that LTC encompasses principally *residential* and institutional accommodation for older persons with special care needs. However, "long-term care" is a broad term, variously defined and interpreted in different countries and even within individual health and social care systems. As distinct from acute

care, LTC is not primarily curative but aims to maintain people either in the community or in residential (institutional) settings of various sorts.

Much discussion of LTC has focused, for demographic reasons, on care for elderly people. They are the main user groups in LTC, although long-term care users also include adults with special needs because of physical disability and mental illness or handicap. There are policy, finance, and practice issues inevitably raised by the mixed clientele of LTC (Binstock et al. 1996). A popular image is that LTC comprises mainly formal facilities and qualified personnel or trained volunteers delivering services in institutions and the community. However, probably the most common form of LTC worldwide and especially in developing countries is that provided by informal caregivers, particularly the families of those needing care. This can be a source of both pride and frustration for many families. There is increasing recognition of the burden and strain on informal family caregivers. In many cultures, the tradition of family care is enshrined in the notion of filial piety. While this is a particularly Chinese and East Asian concept of (reciprocal) duty of care between parents and their children, the realities of family responsibility and interactions in care are readily recognizable in all cultures.

The numbers and proportions of people, elderly persons in particular, living in formal LTC *institutions* vary considerably from one country to another. The size of the population group in question is not generally a very good indicator of the need for LTC, or its likely provision, in any given country. More important are the evolution and philosophy of health and welfare of provision. Epidemiologically and demographically, the gender balance in any given population is also important, as patterns of disability and service use tend to differ considerably between males and females. However, data on LTC are notoriously difficult to compare internationally. There are considerable differences in both definition and provision of the various types of residential facilities, nursing homes, and hostels, as well as of duration of stay. In Europe, for example, the percentages of people aged 65 and over living in an institution in the early 1990s ranged from 1.8 percent in Greece, 2.4 percent in Spain, 5.1 percent in France and the United Kingdom, and 5.4 percent in Denmark and

Germany to 9.1 percent in the Netherlands. The percentages of those living with their children showed an even greater range, from 7 percent in Denmark, and 18 percent in Britain and France to 35 percent in Greece and 48 percent in Spain. In the United States, on any one day, it has been estimated that 5 percent of the older population lives in a nursing home. However, between 25 percent and 43 percent of 65-year-olds (depending on estimates) can expect to use a nursing home at some time in their lives. Indeed, the older the person, the greater the chance of living in a nursing home. A person aged 85 or over in the United States in 1985 had almost a twenty times greater chance than someone aged 65–74 of living in a nursing home (Novak 1997).

ASSESSING NEED FOR LTC

An individual adult's *need* for LTC typically arises when physical or cognitive abilities impair the ability at any age to perform basic activities of daily living (ADL) such as bathing, dressing and toileting and, increasingly, the ability to conduct instrumental ADL such as shopping and house cleaning. To help assess need for and provision of LTC, various forms of ADL scales have been developed. Two of the best known are by Katz et al. (1963) and Mahoney and Barthel (1965). Other important instruments include the Functional Independence Measure (FIM); the principal component of the Uniform Data Set (UDS); and the Minimum Data Set (MDS), a component of the Residential Assessment Instrument (RAI). The nursing home RAI includes a set of core assessment items (the MDS) for assessment and care screening for nursing home residents on, say, admission and periodically thereafter. This enables the identification of any significant change in status and the development of individualized restorative plans of care and it has been successfully applied in the United States and many other countries, for a range of specific purposes in LTC. Another relevant scale is the SF-36 for health-related quality of life, although it is not primarily designed for use in LTC settings.

Aggregate need for LTC is influenced by a wide range of factors. Aging of populations is an important factor, but the health status of populations is perhaps even more important. Expectation of life at birth is increasing almost everywhere, and, more important, expectation of life at

age 60 and over is also increasing. The significance for LTC can be in at least two directions, depending on whether the expansion of morbidity or compression of morbidity hypotheses hold true. The “expansion” hypothesis suggests that further reductions in old-age mortality will expose the remaining population to a longer duration in which the nonfatal diseases of senescence are likely to emerge. The disabled portion of elderly life span will increase faster than the healthy and active portion. If this hypothesis holds true, with growing proportions of the “older-old” in the populations of most countries, there will be a steadily growing demand for community and institutional LTC provision. (See Table 1.)

Alternatively, the compression of morbidity hypothesis holds that mortality and morbidity will be simultaneously compressed and that lifestyle changes will reduce the risk of death from fatal and nonfatal diseases of senescence. A compression of morbidity is likely to have crucial implications for LTC need and provision, but precise details are difficult to assess. It implies that fewer people will need to live for long periods in institutions; conversely, there will probably be an increased need for social and community LTC for increasingly elderly population. Many of these people will be single and may not be very well provided for financially. This is especially true for single (usually widowed) elderly women, among whom many aspects of poverty are concentrated in many societies. They may disproportionately require low-cost or publicly funded community-based LTC. However, while there is some evidence, it is still early to state categorically that compression of morbidity will occur uniformly or continuously. Rather, there is increasing evidence of health *variations* both within and between populations and subgroups.

SERVICES AND PROVIDERS IN LTC

Nursing and Residential Homes. These are the institutions many people associate with long-term care. Definitions of nursing homes vary internationally, but, we will consider a home to be in this category (rather than as a retirement home, as old people's home, a board-and-care home, or the like) if it provides a specified amount of actual nursing and personal care and attention. Internationally, a nursing home has been defined as “an

Factors That May Affect the Demand for Long-Term Care

- Demographic:** Increase in the number of very old people; increased morbidity with increasing age; in particular, increase in numbers of older people suffering from dementing illnesses.
- Social:** Changes in the pattern of family structures and responsibilities at work and at home; increased tendency for some families to live at a distance from each other.
- Economic and consumer:** Improved financial position of many older people; older people making a positive choice about long-term care.
- Service:** Increased pressure on long-stay hospital beds; more effective use of acute hospital beds; closure of psychiatric hospitals.
- Political:** Initial stimulation through public funding of private and voluntary provision via supplementary benefit; community care legislation; attack on residential provision. Transfer of state funding to cash-limited local authority budgets since April 1993.
- Ideological:** Increasing popular support for a pluralist approach to welfare during the 1980s. Increasing reliance during the late 1980s and the 1990s on the market within health and social welfare services.

Table 1

SOURCE: Peace et al. (1997, p. 23)

institution providing nursing care 24 hours a day, assistance with ADL and mobility, psychosocial and personal care, paramedical care, such as physiotherapy and occupational therapy, as well as room and board” (Ribbe et al. 1997, p. 4). In general, nursing homes provide the highest level of nursing cum medical care outside acute hospitals. In many countries, especially in the developed world, they are licensed and inspected and subject to a variety of rules and standards. Some nursing homes have a medical or nursing teaching affiliation. Although the majority of long-term care is home-based and provided by informal caregivers (see below), nursing homes still epitomize the popular view of LTC, especially among those responsible for financing and legislating in this area. Indeed, this view of institutional care as the dominant form of LTC is rather difficult to change and represents a challenge to social scientists.

International Variations in Nursing Home Provision The proportions of people living in nursing homes and the per capita provision manifestly vary internationally, compounded by differences in definitions of nursing and residential homes. (See Table 2.) However, relative preponderance can be illustrated from a multicountry study of provision and structure of LTC systems. The countries studied are developed nations with high life expectancies; they include Sweden (with the oldest population in the study), Iceland (with the youngest), and Japan (forecast to have the highest aging rates in the coming three decades). Between 2 and

5 percent of elderly people were found to live in nursing homes, with variable percentages in residential homes (although the definitions also varied). Iceland, with the youngest age structure, actually showed the highest rates of institutionalization and nursing home residence, while Sweden, with the oldest, had a relatively lower percentage. This study found little correlation between the aging status of a country and the number of nursing home beds. Institutionalization rates differ as much according to population age structure and need as to differences in organization and financing of LTC services, the responsibility assumed for the care of elderly people by various sectors and the availability of LTC beds. Cultural factors and traditions of family care also influence strongly these levels of provision and uptake in any given country.

Residential Homes. Residential homes offer lower levels of care compared with nursing homes and they, rather than nursing homes per se, often provide the bulk of serviced accommodation for elderly people and adults with moderate disabilities. The terminology, scale, standards, registration, and licensing of “residential homes” vary considerably internationally. This category can include old people’s homes, old-age homes, homes for the elderly, residential homes, board-and-care homes, boarding homes, and elderly hostels, among others. Many are small-scale, board-and-lodging establishments with few residents, no specialist staff, and very few facilities. Others are specialized

**Percentage of People Over 65 Years of Age Living at Home and in Institutions
(prevalence data; different years in the early 1990s)**

Place of Residence	Country								
	U.S.	Japan	Iceland ^a	Sweden	Denmark	Netherlands	U.K.	France	Italy
Own home, independently or with informal and/or formal care (including domestic help and home nursing)	–	94.0	87.0	94.0	85.0	90.0	93.0	94.0	96.0
Residential homes, home for the aged, old people's homes (low levels of care)	1.5 ^b	0.5	5.0	3.0	10.5 ^c	6.5	3.5 ^d	4.0	1.0
Nursing homes (high levels of care)	5.0	1.5	8.0	2.0	4.0	2.5	2.0	– ^e	<2.0
Hospitals (intensive medical care)	–	4.0	–	<1.0	<1.0	<1.0	1.5	–	1.0

NOTE: ^aIncluding only elderly of ≥ 67 years.

^bIncluding only residential care homes and not group facilities such as board and care homes.

^cIncluding some sheltered housing and other special dwellings for elderly.

^dIncluding some young disabled.

^eNo facilities described as nursing homes; 2 percent of elderly reside in nursing-home-like facilities.

SOURCE: Ribbe et al. (1997, p.6)

and provide high-standard, often high-cost, residential care with full meal service, facilities, grounds, and services. In some systems, most are licensed and inspected (above a certain size); in other systems, regulations are far more relaxed.

Admission to a residential setting often stems from an inability to manage at home because of difficulties with activities of daily living (ADL). In some residential homes, assistance is given with basic activities of daily living. In others, admission may be for social reasons of company or a lack of wish to maintain a home. However, while most residents will be basically ambulatory, in many aging nations there is a growing overlap among residents in residential homes and those in nursing homes. Indeed, increasing age and deteriorating health status can alter the case mix of some residential homes so that they sometimes resemble nursing homes but lack specialized facilities and staff. This can present a serious problem to the delivery of appropriate and quality care.

Sheltered Housing. Sheltered housing is generally purpose-built accommodation in which residents live in their own unit, with their own front

door, but in a group development, with a system of linkages or alarms and served (usually full time) by a supervisor or warden. A range of services such as cleaning, shopping and entertainment, and common facilities may be provided on site, but these vary a great deal among sheltered housing schemes. Some schemes are small scale and involve only a handful of houses and residents. At the extreme, retirement villages established for older adults, increasingly common in North America and Australia, may be regarded as a type of sheltered housing. In many countries, various types of congregate housing are central to LTC.

Sheltered housing may be publicly provided, but it can be individually owned and provide a means for elderly people to remain in owner-occupancy. Increasingly, in countries such as the United Kingdom, a distinction is emerging between “ordinary” sheltered housing and “very sheltered” accommodation. In sheltered accommodation, residents generally require little more than suitable housing with the moral support of an alarm system to call emergency assistance. Very sheltered accommodation provides a greater intensity of services more akin to those in residential

care settings. Many people feel that sheltered or very sheltered housing is an ideal form of accommodation for LTC delivery, and it certainly does have many positive aspects when the designs are appropriate and residents able largely to live independently. However, the question of what happens when tenants become older and more frail is difficult, as are the potential for ghettoization of elderly people (Tinker 1992, 1997). In a high-density accommodation society such as Hong Kong, sheltered housing has been adapted to accommodate unrelated single elderly people for whom the provision of totally independent homes has proved difficult. Since the late 1980s, under the Housing for Senior Citizens scheme, public housing apartments have been provided. Usually three elderly people share an apartment. Each has an individual bedroom, and they share a communal living room and kitchen. Alarm systems and a warden provide continuity of contact, and certain communal activities are arranged for residents.

Care for Younger Adults: Psychiatric and Group Homes. Younger adults are often in need of LTC because of physical or mental incapacity. Sometimes, specialist care and accommodation is required because of, for example, spinal cord injuries. Younger LTC residents often also have different needs and perspectives from older recipients: a goal might be to find ways to assist younger people get out and about, commute to work, enjoy a full range of activities, and be contributing members of society. Home- and community-based services are as important for the younger as for the older persons in need of LTC (Binstock et al. 1996). However, some younger adults, for example, with severe mental or physical problems, might remain in LTC psychiatric accommodation or community-based group homes or hostels for a very long period of time, while receiving various forms of adult day care or respite care (see below).

Home and Community Care. Community and home-based services have the main aim of enabling people to continue living in their own homes or in the community for as long as possible. They involve a wide range of types of services and facilities provided by the formal and informal sectors. Home health care programs deliver health care and related services to people's homes; they have been called "hospitals without walls." Again, as in LTC generally, definitions of "home care" vary among countries. A recent study of fifteen

countries in Europe found considerable variation and defined *home care* as care provided at home by professional home nursing organizations and home help services. Other professionals—such as general practitioners (family doctors), occupational therapists, and physiotherapists—were excluded, although it is recognized that they do have a clear function in delivering care and often enable people to continue living at home (Hutten and Kerkstra 1996). *Home nursing services* include rehabilitative, promotive, preventive, and technical nursing care, with an emphasis mainly on the nursing of sick people at home. *Home help services* can provide a wide range of care, including shopping, cooking, cleaning, and laundering. They sometimes help with dressing and washing, and they often help care recipients to do administrative paperwork, pay bills, collect pensions, and the like. Many studies show that a home helper is also valued for providing company and someone to talk to. Clients are generally elderly (for example, in Britain, almost 90 percent). In some countries, the growing frailty of clients has led to the development of more intensive home care schemes that provide personal care in addition to doing simple cleaning and other tasks.

Several factors have raised the importance of home-based care: *increasing demand* from aging populations; *policies of substitution* of home care for institutional care (hospital care for the sick and residential care for elderly people) because of health care costs; and the *changing nature of home care* itself, with its increasing ability to deliver innovative services at home. However, while home is becoming the venue for delivery of care for many people of all ages, it is not necessarily a cheaper option than institutional care, especially for those requiring twenty-four-hour care. In addition, its future is not necessarily troublefree. The increasing numbers of older-old mean that complex home and family settings may evolve. For example, there will be increasing numbers of adult children in their sixties caring for parents in their eighties or nineties; likewise, there is an increasing number of elderly parents caring for adult disabled children at home. This is likely to require a very complex mix of support services to be delivered in the community and to people's homes.

Community-Based Care Facilities. These are also very varied and can provide care or more

informal meeting, contact, and social support. *Adult day care*, variously titled, is a community-based provision that provides health, social, and related support services in a protective setting but for less than 24 hours on a daily or less frequent basis. Such facilities are becoming increasingly important in the spectrum of LTC services. Adult day care may follow the medical model or the social model or some combination of both. Day care is sometimes provided in a clinic or hospital, where it may have a specific clinical or rehabilitation aim; it may also be provided in a residential home, a day center, or a club. Purpose-built and converted day centers or clubs often provide social contact, recreation, and education. Some offer meal service, and they may act as a base for home delivery of services such as meals on wheels. Many adult day care centers provide transportation, and some have medically trained staff members. Day care is often helpful in relieving relatives from the care of an elderly person or a disabled adult for a few hours a day; recent innovative services provide care in the evenings or at night. An extension of this is respite services (see below) which may be based in the community or in an institution.

Family and Informal Caregivers. The majority of informal caregivers are family members, of closer or more distant relationship, but some are friends and neighbors. While increasing attention is paid to the professionalization of community-based LTC in most developed-world countries, informal caregivers undoubtedly provide the major portion of care at all levels of need at home. Ironically, ideological shifts from hospital to community in the process of deinstitutionalization have, as a by-product, increased the importance of informal and family caregivers, but often in the absence of full-fledged community care systems. In some societies, especially in the developing world, the family is popularly and sometimes officially regarded as the main and only source of long-term care. Considerable shame and disapprobation can descend on the family that neglects the care of its elderly members, in more traditional societies. Indeed, even in highly developed societies, there is often popular pressure or at least an assumed expectation that the family will take responsibility for LTC of its immediate members, even if this is provided with paid assistants. This can hold true even when the individual is resident

in formal LTC settings and family members have visiting or care-providing roles.

Informal caregivers in LTC are predominantly female. American studies show that family caregivers are wives (23 percent), daughters (29 percent), other females (20 percent), husbands (13 percent), sons (8 percent), and other males (7 percent). This pattern holds true in many cultures. In China, for example, it provides an underpinning for the strong belief in the importance of having a son: Once a daughter marries, she traditionally lives with her husband and his parents, thus depriving her own parents of her potential future LTC help and domestic or financial assistance. Research in the United Kingdom and elsewhere indicates that family care is central to the lives of a substantial proportion of older people. In many countries, however, social change—including smaller families; women increasingly in the workforce; greater longevity; and social factors such as divorce, remarriage, and migration—all render the caring potential of the family more difficult. In developing countries, there is often very strong rural-to-urban migration of young working-age people. This can often render rural elders bereft of children who would provide day-to-day help, especially in the absence of formal LTC provision.

The reciprocal nature of family care is increasingly recognized—care flowing from parents to children, grandparents to grandchildren, and in reverse. This is often intricately bound up with exchange relationships, duties, and inheritance patterns. Elderly people themselves also have key roles as caregivers and, as noted above, among retired couples, the principal LTC provider is generally a spouse, often as old as or older than the recipient. Elderly parents often shoulder great responsibility for the LTC of their adult children with developmental disabilities. Indeed, the aging of children with mental retardation and severe physical disabilities has become an acknowledged research and policy issue only over the last two decades, with the shift from an emphasis on early childhood concerns to those of life-span issues. The progressive aging of almost all societies has increased the average age of caregivers of both elderly people and disabled adults. This necessitates important shifts in policy toward, for example, rendering housing more amenable and providing aging generations with greater frequency

and variety of support, including respite care (see below).

In spite also of the strong emotional preference for being cared for by family members, many older people and their families, as well as the families of disabled younger adults, increasingly favor the support of professional caregivers when there are extensive care needs. This can be a recognition of *caregiver burden*—the stresses placed on family members by their caring responsibilities—but it is also a practical recognition of the limitations of families and informal caregivers. Researchers are increasingly focusing on the problems of family caregivers, especially those coping with physical and mental illness and especially those associated with disorders such as dementia. The impacts of providing LTC on family life, privacy, and on other members of the family besides the primary caregiver are also increasingly being recognized.

Respite Care. Respite care is temporary, short-duration, usually residential care with supervision and/or nursing provided for dependent adults, who typically cannot be left alone to live. The purpose is to provide caregivers (usually family members but often formal live-in caregivers) with temporary relief or respite from their caring roles. This clearly recognizes the family context within which much LTC is provided and acknowledges the burden that can be placed on caregivers. It is also a pragmatic recognition that, given appropriate breaks and holidays, family members may be able to continue to provide LTC support that would otherwise not be possible.

Respite care has the explicit aim of relieving the primary caregivers of impaired elderly persons, and its use has been extended to other caregivers of handicapped nonelderly adults. Many caregivers report that the main service they would like is to be given “a break” from caring duties and the chance for a holiday or participation in social activities. While this is undoubtedly the case, evidence is not conclusive that these services significantly reduce caregiver stress. In addition, a range of other services, such as meals on wheels, transport services, befrienders, and home help services might provide some of the functions of short-term respite care, yet they are not classed as such and are not really in this category. The major problem with respite care is that it is only as a rule available

on a local basis; it has not generally received high funding priority, and caregivers therefore often feel they cannot rely on it to be available if and when they require it. In addition, there is evidence that, for various reasons, respite care places are often not fully occupied, a feature which renders the service vulnerable when budget reviews are undertaken.

FUNDING OF LTC

Sources of financial support for and cost of LTC vary considerably internationally and are likely to become even more variable as many countries undertake health sector reform and reassess public expenditure on welfare. Classically, LTC falls between health and social care; by its very nature, it lies at the interface between the two. Many public or insurance schemes have been able or willing to pay only for eligible clients who are in the residential or nursing home medical end of the LTC spectrum. By contrast, community-based LTC services for individuals and client groups have emerged piecemeal and have often been excluded from private insurance or public welfare payments. They can be very much a patchwork, dependent on local historical provision and the evolution of national programs. Care by the family, neighbors, and volunteers have also been of extreme importance for LTC recipients in the community, so individual resources and funding remain critical in many systems. At least five public policy options (other than total private reliance) exist for funding LTC. These include means-tested public funding; private insurance; public-private partnerships; social insurance; and funding from general taxation. Increasingly, there is an international focus not purely on value for money or efficiency and quality of LTC (as these are notoriously difficult to define) but on the concept of “best value.”

Funding of LTC is fraught with emotion among the public and politicians in many countries, and the moral panic (excess concern about future numbers of elderly people, in particular, and escalation of costs) has frequently made rational debate difficult. The issue is of major concern in the United States, where policies and, by implication, funding, are under considerable debate (O'Brien and Flannery 1997). Welfare states such as the United

Kingdom have in the past been based on a combination of free National Health Service provision for health care aspects and social welfare payments for the social care aspects. Increasingly until the early 1990s, there was assistance from local authorities and from generous publicly underpinned funding of private sector homes for elderly people. Private LTC homes flourished during the 1980s. Much of this has changed in the mid-1990s since an extensive review of the nature and funding mechanisms of community care and the retrenchment of more or less automatic public sector support for residents of private old people's homes. A new approach to privatization has resulted in more stringent assessment of residents in private homes who are to receive public support to target the most needy with care packages. Many private old people's homes have subsequently gained vacancies following this policy shift (Bartlett and Phillips 1996).

Comparative analysis of international systems of LTC can be valuable. A study of the evolution of the United Kingdom's LTC policies and those of Israel, which are based on a system of national insurance, attempts to draw some lessons for the United States (Cox 1997). Israel's 1988 Community Long Term Care Insurance Law sought to ensure that all of the state organizations involved in LTC of elderly people would be integrated into one system. Israel attempted to calculate of costs of alternatives to institutionalization. It was estimated that some 60 percent of disabled elderly people on waiting lists for institutional care could, through a basket of services, home care, day care, and personal care to relieve the burden on families, be cared for in their homes at substantially lower costs than those of the institutions. This is a thorny issue, rarely adequately addressed. Modeling exercises have suggested that, in the case of the United States, for example, efficient allocation of home care services can produce some net LTC cost savings. Greene et al. (1998) estimated that reducing nursing home use and using an optimal allocation of home care services could achieve savings of around 10 percent in the overall LTC costs for an identified frail elderly population. However, this involved targeting and a more medically oriented mix of services than has been implemented to date. It appears that the expansion of personal care services may not be significantly

justified in terms of cost containment or potential to reduce nursing home use.

Some countries have addressed the philosophy and financing of LTC systematically. The United Kingdom appointed a Royal Commission to review the long and short-term options for a sustainable system of funding LTC for older persons, both in their homes and other settings (Royal Commission on LTC 1999). They recommended coverage by "risk pooling," rather than private insurance, and services underwritten by general taxation. The report of the Commission provides useful sources of costs and means of delivery. *Japan*, for example, likely in the next two decades to become proportionately the most elderly country in the world, demonstrates the social, economic, and political importance of LTC. Japan has experienced increased lengthening and seriousness of LTC, with one out of every two bedridden persons being bedridden for two years or more. More than half the care attendants are themselves aged 60 or older. The percentage of elderly people living with their children has fallen to just over one-half, and the proportion of women working is increasing. The Japanese Ministry of Health and Welfare estimates that the percentage of people aged 65 and over who need care will rise from 11.8 percent in 1993 to 14 percent in 2010 and even 16 percent in 2025.

As a result of these pressures, in December 1997, legislation was passed for a new public LTC insurance scheme—*Kaigo Hoken*—to be fully operational from 2000. This makes Japan only the third country, after Holland and Germany (see below), to provide such insurance. These proposals are very significant because they depart radically from the Japanese tradition that families are primarily responsible for long-term care. Eligibility criteria will no longer take into account the extent of informal care available to patients; and ultimate responsibility for care will lie with the state rather than with families. The scheme separates LTC services from medical care insurance and will pay for institutional and home-based care not only for those aged 65 or more, but also for people over 40 years old with "age-related" diseases such as dementia. Each municipal government is deemed a provider, and levels of services are decided by the patients' impairment. Half the

funding is from monthly premiums levied on people over 40, with a 10 percent co-payment at the point of service; rates are altered for those on low income. The rest of the funding comes from general taxation.

The scheme has two potential drawbacks. First, health and social services professionals in each municipal government will have to assess eligibility and decide on care plans, skills that have long been neglected in Japan. Second, the mechanism of quality assurance has not been clearly defined. The scheme nevertheless is a major departure in Japanese social policy (Arai 1997). It aims to underpin the development of a more diverse system in which users have more choice and may use the services they wish. It also hopes to promote the change from the excessive reliance on geriatric hospitals to sanatorium-type wards with suitable environments for long-term recuperation.

Germany introduced a new LTC insurance program in 1995. This required a considerable shift in focus from traditional rights to curative medical procedures toward long-term residential and home care, which previously had to be paid privately or from means-tested social assistance. There was political agreement that LTC costs threatened ordinary citizens with impoverishment in later life, a contrast with high levels of social expenditure available for health and pensions. After extensive public debate, a public insurance system was chosen, which requires equal contributions from all employers and employees; pensioners also contribute. Benefits from the LTC insurance may be taken in kind or in cash for home care and in kind for institutional care. Benefit payment levels are graded according to fairly narrow dependency definitions: dependent, seriously dependent (in need of extensive care), and very seriously dependent (needing extensive twenty-four-hour care) (Evers 1998). The cash alternative for home care is designed to allow private family-based arrangements to be made. Various additional benefits include short-term respite care to allow family caregivers four weeks' holiday, subsidized housing improvements, and contributions to the social security system. The new scheme, ostensibly a simple extension of the German insurance-based welfare approach, does create reliable rights for everyone in serious need of care as opposed to

means testing. However, there have been discussions about the appropriateness of linking care costs to employer and employee payments. In addition, the LTC fixed-sum payments are likely to meet only part of the total costs of care. Residents of nursing homes in particular still have to spend individual resources, albeit at a slower rate. Due to the high proportion of recipients of home care initially opting for cheaper cash reimbursements, the system went into early profit and has amassed a surplus. This preference for cash has been taken to indicate the importance of the family in *Germany's* LTC, but some higher-cost medical care services can still be reimbursed from health insurance.

By contrast, even in some countries with advanced approaches to welfare, full-fledged support for long-term care remains highly dependent on local variations. In *Canada*, for example, what is regarded as continuing care has been called a "patchwork quilt" of long-term care, mainly institutional, and home or community care, mainly noninstitutional. The institutional components are widely provided across the country, with public and private funding. The noninstitutional components are developing, unevenly provided and also funded publicly and privately. While access to acute care is guaranteed, this is not the case for continuing care. The amalgam of services that compose continuing care involve the community-based and residential LTC services outlined above. Funding varies by province in *Canada*, with decreasing federal support, and is typically still complicated by the situation of LTC at the interface of health and social welfare. Various types of continuing care are cost-shared between province and municipality of residence. Ownership of facilities nationally falls under three categories, and the relative balance varies considerably between provinces: public (49 percent), private for-profit (26 percent), and private nonprofit (25 percent) ownership. For illustration, *Quebec* has 78 percent and *Nova Scotia* 36 percent publicly owned facilities on average, but 100 percent of care facilities for advanced chronic mental and physical conditions are publicly owned in *Nova Scotia*. While funding comes from a variety of sources, there is a move toward universal rather than means-tested benefits, and cost sharing with users is the norm. In most provinces, people are not required to spend down their assets to receive public support,

though they will usually have to co-pay daily rates for lower levels of care. Community-based nursing services are virtually universally supplied in Canada, although home care and support vary considerably. The picture is evolving, with increasing emphasis on noninstitutional care and budget reallocation to this sector.

QUALITY ISSUES

Quality of provision in LTC is of increasing international interest and revolves around standard setting, regulation, inspection, and ethics. It can require legislation and a mature and sensitive appreciation of care needs on the part of LTC providers and the many professions involved. Service quality in LTC residential settings has at least five dimensions (Duffy et al. 1997): tangibles (physical facilities, equipment); reliability (ability to perform promised services); responsiveness (willingness and promptness); assurance (conveyance of confidence and trust by personnel); empathy (caring, individualized attention provided by the facility). There is also an important economic aspect to quality related to costs of services delivered: value and satisfaction.

In addition to broader quality issues, specific features such as the use of restraints also give indications of the quality and respect for individuals in a LTC system. In this and other respects, international standards vary. For example, an eight-country study of use of restraints in nursing homes (Denmark, France, Iceland, Italy, Japan, Spain, Sweden, and the United States) found considerable variation. Total use of restraints was less than 9 percent in Denmark, Iceland, and Japan; between 15 and 17 percent in France, Italy, Sweden, and the United States; but almost 40 percent in Spain. The intensity of use of restraints and the types applied varied. In all countries, there was a constant increase in the use of restraints with increasing ADL difficulties and cognitive dysfunction (Ljunggren et al. 1997). It is clear that financial factors concerned with staffing levels, staff culture and training, the balance between better and less well trained staff, and the physical nature of facilities influence levels of use of restraints. Cultural variations and the thresholds for applying restraints also vary greatly internationally. The same is undoubtedly true of many other facets of LTC.

LTC-ISSUES OF POLICY AND PRACTICE

LTC systems have generally emerged as a series of incremental responses to a growing problem or set of problems, over a number of political eras and in many jurisdictions. The result is often a medley of noncomplementary and even conflicting programs for people with chronic disability, which are typically ineffective and inefficient. In many countries, especially in the developing world, there is still enormous emotional and even official attachment to care by the family. At the extreme, placing one's parents or relative into an LTC residential facility can be anathema. Even in countries such as the United States, with expensive health care systems and an established range of community-based programs, LTC does not work well.

It is doubtful whether a universal blueprint for LTC can be devised. The development and financing of long-term care services in many countries has been at best haphazard. Until the Japanese and German experiences, and perhaps those in Australia and the United Kingdom at present, elsewhere it has rarely been asked what the ultimate LTC system should look like. Most systems have evolved piecemeal and have suffered from being at the interface of technically expanding and expensive health care and lower-technology, but fragmented, social care.

Basic policy issues and questions arise. What should LTC encompass? How can the role of housing policy in LTC be recognized? Is LTC an individual, a family, an employer, or a state responsibility, or is it (increasingly) some complex combination of all of these? What is the role of the family, and how can it be supported? Should LTC be provided to various disability groups and ages? If so, how? What is the ideal balance and relationship between LTC and the acute health care sector? What should be the balance between the various residential, social care, nursing, ancillary services, and informal care? What resources should be devoted to home care, assisted living, and other options? Underpinning many of these questions is the basic philosophy within specific countries regarding collective and individual responsibility for vulnerable citizens.

Housing is clearly crucial to the success of LTC. The internal home environment and its interaction with the local external environment adds to the challenge of life for many people with

chronic disabilities, and their ADL are compounded by their environment. Initiatives have appeared such as sheltered housing (assisted daily living), with wardening and support services, residential homes, and various schemes to assist adaptation of existing dwellings, but, in most countries, there has been little coherent policy development in this area. Ironically, many initiatives to build specialist housing for elderly or handicapped people have come from private sector developers, who have identified a new and underserved market segment for specialist housing. Aging in place and care in the community can often be enabled by relatively minor housing improvements. These may be administrative; for example, in public housing, there may be provision for flexibility enabling residents to exchange current units for more appropriate, often smaller ones. Many academic disciplines, including sociology, gerontology, planning, geography, environmental psychology, and architecture, can contribute to this important aspect of policy development.

What will future LTC look like? It can be provided in a number of different settings, by a range of personnel, and to people with varying types and levels of disability. Nevertheless, in many systems, institutional care such as nursing homes still represent the majority of expenditure on LTC. Residential and nursing homes do indeed often represent an important care option, but they would be unlikely to occupy such an important position in a newly designed LTC system. As many systems have gradually emerged piecemeal from a range of initiatives, they do not meet the needs of the recipients or providers of LTC today, nor the needs of those who pay for care. Internationally, there is little agreement about potential policy solutions. In many countries, thoroughgoing debate and reappraisal need to be initiated.

LONG-TERM CARE FACILITIES

THE SPECTRUM OF LONG-TERM CARE

While the nursing home remains the most prevalent option for elderly persons requiring long-term care, in recent years there has been a great upsurge in alternative options. Changes in the spectrum of long-term care services provided have come about primarily based on changes in the demographic profile of long-term care users, in health care financing, and in policies impacting the provision of long-term care.

Nursing homes reflect the major long-term care option that has been available in the United States under Medicare and Medicaid financing. However, recent trends reflect new developments targeting self-financed long-term care, particularly in the form of assisted living, continuing care retirement communities, and special need facilities focusing on dementia or hospice care. In addition, discharge policies of acute care hospitals have resulted in the development of subacute care and rehabilitation facilities sponsored by hospitals or nursing homes. There has also been an increase in the provision of home care services to frail older adults who can forestall entry to sheltered living arrangements, including nursing homes, through the use of these services. Growing recognition of the diversity of elders requiring long-term care is leading to the diversification of settings to meet these needs, and to a blurring of boundaries between home care and residential care (R. A. Kane, 1995–1996).

In spite of the proliferation of new residential options for frail and old-old adults, those requiring extensive assistance or supervision continue to rely on nursing homes as the only viable publicly financed alternative. Consequently, this essay will only briefly touch on some of the more recent options in the spectrum of long-term care, such as

assisted living facilities and continuing care retirement communities. Rehabilitative or subacute care units in nursing homes will not be addressed because they reflect mechanisms for providing short-term care. Nor will we discuss senior housing sites or retirement communities, which serve as residential options to well elders. After considering assisted living facilities and continuing care retirement communities, the major focus of our discussion will be on the nursing home.

ASSISTED LIVING FACILITIES

Assisted living facilities (ALFs) have taken over some of the original functions of nursing homes, providing services to moderately frail elders in the context of a homelike residential setting that includes less surveillance and regimentation, and more privacy and autonomy for residents than the traditional nursing home (R. A. Kane 1995). ALFs combine housing with personal support services such as meals, laundry, housekeeping, and maintenance services. Board and care homes and personal care homes may also be included under the ALF designation. Generally, residents in ALFs pay on a month-to-month basis, although financing of home health services may occur under Medicare (Pearce 1998). Assisted living facilities are an outgrowth of the group home tradition, generally reflecting small business operations. In recent years, however, assisted living facilities have increasingly been sponsored and built by hospitals, nursing homes, and large publicly traded companies (Meyer 1998).

Consistently with the model of social care (R. A. Kane and Wilson 1993), ALF services are geared toward meeting resident preferences and wishes, and consider residents to be consumers rather than patients or clients to be taken care of according to staff-based directives. Assisted living arises from a commercial model of fees for services, and its consumer-driven orientation differs from nursing home care, which generally reflects third-party payment dynamics. While these advantages make assisted living a highly attractive long-term option for frail elders with some means, potential problems include lack of regulation and inaccessibility of this type of care to the poor. Furthermore, assisted living facilities can serve only the needs of older adults with limited disabilities (R. A. Kane 1995–1996).

CONTINUING CARE RETIREMENT COMMUNITIES

Continuing care retirement communities (CCRCs) may also be termed "life care communities," and they typically offer a continuum of services from independent living to assisted living and nursing care. These facilities are appealing to well old-old persons who are still able to live independently but want to have the security of planning for increasing service needs as they arise. These older adults want to know that their changing personal and health care needs can be met within an organizational framework, which they select. Most elderly persons initially enter independent living units of CCRCs. Between 50 percent and 70 percent of entering residents eventually utilize assisted living and/or nursing home components of the CCRC (Newcomer et al. 1995).

CCRCs vary greatly in both the types and the range of services offered and in sponsorship and management. The fees may be structured as a refundable entry fee along with a monthly service fee, or it can be based on an endowment, a rental, or a condominium purchase (Pearce 1998). While fee structures differ, arrangements for these services have generally moved from exclusive reliance on entrance fees to requiring monthly maintenance fees along with fees paid at the time of initiation. With the rapid growth of CCRCs around the country, states have enacted legislation to protect older adults, particularly against bankruptcy of the organizations sponsoring the CCRC (Netting and Wilson 1994). These facilities are generally considered and regulated as insurance programs, and there has been great inconsistency in ways of implementing their regulation across different states.

CCRCs represent not only an emerging comprehensive long-term care alternative, but may constitute a new paradigm for long-term care (Vladeck 1995). Managed care CCRCs can offer flexibility and a more community-responsive paradigm for delivering long-term care. This form of care draws on the know-how of diverse industries, including housing, hospitality, insurance, and health care. This allows for a cross-fertilization of different value orientations regarding care, and different approaches to financing and management.

Large-scale national research on CCRCs finds (Sherwood et al. 1997) that such facilities tend to

be utilized by well-educated, middle-class, white, elderly persons aged 75 and over, with women being overrepresented among the users. More than 85 percent had been white-collar workers (Sherwood et al. 1997). When compared with community residents, CCRC-dwelling elderly were found to be in comparable or better health and to have comparable social supports, although community-dwelling elders interact more frequently with their family members. Social research on assisted living and CCRC communities has not been extensive, and generally considers administrative and organizational dimensions of care, rather than aspects of social life and social interactions. Studies comparing CCRC residents and elderly people living in the community have noted that the former are more likely to utilize nursing units after acute hospital stays and outpatient surgery. At the same time, CCRC residents have lower rates of hospital admissions than do community-dwelling elders (Newcomer et al. 1995).

NURSING HOMES

Nursing homes are of interest to sociologists on both the macro and the micro levels. On the macro level they reflect society's orientation to financing, regulating, and delivering long-term care services to its frail citizens who are no longer capable of fully autonomous community living. Sociologists have been particularly interested in those factors affecting long-term care delivery that reflect social construction of the reality of the lives of marginal individuals such as aged persons.

On a micro level, nursing homes represent formal organizations that regulate and control the daily lives of frail elders, while providing them with medical and social care. The tension between expectations for rehabilitative or prosthetic services and actual delivery of palliative care or of dependency-inducing treatment, with iatrogenic consequences, has been a particular source of fascination and concern to gerontologists (Baltes 1996; E. Kahana, Kahana, and Riley 1989; Kane 1995-1996). Complementing this interest has been the search for understanding person-environment interactions and interpersonal and intergroup relationships involving residents, staff, and families within the institutional context (Diamond 1992; Gubrium 1975, 1993; E. Kahana, Liang, and Felton, 1980).

The following discussion about nursing homes includes an introductory section outlining models of nursing home care, followed by a discussion of demographic profiles of residents and an analysis of nursing home characteristics and financing. Efforts to ensure high quality of care are discussed in terms of both regulatory efforts and formal interventions. We next consider the effects of institutionalization on the social lives of residents, and their adaptation to the nursing home. Discussion then turns to new initiatives in formal program development and effects of interventions on resident life in the nursing home. The article concludes with a discussion of emerging trends in nursing home care and the future of long-term care facilities in the United States.

Even as we aim to review sociological contributions to the understanding of nursing homes, it is important to note that information about this subject has been obtained through the research efforts of diverse disciplines, with epidemiologists, political scientists, social workers, psychologists, nurses, and physicians all contributing to the literature. In fact, medical sociologists have focused their investigation primarily on acute health care delivery in general hospitals, and many of the theoretical constructs they have developed are more applicable to acute illness than to chronic disability (Cockerham 1998; Charmaz and Paterniti 1999). Consequently, this discussion of the nursing home draws upon multidisciplinary sources.

MODELS OF CARE IN NURSING HOMES

Those requiring institutional care represent a highly select group of the most vulnerable aged persons (Hing 1987), particularly since there are now many options which can keep frail elders in the community. Any therapeutic efforts to enhance the functioning of the very frail older adults living in nursing homes thus represent a regimen of limited objectives (E. Kahana, B. Kahana, and Chirayath 1999). Nevertheless, nursing home settings can serve important therapeutic and rehabilitative functions and can enhance the quality of life of frail elders by ensuring comfort and even some measure of autonomy (Agich 1993). Moving away from an exclusive focus on poor quality of care in nursing homes, recent research has begun to consider criteria for high quality of care and even

excellence in nursing home settings (Andersen 1987; Brittis 1996; Groger 1994; Looman et al. 1997).

Conceptualizations of models of care typically reflect the philosophies and traditions of the disciplines from which they originate. Sociology, medicine, nursing, the allied health professions, psychology, and social work—each has a distinct set of traditions that influence its respective conceptualizations of long-term care. Interventions arising from these diverse traditions may include therapeutic interventions (psychology), programs that enhance function (nursing or medicine), and interventions that empower patients (sociology and social work).

The *medical model* of care considers nursing homes as health care institutions designed to deliver high-quality chronic care to patients. As such, nursing homes are expected to provide competent and well-trained personnel to meet health care needs of patients (R. L. Kane et al. 1994). In principle, the criterion for successful care is improved health or at least minimal health decline of the patient. In practice, quality of care is generally approached by the organization through adherence to certain standards of care delivery, such as adequate staff recruitment and training, and high staff-patient ratios (Nyman and Geyer 1989; L. Z. Rubenstein and Wieland 1993).

The organizational climate of managed care has brought with it a new emphasis on *management-centered* interventions and care. Management-oriented approaches often treat patients as objects of intervention who must be manipulated to achieve desired objectives. One such approach, continuous quality improvement (CQI), is an organizational management framework based on older business models such as total quality management (TQM) (Schnelle et al. 1997). The goal of CQI is to make systematic improvements by employing multiple short cycles of designing, evaluating, and implementing interventions. These cycles of continuous intervention and assessment drive long-range systematic change. Attempts at CQI in nursing homes have included interventions in incontinence and physical restraints, but have been hindered by a lack of information technology and by care standards legislated by the Omnibus Budget Reconciliation Act (OBRA) of 1987 (Schnelle et al. 1997).

The *social model* (R. L. Kane and R. A. Kane 1978; R. A. Kane et al. 1998) considers the ideal model of long-term care to be a sheltered housing arrangement for older adults who can no longer function independently in the community. The goal of such sheltered living arrangements is ensuring a good quality of life for residents through encouragement of maximum autonomy in a homelike setting. The criterion for successful care is defined in terms of sustained psychosocial well-being, self-esteem, and life satisfaction of residents.

While medical definitions of care dictate provision of diagnostic and treatment activities, social definitions suggest emphasis on comfort, choice, and adaptation. Advocates of quality-of-life approaches have often argued for major redirection in the way long-term care is handled. They seek greater support for the home-based rather than the institution-based model of care (Leutz et al. 1992). The growing popularity of assisted living options in long-term care reflects this orientation. Empowering older clients to act as consumers provides a major mechanism for the social care model (Burger et al. 1996; Cox and Parsons 1994). Since residents living in nursing homes are typically too frail and powerless to demand active consumer involvement in their care, there is little evidence of actual empowerment-based approaches in nursing home settings (E. Kahana 1999).

The *Patient-Responsive Care Model* (Kahana, Kahana, Kercher, and Chirayath 1999) has been developed to recognize social, psychological, and physical needs of frail patients who are not able to function in residential settings and who require nursing home care. The Patient-Responsive Care Model is an ecological model guided by communitarian principles of sociologists (Bellah 1996; Etzioni 1993). It calls for a systematic and empathetic discernment by staff of resident perspectives and preferences. This approach is based on earlier work on person-environment fit as a determinant of resident well-being in nursing homes (E. Kahana 1973; E. Kahana 1982). Environments may be matched to resident needs by altering the physical or social environment and by enhancing staff responsiveness in an effort to improve residents' quality of life (E. Kahana, B. Kahana, and Riley 1989). This model is also consistent with recently proposed "cultural" models of

nursing home care proposed by Scandinavian scholars who advocate individualized care based on "knowing the patient" (Evans 1996).

The major requisite of patient-responsive care is an understanding and an empathetic appreciation of nursing home life from the patient's perspective. Four major areas of need, loosely based on Maslow's hierarchy of needs (1970), are to be met by staff: reducing physical distress, meeting basic physiological needs, meeting emotional needs, and meeting social needs. Since cognitively impaired and frail elders are limited in their ability to articulate their needs, a major challenge of patient-responsive care is to elicit expressions of resident needs and preferences. This model is predicated on empathetic listening to the patient's lived experience (Gubrium 1993; Savishinsky 1991) as a basis for developing Patient-Responsive Care, and does not rely on need assessments based on objective test data.

Staff behaviors along dimensions of responsiveness can range from total lack of involvement (ignoring or dismissing a problem) to hearing and validating patient concerns. Staff who are responsive to patients provide reassurance and, whenever possible, take constructive actions toward resolving problems. Eliciting information about patient needs and validating those needs are proposed as concrete requisites of providing patient-responsive care. Action components of responsive care also involve communicating with family members and with other staff in advocating on the patient's behalf. Responsiveness involves three central actions by staff: eliciting the patient's definition of need, validating the need, and acting or advocating on the patient's behalf. The pattern of responsiveness thus involves observing, questioning, listening, and responding. Exemplifying this approach, aides who care for the elderly may be trained to redefine their jobs from providing custodial care to providing therapeutic measures. For example, personnel delivering meals could easily be trained to engage in conversation with residents during meals, explaining what the resident is eating and contributing to the enjoyment of the meal. Staff providing responsive care may be empowered through this very initiative. Providing responsive care can serve to enhance staff's self-efficacy and sense of competence (E. Kahana et al. 1999).

While none of the models described above fully fit, the complex realities of frail older persons living in institutional settings within the constraints of managed care, each helps us appreciate the multifaceted nature of efforts to meet resident needs in the framework of long-term care.

PROFILE OF NURSING HOME RESIDENTS

In 1995, about 1.4 million American elderly persons over the age of 65 were residing in 16,700 nursing homes. While 4.5 percent of the elderly are in nursing homes at any given time, 30 percent of older adults can expect to spend some time during their lives in a nursing home. The majority of residents enter a nursing home immediately after discharge from an acute care hospital (Lewis et al. 1985). Most of these patients need ongoing medical care and some may require rehospitalization (Densen 1987). Others enter a nursing home directly from the community, due to multiple risk factors including physical and cognitive frailty and nonavailability of caregivers. Additionally, during the era of deinstitutionalization of the mentally ill, some elderly were transferred to nursing homes from mental hospitals. Among social risk factors for institutionalization, studies have identified that those elderly persons who were never married, those who are widowed, and those who do not have children nearby are overrepresented (R. A. Kane 1995–1996).

A demographic profile of nursing home residents has been provided by the U.S. Bureau of the Census (1998) based on a 1995 survey of residents in U.S. nursing homes (National Center for Health Statistics 1997). According to the report, 24.7 percent of nursing home residents are men and 75.3 percent are women.

Older women are three times as likely as older men to reside in nursing homes, both because of their longevity and because they are more likely to be widowed, and moreover without caregivers.

Nursing home placements are generally due to a combination of functional impairments, mental infirmity and unavailability of caregivers (R. L. Kane et al. 1998; Rovner and Katz 1993).

Of those elderly living in a nursing home, 8 percent were between ages 65 and 74; another 42 percent were between ages 75 and 84, and 40

percent were over age 85. Although the vast majority of nursing home residents are elderly, about 10 percent are younger than age 65 (U.S. Bureau of the Census 1998).

Although representation of minorities in long-term care facilities has been increasing over time, such groups continue to be underrepresented (Bonifazi 1998). Racial composition of nursing home residents is: 89.5 percent white, as compared to 8.5 percent black and 2.3 percent Hispanic (R. L. Kane et al. 1998; U.S. Bureau of the Census 1998). Both the greater willingness of black and Hispanic families to care for elders and barriers to the utilization of nursing home by minorities have been cited as possible reasons for these racial differences (Mui and Burnette 1994; Wallace et al. 1998).

Based on the 1995 National Nursing Home Surveys, the majority of elderly persons residing in nursing homes need significant assistance with both activities of daily living (ADLs) and instrumental activities of daily living (IADLs) (National Center for Health Statistics 1997). The study reports that 96 percent of residents in a nursing home need help with showering, 87 percent need help with dressing, 45 percent need help with eating, 24 percent need help with transferring, and 58 percent need help with toileting. Limitations were also found in IADL function, with 78 percent of respondents needing assistance with care of personal possessions and 69 percent needing help with managing money. High levels of physical impairment in this group are also reflected in extensive use of assistive devices. Thus, 64 percent of all elderly in nursing homes utilize a wheelchair, 25 percent use a walker, and 78 percent occupy a hospital bed. Sensory and communicative impairments are also prevalent among nursing home residents, with 51 percent of residents having moderate to severe hearing loss (Garahan et al. 1992) and 24 percent exhibiting visual problems (National Center for Health Statistics 1997).

There is increasing recognition that the prevalence of diagnosable neuropsychiatric disorders in nursing homes is high, with estimates ranging up to 80 percent or greater (Kim and Rovner 1996; Rovner and Katz 1993). Elders with schizophrenia or other psychoses compose only a very small proportion of the nursing home population. The most prevalent neuropsychiatric disorders include

dementia (primarily Alzheimer's disease) and depression.

Over 50 percent of elderly persons admitted to nursing homes will live out their lives in a nursing facility, with about 10 percent dying during the first year of their nursing home stay. The average length of stay of long-term care residents is two to three years. In any given year, 25 percent of residents return to the community from a nursing home (Cohen-Mansfield et al. 1999). The majority of those returning to the community have spent time in short-term, rehabilitative units of nursing homes.

CHARACTERISTICS AND DISTRIBUTION OF NURSING HOMES

The number of nursing homes in the United States has decreased from 19,100 in 1985 to 16,700 in 1995. This represents a decline of 2,400 homes over the past decade. The number of nursing home residents has increased only slightly over the same decade from 1.49 million residents in 1985 to 1.55 million residents in 1995 (U.S. Bureau of the Census 1998). In 1995, there were about 1.77 million nursing home beds. The average number of beds per nursing home increased from 85 in 1985, to an average of 106 beds per nursing home by 1995. These changes parallel organizational shifts toward the entrance of large nursing home chains into the market. At the most recent 1995 survey, 66 percent of nursing homes were proprietary, 26 percent were nonprofit, and 8 percent were sponsored by the government (U.S. Bureau of the Census 1998). Fifty-five percent of nursing homes were run by commercial organizations operating chains of facilities. Of the total nursing homes, 66 percent were certified by both Medicare and Medicaid, 20 percent by Medicaid only, 6 percent by Medicare only, and 4 percent were not certified by either Medicare or Medicaid (U.S. Bureau of the Census 1998). Nursing homes generally have high occupancy rates (87 percent) in part based on newly proliferating special units such as respite care, rehabilitative services, hospice, dementia units, and acquired immune deficiency syndrome (AIDS) special care units (U.S. Bureau of the Census 1998). Nevertheless, there are some indications that frail older adults are not entering nursing homes at the same rate they

previously did. The increase in assisted living settings and other residential options is likely to contribute to this trend (Strahan 1997).

There are regional differences in both distribution and utilization of nursing homes. Older adults in the Midwest and the South have the largest number of nursing homes available to them, each with 33 percent of the total number of nursing homes in the United States. The Northeast, containing 17 percent of the country's total number of nursing homes, has the highest occupancy rate compared to the Midwest, South, and West. The West, in contrast, has a small proportion of nursing homes and has the lowest occupancy rates (U.S. Bureau of the Census 1998). Migration patterns may influence nursing home occupancy rates. Many older adults, upon retiring, move to warmer Sunbelt states seeking to improve their quality of life. This group is likely to enter nursing homes as they become frail in old-old age, thus contributing a high demand for nursing homes in the South (Longino 1998). At the same time, when they require more extensive care, significant numbers of older adults may return from the Sunbelt to the states from which they originally migrated. These countermoves may also affect the utilization rates of nursing homes in certain regions. Rural-urban comparisons of nursing home distribution reveal that metropolitan areas have a larger supply of nursing home beds per capita than do rural areas (62 versus 45 certified beds per 100 elders, respectively) (Shaughnessy 1994).

FINANCING OF LONG-TERM CARE

It has been argued that, in the United States, funding mechanisms have been largely responsible for shaping the delivery of health care in general and the delivery of long-term care in particular (R. A. Kane et al. 1998). In 1995, nursing home expenses totaled \$77.9 billion, sharply up from \$36 billion in 1985 (Levit et al. 1996). Medicare, a universal age-based health care program, has traditionally covered the acute and rehabilitative health care needs of older adults and reimburses only a very limited number of nursing home expenses. Medicaid, a need-based, state-administered program, on the other hand, covers nursing home expenses for older adults after their financial resources are depleted. Thus, while Medicare paid 9 percent of nursing home expenses in

1995, Medicaid paid 47 percent of the expenditures. Thirty-seven percent of nursing home expenses were paid out of pocket, whereas private insurance paid only 3 percent of nursing home expenses (Levit et al. 1996).

While private nursing home insurance is increasingly advocated as an important protection for older adults, only very few adults are currently benefiting from such coverage. This limited role played by private insurance may be attributable to high cost, limited coverage afforded by such policies, and lack of information about the availability of insurance (Cohen 1998). Most elderly individuals start their nursing home stays as privately paying patients. Nursing home care, in fact, represents the major portion (82.5 percent) of out-of-pocket health care expenses of the elderly (Rice 1989). After personal resources are depleted (usually in less than a year), patients become eligible for Medicaid financing (Lusky and Ingman 1994).

There is continuing pressure for cost containment to reduce burdens of nursing home costs. The major response to these needs has been the proliferation of assisted living facilities, CCRC facilities, and home health care. In 1995, the average annual cost of a nursing home stay was over \$38,000, while out-of-pocket costs for home health care averaged \$370 a month, or \$4,440 annually (Cohen 1998). There have also been reductions in reimbursable nursing home services by Medicare and Medicaid. Efforts directed at cost containment through reduced payments for care pose a serious threat to the provision of high-quality services. In addition, the profit motive inherent in proprietary health care may be seen as posing a conflict of interest with the provision of high-quality care.

ENSURING STANDARDS OF NURSING HOME CARE

Ensuring high quality of care and standards for services has posed a major challenge to the nursing home industry (Vladeck 1980; R. A. Kane 1995–1996). Problems have been encountered in terms of poor staff training (R. A. Kane 1995–1996), high staff turnover rates (Banazac-Holl and Hines 1996), and limited physician involvement (Fortinsky and Raff 1995–1996). Nurses' aides, the

staff members with the most limited training and education and at the lowest end of the pay scale, provide the majority of patient care in nursing homes (IOM 1996). Higher ratios of registered nurses (RNs) to patients are associated with higher patient survival rates, increased functional status, and increased numbers of patients discharged from the nursing home (IOM 1996). Nevertheless, pay differentials between hospitals and nursing homes have contributed to a paucity of RNs working in nursing homes and an overrepresentation of nurses with limited educational backgrounds working in long-term care facilities (IOM 1996). It is noteworthy that nursing assistants employed in nursing homes are also less well paid than their counterparts working in hospitals (BLS 1995). Nursing assistants have limited education, with 46 percent having high school diplomas, while nearly 18 percent have not graduated from high school (IOM 1996). In addition to morale problems resulting from low-status jobs with poor pay, many nursing assistants also face personal problems exacerbated by their low socioeconomic status (Coons and Mace 1996). These factors are related to very high turnover rates among nursing assistants, resulting in poorer quality of care (Schnelle et al. 1993).

Generally speaking, assessing quality of care involves an inquiry into three key ingredients of health care quality: structure, process, and outcomes. Structural measures gauge the presence of certain provider characteristics that are thought to produce good-quality outcomes. Process measures compare the actual care delivered to standards or norms of practice. Outcome measures serve to indicate the results of the care received (e.g., death, functional change). Reliable measures of appropriate outcomes of care are sought by quality-assurance programs in long-term care (R. A. Kane, R. L. Kane, and Ladd 1998). In the context of improvement in care quality, outcome assessments may be used to allocate resources to those areas that require remediation.

Although diverse quality assurance and enhancement programs have been advocated, regulation continues to serve as the major approach to insuring high quality of care. Until Medicare and Medicaid were enacted in 1965, nursing home regulation was each state's responsibility. Once federal programs began paying for nursing home

services, the federal government became more involved in regulating nursing homes. It has been argued that Medicare and Medicaid had a major influence on delivery of care in nursing homes due to the regulations placed on facilities and the standards established for certification and for eligibility for payments (R. A. Kane, R. L. Kane, and Ladd 1998; Lusky and Ingman 1994). Lack of uniformity from state to state in care delivery arises as states decide who is eligible for Medicaid. They also impose their own diverse standards for quality care and regulation of such care through inspections.

Alternative approaches to ensuring standards for services have been advanced through regulation or free market economy (Nyman and Geyer 1989). Regulation seeks to enforce high quality of care through staffing standards, care plans, and result audits. In general, regulation aims to ensure the most basic aspects of quality of care, such as appropriate medical care, sanitary living conditions, sufficient exercise, adequate diet, and at least limited privacy for residents. Regulatory efforts are widely employed and have had at least limited success in defining and monitoring quality of health care. However, regulation is seen by many as a costly and often ineffective approach that is dependent on enforcement of a limited set of universally agreed-upon standards (Nyman and Geyer 1989).

In free market competition, consumers do the work of raising quality by making informed choices and purchasing high-quality services. Ensuring standards through the use of the free market economy rests on the assumption that the consumer can identify good-quality care and has furthermore researched the market and will choose to reside in a facility that provides the best care. However, third-party payment systems limit the effectiveness of consumers in exercising market choices. Severely impaired nursing home patients (who may also lack family or advocates) are limited in their ability to exercise sufficient rational market choice to ensure nursing home quality.

Alternative approaches to improving quality of care have been noted in addition to those of regulation or competition. For example, increased involvement by volunteers, family members, and other representatives of the community may enhance care by increasing public awareness and

accountability. Community advocacy programs that encourage local citizens to press for patient rights and for improved care delivery have been found to be useful (Williams 1986). In addition, there has been increasing education of the public to have patients and families serve as their own advocates in choosing high-quality nursing homes and in seeking high-quality care through awareness of nursing home residents' rights (Burger et al. 1996). There has also been evidence of the useful roles played by nursing home ombudsmen in helping to resolve disputes involving residents (J. Kahana 1994).

In a 1986 report, the Institute of Medicine called for improvements in the quality of care in nursing homes. A landmark development following this report was the Omnibus Budget Reconciliation Act (OBRA) of 1987 setting forth guidelines by the Health Care Financing Administration for nursing home care. This act aimed to protect resident rights and improve residents' quality of life through a broad set of regulations. These included training and certification of nursing assistants, establishment of quality assurance committees, mandated resident assessments to allow for individualized care planning, reduction of physical and chemical restraints and preadmission screening for mental illness (Hamme 1991). OBRA also enforces a regulation that sets standards of care by increasing financial sanctions for noncompliance. Accordingly, noncompliant homes could be subject to fines and have Medicaid and Medicare payments withheld (Hamme 1991).

The enactment of OBRA raised high hopes about ensuring a high quality of care in nursing homes, and its implementation has resulted in improvements in quality of care. There is evidence of reduced use and overuse of drugs, in particular psychotropic medications (Borson and Doane 1997; Lantz et al. 1996), as well as a reduction in the use of physical restraints in nursing homes since the implementation of OBRA (Dunbar et al. 1996; Siegler et al. 1997). Research has also documented improvements in the accuracy of information in residents' medical records and in comprehensiveness of care plans (Hawes et al. 1997). There has also been an increase in positive programs such as presence of advanced directives and participation in activities by residents (Hawes et al. 1997). As an outgrowth of OBRA legislation, psychiatric assessments and screening programs have resulted in

some improvement in matching residents to appropriate mental health services (Borson and Doane 1997). Nevertheless, many problems and challenges have remained in the wake of OBRA. Thus, for example, the OBRA-mandated freedom of residents to select their own physicians can seldom be implemented, because most physicians will not follow their patients to the nursing home to deliver care. Lack of funding for inspections allows violations to go undetected (Day 1996). There have also been only limited advances made in the treatment of the depressed elderly (Snowden and Roy-Byrne 1998).

RECENT TRENDS IN PROGRAMS AND CARE DELIVERY IN NURSING HOMES

In addition to mandated programs to enhance nursing home quality, there have also been notable developments in recent years to introduce innovative or at least new approaches to caring for older adults in nursing homes and other long-term care facilities. We will review two major approaches to such developments: special units and formal intervention programs to improve quality of care and of residential life.

Special Units. Special units within nursing homes are based on homogeneous groupings of people with special needs. The assumption underlying this movement is that specially trained staff may best meet the unique needs of specific patient groups. Segregating populations of residents with stigmatized or disruptive characteristics may also be seen as benefiting other residents by limiting their exposure to these populations.

Special programs can be targeted to unique groups such as dementia patients and patients in the final stages of life. Each of these will be discussed below. Although there is increasing recognition of the role of nursing homes in meeting the special needs of populations such as patients with AIDS (Zablosky and Ory 1995) or patients with brain injuries (Parsons 1997), programs for such individuals have been sporadic and limited. Often these special needs groups include higher proportions of younger patients and models of nursing home care geared to the elderly are poorly matched to their needs. Furthermore, research evaluating such programs is generally lacking.

Dementia Care Units Special care units in nursing homes have been proliferating for dementia patients. About 20 percent of nursing homes had dementia-specific special care units in the mid-1990s (Aronson 1994). These units are based on presumed benefits of functionally homogeneous resident groupings and generally target programs for confused but ambulatory residents.

It has been argued that dementia patients need “high-touch” rather than “high-tech” interventions (Aronson 1994). Many programs targeting dementia patients, are not reimbursable under skilled care guidelines. Special units for dementia care have been in the forefront of the development of certain innovative programs and particularly in integrating family members in patient care (Gaston 1994). Family members’ prior knowledge of the older adult when he or she was functioning well can enable expressions of emotional support, which in turn facilitates maintenance of the dignity and self-worth of these elders. Effective formal programs in dementia units that involve families in the care of elders range from family stories workshops (Hepburn et al. 1997) to the inclusion of families in staff-initiated treatment programs (Grower et al. 1994).

Hospice Units As greater numbers of older adults are dying in nursing home settings, the provision of hospice care is becoming a more central function of nursing homes. Between 1992 and 1995, the number of nursing homes with hospice units increased 100 percent, although the development of such units is constrained by market forces such as Medicaid reimbursement (Castle 1998). The value of the hospice as a useful model for end-of-life care has been increasingly recognized. This approach to care emphasizes holistic patient care aimed at diminishing pain and enhancing comfort and meaning. This orientation brings both dignity and autonomy to the process of dying for the elderly resident (Hayslip and Leon 1992).

The hospice model also points the way to recognition that the nursing home often serves as the context where older adults prepare for dying. Accordingly, a much-needed and often-absent function of nursing homes is helping residents come to terms with awareness and acceptance of their finitude (Johnson and Barer 1997).

Formal Interventions to Improve Quality of Life in Nursing Homes. While sociologists have generally focused on the specification of broad social features of nursing homes that impact on the life and welfare of the resident, psychologists, nurses, and social workers have been more involved in implementing specific and circumscribed intervention efforts in nursing homes. Direct interventions to improve resident functioning and/or the quality of resident life in nursing homes have been limited by the absence of systematic theories, on the one hand, and lack of resources, on the other. Diverse efforts to improve care have generally yielded some success, suggesting that almost any type of intervention can improve the quality of life or functioning of residents (E. Kahana, B. Kahana, and Chirayath 1999). Interventions may be broadly classified into two types: those aiming to improve the physical or social environment of the setting, and those aiming to improve the coping strategies, psychosocial well-being, or cognitive functioning of residents. Interventions may alternatively be directed at the resident, the environment, family, or staff.

Interventions to improve health and physical functioning of nursing home residents typically include programs that attempt to reduce impairment and disability (e.g. nutritional problems, urinary incontinence) or the risk of falling. Some interventions aimed at improving health and physical functioning expand their scope by attempting to improve overall quality of life for the resident. Such interventions include programs which grant residents greater autonomy and locus of control (Wagner et al. 1994), and those that incorporate self-image enhancements (Plautz and Timen 1992). Intergenerational programs that promote interaction between nursing home residents and children or young adults have been found to be successful in enhancing quality of life for nursing home patients as well as young children (Gaston 1994; Newman 1985). Such programs have generally been found to improve the activities and social interactions of the elderly.

Interventions targeting cognitively impaired residents include divergent approaches. Montessori methods have also shown success in improving the cognitive functioning of demented elders (Camp and Mattern 1999). Cueing and reality orientation have been therapeutic strategies aimed at reinforcing orientation to time, place, and person among

cognitively impaired elderly (Aronson 1994; Whanger 1980). Fantasy validation therapy takes a divergent view, providing staff acceptance of nursing home patients through expressing empathy in response to unrealistic beliefs or behaviors (Feil 1982).

Behavioristic approaches to the treatment of psychiatric problems in nursing homes include reinforcement of appropriate behaviors through token economies or habit training (Whanger 1980). Educational opportunities to enhance competent coping strategies have also been advocated (E. Kahana and B. Kahana 1983). Regarding the physical environment of the nursing home, prosthetically designed environments have been found to retard decline among mentally impaired elderly (Lawton et al. 1984). Milieu therapy is a systematic approach to enhancing all aspects of the social and physical environment in order to encourage social interactions among residents (Soth 1997).

As illustrated in the above discussion of systematic interventions in nursing homes, much of the empirical work relevant to person-environment transactions focuses on only one of the two related influences: the patient or the milieu. Thus, while conceptual frameworks recognize the dynamic nature of person-institution transactions, these complex interactions have not yet been incorporated in therapeutic interventions.

Focus on the Life of the Nursing Home Resident: Effects of Institutionalization. We will now consider those aspects of institutionalization that impact on the experiences, lifestyles, and well-being of the individuals who enter even the best of nursing homes. It is primarily this area of inquiry, relating social processes to the life experiences of the individual patient, to which sociologists have addressed their research on nursing homes. Considering the individual resident in the context of the physical and social milieu of a given institution, we can appreciate both the factors that induce negative reactions and those resources which facilitate positive responses to institutionalization. On this level of analysis, the sociologist moves away from considering the patient as a mere object of care and notes the interactive nature of the encounter between the institutionalized person and diverse elements within the nursing home environment.

The problems brought about by institutionalization go beyond problems of quality health care

and in fact, may be inherent in the very nature of congregate care. Accordingly, sociologists have recognized that the nursing home, by its very nature, represents a unique social context with homogenizing qualities, and that there are alterations in the normal patterns of interaction and social exchange, even in facilities providing high-quality care (Linz et al. 1993). Holistic analyses of life in the nursing home have been conducted primarily in a qualitative tradition. They range from firsthand accounts to in-depth interviews and participant observations of the nursing home (Diamond 1992; Gubrium 1993; Henderson and Vesperi 1995; Laird 1979; Savishinsky 1991; Shield 1988). There have been few, if any, quantitative research projects to address the complex fabric of residents' experiences of nursing home life in the past two decades. Conceptual developments have also been limited, highlighting the seminal nature of Goffman's original conceptualizations of the total institution as the most comprehensive and best model in our field.

Goffman's classical depiction of the total institution (1961) still serves as a standard for understanding the problems of institutional living. The *total institution* is described as a place where inmates are brought together under a common authority, are stripped of their normal identities, and are expected to engage in activities of daily living according to formal rules and a rational plan that regiments them. Activities of work, play, and sleep overlap and are typically conducted in the presence of others. The institution (which is often located at a distance from friends and from the previous community of the resident) also effectively cuts residents off from social ties in the outside world. It has been suggested that, among nursing home residents, isolation from society and loss of control over one's life lead to learned helplessness (Coons and Mace 1996; Baltes 1996; Baltes and Baltes 1986).

Frail older persons who typically enter nursing homes are particularly vulnerable because of physical and mental infirmities, sensory impairments, and loss of social supports that have created the need for such placement (Resnick et al. 1997; E. Kahana, B. Kahana, and Kinney 1990). Such vulnerable individuals are particularly sensitive to environmental change, and adverse living conditions (Lawton 1980). Elderly persons living

in the community generally fear institutional placement and seldom plan for a move to an institution (E. Kahana, B. Kahana, and Young 1985; Schoenberg and Coward 1997). The transition to living in a nursing home is typically involuntary, with patients seldom playing major roles in the relocation decision or choice of facility (Reinardy 1992). Furthermore, the new institutional setting is unfamiliar to the resident in terms of both physical features and social expectations. Fewer than half of family members visit facilities prior to placement of an elder (Lieberman and Kramer 1991). Unpredictability and uncontrollability are major risk factors accounting for the negative outcomes of institutional relocation (Schultz and Brenner 1977). Lack of involvement in decision making has also been associated with adjustment problems (Rubenstein et al. 1992). Alternatively, positive adjustment can be facilitated where older adults participate in decision-making about relocation (Armer 1993).

It is difficult to establish conclusively which elements of institutionalization are responsible for negative outcomes among residents because the effects of morbidity, relocation, and institutionalization occur concurrently and are difficult to separate (Lieberman and Kramer 1991). Yet the negative personal consequences of life in nursing homes have been documented. Institutionalization has been described in terms of dismantling one's home with its comforts, memories, and freedoms (Savishinsky 1991). Institutionalized elders have shown loss of self-esteem and identity (Tobin 1991), and often manifest withdrawal, apathy, and depression (Gubrium 1975, 1993; R. A. Kane 1995-1996; Vladeck 1980).

Gubrium (1993) conducted qualitative interviews with nursing home residents and found great disjunctures in meaning between the workings of the nursing home as an organization and the textured realities of the "lived experience" of residents. Residents live in a rich world of subjective meaning, which is seldom recognized and validated by the nursing home. In fact, nursing homes may actively resist responding to subjective realities of residents, in an effort to introduce an organizational rationality (Diamond 1992). It has been documented that institutional environments providing limited control over the daily lives of residents result in negative resident outcomes,

including diminished life satisfaction (R. L. Kane et al. 1990; Timko et al. 1993).

In spite of the evidence of adverse effects of institutionalization, there is a growing body of research and clinical observation that documents positive features and potential benefits of residential life in nursing homes (Patchner and Balgopal 1993; Pynoos and Regnier 1991). For isolated older persons who can no longer care for themselves, the nursing home can offer protection, improved living conditions, and even homelike qualities (Groger 1994). Advantages of living in a nursing home can also include behavioral expectations that are well matched to the competencies of the frail resident (Baltes and Werner 1992; Werner et al. 1994; Lawton 1980).

Nutritious meals, regular medical care, and supervised administration of medications may maximize health for frail elders living in nursing homes. Proximity to other residents may allow for social needs to be met, and organized activities can lead to meaningful social participation (Bitzan and Kruzich 1990). Indeed, there is some evidence that resident satisfaction subsequent to institutionalization exceeds expectations (E. Kahana, B. Kahana, and Young 1985). Some early studies have noted improved morale (Spasoff et al. 1978) and enhanced family relationships subsequent to institutionalization of elders (Smith and Bengtson 1979).

There are indications that elderly nursing home residents find their lives to be meaningful and that their sources of meaning do not differ significantly from those of community-living older adults (DePaola and Ebersole 1995). Well-being among residents subsequent to institutionalization may reflect not so much the positive influences of institutional life as the resilience and survival skills of residents. Accordingly, Lieberman and Tobin (1983) demonstrated that even in the face of major involuntary environmental changes such as institutionalization, many elderly persons continue to preserve a coherent and consistent self-image.

Adaptation in Institutions. There is growing evidence supporting the view that residents are active agents who attach meaning to and impact actively on their environment, continuing to take personal initiatives to remain socially engaged in the face of personal and environmental obstacles for doing so (E. Kahana, B. Kahana, and Chirayath 1999; Mor et al. 1995; Gubrium 1993).

Goffman (1961) described a range of adaptive responses among inmates of total institutions. *Withdrawal* refers to the resident's efforts to curtail interaction with others and to withhold emotional investment in his or her surroundings. *Intransigence* is a response that challenges institutional authority through noncooperation. These two modes of responding are likely to result in further alienation and to invite negative responses from staff and other residents. *Colonization* represents a strategy of maximizing satisfactions within the confines of the institution by accepting the rules and norms of institutional life. *Conversion* represents an identification with both the outward characteristics and the values of staff. Patients who opt for conversion submerge their identities into their patient roles. Although Goffman's conceptualization and description provide the earliest and possibly the richest sociological efforts to understand resident adaptation in nursing homes, there has been little follow-up research to confirm the typologies that he proposed.

Research has documented that there are active efforts even among frail institutionalized elderly to adapt to demands and stresses of institutional living and to remain socially engaged even while living in an institution (Mor et al. 1995). Instrumental coping strategies have been associated with maintenance of psychological well-being subsequent to institutionalization, whereas affective modes of coping have been related to decline in morale (E. Kahana, B. Kahana, and Young 1987).

Appraisals of life in a nursing home may contribute greatly to perceptions of stress, to coping responses, and ultimately to adaptive outcomes. In fact, an understanding of the interpretive meaning of institutional life may help integrate conflicting findings about effects of selection, relocation, and institutionalization on psychosocial well-being of elders residing in nursing homes (Gubrium 1993).

Aspects of physical frailty that create a need for institutional placement, along with perceived or real abandonment by family, require major reappraisals of both one's worldview and one's self-concept. Given a vulnerable self and loss of intimacy with significant others, the safety of one's physical and social milieu becomes a critical concern. To the extent that new residents of nursing homes can appraise their physical and social environment as safe, they will feel protected. To the

extent that they feel that other residents who compose their new reference group are helpful, social integration may be possible, and depersonalization may be avoided. There is evidence that residents in assisted living facilities engage in reciprocal helping social interaction and derive satisfaction from being providers of assistance to others (Litwin 1998). This research supports earlier work (E. Kahana, B. Kahana, Sterin, Fedirko, and Brittis 1990) which demonstrated that perceptions of even minor acts of helpfulness by other residents help the institutionalized elderly reinterpret their surroundings as benign. Formation of social ties with other patients represents an important mode of positive adaptation for nursing home residents (Mor et al. 1995).

Personal backgrounds of residents as well as environmental influences affect the nature of adaptations that residents make in institutions. Lack of mental impairment and few mobility limitations and sensory deficits are associated with maintenance of close social ties within the nursing home (Bitzan and Kruzich 1990). Personality and cognitive traits such as impulse control have been found to be associated with psychosocial well-being subsequent to institutionalization (B. Kahana and E. Kahana 1976).

In order to better understand and operationalize person-environment transactions in nursing homes, several conceptual models have been articulated that take into account both personal and environmental features. Lawton's ecological model (1980) focuses on the importance of matching environmental elements to personal competencies of frail elders. E. Kahana's person-environment congruence model (1982) emphasizes the role of individual differences in needs and environmental preferences, and specifies alternative formulations for expected outcomes based on oversupply, undersupply, or congruence of environmental characteristics, such as stimulation or homogeneity, in relation to personal preferences. It is notable that there has been very limited attention to advancing conceptual models in this arena during the past two decades.

Interactionist perspectives lead to a better understanding of social influences in nursing homes by calling attention to the importance of both personal reactions and environmental presses. Environmental design and intervention approaches

in nursing homes have focused on improving adjustment of residents to nursing homes by providing environments that benefit residents in general, or interventions that improve fit between the environment and personal needs of residents. Research has demonstrated that resident characteristics interact with environmental features of the nursing home to predict outcomes (Baltes et al. 1991; Timko et al. 1993). Accordingly, supportive physical features and assistive services were found to benefit impaired residents while policies permitting resident control were most likely to benefit independent residents. Furthermore, specification of salient dimensions of the institutional milieu has been one important area of progress toward designing better nursing home environments. Moos and Lemke (1996) have conducted pioneering work in providing reliable and valid indicators of social dimensions of the institutional environment.

Specific components of the institutional environment determine the demands, constraints, and benefits of institutional life for residents. They include the administrative structure, the physical environment, and the social environment. The social environment may be further subdivided into staff environment; patient environment; and community representatives such as volunteers, or friends and family, who visit the resident in the institution. There is growing evidence that the perspectives of residents, staff, and families diverge with regard to quality of life in nursing homes (Brennan et al. 1988). Research on administrative structure has focused primarily on size, financing, and type of ownership. Although it has been argued that proprietary ownership may result in poorer quality of care, the link between type of ownership and level of care has not been conclusively established. Similarly, suggested links between size of home or proportion of Medicaid patients and quality of care have not been fully documented (Shapiro and Tate 1995).

Similarities in ethnic, cultural, and social backgrounds of staff and residents appear to facilitate positive interactions, whereas discrepancies in cultural values have been found to hamper communication and mutual understanding (E. Kahana, B. Kahana, Sterin, Fedirko, and Taylor 1993; Harel 1987). Institutional norms as well as formal policies have been found to shape the impact of institutions on residents (Kiyak et al. 1978). Research

also suggested that perceived social support from family not only deters institutional placement but also relates to higher self-esteem and diminished depression among elderly nursing home residents (McFall and Miller 1992).

Resident-to-Resident Interactions There has been very little research focusing on the social milieu of nursing homes in terms of resident-to-resident interactions. It is indeed noteworthy that, in one study of nursing home residents, nearly 50 percent of all residents were found never to talk to their roommates, typically because of barriers to communication such as hearing or speech problems (Kovach and Robinson 1996). Nevertheless, among those residents able to talk to their roommates, rapport with the roommate was found to be a significant predictor of life satisfaction. It is notable that communication rules about talking often inhibit communication and contribute to living in silence among nursing home residents (Kaakinen 1992).

The salience of friends appears to be limited for nursing home residents, as there are many barriers to elderly friends maintaining contact with their noninstitutionalized friends. Accordingly, perceived social support from friends did not significantly relate to positive outcomes of nursing home residents (Commerford and Reznikoff 1996).

Family-Resident Interactions Interactions with family also play an important role in social integration of residents. Research has underscored that the majority of institutionalized elderly maintain meaningful ties and interactions with family members (Schwartz and Vogel 1990; High and Rowles 1995; Smith and Bengtson 1979). Ties to children who visit most frequently appear to be closest, followed by ties to other family members and friends (Bitzan and Kruzich 1990). Proximity of family members and previous history of extensive social interactions facilitate continued contact between residents and kin (York and Calsyn 1977). In turn, visitation by families and friends has been associated with enhanced residential functioning and well-being (Greene and Monahan 1982).

Broader roles for family members for being involved in the support and direct care of patients have been discussed, particularly in the social work literature (LaBrake 1996). However, systematic investigations of the efficacy of such efforts are

sparse. Some family support group activities as well as family counseling programs have reported success in bringing family and staff closer together (Campbell and Linc 1996). There have also been some educational efforts directed at assisting family members in coming to terms with psychological issues that they face regarding institutionalization of the elder relative (Drysdale et al. 1993).

Even while there is limited indication of systematic and welcoming programs initiated by the nursing home for the involvement of families in the care of residents, there are indications about naturally occurring involvement by family members in the lives and care of institutionalized older adults. Thus, for example, studies indicate that families are highly involved in assisting their relatives with decision making, and in actually making decisions when needed (High and Rowles 1995). Although researchers had expected to find less participation in decision making by families over time (since it was assumed that they would gradually defer to staff in making decisions), it was found that families do remain highly involved in their relatives' lives and well-being, even after four years. Families reported involvement in a broad range of decisions, ranging from those made during crises to those concerning the physical environment and treatment decisions.

There is also evidence, from surveys of family perspectives on nursing home care, that family members are typically sensitive and understanding about the constraints under which nursing home staff work and the difficulties posed by caring for frail elders, and particularly those with dementia (Looman et al. 1997). This research found that families also appreciate positive interpersonal ties between nursing assistants and residents.

The potential of constructive family involvement for improving resident life in nursing homes is yet to be recognized. It could have a major positive influence on helping break down barriers between the outside world and those of the institutions, addressing Goffman's classic challenge to the total institution (1961).

Future Prospects for Policy and Long-Term Care Delivery. It has been argued that, in the future, home care may evolve into a model of personal assistance services, and thus could blur the boundaries between institutional (nursing

home) and community-based care (R. A. Kane 1995). To the extent that personal care and housing-related services in nursing homes could be separated, residents and families could gain greater control of their lives. With the support of flexible home care options, many frail older persons could remain in innovative community residential options, such as assisted living arrangements, for the remainder of their lives. Such potential developments are attractive, but assume major changes in the financing of long-term care and the building of private accommodations, which include baths and kitchenettes, in housing for nursing home residents. Such new trends in financing and delivery of care would have to be based on dramatic expansion of personal long-term care insurance and/or availability of savings to finance long-term care. Alternatively, they could be implemented based on major new universal services furnished through social insurance programs (Kingson 1996). However, there are no clear indications that any of these financing options is likely to materialize in the near future. Furthermore it is likely that in the future most new and even existing long-term care services will be implemented by individual states. Increasing involvement in delivery of long-term care by states is likely to lead to increasing variability in the quality of care delivered (R. L. Kane et al. 1998).

In spite of expected increases in alternative long-term care facilities, the population of old-old adults residing in nursing homes is expected to increase dramatically, due largely to the ever-increasing age structure of the U.S. population. It is notable in this regard that research projecting future nursing home use demonstrates that better health in future cohorts of the old-old will only slightly decrease the proportion of time older adults will spend in nursing homes, or the proportion of this cohort who will enter nursing homes (Laditka 1998). Thus the nursing home as an organization is here to stay for the foreseeable future.

Furthermore, it is important to recognize that all the numerous alternatives proposed to address the shortcomings in the current system involve potential problems and tradeoffs (R. A. Kane et al. 1998). Ultimately, the planning, financing, delivery, and oversight of long-term care challenges our values and ingenuity as a society. Accordingly, sociologists, who have generally opted out of the

study of long-term care, are very much needed to get involved in this area, if we are to gain deeper understandings and develop systematic research based guidelines for improving services in this field.

CONCLUSION

The foregoing discussion has highlighted a series of counterpoints in consideration of nursing home care on the macro and micro levels. On the macro level, distinctions between medical and social models of care, quality-of-care, and quality-of-life issues have been discussed. Societal needs for cost containment have been juxtaposed with the need to invest greater resources in long-term care to ensure provision of high-quality care. Regulation and free market competition have been presented as alternative strategies to improve standards of care. Uncertainty about service models, along with a great concern about costs of care, have resulted in a stalemate in the field of long-term care (Vladeck 1995).

On the micro level, we have noted evidence for depersonalizing aspects of institutional living, along with data about protective features and benefits of long-term care environments. Furthermore, residents of nursing homes have been described as frail and vulnerable on the one hand, and as adaptable and resilient on the other. The ultimate well-being of nursing home residents is seen as a function of the environment, of the person, or of transactions between the two. These dualities are useful to propel dialogue and to permit a thorough examination of nursing home care. At the same time they hold the danger of oversimplification of issues that may be approached from a unidimensional framework as proponents advocate one pole of the duality or the other. In fact, a sociological understanding of nursing homes underscores the complexity and multidimensionality of the social context and the social world of the nursing home. Thus, there is great benefit in attempting to integrate insights gained from both poles of the dualities discussed.

The nursing home resident of the future is likely to be ever more frail, especially if we succeed in developing more home-based alternatives to care. Hence, we cannot reject the medical model in favor of a social model of care, or focus exclusively on quality of life rather than on quality of

care. Instead, we need to complement concerns of high-quality health care with those of high standards for social care. Similarly, just as proprietary care is likely to remain a part of health care in the United States, so regulation is here to stay. Although prospective nursing home residents are likely to be ever more frail, they are also likely to be more highly educated and more conscious of their rights as consumers. Financing mechanisms that enhance the ability of the consumers of long-term care to exercise control over their lives can complement regulatory efforts to upgrade quality of care in nursing home settings. On the broadest societal level, decisions about both commitment of resources and development of creative alternatives to institution-based, long-term care are likely to shape the parameters and qualities of nursing homes of the future.

The experience of a given individual in being cared for in a nursing home must ultimately be understood in the context of the complex matrix of influences posed by institutional living. Accordingly, it is not fruitful to focus exclusively on either the ill effects or the benefits of institutionalization. Reviews of nursing homes continue to focus on normative understandings, generally highlighting poor quality of care in such facilities. As we have noted in this essay, empirical support for such negative conclusions is generally derived from qualitative research. Quantitative studies generally provide less support for expectations of decline and adverse patient reactions. In an effort to understand conflicting conclusions of different genres of research in this area, it is useful to focus on personal as well as environmental and situational influences that moderate the effects of institutional living. More carefully designed nursing home-based research, utilizing quantitative as well as qualitative approaches, is needed to specify conditions of both person and environment that maximize the well-being of the individual requiring institutional care.

Newer health care options, such as CCRCs, assisted living, and special care units, have been touted as more patient-responsive solutions to care than traditional nursing homes. Nevertheless, true consumer control and resident outcomes are still largely contingent on the resident's power to demand and advocate for appropriate care options. If an older adult becomes physically frail or

mentally impaired, such options are likely to diminish, or even evaporate. Consumers are once again at the mercy of bureaucratic decision making about their best interests.

Even advocates of alternative forms of long-term care acknowledge that nursing home care will continue to be needed and utilized by the increasing segment of old-old citizens. Sanctions, incentives, and intervention programs have all been shown to be beneficial, at least to a limited extent, in improving the quality of care and the quality of life in nursing homes.

Enhancing the quality of nursing home care creates a challenge for society to commit greater resources generated by currently productive citizens to the care of those who have made previous contributions. The resources society devotes to long-term care ultimately mirror the value placed by society on its frail or dependent citizens. Thus, a devaluing of older people is likely to result in a devaluing of institutions that care for them, along with a devaluing of the providers of their care. Conversely, more positive societal attitudes toward frail elders are likely to be translated into increasing involvement by high-caliber, trained professionals in the care of the institutionalized elderly. In addition, positive societal attitudes should bring family members and community representatives into closer contact with institutions, and should help to break down barriers between the nursing home and community living.

LONGITUDINAL RESEARCH

NOTE: Although the following article has not been revised for this edition of the Encyclopedia, the substantive coverage is currently appropriate. The editors have provided a list of recent works at the end of the article to facilitate research and exploration of the topic.

According to Heckman and Singer, "Longitudinal data are widely and uncritically regarded as a panacea . . . The conventional wisdom in social science equates 'longitudinal' with 'good' and discussion of the issue rarely rises above that level" (1985, p. ix).

There is probably no methodological maxim in sociology more often repeated than the call for longitudinal data. From the work of David Hume more than 250 years ago, to the exhortations for a "radical reformation" in the work of Stanley Lieberman (1985, p. xiii), the importance of longitudinal data has been emphasized and reemphasized. Yet it is doubtful that there is an area of sociological method in which more disagreement exists both as to rationale and as to method. Until relatively recently, it has been possible to ignore the problem because longitudinal data have been relatively rare, and methods for their analysis quite sparse. Since 1965, however, there has been a virtual flood of new longitudinal data and a concomitant increase in sophisticated methods of analysis. In large part the computer has made both developments possible, permitting the management of data sets of enormous complexity along with analyses undreamed of only a short while ago.

At the micro level, numerous longitudinal studies have tracked individuals over a good share of their lifetimes. For example, some participants in the Oakland and Berkeley studies of growth and development have been sporadically studied from birth until well into their seventies (Elder, this volume). On a more systematic basis, the Panel Study of Income Dynamics (PSID) has interviewed a panel based on an original sample of five thousand families (households) on an annual basis since the mid 1960s, supplementing the sample with new households formed as split-offs from the original families (Duncan and Morgan 1985). Many other large-scale panel studies, some extending over periods of thirty years and longer, are in progress (Migdal et al. 1981).

At the macro level, extended time series on various social and economic indicators such as GNP, fertility, mortality, and education are gradually becoming available in machine-readable form from virtually all industrialized societies and from many that are less developed. In some cases, data series, particularly for vital statistics, go back for decades. In other cases, such as China and the

Soviet Union, modern-era data are gradually being accumulated and linked to earlier series. Descriptions of many such data sets can be found in the annual guide published by the Inter-University Consortium for Political and Social Research (ICPSR 1991).

Perhaps the most exciting developments are at the nexus of macro- and micro-level analysis. In the United States, for example, the General Social Survey (GSS) has obtained data on repeated cross-sectional samples of the population (that is, the population is followed longitudinally but specific individuals are not) on an annual basis (with two exceptions) since 1972. More recently, annual surveys modeled on the GSS have been started in a number of other countries (Smith 1986). Because of the careful replication, these surveys permit one to track aggregate responses of the changing population on a wide variety of issues (such as on attitudes toward abortion or capital punishment) over time. As the time series becomes ever longer, it is possible to carry out a multilevel analysis, linking micro and macro variables. For example, using the GSS, DiPrete and Grusky (1990) attempt to link short-term changes in rates of social mobility to macro-level changes in the U.S. economy.

Although the size and complexity of the longitudinal data base has expanded rapidly, so have the statistical tools with which to analyze it. Perhaps the most exciting development is in the area of "event history models," which permit one to relate an underlying rate of transition in continuous time to a set of "covariates" or independent variables. However, event models are by no means the only development. New and powerful approaches to the analysis of means over time, to structural equation models, and to various forms of categorical data analysis have given the researchers unprecedented power. Standard computer packages now make routine what was impossible in the 1980s.

THE RATIONALE FOR LONGITUDINAL RESEARCH

Longitudinal studies are carried out in virtually every area of the social sciences. Although studies of infant development and national development share certain similarities, it is not likely that a single rationale, design, or approach to analysis will simultaneously apply to every area in which longitudinal data might be collected. At the most

abstract level, there are three basic reasons for conducting a longitudinal study.

First, in any area in which development and change over time are at issue, there is, almost by definition, a necessity to obtain time-ordered data. Questions pertaining to rate and sequence of change, and to variability in rates and sequences are at the heart of longitudinal research. At one level, these questions are essentially descriptive, and getting an adequate descriptive handle on time-ordered data is an essential first step in coming to any understanding of change.

A second reason involves the role of temporal priority in causal analysis. There are few things on which philosophers of science agree when it comes to causation (see Marini and Singer 1988 for a superb review), but one is that A must precede B in time if A is to be taken as a cause of B. It is natural to assume that observing A before B means that A precedes B. Unfortunately, designs that actually allow one to establish temporal, let alone causal, priority are not as easily arrived at as one might think.

Related to the issue of temporal priority is the cross-sectional fallacy. Lieberman (1985, pp. 179–183) argues that assertions of causality based on cross-sectional data must necessarily imply a longitudinal relationship. To show that city size “leads to crime” based on cross-sectional data implies a dynamic relationship that may or may not be true. The problem is particularly acute in cross-sectional age comparisons that are necessarily confounded with cohort differences. All cross-sectional attempts to ascertain the “effect” of age on income confound cohort differences in average income with age differences.

A third reason, particularly relevant to sociologists, is the necessity to distinguish gross change from net change. A census taken at two points in time shows changes in the distribution of a variable, say occupation, at the macro level. We might find that the proportion of the population in service-oriented occupations increases over the period of a decade. That indicator of net change conceals myriad patterns of gross change at the individual level. The count of persons in service occupations at two points in time consists of persons who were occupationally stable over the interval and persons who changed in various ways. Of course the population itself changed over the interval due to age-related changes in the labor

force, migration, and differing levels of labor-force participation. All of this is masked by repeated cross-sectional samples.

Finally, although not really a “rationale” for longitudinal research, observation plans with repeated measures on the same individuals can offer certain statistical advantages. Cook and Ware (1983) discuss these in detail.

TYPES OF LONGITUDINAL DATA

For many sociologists, the term *longitudinal* connotes a particular design, usually referred to as a panel study, in which individual subjects are measured repeatedly over time. A more general definition is desirable. Longitudinal data consist of information that can be ordered in time. Such data can be obtained in a variety of ways: by measuring the subject prospectively at repeated intervals, by obtaining a retrospective history in one or more interviews, from institutional records, or various combinations of these approaches. “Strong” longitudinal data preserve exact time intervals, while “weak” data provide sequence and order but lose interval. The distinction is parallel to that between interval and ordinal measurement.

As Featherman (1977) notes, under some circumstances, retrospective data collection may have substantial advantages of time and cost. Most surveys collect retrospective data of one kind or another, such as educational attainment, family background, and marital histories. Using structured interviewing methods in which the respondent is provided with a time-oriented matrix, it is possible to collect quite accurate information on many aspects of the life course. For example, as part of an ongoing panel, Freedman et al. (1988) obtained retrospective reports of family structure and other demographic variables that had previously been measured contemporaneously. The results are highly encouraging; when retrospective questions of this kind are asked carefully and interviewers are well trained, respondents can provide accurate and detailed information.

Of course not all variables can be measured retrospectively. Most researchers would argue that any attempt to measure past psychological states is invalid on its face. Reporting of the timing and frequency of events, even those which are quite salient, such as hospitalization, appears to suffer

from serious recall problems. Subjects tend to forget them or to telescope them in time. Reports of exact earnings, hours worked, and other economic variables may suffer from similar problems. The truth is that we don't have much information on what can and cannot be measured retrospectively. A systematic research program on these issues is becoming more and more necessary as new methods of data analysis that depend on the exact timing of events continue to evolve.

Another serious weakness of the retrospective design is that it represents the population that survives to the point of data collection and not the original population. In some situations this kind of selection bias can be quite serious—for example, in intervention studies that are subject to high levels of attrition.

Prospective studies in which a subject is measured at some baseline and then at repeated intervals are usually referred to as panel studies. Panel designs have a number of strengths along with several significant weaknesses. The primary strength, at least in principle, is accuracy of measurement and correct temporal referents. Depending on the exact design of data collection, subjects are measured at a point close enough in time to the event or status in question to permit reliable and valid assessment. Under certain circumstances temporal priority may be more firmly established.

Second, the prospective design provides greater leverage on attrition. Besides measuring a population defined at baseline, preattrition information can be used to determine the extent to which attrition is "random" and perhaps can be used to correct estimates for selection bias. There is a trade-off, however. Frequent measurement has two potentially undesirable side effects. First, subjects may tire of repeated requests for cooperation and drop out of the study. Second, "panel conditioning" may result in stereotypic responses to repeated questions. Thus, relative to the retrospective design, there may actually be a net *decrease* in data quality.

On the surface, prospective designs that extend in time are far more costly than retrospective designs. There is a clear cost/quality trade-off, however, that cannot be easily evaluated without consideration of the purposes of the survey. In obtaining population estimates over time, the panel may actually be less expensive to maintain than

resampling the population repeatedly. On the other hand, using a panel for this purpose brings problems of its own in the form of attrition and panel conditioning.

QUASI-EXPERIMENTAL AND DESCRIPTIVE APPROACHES

The large-scale, multiwave surveys so common now have rather diffuse origins. Paul Lazarsfeld introduced the panel design (Lazarsfeld and Fiske 1938). In his hands, the panel study was basically a *quasi-experimental design*. A panel of subjects was recruited and measured repeatedly, with the foreknowledge that a particular event would occur at a particular time. The most famous application is to election campaigns. As such, the design is a simple example of an interrupted time series.

A second source of current designs is the child development tradition. Baltes and Nesselroade (1979) cite examples going back to the late eighteenth century, but systematic studies date to the 1920s (Wall and Williams 1970). The best of these studies emphasized cohort-based sampling of newborns and systematic assessment of development at carefully determined intervals. In the tradition of experimental psychology, investigators paid attention to careful control of the measurement process, including the physical environment, the raters and observers, and the measurement instruments. The development of age-specific norms in the form of averages and variation about them was seen as a primary goal of the study. Unanticipated events, such as an illness of either mother or child or factors affecting the family, were seen as undesirable threats to the validity of measurement rather than as opportunities to assess quasi-experimental effects.

Large-scale multiwave panel studies of the kind described above combine aspects of both traditions, often in somewhat inchoate and potentially conflicting ways. On the one hand, investigators are interested in describing a population as it evolves. Often basic descriptive information on rates, variability, and sequence is unknown, calling for frequent measurement at fixed intervals. On the other hand, there is also interest in evaluating the impact of specific transitions and events, such as childbearing, retirement, and loss of spouse. Meeting these two objectives within the constraints of a single design is often difficult.

DESIGN ISSUES

Although it might be argued that the ideal longitudinal study should take a huge sample of the population without age restriction, measure it constantly, and follow it in perpetuity with systematic supplements to the original sample, cost and logistics intervene. Although there is an infinite range of potential designs, longitudinal studies can be classified on various dimensions including (a) the consistency of the sample over time, (b) population coverage, particularly with regard to age, and (c) measurement protocols, including not only choice of variables but also timing, interval, and frequency. These factors will influence the extent to which the study can be used for descriptive purposes, relating information to a well-defined population, and/or drawing causal inferences on temporal and quasi-experimental aspects of the design.

Consistency of the Sample. The following classification is based on Duncan and Kalton (1987) and on Menard (1991).

1. *Repeated Cross-Sectional Surveys.* A new sample is drawn at each measurement point. The GSS, described above, is an example. This is a longitudinal study at the macro level. It describes a dynamic population.
 2. *Fixed-Sample Panel.* A sample is drawn at baseline and measured repeatedly over time. No new subjects enter the sample after baseline. Several examples are described above. The sample refers only to the cohorts from which it was drawn. It may continue to represent them adequately if panel attrition is completely at random.
 3. *Dynamic Sample Panel.* After baseline, subjects are added to the panel in an attempt to compensate for panel attrition and represent changes in the underlying population. The PSID is a major example.
 4. *Rotating Panels.* A sample is drawn and interviewed for a fixed number of waves and then dropped. At each measurement point a new sample is also drawn so that samples enter and leave on a staggered basis. The best-known example is the Current Population Survey carried out by the U.S. Bureau of the Census. At any given time, the sample consists of subjects who have been in the panel from one to four months.
 5. *Split Panels.* In addition to a basic panel survey, a coordinated cross-sectional survey is drawn at each measurement point. In effect, this is a quasi-experimental design in which comparisons between samples permit tests of panel conditioning, among other things. This design is rare.
- Population Definition.** The broader the population sampled, the wider the potential generalization. On the other hand, homogeneity provides greater leverage for some kinds of causal inference. The following rough classification is useful. See Campbell (1988) for elaboration.
1. *Unrestricted Age Range.* A sample of the entire (adult) population is selected and followed.
 2. *Restricted Age Range.* A sample of persons in a narrow age band, such as adolescents in developing nations, is selected, with resulting homogeneity of developmental process.
 3. *Event-Based.* A sample is selected on the basis of a particular event. Birth is the prime example; others are motherhood, school completion, business start-up, and administrative reorganization. Subjects can be members of a cohort experiencing the event at a fixed time or can be drawn on a floating baseline, as is the case when each new patient in a given clinic is followed prospectively.
 4. *Population at Risk.* A sample is selected on the likelihood (but not the certainty) that it will experience a particular event. Although similar to an event-based sample, it is less controlled. Age-restricted samples are usually at risk for certain events, which is one reason for restricting age in the first place. An interesting example at the macro level is a sample of cities likely to experience a disaster such as an earthquake or a hurricane.
- Measurement Protocols.** What variables should one measure with what frequency at what time

intervals? Answering such a question requires a clear appreciation of the linkage between the substantive purpose of an investigation and the mode of data analysis. For example, if one's intent is to study labor-force participation using event history models, then frequency of measurement would be dictated primarily by (a) the frequency of change of labor-force status among subjects, (b) the amount of variability in individual rates of change, (c) the necessity to obtain exact dates of transitions for the analysis, and (d) the maximum time interval at which subjects can provide reliable and valid recall data. If the investigators have explanatory models in mind, then the measurement protocol will have to deal with similar issues for the regressors.

If one is, however, interested in the effects of widowhood, which might be studied either descriptively or as a quasi-experiment using an interrupted time series approach, very different measurement strategies would be optimal. At the very least, one would try to schedule measurements at fixed intervals *preceding and following* the event. If economic effects were the primary focus, annual measurement might be sufficient; but if the grief process was the focus, more frequent measurement would be required.

The more undifferentiated the sample, and the more multipurpose the study, the more difficult it is to achieve an effective measurement strategy. Many of the large-scale longitudinal studies carried out since the 1960s have one or more of the following characteristics that tend to interfere with analysis:

1. Multiple substantive foci that result in attempts to measure scores, if not hundreds, of variables.
2. Nonoptimal measurement intervals because of conflicting demands of different kinds of variables and topics. A secondary problem is that intervals are often determined by administrative and funding criteria rather than by substantive intent.
3. Measurement strategies that are chosen without regard to statistical analysis. The problem is acute for event history models

that require dated transitions rather than reports of status at fixed intervals. Other examples are failure to acquire multiple indicators of constructs for LISREL models and intersubject variation in measurement intervals that interferes with growth curve estimation.

4. Weak identification of temporal sequence. This problem is most often a result of a "snapshot" orientation to measurement in which the subject's status is ascertained at a sequence of fixed measurement points. Knowing that at time 1 someone is married and prosperous and that at time 2 that person is single and poverty-stricken doesn't tell us much about causal order or effect.

CAUSAL INFERENCE AND LONGITUDINAL DESIGN

As noted, the extent to which longitudinal studies allow one to establish causal effects is the subject of some controversy. Indeed, the whole issue of causal inference from nonexperimental data is extremely controversial (Berk 1988; Freedman 1991), with some taking the position that it is impossible in any circumstance other than a randomized design involving an experimentally manipulated stimulus. Although that may be an extreme position, the assumption that one can use time-ordered observational data to establish causal order is difficult to defend.

Cross-sectional analyses and retrospective designs suffer from the fact that variables which are supposed to have time-ordered causal effects are measured simultaneously. As a result, various competing explanations of observed associations, particularly contaminated measurement, cannot be ruled out. Asking about educational aspirations after completion of schooling is an example. Panel designs at least have the advantage of measuring presumed causes prior to their effects. Even in that case, establishing temporal order is not as easy as it might appear. This is particularly true when one attempts to relate intentions, attitudes, and similar

cognitive variables to behaviors. Marini and Singer (1988) give an example based on education and marriage. Consider two women who leave school and get married. One may have decided to terminate her education in light of a planned marriage, and the other may have decided to marry following a decision to terminate education. The observed sequence of events tells us nothing. They note:

Because human beings can anticipate and plan for the future, much human behavior follows from goals, intentions and motives, i.e., it is teleologically determined. As a result, causal priority is established in the mind in a way that is not reflected in the temporal sequences of behavior or even in the temporal sequence of the formation of behavioral intentions. (Marini and Singer 1988, p. 377)

Because of the many varieties of longitudinal research design and the many controversies in the field, it is difficult to give hard-and-fast rules about when causal inference may be justified. Dwyer (1991), writing for epidemiologists, provides a useful way to approach the problem based on whether there is variance in presumed causes and effects at baseline.

Variation in Independent Variable

		NO	YES
Variation in Dependent Variable	NO	I	II
	YES	III	IV

Examples include the following:

- I. Follow crime-free baseline sample through possible arrest, incarceration, and later recidivism.
- II. Relate aspirations of eighth graders to eventual level of educational attainment.
- III. Carry out an experimental intervention, such as a job training program, that attempts to increase existing skill levels.
- IV. Relate organizational characteristics at baseline to later levels of productivity.

Cases I and III can be observational or (quasi-) experimental. Cases II and IV are strictly observational. In each case, although variation may not

exist in the variable of direct interest, there may be variation in closely related variables. In the experimental case, this corresponds to lack of randomization and, thus, uncontrolled variation in potential causal variables. The same is true in purely observational studies. In case II, although there is no variation in the direct outcome of interest, there is often variation in related variables at baseline. In the example given, although there is no variation in educational attainment in terms of years of schooling completed, aspirations are certainly based in part on the child's prior academic success in the grade school environment. Case IV presents the most difficult situation because it picks up data in the middle of an ongoing causal sequence. This is precisely the situation where many researchers believe that panel data can untangle causal sequence, but neither temporal-sequenced observations nor complex analysis is likely to do so.

To reiterate an important point about design, in large-scale longitudinal research each of these four cases is typically embedded in a complex design, and the degree of causal inference depends on many factors ranging from the timing of measurement to attrition processes.

COMMON PROBLEMS IN LONGITUDINAL DATA ANALYSIS

Those who collect and analyze longitudinal data face certain generic problems. Virtually any researcher will face some or all of the following difficulties.

Conceptualizing Change. James Coleman notes that the concept of change is "a second order abstraction . . . based on a comparison, or difference, between two sense impressions, and, simultaneously, a comparison of the times at which the impressions occurred" (1968, pp. 428-429). It is particularly difficult to think about the *causes* of change, and this difficulty has been reflected in arguments about how to model it. In particular, there has been a running debate about the use of change scores, computed as a simple difference ($\Delta Y = Y_2 - Y_1$) versus a regression approach in which

the time 2 variable is regressed on time 1 plus other variables. In an influential paper, Bohrnstedt (1970) showed that simple gain scores tended to have very low reliability relative to either variable composing them. In light of that and other problems, Cronbach and Furby (1969) argued that the best way to model change was to treat “residualized gain scores” as dependent variables in regression analysis. The basic equation is

$$Y_2 = a + \beta_1 Y_1 + \beta_2 X_1 + \dots + \beta_k X_k + \varepsilon$$

where Y_1 is the baseline measure and the X 's are any set of independent variables. Hence the effect of X is net of the baseline score. This method has become standard in many fields of inquiry.

More recently, a number of papers have appeared that question the use of residualized gain scores. Liker, Augustyniak, and Duncan (1985) argue that equations in which one takes differences on both sides of the model ($\Delta Y = \alpha + \beta(\Delta X) + \varepsilon$) have strong advantages, particularly when one wants to “difference out” unchanging characteristics of subjects. Allison (1990) argues that in some cases the difference score as a dependent variable is not only acceptable but necessary. The issue is not purely statistical; it depends in large part on exactly what process one is attempting to model. Suffice it to say here that an issue which was once thought to be resolved has been reopened for serious examination.

Related to the issue of change scores and their reliability is the problem of regression toward the mean. Whenever a variable is positively correlated over time, subjects with high scores at time 1 will tend to have somewhat lower scores at time 2, while those with lower time 1 scores will tend to have higher scores at time 2. As a result, gain scores will be negatively correlated with initial values. This problem is exacerbated by random measurement error and was a primary reason for the predominance of residualized gain models in the past. Again, however, the issue is one of the underlying model. There are cases where feedback processes do indeed result in regression to the mean (Dwyer 1991) and the regression is by no means an “artifact.” There is no question that one

always needs to correct for measurement error, but regression to the mean should not necessarily be treated as an annoyance to be gotten rid of by statistical manipulation.

Lack of Independence. A standard assumption in elementary statistical models such as least squares regression is that errors are independent across observations. In the equation we typically assume $\text{cov}(\varepsilon_i, \varepsilon_j) = 0$. If the same subject is observed at two or more points in time, the independence assumption is almost certain to be violated due to omitted variables, correlated errors of measurement, or other problems. This difficulty permeates virtually all statistical approaches to longitudinal data and requires complex methods of estimation.

Articulating Analysis with Observation Plan. Ideally, one should have in mind a model for how the underlying process of change in a variable articulates with the observation plan. In part, this requires some knowledge of causal lag or how long it takes for changes in X to result in changes in Y . The data analysis method chosen should be congruent with both the underlying process of change and the observation plan. Observation plans may obtain exact dates of transitions (when did you quit your job?), locate the subject's state at time t (are you currently working?), or obtain retrospective information relative to some other time point (were you working as of June 30?). Studies that have multiple goals are difficult to optimize in this respect.

Construct Validity. In long-term longitudinal studies, the validity of constructs may degrade over time, sometimes through changes in the subjects themselves, sometimes through measurement problems such as conditioning, and sometimes through changes in the environment. For example, the meaning of terms used in political research such as *liberal* may change with time, or references to specific issues such as abortion may become more or less salient. In growth studies, subjects may “age out” of certain variables. This issue is quite understudied, at least by sociologists.

Measurement Error. Measurement error is a serious problem for statistical analysis, particularly regression, because it results in biased estimates.

The problem is particularly acute when independent variables are subject to error. In the longitudinal case, errors of measurement tend to be correlated across subjects over time, causing even greater difficulty. A major reason for the popularity of structural equation packages like LISREL (Jöreskog and Sörbom 1988; Bollen 1989) is that they permit one to model correlated error structures. This is not to say that LISREL is an all-purpose solution; indeed, its error-handling capabilities probably lead to its use in situations where other approaches would be better.

Time-varying Independent Variables. In a typical situation one is faced with a set of fixed independent variables such as age, sex, and race, and a set of variables whose values may change over the course of a study. In studies of income, for example, educational levels and family structure may change between observations. Although work on this problem has been going on in economics for some years (Hsiao 1986), sociologists have been slow to respond. The problem always leads to great statistical and computational complexity.

Missing Data, Attrition, Censoring, and Selection Bias. Attrition in panel studies is inevitable. In rare cases attrition is completely random, but more commonly it is associated with other variables. Standard listwise and pairwise missing data “solutions” are rarely appropriate in this situation. Three types of solutions are available. First, one can develop weights to correct for attrition. Second, one can model the attrition process directly, using “selection bias” models (Heckman 1979; Berk 1983). Finally, one can impute estimates of missing data (Little and Rubin 1987). This entire area is controversial and under rapid development. A special case of attrition occurs when observations are *censored* in such a way that measurement stops before a transition of interest, such as ending a panel study of fertility before all subjects have completed childbearing.

APPROACHES TO DATA ANALYSIS

The period since 1975 or 1980 has seen enormous increases in the power and sophistication of longitudinal data analysis. Singer (1985) is a useful

overview; Dwyer and Feinleib (1991), especially chapter 1, provides a comprehensive review, as does Von Eye (1990). This material is much too complex to cover in this brief review. A more reasonable goal is to provide a few examples of the kinds of substantive questions that one can ask with longitudinal data and appropriate methods for answering them.

Outcomes at Fixed Points in Time. Example: “predicting” a person’s savings at age sixty-five. This is the simplest longitudinal question; indeed, in one sense it is not longitudinal at all. The dependent variable involves change over time very indirectly, and the independent variables usually involve life cycle variables like the nature of labor-force participation. These data can often be collected retrospectively, and the only advantage of a *repeated measures* approach is control over measurement error.

It is not uncommon to see models for fixed outcomes at arbitrary time points—for example, level of education attainment as of the last available wave of an ongoing panel study. This is a particular problem when the sample consists of subjects who vary in age or is not defined on the basis of some reasonable baseline. When the outcome is a discrete transition, such as marriage, censoring is often a problem.

Means over Time. Example: Comparison of aspiration levels of boys and girls over the middle school years. With a sequence of independent samples, this is a straightforward analysis-of-variance problem. If the same individuals are measured repeatedly, a number of problems arise. First, the observations are not independent over time; we have to assume that the usual statistical assumption of independence in the error terms will be violated. Within the ANOVA tradition, this problem can be approached via multivariate analysis of variance or as a classic univariate design. Hertzog and Rovine (1985) compare the two approaches. Sociologists have tended to ignore mean comparisons, preferring to work with structural equations; however, analyses of means are often far more direct and informative. See Fox (1984) for an interesting application to an interrupted time series.

Classic ANOVA ignores individual-level heterogeneity. Over the course of five observation points, students vary about the group means. The description of change at the individual level rather than at the group level may be of some interest. A simple approach is to use “blocking variables” such as race to account for additional heterogeneity. Adding covariates to the model is another. A more sophisticated approach is to model the individual-level growth curve directly. Conceptually, analysis begins by estimating an equation to describe each respondent’s score with respect to time, often using a polynomial model. The coefficients of these equations are then treated as dependent variables in a second-stage analysis. There are a number of different statistical approaches to this kind of analysis. Rogosa (1988) has argued forcefully in favor of approaching longitudinal analysis in this way. Dwyer (1991) provides an interesting example. McCardle and Aber (1990) deal with such models in a LISREL context.

Structural Equation Systems. Figure 1, based on Blau and Duncan’s classic path model of occupational mobility, is a longitudinal analysis, although it is not often thought of in those terms. For our purposes, the important point is that the exact timing of variables was not assumed to be of great import, although the sequence was. Education was taken to intervene between measures of family background and occupational attainment, and its timing was not specified. The latter variable was assumed to reach some plateau relatively early in the occupational career; again, timing was not important. Models of this kind, with rather vague time referents and in which it is assumed that the order of events does not vary across subjects, have played an important role in sociology for some time, adding great clarity to the notion of intervening variables. It is natural to assume that structural equation models are a natural way to analyze multiwave panel data.

Kessler and Greenberg (1981) deal at length with the application of structural equation models to panel data, particularly to cross-lagged structures where both variables vary at baseline. They show that attempting to estimate relative causal effects must be handled in the context of a formal

Figure 1

NOTE: A Basic Model of Attainment (Adapted from Blau and Duncan 1967)

model rather than by comparing cross-lagged partial correlations. Figure 2, based on Campbell and Mutran (1982), is a multiwave panel model with intervening variables. Here, a number of statistical and conceptual difficulties become obvious. First, what is the lag time for the effect of health on income satisfaction and vice versa? Second, how does one deal with the potentially complex error structure of observed variables? Third, if illnesses intervene (as measured by times in hospital), how does the timing of events relative to the timing of observations affect the results? Fourth, how does one deal with discrete intervening variables that fail to meet standard distributional assumptions? Finally, how does one handle correlated errors in equations over time? These are by no means the only questions that could be raised, and it is not clear that models of this kind are the most effective way to approach multiwave panel data.

Event History Models. This class of models treats the underlying rate of change in a discrete variable as the dependent variable in a regression-like framework. Typically, the dependent variable is conceived of as the instantaneous risk of transition at time t conditional on prior history. The formulation is dynamic rather than static, and time enters the analysis explicitly. Allison (this volume) discusses a number of such models in detail. At first glance, the model may seem mathematically esoteric, but the basic ideas are straightforward. The underlying concepts are closely related to the life table and to Markov models. The Markov model, as applied in the classic labor-force studies of Blumen, Kogen, and McCarthy (1955), assumes a transition process that is constant over time and invariant across subjects. Event history

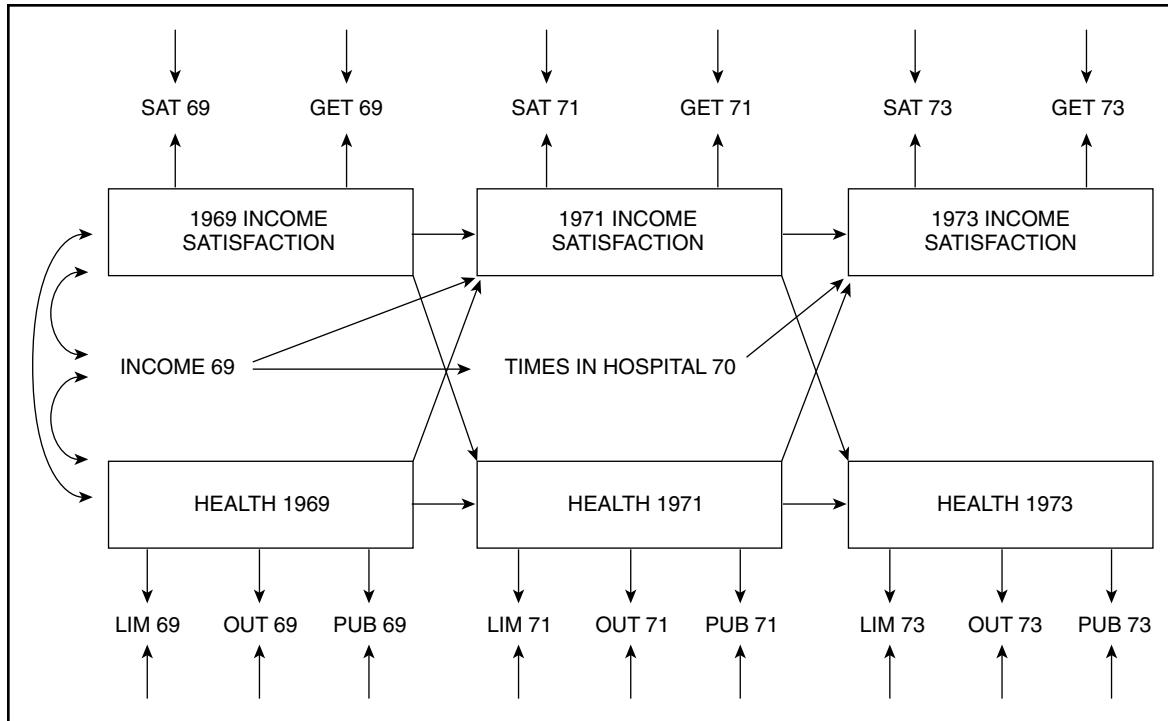

Figure 2

NOTE: A Model for Health and Income Satisfaction (Adapted from Campbell and Mutron 1982)

models allow one to relax both assumptions, specifying a time-dependent rate of change and a set of individual-level “covariates” that allow transition processes to vary with characteristics of the subjects. Covariates can be allowed to change with time as well, at the cost of substantial computational complexity.

In one of the first applications in sociology, Tuma, Hannon, and Groeneveld (1979) showed that the rate of marital dissolution among subjects in an income-maintenance experiment depended on the treatment condition, thus demonstrating that event models could be used for causal analysis. Event models are inherently dynamic and take the timing of transitions explicitly into account. They are having enormous impact not only on how sociologists analyze data but also on how they conceptualize problems and design data collection.

Differential Equation Models. Coleman (1964, 1968, 1981), among others, has argued that the appropriate way to study change in continuous

variables is via differential equation models. A simple differential equation relating Y to its own level and to an exogenous variable takes the form

$$\frac{dY}{dt} = a + b_1Y + b_2X_t$$

where dY/dt is the rate of change in Y with respect to time, that is, the derivative. The rate of change is not directly observed, of course; and to estimate the coefficients of the model, it is necessary to integrate the equation. Coleman (1968) shows that for this particular model, it is possible to obtain estimates of a , b_1 , and b_2 by first estimating a regression equation of the form

$$Y_t = a^* + b_1^*Y_{(t-1)} + b_2^*X_t$$

using ordinary regression and then transforming the regression coefficients to obtain the coefficients of the differential equation model. In this particular case the coefficients of the differential equation model are

$$a = \frac{a^* C^*}{\Delta t}$$

$$b_1 = \frac{\ln b_1^*}{\Delta t}$$

$$b_2 = \frac{b_2^* C^*}{\Delta t}$$

where

$$C^* = \frac{\ln b_i^*}{(b_i^* - 1)}$$

The resulting coefficients describe the time path of Y as a function of its initial value and the value of X . Note that this model assumes that X is not changing over time. One implication of this model is that if one wishes to assume that Y at time t does not depend on its initial value, then residualized gain score models of the kind described above are inappropriate.

Applications of differential equation models in sociology have been relatively rare, although they would seem to be a natural way to approach the analysis of change. Many of the seemingly endless arguments about the representation of change in regression models stems from the application of static methods to dynamic processes. The difficulty is that it is not easy or always possible to transform the differential equations in such a way that they can be estimated by simple regression. Doing so requires considerable mathematical sophistication on the part of the researcher. Tuma and Hannon (1984) discuss these and related models at length. Arminger (1986) provides an example of how to recast a standard three-wave LISREL-based panel analysis into a differential equation model.

CONCLUSION

It is no accident that words like *controversial* and *under discussion* recur frequently in this review. Many important issues regarding the collection, analysis, and interpretation of longitudinal data remain to be resolved. Frequently, what are in fact conceptual issues are argued in statistical terms. The literature is technical and mathematically demanding. But important progress is being made

and will continue as new methods of research continue to emerge.

RICHARD T. CAMPBELL

LOVE

Sociologists agree that love is one of the most complex and elusive concepts to deal with from a scientific point of view. Indeed, they often point out that poets, novelists, and musical composers are much more adept at producing eloquent expressions about this pervasive sentiment. Dictionary definitions are of limited use in categorizing

the essential ingredients of love, except to connote its many variations as an attitude, an emotion, or a behavior. No one definition can capture all the dimensions of love, which can involve a wide range of elements such as romantic obsession, sexuality, caring, even irrationality. Indeed, some have argued: "There is no single, subjective meaning of love that everyone experiences in the same way" (Hendrick and Hendrick, 1992). Part of the difficulty is that individuals and their cultures define love very differently, depending on particular relationships and circumstances.

HISTORICAL CONCEPTIONS OF LOVE

Conceptions of love have varied not only from one culture to another, but also from one historical era to another (Murstein 1974; Hunt 1959). Prominent among these are courtly love, Romanticism, and Victorian-era love (Hendrick and Hendrick 1992), as well as the modern era of love (Seidman 1991). Various forms of courtly love appeared in the twelfth century. This marked the beginning of the transformation of love from a philosophical or theological ideal to a practical way of relating between men and women. Sexual desire and expression were seen as one of the goals of love, and the love relationship was seen as intense and passionate. This bond was not limited to one's spouse, however. Marriage was seen as a more mundane and practical relationship. In contrast, courtly love was impractical, as the time commitment necessary to follow its elaborate rules and customs limited involvement to the wealthier or aristocratic classes. It often found its expression—sometimes sexual, but often not—in the idealized devotion of a knight or nobleman to a lady of nobility, who symbolized the perfect partner. Men and women did not relate in the day-to-day interaction associated with more recent intimate relationships.

In the late eighteenth to early nineteenth centuries, Romanticism replaced courtly love. In Romanticism it is possible to recognize the origins of some of our modern ideas about love: concern with similarities between partners, equality in the relationship, and the experience of the emotional side of love. This form furthered the courtly love ideal of sexual expression between partners as a worthy goal, with the added recognition that this fusion of emotion and sexuality could (and ideally should) occur with one's spouse.

The Victorian era (approximately 1830–1900) brought great changes to the idea of romantic love. This is hardly surprising, as people of this time were also adjusting to the changes in work and community life brought about by the Industrial Revolution. In the shift from the home economy to paid labor, the status of women declined, and new myths and ideas about love and its expression emerged. The partnership-oriented focus of Romanticism all but disappeared. Women in the Victorian era were seen as weaker and less intelligent than men. Within marriage, this assumption defined women as mothers and helpers, not individuals who might have complementary interests and a rightful concern for equality within a relationship. Women were also seen as childlike and asexual during this time, and were thought to need their husband's protection. This is an abrupt departure from earlier modes of loving, which acknowledged sexuality as an important aspect of the experience of love. In the Victorian era, sexual matters were not discussed between spouses.

In the modern era (1890–1960), the literature on love and marriage once again recognized the importance of an intimate bond between partners. Marital advice from this time shows a preoccupation with couples' happiness and the security of the marital bond. During this period, romantic love and sexual compatibility were inseparable, and this sexualization of love (Seidman 1991) brought the perception of sexual expression in romantic relationships full circle. Sexual expression was no longer seen as a component of love (whether an idealized or neglected one) but the very basis of love itself.

Sexual impulses and romantic love are often directed at the same person, but they are not the same. People are known to pursue sexual encounters in the absence of any romantic feelings. Sexual impulses are derived from our biological heritage, and romantic love is a learned cultural pattern. The two bear a relationship to one another, however, in that romance often encompasses sexually motivated behavior plus a cluster of cultural expectations (Hatfield and Rapson 1993)

CULTURAL DIFFERENCES

The range of psychological and social meanings attached to love would, therefore, appear to be limitless. However, we experience and express

love mostly according to the culture and subcultures in which we have formed our sentiments. The formation of these sentiments begins very early and evolves through the physical and emotional attachments that characterize the parent-child relationship. While idiosyncratic patterns exist, love scripts by and large reflect the influence of social conditioning. In short, love is largely a learned response.

Despite cultural differences, several aspects of love seem to be universal (Sternberg 1998). Everywhere love involves four ideals: the suitable partner, the emotional experience of loving, the mental experience or thought process of loving, and the actions deemed acceptable and expected between the lover and his or her partner. Although these components seem to be found in all societies, how they are defined is culturally specific. The suitable partner may be of the opposite or the same sex, younger or older than oneself (or the same age), and tall and thin or short and heavy. Similarly, thoughts about love may be pragmatic or passionate, and emotions may range from deeply affectionate to reserved and respectful. The potential combinations that add up to "love" vary widely, and might be unrecognizable to a person from another culture. For example, in some tribes in Africa there is a traditional system known as "sweethearting" in which young people choose partners based on emotional and physical attraction (Goode, 1963). Even within this system there is variation. Some tribes allow sweethearting to lead to marriage, while others permit their young people to take lovers by choice but maintain the practice of arranging marriages for girls when they are still children. In the Arab world, love may also take secondary importance to familial concerns in taking a spouse. Many unmarried adults in Arab countries report that love is their ideal basis for marriage. However, married adults report varying levels of emotional closeness with their spouse prior to marriage, including love, acquaintance, and kinship ties without either love or acquaintance.

Cultural norms are internalized and program us to fall in love with specific types of people, within certain social contexts, to the exclusion of others. However, love is not necessarily related to marriage. There is a saying, for example, that in the West one falls in love and then gets married, whereas in the East one marries and then falls in love. In some societies, arranged marriages were

and still are contracted. The emotional intensity a couple feel toward each other is given little or no consideration. Instead, emphasis is given to the sociopolitical implications of the marital alliance for the families and kinship groups involved.

In the United States, on the other hand, love is viewed as an important condition to marriage. We are generally suspicious of anyone who would marry for any other reason. We are not comfortable with the idea that in some cultures a man marries his mother's brother's daughter because that is the prescribed pattern. Even among our upper classes, where concern about protecting family resources leads to a greater emphasis on practical considerations in mate selection, couples are expected to espouse mutual love as the basis for their marriage, or else their motives become suspect. Revelation of marital alliances designed to preserve or enhance family wealth often receive a cynical response from the public at large.

Families recognize that courtship and mate selection merge not only two individuals but also two different kinship lines, which in turn may affect their socioeconomic and political stature. Consequently, families invest considerable energy and resources to control love (Goode 1959). Several mechanisms to accomplish this have been identified, including the direct control provided by (1) child marriages, in which betrothal may occur before puberty or even before the child is born; (2) defining the pool of eligibles, that is, delineating whom one can and cannot marry; (3) physical or social isolation to limit the probabilities of contact; and (4) various indirect controls such as moving to preferred residential neighborhoods, enrolling children in appropriate schools, joining select organizations, or attending certain churches. The latter mechanism is most characteristic of Western societies.

THE ROMANTIC LOVE COMPLEX

In American society a *romantic love complex* exists, and this complex posits love as a central prerequisite to marriage. The basic components of this complex are assimilated through the mass media—through romantic stories in novels, magazines, television, and movies. In this way we are psychologically prepared to fall in love. The major

characteristics of romantic love include *romantic democracy*; that is, cultural differences between couples are minimized or ignored because “love and love alone” is sufficient. Indeed, it involves the notion that romantic love thrives on such differences. Romantic love also includes *romantic intensity*; that is, people are expected to fall in love instantly (to experience love at first sight) and deeply, with great emotional attachment. Finally, romantic love includes *romantic monopoly* in that once the “bolt from the blue” strikes, the couple presume exclusive emotional and social rights to each other, in perpetuity (Merrill 1959). A person experiencing the full thrust of this complex is, supposedly, consumed by constant thoughts about the beloved, a longing to spend all one’s time with that person, a sad pining in the beloved’s absence, and a feeling that life would not be worth living without him or her (Tennov 1980).

There is disagreement about the extent to which people adhere to the tenets of the romantic love complex and whether it actually influences mate selection. Sociologists have generally viewed it as a poor basis for the establishment of permanent unions, inasmuch as it involves an element of capricious choice based upon an unpredictable emotion. Moreover, romantic love is not completely rational. Part of its credo is that there is one and only one true love or ideal mate. Yet we know that people fall in and out of love several times in a lifetime.

People caught up in the romantic complex often idealize their partners. Some argue that this process of *idealization*, in which a distorted positive picture of the love partner is constructed, results from the blockage of sexual impulses by cultural prohibitions. If this were true, then one would expect a liberalization of our sexual mores to be accompanied by a decline in romanticism. However, this does not appear to have happened, at least in Western societies. What does happen is that the elements of the romantic love complex, including the idealized picture of the partner, are modified to fit the reality of that person that emerges through close and intimate interaction over time. Couples unable to make this accommodation are apt to suffer disillusionment, and their marriages may encounter persistent difficulties. For marriage to succeed, the overly romanticized notions and idealizations of romantic love must eventually be replaced by *conjugal love*, which is

based upon habits, common interests, mutual acceptance, and mature companionship derived from a shared history.

THE MASS MEDIA AND LOVE

The mass media undoubtedly encourages many romantic myths about love. This can be problematic for several reasons (Ellis 1985). Fictional lovers, whether in the movies or in novels, can magically go about their romantic business without the mundane everyday constraints faced by real people. Fictional portrayals of romantic love also tend to idealize the partners as beautiful, perfect people who are in the earliest passionate stages of love. It is assumed that this stage of love will last forever for the couple. In reality, few of us are unencumbered by family expectations or blessed with perfect beauty. Perhaps more damaging, the passionate stage of love shown on the silver screen tends to mature and deepen in real life into a more companionate form of love—which may then be taken as not being “real” love by those who subscribe to the romanticized media ideal.

Media portrayals of love and family life may also set up a template for behavior that is difficult or impossible for a couple to enact and sustain, while at the same time making them feel wrong somehow for failing to meet this expectation (Coontz 1992). Many intimate partners do not choose to follow the homemaker-breadwinner pattern in their relating. For some others who would like to be able to do so, this may be a financial impossibility. To make matters even more complicated, mass media presents other images of lifestyles that are at odds with the nuclear family image. Messages of consumerism and mass consumption in television shows and commercials encourage individuals to keep their choices open and to accept only the best. This message of individualism makes intimacy and commitment between romantic partners more difficult, as some may shy away from choosing a partner out of fear that something better may come along. Our kinship system does not provide a protective mechanism against this individualism. Because we trace kinship bilaterally through both the mother and the father, lineage concerns do not keep couples together (Farber 1964). As a result, marital status and presumed romantic exclusivity do not prevent

partners from being available as a potential mates to others.

GENDER AND LOVE

There appear to be gender differences with respect to love and loving. It is generally assumed that such differences reflect culturally defined sex roles. Women have been stereotypically portrayed as starry-eyed romantics, while men are viewed as exploitative realists. However, research shows that men fall in love more quickly than women do and with less deliberation, score higher on scales of romanticism, express stronger romantic attitudes, and suffer greater emotional stress when relationships are terminated. Compared to men, women are more apt to exhibit a companionate rather a passionate approach to love. The difference between the two centers around the element of emotional intensity. Companionate love "is a calm, steady, relaxed state; passionate love is an emotional roller coaster, with intense highs and lows" (Fehr 1995). Because women may have potentially more to lose from a social and an economic standpoint, they tend to be more prudent or discriminating in establishing and maintaining love relationships (Hochschild 1983). They are more apt to take into account practical considerations regarding mate selection. Hence, in comparison to men, women are more likely to terminate relationships and are able to disengage emotionally more easily when they break up (Rubin 1973).

Men and women also have different expectations of love (Cancian 1987). The common denominator among many of these differences seems to be communication styles and preferences. Women have an advantage in communicating emotionally, because traditional gender norms have allotted the jobs of nurturing and relationship maintenance to them. They also tend to have more emotionally close (but not sexually intimate) relationships than do men. This suggests that women have less difficulty with emotional vulnerability and communication. Women tend to want more intimacy through verbal communication from their partners. This can cause a host of problems, as men tend to express feelings of love actively rather than verbally.

Love is also experienced differently by men and women partly because of varying levels of

dependency. Although a large proportion of women now hold paid employment, economic dependence on men is still a factor in many wives' and mothers' experience. They are more likely to put their careers on hold to raise children than are men, to earn less than their spouses, and to relocate due to a spouse's career needs. The critical link between gendered experience of love and financial concerns can be seen in socioeconomic class differences. Working- and middle-class men are less likely to identify strongly with their work than are men in the upper middle class. As a result, it is in the upper middle class that conflict between wives' needs for intimacy and husbands' desires for self-fulfillment and career achievement may be felt most acutely.

The gendered differences inimical to romantic love are found in communication as well (Gray 1992). Men and women have vastly different communication styles, and problems arising from miscommunication may lead to difficulties within a relationship. For a man to feel truly loved he must feel that he is needed. For a woman to feel loved she must feel understood and appreciated as well. These requirements stem from men's desire to feel competent and women's desire to feel socially and emotionally connected to others. When partners relate, however, they tend to speak to one another in ways that they would like to be spoken to themselves because they do not recognize these differing bases for feeling loved. Women tend to air their problems and difficulties with their partners in order to feel validated and understood. In response, men tend to offer solutions to women's problems or to minimize these problems—offering the vote of confidence in their partners' competency that they would want in similar circumstances. These differences can potentially undermine feelings of love experienced by the partners (Gray 1993). A woman is left feeling that her partner does not truly listen or understand her when he offers solutions to her grievances, and she feels abandoned when he withdraws to consider his own problems in privacy. A man can feel blamed by his partner's complaints and stunned by her negative reaction to his proposed solutions, and tends to feel hounded if she attempts to penetrate the silence he needs to work issues out for himself.

Social scientists have explored the sequences through which the dimensions of love relationships develop and have constructed numerous

theories, models, and typologies of love (Fehr 1995). They have also detected and described a number of styles of loving (Kemper 1988; Lee, 1988; Hendrick and Hendrick, 1986; Lasswell and Lasswell 1980). Love is said to begin typically with physical symptoms—palpitations of the heart, rapid breathing, sweating, and so on. At this stage the symptoms are essentially similar to those associated with other emotions such as fear. Next the person proceeds to label his arousal as a love response. This labeling process gains impetus from social pressures and cultural dictates, which prod one to define the experience as love and to follow its ritualistic patterns.

The optimum conditions for love to flourish require that the couple be equally involved in and committed to each other and the relationship. Where there is unequal involvement, the person with the strongest commitment may be vulnerable to exploitation. This is known as the *principle of least interest*, in which the partner with the least interest has the most control. Few relationships that are based on this principle can endure.

MACROSOCIOLOGY

The term “macro” denotes “large”; thus *macrosociology* refers to the study of large-scale social phenomena. This covers a very broad range of topics that includes groups and collectivities of varying sizes, the major organizations and institutions of one or more societies, cross-sectional or historical studies of a single society, and both comparative and historical analyses of multiple societies. At the grandest level it may cover all human society and history.

Sociologists distinguish macrosociology from microsociology, which focuses on the social activities of individuals and small groups. The micro-macro distinction forms one of the central dualisms characterizing divergent sociological perspectives. Seemingly polar opposites such as conflict-consensus, stability-change, structure-agency, subjective-objective, and materialist-idealist, as well as micro-macro, provide a shorthand method for denoting differences in central assumptions, subjects, and models. As with many other oppositional concepts, however, the boundary between microsociology and macrosociology is not clearly distinguished, and at the margins there is much room for overlap.

Typically, micro-level studies examine individual thought, action, and interaction, often coinciding with social-psychological theories and models, whereas macro-level investigations target social structures and those forces that organize as well as divide individuals into political, social or religious organizations, ethnic populations, communities, and nation-states. Nevertheless, in defining these

terms there is major conceptual ambiguity that can be formulated as a question: Should the distinction be based on substantive criteria (specialty and subdisciplinary areas within sociology such as social change and development), theoretical criteria (e.g., functionalist, Marxist), metatheoretical criteria (type of paradigm, epistemology), or methodological criteria (type of research design and analysis techniques)? Since sociologists often use the terms “micro” and “macro” quite casually as convenient devices for categorizing broad areas of theory and research, each of these criteria can be found in the literature, and quite often they are seriously confounded.

A useful means of distinguishing between the two approaches is based on the concept of “units of analysis.” Macrosociology uses as its subjects structural-level units of analysis or cases that are larger than observations of individual action and interaction. Even here, however, there is ambiguity, since it is quite possible to make observations on smaller units (e.g., individuals) with the intention of analyzing (making inferences about) larger entities (e.g., groups, classes). Also, the issue of where to draw the line remains. Rather than attempting to draw any hard-and-fast line delineating macro-level from micro-level phenomena, it is helpful to conceptualize a continuum of the subject matter of sociology with “micro” and “macro” defining two end points and with societal-level phenomena clearly placed at the macro pole. George Ritzer, for example, describes one “level of social reality” as a micro-macro continuum moving from individual thought and action through

interaction, groups, organizations, and societies to culminate in world systems (Ritzer 1988, pp. 512–518).

Since the macro end of the continuum focuses on social structure, it is important to clarify the use of this term. In a review essay, Neil Smelser (1988, pp. 103–129) describes structure as patterned relationships that emerge from the interaction of individuals or groups over time and space. Institutions and identifiable collectivities are the outcomes of systematically related structures of activities. Structure is dually defined as located in collective actors and in their interaction. Thus social class is an example of social structure, as are the relationships between classes whose locus is the economy. The study of social class and the study of the economy are examples of macrosociology.

Other examples emerge from the macrosociological focus on large-scale structural arrangements and activities of a great number of individuals in large-scale geographical space over long periods of time. Thus macroscopic questions in sociology conventionally revolve around the largest social, spatial, and temporal processes, such as the rise and decline of civilizations; the origins and development of modern nation-states, social movements, and revolutions; and the origins and consequences of social, political, economic, and cultural transformations. Examples include the rise and spread of secular ideologies and religious belief systems, democratic transitions, and the nature and effects of large-scale institutions and organizations. Macro-level analysis is usually embedded in structural and conflict theories, and in studies of societal dynamics and epochal transformations of cultures and social structures. Topics are located within numerous subfields of sociology, including but not limited to stratification and inequality, resource mobilization, political and economic sociology, world systems, human evolution, and ecology. They are equally likely to cross or link disciplinary boundaries to incorporate history, geography, political economy, and anthropology.

HISTORICAL BACKGROUND

The concern with macro-level phenomena is as old as the discipline of sociology and arguably is the primary motivation for the creation of classical sociological theory and research. The men generally accorded honored places in the pantheon of

sociology's founders, such as Auguste Comte, Herbert Spencer, Karl Marx, Emile Durkheim, and Max Weber (and additional historical figures such as Alexis de Tocqueville), all included macro-level phenomena among their dominant concerns. The traditions they established retain their definitive role for the central issues of sociology in general and macrosociology in particular.

The themes pursued by these and other classical theorists are found in subsequent theory and research. For example, the evolutionary perspectives on the development of human society advanced by early theorists have been modified, revised, and developed by contemporary evolutionary theorists such as Lenski (Lenski et al. 1995) and in the modern functionalist and neo-functionalist theories of Talcott Parsons (1966), Niklas Luhmann (1982), and Jeffrey Alexander (1998). Marx's historical materialist explanation of the unfolding of capitalism has spawned numerous offspring, including dependency and world system theories (Amin 1976; Frank 1967; Wallerstein 1974), and studies of the rise of the modern state and class conflict by Moore (1966). Similarly, Weber's comparative and historical studies of social stratification and the development of modern states are reflected in the works of Reinhard Bendix (1977; 1978), Theda Skocpol (1979) and Michael Mann (1986; 1993). Emile Durkheim's analysis of the division of labor in modern societies as well as the sources of societal integration underlie all modernization theory and functional perspectives on race and ethnic relations, as well as most contemporary studies of occupational structures. Alexis de Tocqueville's comparative study of democracy has remained an inspirational source for contemporary theories of democracy and social change. In short, the macrosociological problems defined early in the history of sociology remain major focuses of current sociological research.

Also located in these early works but often overlooked in subsequent interpretations is an issue that is the current central project of many social theorists: the links between macro- and micro-level phenomena. At least in the writings of Marx, Weber, and Durkheim, to a greater or lesser degree, efforts are made to connect individual and structural level activities in some coherent fashion. For example, Marx is often considered the quintessential macrosociologist, providing the foundation for much current macrosociology. Yet as

Bertell Ollman (1976) and others point out, there is a distinct social psychology anchored in Marx's concept of alienation that in turn motivates and is motivated by his macro-level modes of productive relations and class conflict. This concern with linkage has often been ignored or forgotten in the distinctive development of different schools of sociological thought. After years of separate development and sometimes acrimonious debate, efforts to conduct research and develop social theories that include both ends of the micro-macro continuum now constitute a major agenda for many sociologists.

THEMES IN MACROSOCIOLOGICAL THEORY AND RESEARCH

Macrosociological studies vary in both subject and theoretical orientation, but the two are closely related. For example, large-scale studies of single total societies or particular societal institutions often operate from a functionalist or systems perspective in which the effort is to understand how component parts fit together and serve larger social goals. On the other hand, studies of social change, either within a single society or across cultures, more often use one of the many variants of conflict—Marxist, neo-Marxist, and Weberian perspectives. They do so because such theories are better equipped to explain conflict and change than the relatively static models promoted by functionalism, and because functionalism no longer dominates sociology. These are broad generalizations, however, which invite counterexample.

Given the sweeping scope of macrosociology, it is not possible to provide comprehensive coverage of all the topics and theories subsumed under this approach. The next section will illustrate key concerns of macrosociologists by describing exemplary theory and research in some major areas of macrosociology.

Societal Evolutionary Change. The numerous approaches to the study of societal change illustrate the diversity of sociological perspectives. At the most sweeping level, evolutionary theories take all human history and society as their subject, but there are numerous variants to this approach. For example, evolutionary theory has gone hand in hand with functionalism, as in the later work of

Talcott Parsons on human societies (1966), which features the basic assumptions of evolutionary theory in terms of holism (the whole unit rather than its parts), universalism (natural and perpetual change), and unidirectionality (progressive and cumulative change). An idealist version of an evolutionary perspective can be found in Jurgen Habermas (1979), who uses an evolutionary model to explain the development of normative structures and forms of rationality. Alternatively, it has also taken a materialist form, as developed by anthropologists (Harris 1977) and a few sociologists (Lenski, 1966, Lenski et al. 1995), to explain inequality and uneven distribution of social resources. Another version of societal evolutionary change that deviates somewhat from the mainstream of progressive evolution are the cyclical dynamics of societal and cultural change proposed in works of Pitirim Sorokin (1962). Evolutionary analysis also was once popular in the fields of human ecology (Hawley 1971), modernization (Smelser 1964), and structural and cultural assimilation of different racial groups in modern society (Gordon 1964).

Currently, there are relatively few sociologists who operate on this scale or who find it useful for analyzing more confined periods of historical change. Nevertheless, contemporary theories of human evolution have been influential in providing comparative evidence for the material and normative bases of different forms of social organization and for describing the broadest patterns of societal change. These include the distribution of societal goods and services, enduring forms of inequality (e.g., patriarchy), and normative systems.

Modernization and Development. Sociologists often limit their study of change to the emergence of modern industrial society, either to trace the paths taken by mature industrialized societies to reach their current state of development or to investigate the problems of developing nations. Here, too, different approaches emerge from different theoretical perspectives.

Modernization theory, which until the 1960s dominated accounts of development and change, grew out of functionalism and evolutionary perspectives. In the version articulated by economist W. W. Rostow (1960), nonindustrial societies,

through diffusion and a natural developmental sequence, were expected to follow a series of stages previously traversed by fully industrialized nations to attain the significant characteristics of modern societies considered prerequisites for development. This process required breaking from traditional social norms and values to build institutions based on "modern" values such as universalism, rationalization, and achievement orientation.

Although today largely abandoned in favor of more historically and materially grounded theories, modernization theory was highly influential among both scholars and policy makers of the post-World War II era. In fact, it can be argued that the influence of modernization theory in part explains its repudiation, since students of and from emerging developing nations viewed it as an instrument of continued colonial domination and capitalist exploitation. Their search for tools to provide a better explanation for their disadvantaged and subordinate position in the international arena led to the adoption of Marxist-based models of dependency, underdevelopment, and world systems to replace modernization as the dominant approach to change and development within the modern era. As summarized by Peter Evans and John Stephens (1988, p. 740), these "approaches turned the modernization theorists' emphasis on diffusion . . . on its head, arguing instead that ties to 'core' countries were a principal impediment to development."

In an influential early formulation, dependency theorist Andre Gunder Frank (1967) maintained that the experience of most nonindustrial nations is explained by the "development of underdevelopment." In other words, the exploitation of peripheral Third World nations by capital in the core, developed world increased the economic, social, and political misery experienced by the majority populations of those Third World countries. Alliances between local and international elites actively worked to defend the status quo distribution of power and privilege at the expense of peasant- and working-class majorities. Later versions refined the models of class conflict and competition or, as in the writings of Samir Amin (1976), elaborated the model of the relationships between center and periphery economies to show how underdevelopment grows out of the exploitive links between the two types of systems.

All versions contribute to a refutation of the trajectory of development described by modernization theory.

A more global approach to development issues was formulated by Immanuel Wallerstein (1974, 1980, 1988) and his followers. World system theory elaborates the Marxist model of economic domination into a system in which exploitation occurs worldwide. Wallerstein broadens the focus on class relations among and across nations to examine the development of an international division of labor in the capitalist world economy where core industrial nations exploit peripheral regions as sources of raw materials and labor. This approach has been both enormously influential and controversial, generating massive amounts of research on the model itself, particular spatial and historical portions of the world system, and particular subsectors and groups. A helpful overview that charts the intricacies of this perspective can be found in a text by Thomas Shannon (1989).

The emphasis on First World as well as Third World development found in world-system theory provides a bridge to a slightly different tradition that focuses on the emergence of the core industrial nations and their political systems. Much of this literature is concerned with development of modern political as well as economic systems. For example, while Barrington Moore's study (1966) of the transformation of agrarian societies into modern industrial states remains firmly anchored in a Marxist emphasis on class relations and productive systems, it is also concerned with the political roles played by antagonistic classes and the political outcomes of their confrontation. Numerous other studies pursue a similar comparative perspective on the upheavals that accompanied the emergence of modern Western industrial nations (cf. Tilly et al. 1975).

One other type of study in this tradition deserves mention. These are studies of social and political change that occur within a particular society at various stages in the industrialization process. John Walton (1987) provides a convenient typology based on cross-classifying epochs and processes of industrialization. The resulting types range from protoindustrialization through deindustrialization. Studies from early periods focus on the emergence of particular classes, on class

conflict, and on the influence of classes on the historical development of modern nations, as in E. P. Thompson's and John Foster's influential accounts of English class formation (Thompson 1963; Foster 1974), Ron Aminzade's analysis of nineteenth-century France (1984), and Herbert Gutman's studies of American class culture and conflict (1966). Influential studies of transitions in later periods of industrial development examine the consolidation of control of the labor process (Burawoy 1979; Edwards 1979), deindustrialization (Bluestone and Harrison 1982), informalization of labor markets (Portes et al. 1989), and post-Fordist production systems (Mingione 1991).

Finally, while beyond the scope of this review, there are also other important traditions that have strong links to one or the other approaches described above. One of these is found in a vast literature on social movements that has many points of intersection with the work on comparative and historical social and political change discussed here. Another is work that applies the theories of dependency and uneven development to regional development problems internal to particular societies. Finally, there are structural and poststructural approaches to the development of major social institutions and forms of repression, as found in the complex but influential work of Michel Foucault (1979, 1980, 1985). While this last example could as easily be classified under studies of social institutions and processes, it is included here because of its focus on changes in historical times that have produced modern social forms.

State Formation and State Breakdown. The study of state formation and state breakdown has always been a central focus of macrosocial inquiry, especially in the area of comparative historical sociology. Studies of state formation examine the nature of state power and the processes by which it develops. While some sociologists have seen the state as emerging from internal dynamics of society, largely in terms of the interests and struggles of social classes, others have turned their attention to the external dynamics of society along with the market forces of the capitalist system. Tilly (1975, 1990) demonstrates that the modern states were created in the process of capital concentration and consolidated under the pressure of increased international military competition (war and preparation for war).

Michael Mann (1986, 1993) examines the nature of power in human societies by focusing on the interrelations of four principal sources of social power—economic, ideological, military, and political resources—and relates them to the rise of city-states, militaristic empires, modern nation-states, and nationalism. Another important theory on the relations between the state and society is Robert Wuthnow's (1989) analysis of how conflicts between the state, elites, and cultural entrepreneurs caused the great ideological movements to challenge the status quo in the development of modern society.

Contemporary theory of revolution and state breakdown starts with Barrington Moore (1966) who proposed a model of agrarian class politics. Drawing upon both Marxian and Weberian theoretical perspectives, Skocpol's (1979) breakthrough analysis introduced the state-centered theoretical paradigm of revolution in her case study of French, Russian, and Chinese revolutions. Treating the state as an "autonomous entity," Skocpol argues that the state has its own military and fiscal interests, and that under certain circumstances, state interests necessarily are in deep conflict with the interests of social classes. State breakdown occurs when the state experiences high levels of fiscal crisis induced by strain on resources from both internal elite conflicts and external military pressure. In Skocpol's theory, the state thus becomes the central actor and the location of crisis in revolutionary situations.

This state-centered theme developed by Skocpol has been further expanded by Goldstone (1991), who uses a structural-demographic approach to indicate that the early modern boom in population led to strain on state resources associated with the taxation system and economic development. Goldstone argues that in a system tied to agricultural output, the agrarian state depends mainly on land taxes for revenue. As growing population places pressure on the agricultural economy, rising grain prices result in inflation that erodes state revenues, leads to higher taxes, and exacerbates elite conflict. Rising prices generate profits for some elites who are quick to take advantage of commercial opportunities, but hurts other elites who are slow to adjust and lag behind in social mobility. Revolution is the ultimate outcome of the state's failure to meet its obligations.

While Skocpol's and Goldstone's models emphasize either structural or demographic sources of strain on the state, interest in geopolitical principles and strains became increasingly prominent during the 1980s, inspired by Paul Kennedy's analysis (1987) of the rise and fall of great powers. Randall Collins's geopolitical theory (1986, 1995) offers another route to state breakdown. Bringing in the Weberian principle that legitimacy of the governing apparatus at home depends on the state's power and prestige abroad, Collins's analysis, given validation by his prediction of the collapse of the Soviet Union, demonstrates that a state's geopolitical position has a crucial effect on its ability to mobilize critical resources and manage internal politics. In Collins's model, geopolitical strains result in inability to maintain fiscal health. A state that suffers the geopolitical disadvantage of being surrounded by multiple enemy states experiences logistical overextension and fiscal crisis, and thus tends to decline and disintegrate to the point of revolution and state fragmentation.

Social Structures, Processes, and Institutions.

The research described above incorporates investigation of many of the major social structures, processes, and institutions that form the core subject matter of sociology. Studying change in economic and political systems requires scrutiny of economies, politics, and other social institutions and their major organizational manifestations and constituencies. However, other theoretical and substantive approaches subsumed under macrosociology either have fallen outside the scope of these large-scale studies of social change and development or are at their periphery. Theoretical perspectives include relatively recent developments such as structural, poststructural, postmodern, and feminist theories. Important substantive areas are defined by cumulating empirical bases of knowledge about power structures; work structures; social stratification and mobility; labor markets; household and family arrangements; and the intersections of race, class, gender, and nationality.

While it is impossible to survey each of these areas, the explosive growth of feminist theories to investigate both gender stratification and economic change and development provides a prime example of new influences on macrosociology. Feminist theorists argue that gender analysis must be

integrated with class, race, ethnicity, nationality, and other sources of social cleavage, and that analyses that ignore the system of gender relations embedded in society are incomplete. Feminist theories have contributed to macrosociology by demonstrating how theories of social reproduction must be joined to theories of economic production to understand social life fully, thus delineating the ways patriarchy coexists with particular economic and political systems to explain the position of women in society.

For example, the subordination of women is predicated on the allocation of tasks that exist outside formal labor markets such as household and reproductive labor and consumption activities as well as labor market work. Heidi Hartmann's early, influential, socialist feminist analysis of the intersection of capitalism and patriarchy (1981) explains women's disadvantaged status in both the labor market and the household in late capitalism as the outcome of an uneasy alliance between the two systems. With increasing demand for women's labor in the second half of the twentieth century, the intersection of the two systems has taken the form of the double and even the triple day—that is, women burdened by responsibility for formal labor market activity; household work; and, frequently, informal work as well.

Similar insights from feminist perspectives have informed studies of developing nations and processes of industrialization and globalization. For example, Ester Boserup's critique of conventional development theories (1970) demonstrates the pitfalls for development projects resulting from ignoring women, as well as the ways women have been marginalized by development scholars and practitioners. Numerous feminist scholars have built on this and related work, combining it with other theoretical perspectives such as world systems and globalization theories, to expand knowledge of the gendered social consequences of core nation exploitation of the periphery (Ward 1990) and the general pattern of ignoring women in large-scale societal accounting schemes (Beneria 1981). Postcolonial theories and "Third World feminism" further explore the intersections of race, class, and gender as they influence different populations in the global economy (Alexander and Mohanty 1997). Finally, the historical research of Louise Tilly and Joan Scott (1978), among

others, has been important in an understanding of how the shift from household economies to wage labor affected working-class women and their families. Unfortunately, much of this work remains underutilized and unincorporated in the kind of macro-level analyses reviewed in previous sections, representing parallel developments rather than integrated studies of macrosocial processes.

RESEARCH METHODOLOGY OF MACROSOCIAL INQUIRY

In the past decades, research methodology in macrosociology has been widely discussed among sociologists. Both quantitative and qualitative methods are used extensively, often in the same larger study. Virtually any methodological tool available to social science is found in macrosocial analysis, ranging from survey research to hermeneutic inquiry.

Quantitative approaches include quantification of documentary and archival data, such as analysis of the lists of grievances, or *cahiers de doléances* (Markoff 1996); analysis of official socioeconomic, demographic, and political data aggregated for larger geopolitical units such as counties, states, or nations; time series of such data for a single state or nation; and standard survey research techniques interpreted to represent structural and contextual process (Coleman et al. 1970). Trend analysis using survey data is one method frequently used by sociologists to establish long-term patterns of change by examining historical change in statistical data. Quantitative methods that use longitudinal designs of panel and cohort analyses to conduct observations at two or more points in time have been extensively employed in the assessment of social change and development at the local, national, and global levels.

Historical and comparative methods are featured prominently in macrosociological analysis and have been consistently used by the most prominent classical and contemporary sociologists. This approach develops ideal-typical case studies of large-scale organizations, nations, and civilizations across time and space. Thus, social and cultural differences manifest in temporal processes and contexts are the focal point of macrohistorical studies that, as Skocpol (1984, p. 1) summarizes:

(1) “address processes over time, and take temporal sequences seriously in accounting for outcomes,” (2) “attend to the interplay of meaningful actions and structural contexts in order to make sense of the unfolding of unintended as well as intended outcomes in individual lives and social transformations,” and (3) “highlight the particular and varying features of specific kinds of social structures and patterns of change.”

In the existing literature on macrosociological research, historical and comparative methods, with their focus on case studies devoted to understanding the nature and effects of large-scale structures and fundamental processes of change, have proven to be an effective approach to macrosociological explanations of macrosocial phenomena. While most historical and comparative research still involves qualitative analyses using available documents and records, more and more research attempts to employ both qualitative and quantitative approaches.

In advocating “moving beyond qualitative and quantitative strategies” Charles Ragin (1987) points out that, in macrosociological analysis, there are two basic strategies: the case-oriented strategy and the variable-oriented strategy. The former is very much evidence oriented, while the latter is theory centered. The goals of case-oriented investigation, with its extensive use of ideal types, often are both historically interpretive and causally analytic. “Investigators who used case-oriented strategies often want to understand or interpret specific cases because of their intrinsic values” (Ragin 1987, p. 35). Work by Bendix (1977, 1978) exemplifies this approach.

Unlike the case-oriented strategy, the variable-oriented strategy tests hypotheses derived from theory, often using quantitative techniques such as multivariate statistical analysis. In macrosocial analysis, a typical variable-oriented study “examines relationships between general features of social structures conceived as variables. Social units, such as nation-states, have structural features which interact in the sense that changes in some features produce changes in other features, which in turn may produce changes in others” (Ragin 1987, p. 55). For example, a cross-national study of modernization by Delacroix and Ragin (1978) is a typical example of variable-oriented research, and

this approach has remained quite popular in the study of development issues as well as in macro-level studies of organizations.

Each of these two strategies has its strengths and weaknesses. The case-oriented research enables investigators to comprehend diversity and address complexity by examining causal processes more directly in historical and comparative context. In variable-oriented research, by contrast, generality is given precedence over complexity when investigators are able to digest large numbers of cases. In some macrosociological studies, scholars combine the two approaches, as in Jeffrey Paige's *Agrarian Revolution* (1975).

THE FUTURE OF MACROSOCIOLOGY

Macroscopic analysis of human society stands as a foundational area of research in sociology, and it is safe to predict that it will continue to grow and expand its scope of inquiry. In an increasingly global economy, marked by shifting boundaries and allegiances, and linked by rapidly advancing communications and information technology, there will be pressing need for explanation and analysis of the major historical and contemporary social movements and upheavals. Events of state formation, transition, and breakdown; revolution and devolution; conflicts based on gender, race, ethnicity, religion, region, and class; global movements of populations; and numerous other large-scale processes that increasingly mark the post-cold war era will provide the raw materials for scholarly and policy relevant analysis.

At the same time, in the interests of advancing social theory, sociologists will continue to seek ways to link macroprocesses to microprocesses. One of the perennial debates that surfaces among sociologists is whether macroprocesses or microprocesses have primacy in explaining social life. A variant revolves around the issue of whether microprocesses can be derived from macroprocesses or vice versa. Those who believe that the macro has causal priority risk being labeled structural determinists. Those who think that macrophenomena can be derived from microprocesses are dismissed as reductionists. Quite often an uneasy truce prevails in which practitioners of the two types of sociology go their own ways, with little interaction or mutual influence.

Despite pendulum swings that alternately emphasize one approach over the other, there are ongoing efforts to construct theory and conduct research built on genuine principles of micro-macro linkage. These have come from a variety of theoretical traditions and perspectives, including those with both macro and micro foundations. While many of these efforts ultimately result in de facto claims for theoretical primacy of one or the other approach, they nonetheless represent an interesting effort to create uniform and widely applicable sociological theory (Huber 1991).

Ultimately, most of the efforts to integrate micro and macro levels reflect the initial concerns of the theorist. For example, Randall Collins's efforts (1998) begin with a microfocus on interaction to derive macrophenomena, while neofunctionalist Jeffrey Alexander (1985) gives primacy to subjective forms of macrophenomena. Perhaps the most highly developed integrative effort is found in Anthony Giddens's theory of structuration (1984) in which social structure is defined as both constraining and enabling human activity, as well as being both internal and external to the actor.

The efforts to link microphenomena and macrophenomena are mirrored in a growing body of empirical research. Such work appears to follow Giddens's view of the constraining and enabling nature of social structure for human activity and the need to link structure and action. It appears safe to say that, while macrosociology will always remain a central component of sociological theory and research, increasing effort will be devoted to creating workable models that link it with its micro counterpart.

ANN R. TICKAMYER AND JIELI LI

MAJOR PERSONALITY THEORIES

Problems of definition arise with the terms *personality* and *personality theories*. Personality is understood by some people to mean self-concept; by others, the consensus of other people's opinions about one's character, and by others, one's true character. Some personality theories have elaborate coordinated concepts discussing how personality originates and develops from conception to senescence, taking up cognitive, conative, and affective aspects of the mind as well as free will, holism, philosophy, and other issues. On the other hand, there are relatively simple, one-dimensional theories of personality that pay little attention to what seems important to other theorists.

This topic is complicated not only by its complexity and variations but also by intellectual belligerence among those who favor one theory over another and those who differ about the same theory. The analogy to religions is inescapable.

In view of this situation, personality theories will be handled in an unusual way. Sentences in italics are reprinted from *Personality Theories, Research, and Assessment* (Corsini and Marsella 1983).

NOTE: Some Personality Theories and Their Originators

They contain quotes of selected assertions about the various theories written by authorities of nine major systems. Additional sources presenting comparative information on personality theories include: Burger 1993; Cloninger 1993; Corsini and Wedding 1995; Drapela 1995; Engler 1999; Ewen 1997; Schultz and Schultz 1994.

Table 1 is a list of a number of other important personality theories.

PSYCHOANALYSIS (SIGMUND FREUD, 1856–1939)

Psychoanalysis is both a theory of personality and a form of psychotherapy (see Freud 1952–1974). Highly controversial throughout Freud's lifetime, it continues to be so.

Freud saw personality as a dynamic conflict within the mind between opposing instinctual and social forces. *The topographical hypothesis views the mind in terms of three systems.* They are: the unconscious, the preconscious, and the conscious. *The mind is composed of the id, ego, and superego.* The id

consists of primitive instinctual demands, the superego represents society's influence restricting the id's demands, and the ego is dynamically in between the two. *Fundamental motives are instinctual.* Instincts are the basic forces (drives) of the psyche. The aim of drives is their satisfaction. *All instincts are basically sexual.* Freud's concept of sexuality was equivalent to physical pleasures. *There is a series of built-in stages of sexual development.* Freud postulated that people went through three sexual stages: An oral stage following the primary infantile narcissistic stage, then an anal phase, and finally a phallic phase. *Children develop libidinal attitudes towards parents.* This notion of the Oedipus and Electra complex of children having sexual attractions to parents of the opposite sex has especially generated controversy.

The psyche develops a number of defenses. To survive, the human being's ego develops a number of processes intended to repress awareness of conflicts. Repression is the main mental mechanism, but others defenses are related to it, including rationalization, displacement, identification

and conversion. *Dreams have meaning and purpose.* According to Freud, dreams are disguised desires permitting people to sleep by permitting expressions of illicit desires disguised by various symbolisms.

INDIVIDUAL PSYCHOLOGY (ALFRED ADLER, 1870–1937)

Alfred Adler's personality theory is distinguished by its common sense and simple language (see Adler 1956). In contrast to Freud and Jung, Adler's views demonstrate social concern.

Man, like all forms of life, is a unified organism. This basic holistic notion contradicts Freud's classifications and opposing theses and antitheses. Adler viewed the individual as an indivisible totality that could not be analyzed or considered in sections. *Life is movement, directed towards growth and expansion.* Adler took a dynamic and teleological attitude toward life, that people were always striving toward goals of personal self-improvement and enhancement. *Man is endowed with creativity and within limits is self-determined.* Instead of taking the usual position that only biology and society were to be considered in the formation of personality, Adler posited a third element: personal creativity or individual responsibility, akin to the concept of free will. Adler accepted that we all have certain biological and social givens and what is made of them is the responsibility of individuals.

Man lives inextricably in a social world. Adler had a social personality theory. *Individuale* in German does not have the same denotation as *individual* in English but rather denotes indivisibility or unity. Adler did not see humans apart from society. *The important life problems—human relations, sex, occupation—are social problems.* Adler believed that to be successful in life all humans had to complete the life tasks of socialization, family, and work.

Social interest is an aptitude that must be consciously developed. Social interest is the criterion of mental health. Social interest is operationally defined as social usefulness. This trio of related statements is an explicit philosophy unique for personality theories. Adler believed that psychological normality

depended on *Gemeinschaftsgefühl*—social interest. He saw all human failures, such as criminals, the insane, and neurotics, as lacking this element.

ANALYTICAL PSYCHOLOGY (CARL G. JUNG, 1875–1961)

Jung's analytical psychology stresses unconscious mental processes and features elements in personality that derive from mankind's past (Jung 1953–1972).

Personality is influenced by potential activation of a collective transpersonal unconscious. Jung believed that individuals upon conception came with something from the past that directed their personalities, a concept somewhat like Lamarckism relative to physical heredity. *Complexes are structured and energized around an archetypical image.* This is an extension of the first assertion. Complexes refer to important bipolar aspects of personality, such as introversion–extraversion. Complexes, directed by archetypes, are seen as innate and universal capacities of the mind to organize human experiences. Archetypes are considered innate potentials of the mind derived from the experiences of ancestors, a kind of directing blueprint of one's character.

The ego mediates between the unconscious and the outside world. According to Jung, a strong, well-integrated ego is the ideal state for a person. *Unconscious psychic reality is as important as the outside world.* Jung stressed the importance of phenomenology in contrast to overt behavior. He explored people's inner realms with great diligence. He even exceeded Freud in concentrating on the importance of the unconscious. *Personality growth occurs throughout the life cycle.* Jung saw individuals in constant growth and development with imperceptible stages that sometimes, as in the case of adolescence and midlife crises, became evident. *The psyche spontaneously strives towards wholeness, integration, and self-realization.* This last statement is echoed in many different ways by a number of other theorists, including the two just considered, and is made a central point by some theorists such as Carl Rogers and Kurt Goldstein.

PERSON-CENTERED THEORY (CARL ROGERS 1902–1987)

Carl Rogers developed his theory as part of his system of client-centered or nondirective therapy (see Rogers 1951). He had a lifelong abiding faith in the potentials of people to correct the errors of their past if a therapeutic environment could be created in which the client felt understood and accepted by a neutral nonevaluative therapist. His system emerges from one central theme, the first assertion below.

Each person has an inherent tendency to actualize unique potential. Rogers viewed each person as having a built-in tendency to develop all his or her capacities in ways that serve to maintain or enhance the organism. *Each person has an inherent bodily wisdom which enables differentiation between experiences that actualize and those that do not actualize potential.* Rogers's trust in people is indicated here: There is a wisdom of the body in that everyone knows what is best for one's self in terms of the ultimate goal of self-realization.

It is crucially important to be fully open to all experiences. Experiencing becomes more than bodily sensing as one grows older. Through complex interactions with our body and with other persons we develop a concept of self. These three assertions belong together, and in them Rogers is taking up the nature-nurture, heredity-environment controversy. Essentially, his position is that personality is a function of bodily wisdom and the effect of others (primarily parents).

One can sacrifice the wisdom of one's own experiences to gain another's love. Rogers as a therapist came to the conclusion that a great deal of human suffering is due to the tendency of people to sacrifice their own body wisdom to gain positive regard from others. Children, in order to gain acceptance by their parents, will too often agree with them, accept their premises, and maintain them throughout life, generating problems thereby if the premises are incorrect. His therapeutic system was intended to get people to understand their historical processes and to be able to revise the history of their life. *A rift can develop between*

what is actually experienced and the concept of self. The same theme is here elaborated. A person may deny reality to gain approval from others, and this bifurcation can generate a host of problems. *When the rift between experiencing and self is too great, anxiety or disorganized behavior can result.* Once again, the same theme is emphasized. We all want to be loved and accepted, but the continued pursuit of acceptance may separate us from reality. *Validating experiencing in terms of others can never be completed. All maladjustments come about through denial of experiences discrepant with the self-concept.* And so, one must depend on one's self for reality and not on others. Adler believed that maladjusted people lacked social interest, while Rogers stated that maladjustment essentially came from people listening to others rather than to their own bodily wisdom.

PERSONAL CONSTRUCTS THEORY (GEORGE A. KELLY, 1905–1967)

Kelly was a highly original thinker. He developed a unique cognitive system that called for the use of idiosyncratic language (see Kelly 1955). While his personal constructs theory covers all of psychology from the ideographic point of view, he bypassed usual terms and concepts such as *learning* and *emotions* and paid no attention to the environment or heredity.

All our interpretations of the universe are subject to revision. Kelly starts with a skepticism about beliefs and takes the position that there is no absolute reality. He took the position of constructive alternativism to indicate that people with differences of opinions could not necessarily be divided in terms of right and wrong. Two people can view the same situation in quite different ways and both can be right, both can be wrong, or one or the other may be right. *No person needs to be a victim of his own biography.* Here we have a statement of the freewill concept in a different form.

A person's processes are psychologically channelized by the ways in which he anticipates events. This is Kelly's fundamental postulate. Essentially, this viewpoint states that what is important is how events

are interpreted rather than the events themselves. This assertion leads naturally to Kelly's major contribution to personality theory, a series of other personal constructs, relative to how people view reality. We need not attempt to cover all of his constructs, but a few of them will give the reader a sense of Kelly's thinking: *A person anticipates events by construing their replication.* (The construction corollary.) *Persons differ from one another in their construction of events.* (The individuality corollary.) *A person may successively employ a variety of construction subsystems which are inferentially incompatible with each other.* (The fragmentation corollary.) This last corollary relates directly to Carl Rogers's theme that maladjustment comes from divergent forces: from within and from without.

Many of the important processes of personality and behavior arise as a person attempts to change or is threatened with forced change in his construct system. Kelly's point here is echoed by many other theorists, that one establishes some sort of life pattern or life-style, but changes in thinking about one's self and others will disrupt the individual.

Kelly's system is the purest cognitive system of any discussed here, solely dependent on perceptions and interpretations.

OPERANT REINFORCEMENT THEORY (B.F. SKINNER 1904–1990)

Skinner has denied that his operant reinforcement is a personality theory, but rather that it covers all aspects of overt human behavior (Skinner 1938). In contrast to those theorists who view personality as essentially phenomenological, Skinner decries the term mind and concerns himself solely with overt behavior. As a radical behaviorist, Skinner does not deny internal processes but considers them not relevant to psychology as an objective science of behavior.

Personality is acquired and maintained through the use of positive and negative reinforcers. Skinner applies operant reinforcement to all aspects of human behavior. We tend to repeat what works and to give up what does not work, to continue behavior that leads to pleasant consequences and

to discontinue behavior that leads to unpleasant consequences. *Behavior may be altered or weakened by the withholding of reinforcers.* If other people change their ways of operating towards an individual, this in turn will affect that person's behavior and consequently his personality.

Personality develops through a process of discrimination. In life, we experience all kinds of consequences, and we have to make decisions about our future behavior to these consequences. *Personality becomes shaped or differentiated.* Over time, our personalities are shaped by generalizations about ways that lead to the achievement of goals.

SOCIAL LEARNING THEORY (ALBERT BANDURA, 1925–)

Bandura, like Skinner, came to his opinions about personality mostly through research (Bandura and Walters 1963). His system is of the cognitive-learning type stressing the capacity of individuals to generalize in terms of symbols.

The causes of human behavior are the reciprocal interaction of behavioral, cognitive, and environmental influences. Bandura believes personality is a function of how we think and act and our responses of the environment's reactions to our behavior. In terms of the three elements of biology, society, and creativity, Bandura stresses the latter two. Heredity is discounted as a major determiner in personality development: How a person thinks and acts and how the environment responds to a person's behavior determines one's personality. *Behavior can be self-governed by means of self-produced consequences (self-reinforcement).* This assertion also emphasizes the importance of reciprocity: life is interaction: the individual versus the world, with the individual changing the world and the world changing the individual.

Individuals may be influenced by symbols which act as models. Reality to people need not only be direct stimuli, such as a smile or a slap, but reality can also be via symbols, such as pictures or words. Bandura's major research studies called for children to watch the behavior of others. He found that if a person considered to be a model acted in an aggressive

manner and got what he wanted, that observers were likely to imitate the model. Consequently, not only direct stimuli and responses (as per Skinner) but symbolic experiences also determine personality. *Reinforcements (and punishment) can operate in a vicarious manner.* This is more of the above. Various kinds of behavior can be changed by seeing what happens to others. We learn not only by doing and getting responses but also by observing.

EXISTENTIAL PERSONALITY THEORY

Existential psychology is a loosely organized and ill-defined set of concepts mostly based on the work of philosophers and theologians (see Blackham 1959; Grimsley 1955). Essentially, existentialists see individuals as being in search of meaning. People are also seen as striving to achieve authenticity.

Personality is primarily constructed through attribution of meaning. Essentially, this point of view is similar to Kelly's concept of constructs. *Persons are characterized by symbolization, imagination, and judgment.* These are seen as attempts to find meaning. The human being is always trying to make sense out of existence, others, and self and uses mental processes in interaction with self and the world.

Life is best understood as a series of decisions. The human individual not only has to make evident decisions such as what to eat, but more subtle and important ones, such as who he or she really is. One has to decide what the world is like, what is real, what is important, and how to participate in the world. *Personality is a synthesis of facticity and possibility.* Facticity means the givens of heredity and environment and possibility becomes the creative aspect of personality. The facts of reality limit behavior variations.

A person is always faced with the choice of the future, which provokes anxiety, and the choice of the past, which provokes guilt. The human condition is such that people looking backwards in time can find reasons to be guilty and looking forward can find reasons to be afraid. Existentialists see anxiety and guilt as essential elements of the human being.

Ideal development is facilitated by encouraging individuality. Here we find traces of Carl Rogers's

concept of the importance of listening to one's own body or Adler's and Kelly's requirement for personal courage. A human problem is to escape the effects of one's early environment, especially the effects of one's family.

CONSTITUTIONAL THEORIES

The oldest theories of personality formation are the constitutional that state that personality is a function of the nature of one's corporeal body. Aristotle (1910) in his *Physiognomica*, for example, stated that the "ancients" had a variety of theories to explain differences in human character. The Greek physician Galen took Hippocrates's physiological explanation of bodily health as a function of the balance between certain bodily fluids and stated that various personality types were a function of excesses of these fluids. Gall and Spurzheim (1809) extolled phrenology (the shape of the human head) in establishing personality. Kretschmer (1922) declared that people with certain kinds of body types tended to have particular types of mental conditions. Lombroso (1911) declared that criminal types were distinguished by a number of physiological anomalies. The list goes on and on. At present there are a variety of constitutional personality theories, some of which will be discussed below.

Structural Approach. William Sheldon (see Sheldon and Stevens 1942) classified individuals in terms of body shapes claiming that there was a positive correlation between various structural variations and personality types. He spent many years in doing basic research to find evidence for his theory. He found strong evidence to support the validity of his views. Other investigators also found supporting evidence but not to any useful degree.

The somatotype provides a universal frame of reference for growth and development that is independent of culture. This statement by implication discounts society and creativity. Born with a particular body type and you will have a specific personality type. *Three polar extremes called endomorphy, mesomorphy, and ectomorphy identify the essential components of the somatotype.* Sheldon had a somewhat complex classificatory system with three main body types:

mesomorphs had an excess of muscle, endomorphs an excess of fat, and ectomorphs were relatively thin. For example, mesomorphs were considered to be bold, endomorphs to be extraverted and ectomorphs to be introverted.

Experiential Approach. This particular constitutional position is championed by Schilder (1950) and Fisher (1970) among others. It is a combined learning/physiological approach, referring to the nature of the experiences that a person has via contact during life, between the inner viscera, the skin, and the environment's effect on the body.

Body sensations provide the primary basis for initial differentiation of self from environment. The basic notion is that an unborn infant is only aware of internal sensations, but following birth, now becomes aware of stimuli from the outside world. Thus, the body surface becomes the locus of separation of self from the environment and the child now becomes able to identify the self and the outer world. *The development of the body image proceeds through stages, each of which has a lasting effect upon the body image as a whole.* This assertion has elements of the Freudian sexual stages and of Skinner's behaviorism in that contact with the outside world not only establishes the world but also the individual's personality.

Holistic Approach. Kurt Goldstein, who worked primarily with brain-injured patients, is primarily identified with this viewpoint (see Goldstein 1939). In working with various cases of physical pathology, such as stroke victims, he came to the realization of the importance of a human's attempt to maximize and organize potentials to survive and to enhance one's situation.

The normal human organism is equipped to maximize self-actualization, provided environmental forces do not interfere. This statement is accepted in a variety of ways by a number of other personality theorists, but Goldstein made this his central point. Of those theorists already discussed, Adler, Jung, and Rogers would have agreed completely. *Self-actualization is manifested by maximum differentiation and by the highest possible level of complexity of an integrated system.* This statement follows from the

prior one and gives emphasis to the concept of the wisdom of the body. *The key to effective behavior is adequate functioning of part-whole relations.* Goldstein used Gestalt concepts of figure and ground to give evidence of the importance of understanding behavior as a totality, and consequently he can be considered an holistic theorist.

SUMMARY

At present there are a considerable number of personality theories, each working as it were completely independently of one another. There is lack of a common vocabulary that in turn leads to different people saying the same thing in different words. A complete eclectic theory would consider all elements mentioned, taking up the issue of personality in terms of the issues of heredity, environment and creativity, self and the environment.

MARGINAL EMPLOYMENT

INTRODUCTION

In industrialized countries the principal way in which adults and their families make ends meet

economically is through employment in the formal labor force. In the United States, earnings in the form of wages and salaries account for 71 percent of household income, on average. Even among individuals in poor families, half (49 percent) of all household income comes from earnings—their single most important source of income (Current Population Survey 1998). The centrality of work for economic well-being also is reflected in the close connection between finding gainful employment and exiting poverty on the one hand, and losing employment and sliding into poverty on the other. While formal employment is a necessary condition for economic well-being among almost all nonwealthy, able-bodied adults and their families, it is not a sufficient condition. Not all jobs pay well, many come without health and other benefits that workers must either pay for through their wages or do without, some are merely part-time, and some jobs are highly unstable and offer little long-term security. *Marginal employment can be conceptually defined as the circumstance in which the formal employment of adults (or groups of adults within families) fails to generate the earnings needed to achieve a minimally acceptable standard of living, either because they work too few hours (insufficient labor supply), and/or because their wages are too low.*

Two trends motivate increasing concern over marginal employment. The first is a shift in social welfare systems which, as in the United States, have come to place greater emphasis on formal employment as the route out of poverty and reliance on the state. In recent years industrialized nations have reoriented their social welfare programs to encourage employment and work preparedness (Cornea and Danziger 1997). In the United States, the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 has placed strict time limits on Public Assistance receipt. The image of thrusting people off the welfare rolls to fend for themselves in the open labor market has generated deep concern over their employment prospects. Second, in recent decades the structure of employment opportunities has changed in ways detrimental to low-skilled workers. Whether due to changing technology (e.g.,

computerization), which is displacing labor; to the globalization of production and trade, which is leading to outsourcing of low-skilled work; to competition through increased immigration; or to changes in wage-setting institutions (e.g., declines in unionization or real minimum wages), low-skilled workers have slipped further behind their better-skilled counterparts in terms of wages and total compensation (Freeman and Gottschalk 1998). The point is, just when many governments are foisting more responsibility for the economic well-being of citizens on the labor market and workers themselves, questions are being raised about the implications of macroeconomic changes for the quality of jobs available, especially for low-skilled groups. As such, marginal employment—its severity, causes, and consequences—has become an important concern for sociologists and policy makers alike.

MARGINAL EMPLOYMENT AS UNDEREMPLOYMENT

Marginal employment per se is not as yet a conventional concept in sociology and thus there are no standard empirical definitions of this term. As noted, we conceptualize it as consisting of both the degree of attachment to the labor force and the quality of jobs. A composite measure that incorporates both these dimensions is *underemployment*. Drawing on the Labor Utilization Framework of Phillip Hauser (1974), Clifford Clogg (1979) developed a measure of underemployment that consists of the following categories. The *working poor* are those people who are working full-time, full-year, but whose labor market earnings are less than 125 percent of the poverty threshold for single individuals. *Involuntary part-time workers* include those who are working fewer than full-time hours (thirty-five-hours per week) only because they are unable to find full-time work. The *unemployed* are those who are not currently working and are either actively looking for work or on layoff. (The unemployment rate—a standard aggregate measure of the health of the economy—is simply calculated as the number unemployed divided by the number in the labor force, where the latter is the sum of those employed and those unemployed.) Finally, *discouraged workers* (sometimes referred to as the

subunemployed) are neither working nor looking for work, but would nonetheless like to be working if they could find a job. All other adults, those who are not working and do not want to be, are considered *not in the labor force* and are excluded from analyses of underemployment. It is important to recognize that this operationalization of underemployment is an imperfect empirical measure of marginal employment as conceptually defined above. Discouraged or involuntary part-time workers, for example, could be in families that are otherwise well off economically. While this caveat needs to be borne in mind, the statistical patterns described below suggest underemployment is a reasonable measure of marginal employment.

Table 1 shows the distribution of underemployment and its types for the U.S. population as a whole, and for important demographic groups. The data are from the March 1998 Current Population Survey, a nationally representative survey of 64,659 U.S. households and a key source of official employment data (Current Population Survey 1998). In 1998, of all U.S. adults aged 18–64 who either were working or would like to have been working, 18.0 percent were underemployed. We stress that by this definition, over one in six U.S. workers or would-be workers are marginally employed. Of these, 4.7 percent were unemployed, 6.3 percent were working part-time but wanted full-time work, 6.1 percent were working full-time but for near- or below-poverty wages, and 0.8 percent had given up in the search for work, despite wanting a job.

Underemployment is not distributed equally across demographic groups, but parallels well-known correlates of economic well-being generally. At over one-third, the young (those aged 18–24) are far more likely to be underemployed than older adults. A more refined age breakdown for all adult age groups (not shown) suggests a curvilinear pattern, with young adults and elderly Americans at greater risk of underemployment than those in their prime working ages. Women have long been disadvantaged in the U.S. labor market with respect to wages and occupational prestige, so it is little surprise that there also is gender inequality in underemployment. In relative terms,

MARGINAL EMPLOYMENT

Percentage distribution of underemployment by selected characteristics

	Underemployed					Adequately Employed
	Total	Low income	Low hours	Unemployed	Discouraged	
Total	18.0%	6.1%	6.3%	4.7%	0.8%	82.0%
Age						
18-24	33.8	1.34	9.0	9.5	1.9	66.2
25-34	17.7	5.5	6.6	5.0	0.6	82.3
45-54	15.5	5.0	5.9	3.9	0.6	84.5
55-64	14.4	5.4	5.4	5.3	3.0	85.6
Gender						
Men	16.9	4.9	6.4	5.0	0.6	83.1
Women	19.2	7.5	6.2	4.5	1.0	80.8
Race/ethnicity						
Non-Hispanic white	15.2	5.4	5.6	3.7	0.6	84.8
Non-Hispanic black	25.3	7.1	7.5	8.8	1.9	74.7
Hispanic	28.3	10.2	10.0	7.1	1.1	71.7
Asian	17.5	6.5	6.2	3.9	1.0	82.5
Native American	19.4	9.1	8.8	9.8	1.7	70.6
Marital status						
Married	13.2	4.6	5.1	3.1	0.5	86.8
Divorced/separated	19.7	5.7	7.8	5.3	0.9	80.3
Widowed	23.1	8.4	9.3	4.1	1.3	76.9
Never married	17.1	9.6	8.1	8.0	1.5	72.9
Immigrant status						
Third (or higher) generation	17.0	5.7	6.0	4.6	0.8	83.0
Second generation	18.1	5.9	5.9	5.2	1.0	81.9
First generation	24.6	9.2	8.8	5.6	1.0	75.4
Education						
Less than high school	36.3%	12.2%	11.5%	10.5%	2.2%	63.7%
High school or GED	20.8	7.0	7.4	5.5	0.9	79.2
Some college	16.5	6.1	5.8	4.0	0.7	83.5
College degree or more	7.5	2.4	3.1	1.8	0.2	92.5
Residence						
Nonmetropolitan	21.6	8.2	7.4	5.3	0.8	78.4
Metropolitan	17.2	5.7	6.1	4.6	0.8	82.8
Central city	20.5	6.7	6.8	5.7	1.2	79.5
Non-central city	15.0	5.0	5.5	3.9	0.6	85.0
Not identified	18.3	5.9	6.8	5.0	0.6	81.7

Table 1

NOTE: Percentage Distribution of Underemployment by Selected Characteristics.

SOURCE: Original calculations from the March 1998 Current Population Survey.

women are 14 percent (2.3 percentage points) more likely than men to be underemployed, a difference that is due primarily to their greater risk of being working poor. Blacks, Hispanics and, to a lesser degree, Native Americans, are distinctly disadvantaged with respect to non-Hispanic whites. Indeed, about one-fifth of Native Americans, and over one-quarter of blacks and Hispanics, are underemployed, which compares to only 15 percent of non-Hispanic whites. Being married carries an advantage, while being divorced, separated, or widowed increases the risk of underemployment.

With respect to immigrant status, first-generation adults (immigrants themselves), are far more likely than the native-born to be underemployed, and among natives, those with a foreign-born parent (the second generation), are slightly disadvantaged compared to those with native-born parents (the third and higher generations). (This pattern should not be taken as direct evidence of economic assimilation, however, given immigrant-cohort differences in factors that determine the risk of underemployment.) The rising wage inequality of the 1980s and 1990s is due largely to deteriorating

conditions among low-skilled workers (Freeman and Gottschalk 1998). Indeed, as shown in Table 1, education is strongly associated with underemployment. Whereas 36.3 percent of those with less than a high school education are underemployed, only 7.5 percent of college graduates are similarly situated. Finally, the risk of underemployment is not distributed evenly across space. Despite legitimate and well-chronicled concern over declining employment opportunities in the inner city (Wilson 1996), at 21.6 percent the prevalence of underemployment is higher in nonmetropolitan (nonmetro) counties of the United States, than in metropolitan areas. Indeed, the nonmetro risk is even higher than that for those living in central cities of metro areas (20.5 percent). Thus, marginal employment is both an inner city and a rural problem.

THE DYNAMICS OF MARGINAL EMPLOYMENT

Underemployment and its component parts are countercyclical. They rise in prevalence when the state of the wider economy declines, and they fall as the economy heats up. For example, above we noted the underemployment rate in 1998—a relatively good year economically—was 18.0 percent. In 1968, another good year, it stood at 15.2 percent. Amid recession in 1983, by comparison, 24.3 percent were underemployed. The rise and fall in the prevalence of marginal employment over time reflects the dynamic nature of labor markets. In large numbers individuals are constantly moving into and out of the labor force, between part-time and full-time work, and between good jobs and bad jobs.

While cross-sectional studies are useful for describing the broad contours of marginal employment and identifying sociodemographic groups that are more vulnerable, sociologists have begun to turn their attention to the nature and determinants of the movement between labor-force states. In an analysis of data from the Current Population Surveys of 1968 through 1993, Jensen and colleagues (1999) explored the determinants of transitions between adequate employment and underemployment. They found that adequately employed adults are more likely to slide into underemployment from one year to the next if they are black or Hispanic, female, less well educated, or young, or

if they live in a nonmetropolitan area. The risk of becoming underemployed also was higher amid a souring economy, and lower when the economy was strengthening. Once underemployed, these same groups were found to be disadvantaged with respect to their likelihood of finding adequate employment. Similarly, using data from the Survey of Income and Program Participation, Hsueh and Tienda (1996) explored transitions between being employed, unemployed, and out of the labor force altogether. They document greater labor-force instability among women, blacks and Hispanics, young adults, those with only a high school degree or less, and those who are not married.

That minorities and women, particularly those who are less well educated, have greater labor-force instability is important for understanding persisting gender and racial or ethnic inequality in society. The checkered work history that comes from frequent transitions into and out of the labor force means less opportunity to gain valuable work experience, and may signal to prospective employers a questionable commitment to work (Tienda and Stier 1996). The negative implications of work instability can accumulate over time, darkening future labor market outcomes and increasing the likelihood of marginal employment (Clogg et al. 1990).

JOB DISPLACEMENT

Even a stable work history is no guarantee against future employment hardship. An important determinant of labor-force instability is job displacement. Displaced workers are often technically defined as “persons 20 years and older who lost or left a job [which they had held for three or more years] because their plant or company closed or moved, there was insufficient work for them to do, or their positions or shifts were abolished” (Hipple 1997, p. 38). Sometimes referred to as “structurally unemployed” (because their unemployment is due to structural rather than cyclical shifts in the economy), displaced workers have little prospect of getting their old jobs back: Their job loss is permanent. To get a sense of the magnitude of the

problem, consider that between 1993 and 1995, 15 percent of U.S. workers experienced job displacement (Kletzer 1998). The underlying causes of displacement are not well documented, but are likely rooted in technological change, rising foreign competition, and declining productivity within industries (Kletzer 1998). More is known about differences across sociodemographic groups in the risk of displacement. Recent evidence indicates that those who are black, less well educated, and employed in production occupations (as craftsmen, operatives, or laborers) and in manufacturing industries have higher rates of displacement (Kletzer 1998). Once displaced, there also is inequality in the prospects of finding new work after displacement. Here it helps to be white, male, and better educated.

CONTINGENT AND TEMPORARY WORKERS

Also contributing to volatility of labor-force attachment is the emergence of contingent labor and temporary workers. In the 1970s, international competition had begun to challenge U.S. industries, marking an end to two decades of economic expansion and growing corporate profits. In response U.S. firms began to restructure in order to maintain their competitive edge. By the mid-1980s, terms such as “mergers,” “acquisitions,” “deindustrialization,” and “downsizing” had become commonplace (Harrison and Bluestone 1988). In the process, the traditional relationship between employer and employee began to change. Today, for a growing percentage of U.S. workers the postwar model of relatively stable and secure full-time employment with fringe benefits, steady wages, and the opportunity, if not expectation, of internal advancement within a firm, is no longer a reality (Henson 1996). Instead an increasing proportion of the American workforce is now engaged in *contingent work*.

To date there is no conventional definition of contingent work. The term has been used broadly in the literature to refer to a range of nonstandard employment practices including “part-time work, work performed by independent contractors and

on-call workers, and work done by temporary workers, hired either directly for limited-duration projects or through temporary help firms” (Blank 1998, p. 258). In 1989, the Bureau of Labor Statistics (BLS) developed the following definition: “Contingent work is any job in which an individual does not have an explicit or implicit contract for long-term employment” (Polivka 1996, p. 3). In sum, despite disagreements over specifics, contingent work usually refers to nonstandard employment relationships that are associated with temporary or insecure employment duration, inadequate wages and benefits, and a conditional relationship that limits the attachment between employer and employee. Compared to permanent employees, contingent workers earn less and are less likely to be covered by employer health insurance or pension plans (Cohany et al. 1998; Hipple 1996). Depending upon the definition used, contingent workers composed between 2.2 and 16 percent of the labor force in 1995 (Barker and Christensen 1998).

The use of contingent workers has grown rapidly in recent decades. This growth has been driven primarily by a combination of employee desires (supply-side explanations) and employer strategies (demand-side explanations). On the supply side, contingent work often has features that some workers prefer, such as limited and flexible hours, independence, and variety. And some workers use contingent work as a way to shop around for good jobs and employers, in the hopes of obtaining more permanent work (Blank 1998). However, the idea that the rise in contingent work is being driven by worker preferences should not go too far since, by one estimate, two-thirds of contingent workers would prefer permanent work (Cohany et al. 1998). Demand-side factors include fluctuations in product demand which give rise to the need for flexibility in hiring and firing, reduced labor costs, and the ability to screen employees for permanent, full-time work (Blank 1998). Thus, in response to the growth of global competition and increasingly volatile consumer demand, employers have used contingent workers to shift the risk of market uncertainties from the firm to the worker. By reducing the obligation of the employer to the employee, firms are able to be

more flexible in adjusting labor inputs and reducing labor costs. One of the primary reasons that firms have been able to cut costs at the expense of labor is the transition in the balance of power between labor and management in recent decades (Golden and Applebaum 1992). As labor unions have gradually lost bargaining power, management has increasingly been able to exercise cost cutting strategies at the expense of workers.

A subgroup of contingent workers that appear to be particularly marginalized are temporary help workers or "temps." Temps are typically employees of temporary help supply (THS) firms, which provide workers to other businesses on a contractual basis (Ofstead 1998). In most cases, THS firms remain the worker's legal employer while the worker provides services to another establishment. THS firms emerged as labor market actors in the 1940s, but have seen tremendous growth in recent decades. Research by the Bureau of Labor Statistics shows that the number of temporary jobs filled daily by THS firms has increased more than two and a half times since 1982 (Golden and Applebaum 1992). Further, research has found that over 90 percent of employers use temporary workers and that more than five million workers seek employment through THS firms in a given year (Golden and Applebaum 1992). THS firms typically specialize in worker placement in one of four occupational areas: office, industrial, medical, or engineering and technical, with office workers comprising over half of all temporary workers (Carey and Hazelbaker 1986).

Temporary workers are subject to an earnings penalty in comparison to permanent workers. Research has shown that temporary workers typically earn between 80 and 52 percent of the wage earned by their permanent counterparts (Barker and Christensen 1998). Further, research shows that the temporary workforce is disproportionately composed of individuals that face disadvantage in the labor force in general: women, minorities, and the young (Barker and Christensen 1998; Howe 1986). The predominance of women and the young among temporary workers is likely due in part to the flexibility allowed by the employment relationship. However, limited alternative

employment opportunities and employer perceptions of what types of workers prove to be risky investments as permanent employees, also may be at play.

As it continues, the growth of contingent labor and proliferation of temporary workers will likely contribute significantly to the segmentation and bifurcation of the labor force. Permanent workers are able to realize higher wages, receive fringe benefits, receive on-the-job training, and have opportunities to climb the occupational ladder. On the other hand, contingent workers earn lower wages; receive few, if any, benefits; and enjoy little opportunity for advancement. In the case of those who engage in contingent employment because of personal preference, this may not present a problem. However, that many of those engaged in contingent work do so involuntarily is of concern. There is potential for the expansion of a fringe class of workers disenfranchised and marginalized from the mainstream labor force. At the very least, the growing use of contingent workers represents a fundamental shift in the relationship between employer and employee.

To summarize, marginal employment is a concept of increasing importance for sociologists. Structural economic shifts that are giving rise to job displacement and deterioration in the employment circumstances of low-skilled workers, combined with the increasing tendency for industrialized countries to link government help with work and/or work preparedness, have thrown a spotlight of concern on those most vulnerable to employment hardship. In addition to simply documenting the nature and trends in marginal employment, sociologists have begun to adopt more dynamic empirical approaches to model the movement of workers into and out of various states of marginal employment. All this work points to significant and persisting difficulties faced by women, racial and ethnic minorities, immigrants, young adults and elders, those with low achieved human capital, those who are unmarried, and rural or inner-city residents. Sociologists have also begun to explore the institutional changes that have contributed to the persistence of marginal employment and its unequal distribution across

sociodemographic groups. Key among these is the rise in contingent work which is characterized by part-time and temporary employment arrangements, often at lower wages and lacking in the fringe benefits enjoyed by permanent workers.

MARITAL ADJUSTMENT

Marital adjustment has long been a popular topic in studies of the family, probably because the concept is believed to be closely related to the stability of a given marriage. Well-adjusted marriages are expected to last for a long time, while

poorly adjusted ones end in divorce. Simple as it seems, the notion of marital adjustment is difficult to conceptualize and difficult to measure through empirical research. After more than half a century of conceptualization about and research on marital adjustment, the best that can be said may be that there is disagreement among scholars about the concept, the term, and its value. In fact, several scientists have proposed abandoning entirely the concept of marital adjustment and its etymological relatives (Lively 1969; Donohue and Ryder 1982; Trost 1985).

CONCEPTUAL ISSUES

Scientists have long been interested in understanding which factors contribute to success in marriage and which to failure. As early as the 1920s, Gilbert Hamilton (1929) conducted research on marital satisfaction by using thirteen clusters of questions. In 1939, Ernest Burgess and Leonard Cottrell published *Predicting Success or Failure in Marriage*, in which they systematically discussed marital adjustment. They defined *adjustment* as “the integration of the couple in a union in which the two personalities are not merely merged, or submerged, but interact to complement each other for mutual satisfaction and the achievement of common objectives” (p. 10).

Researchers have not agreed upon the use of any one term. To describe the seemingly same phenomenon, some have used the terms “marital quality,” “marital satisfaction,” and “marital happiness.” Robert Lewis and Graham Spanier have defined *marital quality* as “a subjective evaluation of a married couple’s relationship” (1979, p. 269)—a concept similar to that of “marital adjustment.” There have been numerous definitions of “marital adjustment” and “marital quality” (Spanier and Cole 1976), and it may not be fruitful to attempt to define the concept in a sentence or two. Rather, the following description of the factors that constitute marital adjustment or quality may prove more meaningful.

Since Burgess and Cottrell’s formulation, scientists have examined extensively the factors constituting marital adjustment. Although there has

been no consensus among researchers, factors constituting marital adjustment include agreement, cohesion, satisfaction, affection, and tension. Agreement between spouses on important matters is critical to a well-adjusted marriage. Though minor differences may broaden their perspectives, major differences between the spouses in matters such as philosophy of life, political orientations, and attitudes toward gender roles are detrimental to marital adjustment. In addition, agreement on specific decisions about family matters must be reached in good accord. *Marital cohesion* refers to both spouses’ commitment to the marriage and the companionship experienced in it. In a well adjusted marriage, both spouses try to make sure that their marriage will be successful. They also share common interests and joint activities. In a well-adjusted marriage, both spouses must be satisfied and happy with the marriage. Unhappy but long-lasting marriages are not well-adjusted ones. Spouses in well-adjusted marriages share affection, and it is demonstrated as affectionate behavior. Finally, the degree of tension in a well-adjusted marriage is minimal, and when tension arises it is resolved amicably, probably in discussion, and the level of tension and anxiety is usually low.

The core component of marital adjustment is marital satisfaction, and it has been extensively studied as a stand-alone concept. As such, it deserves separate consideration. *Marital satisfaction* has been defined as:

The subjective feelings of happiness, satisfaction, and pleasure experienced by a spouse when considering all current aspects of his marriage. This variable is conceived as a continuum running from much satisfaction to much dissatisfaction. Marital satisfaction is clearly an attitudinal variable and, thus, is a property of individual spouses. (Hawkins 1968, p. 648).

Again, scientists disagree about the definition. Some scholars conceptualize satisfaction rather as “the amount of congruence between the expectations a person has and the rewards the person actually receives” (Burr et al. 1979, p. 67). Because marital satisfaction is influenced not only by the

congruence between expectations and rewards but also by other factors, the former definition is broader than the latter and thus is adopted here.

Although Hawkins's definition of marital satisfaction subsumes happiness, marital happiness is usually considered a distinct variable. According to Campbell et al. (1976), happiness is similar to satisfaction, but these two qualities do differ in one important aspect:

[A] term like "happiness" seems to evoke chiefly an absolute emotional state, whereas "satisfaction" implies a more cognitive judgment of a current situation laid against external standards of comparison such as "other people I know" or more private levels of aspiration. (p. 31)

Since happiness (and marital happiness) denotes an emotional state, it has been known to be affected by the mood swing of the respondent. For that reason, this article does not specifically use the concept "marital happiness." Since marital happiness, marital satisfaction, marital quality, and marital adjustment are highly related to each other, interchangeable use of these terms is relatively common.

Although many scientists treat marital satisfaction as a factor of marital adjustment, there exist possibly major differences between these two concepts about the unit of analysis. Because satisfaction is a subjective property of an actor, there are two kinds of marital satisfaction in a marriage, the husband's and the wife's, and they are conceptually distinct. As Jessie Bernard (1972) stated, there are always two marriages in a family; the husband's marriage and the wife's marriage. Then, do these two marital satisfactions go hand in hand, or are they independent of each other? Research has produced mixed findings. In general, the more satisfied one spouse is with the marriage, the more satisfied is the other, but the correlation between the husband's and the wife's marital satisfactions is far from perfect (Spanier and Cole 1976). Marital adjustment or quality, on the other hand, can be either an individual or a dyadic property. When we say "a well-adjusted marriage," we refer to the dyad, while when we say, "She is well adjusted to

her marriage," we refer to the individual. No one has proposed valid measurement techniques for examining marital adjustment as a dyadic property, although some observational methods might be considered.

Another difference between marital satisfaction and marital adjustment is that while the former is a static product, the latter can be a dynamic process. In fact, marital adjustment is sometimes defined as a dynamic process, and marital satisfaction is listed as one of the outcomes of the adjustment process (Spanier and Cole 1976, pp. 127-128). It has also been proposed that marital adjustment be defined as a dynamic process and yet be measured as a state at a given point in time, a "snapshot" conception (Spanier and Cole 1976). Nevertheless, this connotation of dynamic process in the term "adjustment" has been criticized (Trost 1985) as a confusion of its meaning, because no measure of "adjustment" involves dynamic change, such as negotiation between the spouses.

Without agreeing on either which term to use or on the definition of such a term, researchers have tried for decades to measure marital adjustment, quality, or satisfaction. Burgess and Cottrell (1939) created one of the first measures of marital adjustment from twenty-seven questions pertaining to five subareas (agreement; common interests and joint activities; affection and mutual confidences; complaints; and feelings of being lonely, miserable, and irritable). Along with numerous attempts at measuring marital adjustment, Locke and Wallace (1959) modified Burgess and Cottrell's measure and called it the Marital Adjustment Test. Based on factor analysis, the test consists of fifteen questions ranging from the respondent's overall happiness in the marriage, the degree of agreement between the spouses in various matters, how they resolve conflicts, and the number of shared activities, to the fulfillment of their expectations about the marriage.

This measure was widely used until a new measure, the Dyadic Adjustment Scale, was proposed (Spanier 1976). It is composed of thirty-two questions and four subscales. The dyadic satisfaction subscale is composed of ten questions such as

“How often do you and your partner quarrel?” and “How often do you discuss or have you considered divorce, separation, or terminating your relationship?” The dyadic cohesion subscale is made up of five questions, “Do you and your mate engage in outside interests together?” and “How often would you say the following events occur between you and your mate?—have a stimulating exchange of ideas, laugh together, calmly discuss something, or work together on a project.” The dyadic consensus subscale is based on thirteen questions on “the extent of agreement or disagreement between you and your partner.” Items range from handling family finances, religious matters, and philosophy of life, to household tasks. Finally, the affectional expression subscale is composed of four questions related to affection and sex, two of which are agreement questions on demonstration of affection and sex relations.

All the above measures have been criticized as lacking a criterion against which the individual items are validated (Norton 1983; Fincham and Bradburn 1987). Some scholars have argued that only global and evaluative items, rather than content-specific and descriptive ones, should be included in marital adjustment or quality measures, because the conceptual domain of the latter is not clear. What constitutes a well-adjusted marriage may differ from one couple to another as well as cross-culturally and historically. Whether or not spouses kiss each other every day, for example, may be an indicator of a well-adjusted marriage in the contemporary United States but not in some other countries. Thus, marital adjustment or quality should be measured by the spouses’ evaluation of the marriage as a whole rather than by its specific components. Instead of “How often do you and your husband (wife) agree on religious matters?” (a content-specific description), it is argued that such questions as “All things considered, how satisfied are you with your marriage?” and “How satisfied are you with your husband (wife) as a spouse?” (a global evaluation) should be used. By the same reasoning, the Kansas Marital Satisfaction (KMS) scale has been proposed. This test includes only three questions: “How satisfied are you with your (a) marriage: (b) husband (wife)

as a spouse: and (c) relationship with your husband (wife)?” (Schumm et al. 1986).

Traditional indexes also have been criticized for their lack of theoretical basis and the imposition of what constitutes a “successful marriage.” On the basis of exchange theory, Ronald Sabatelli (1984) developed the Marital Comparison Level Index (MCLI), which measures marital satisfaction by the degree to which respondents feel that the outcomes derived from their marriages compare with their expectations. Thirty-six items pertaining to such aspects of marriage as affection, commitment, fairness, and agreement were originally included, and thirty-two items were retained in the final measure. Because this measure is embedded in the tradition of exchange theory, it has strength in its validity.

PREDICTING MARITAL ADJUSTMENT

How is the marital adjustment of a given couple predicted? According to Lewis and Spanier’s (1979) comprehensive work, three major factors predict marital quality; social and personal resources, satisfaction with lifestyle, and rewards from spousal interaction.

In general, the more social and personal resources a husband and wife have, the better adjusted their marriage is. Material and nonmaterial properties of the spouses enhance their marital adjustment. Examples include emotional and physical health, socioeconomic resources such as education and social class, personal resources such as interpersonal skills and positive self-concepts, and knowledge they had of each other before getting married. It was also found that good relationships with and support from parents, friends, and significant others contribute to a well-adjusted marriage. Findings that spouses with similar racial, religious, or socioeconomic backgrounds are better adjusted to their marriages are synthesized by this general proposition.

The second major factor in predicting marital adjustment is satisfaction with lifestyle. It has been found that material resources such as family income positively affect both spouses’ marital adjustment. Both the husband’s and the wife’s satisfaction with their jobs enhances better-adjusted

marriages. Furthermore, the husband's satisfaction with his wife's work status also affects marital adjustment. The wife's employment itself has been found both instrumental and detrimental to the husbands' marital satisfaction (Fendrich 1984). This is because the effect of the wife's employment is mediated by both spouses' attitudes toward her employment. When the wife is in the labor force, and her husband supports it, marital adjustment can be enhanced. On the other hand, if the wife is unwilling to be employed, or is employed against her husband's wishes, this can negatively affect their marital adjustment. Marital adjustment is also affected by the spouses' satisfaction with their household composition, by how well the couple is embedded in the community, and the respondent's health (Booth and Johnson 1994).

Parents' marital satisfaction was found to be a function of the presence, density, and ages of children (Rollins and Galligan 1978). Spouses (particularly wives) who had children were less satisfied with their marriages, particularly when many children were born soon after marriage at short intervals. The generally negative effects of children on marital satisfaction and marital adjustment could be synthesized under this more general proposition about satisfaction with lifestyle.

It has been consistently found that marital satisfaction plotted against the couple's family life-cycle stages forms a U-shaped curve (Rollins and Cannon 1974; Vaillant and Vaillant 1993). Both spouses' marital satisfaction is quite high right after they marry, hits the lowest point when they have school-age children, and gradually bounces back after all children leave home. To illustrate this pattern, publicly available data from the National Survey of Families and Households (collected in 1987 and 1988) are analyzed here. Figure 1 shows the result. While husbands' average marital satisfaction hit the lowest point when their oldest child was between 3 and 5 years old, wives satisfaction was lowest when their oldest child was between 6 and 12 years old.

This pattern has been interpreted as a result of role strain or role conflict between the spousal, parental, and work roles of the spouses. Unlike

right after the marriage and the empty-nest stages, having children at home imposes the demand of being a parent in addition to being a husband or wife and a worker. When limited time and energy cause these roles to conflict with each other, the spouses feel strain, which results in poor marital adjustment (Lavee et al. 1996). Along this line of reasoning, Wesley Burr et al. (1979) proposed that marital satisfaction is influenced by the qualities of the individual's role enactment as a spouse and of the spouse's role enactment. They argue further, from the symbolic-interactionist perspective, that the relationship between marital role enactment and marital satisfaction is mediated by the importance placed on spousal role expectations.

As seen above, the concept of family life cycle seems to have some explanatory power for marital adjustment. Researchers and theorists have found, however, that family life cycle is multidimensional and conceptually unclear. Once a relationship between a particular stage in the family life cycle and marital adjustment is identified, further variables must be added to explain that relationship—variables such as the wife's employment status, disposable income, and role strain between spousal and parental roles (Crohan 1996; Schumm and Bugaighis 1986). Furthermore, the proportion of variance in marital adjustment "explained" by the family's position in its life cycle is small, typically less than 10 percent (Rollins and Cannon 1974). In the case of our analysis above, it is only 3 percent for both husbands and wives. Thus, some scholars conclude that family life cycle has no more explanatory value than does marriage or age cohort (Spanier and Lewis 1980).

The last major factor in predicting marital adjustment is the reward obtained from spousal interaction. On the basis of exchange theory, Lewis and Spanier summarize past findings that "the greater the rewards from spousal interaction, the greater the marital quality" (Lewis and Spanier 1979, p. 282). Rewards from spousal interaction include value consensus; a positive evaluation of oneself by the spouse; and one's positive regard for things such as the physical, mental, and sexual attractiveness of the spouse. Other rewards from spousal interaction include such aspects of emotional gratification as the expression of affection;

Figure 1. Husbands' and Wives' Average Marital Quality Scores by Family Life Cycle Stages^{1,2,3}

NOTE: 1. See Sweet, Bumpass, and Call (1988) for the structure and data of the survey. Included in this figure are first-time married couples with at least one child or no child but married for less than 10 years.

2. Family life cycles stages are defined as follows (see Duvall 1977):

Stage 1 (Married Couples): Married for less than 10 years with no children

Stage 2 (Childbearing Families): The oldest child younger than 30 months

Stage 3 (Families with Preschool Children): The oldest child younger than 6

Stage 4 (Families with School Children): The oldest child younger than 13

Stage 5 (Families with Teenagers): The oldest child younger than 20

Stage 6 (Families Launching Young Adults): The oldest child 20 or older

Stage 7 (Middle-Aged Parents): The youngest child 20 or older

Stage 8 (Aging Families): The youngest child 20 or older and one of the spouses is 60 or older

3. Marital quality is measured by three questions: "Taking things all together, how would you describe your marriage? Very happy (7) to Very unhappy (1)." "Do you feel that your marriage might be in trouble right now? Yes (2) or No (1)." "What do you think the chances are that you and your husband/wife will eventually separate or divorce? Very low (5) to Very high (1)." The last two items are rescaled in such a way that the three items are given the same weight and the mean is set to 0. The final score is the average of these three scores.

respect and encouragement between the spouses; love and sexual gratification; and egalitarian relationships. Married couples with effective communication, expressed in self-disclosure, frequent successful communication, and understanding and empathy, are better adjusted to their marriages (Erickson 1993). Complementarity in the spouses' roles and needs, similarity in personality traits, and sexual compatibility all enhance marital adjustment. Finally, frequent interaction between the spouses leads to a well-adjusted marriage. The lack of spousal conflict or tensions should be added to the list of rewards from spousal interactions.

In this context, it is interesting to compare the average marital quality between men and women (Figure 1). The husbands' average marital quality is higher than the wives' *except* before they have their first child. The wife's marital quality is initially higher than the husband's, but it decreases after the arrival of her first baby. After that, it tends to be lower than that of her husband during the entire span of their marriage. Given that women perform most of the child care and household work, the steep decline in the average marital quality for women from Stage 1 to Stage 3 can be interpreted as a result of this burden of household

work and child care. Women's rewards from marriage are lower than those of men, on the average, and this differential appears as a gender difference in marital adjustment over the family life-cycle stages.

Symbolic interactionists also argue that relative deprivation of the spouses affects their marital satisfaction: If, after considering all aspects of the marriage, spouses believe themselves to be as well off as their reference group, they will be satisfied with their marriages. If they think they are better off or worse off than others who are married, they will be more or less satisfied with their marriages, respectively (Burr et al. 1979).

CONSEQUENCES OF MARITAL ADJUSTMENT: PERSONAL ADJUSTMENT AND MARITAL STABILITY

It has been widely shown that married persons tend to be better adjusted in their lives than either never-married, separated, divorced, or widowed persons. This seems true not only in the area of psychological adjustments such as depression and general life satisfaction, but also in the area of physical health. Married people are more likely to be healthy and to live longer. Two factors should be considered to account for this relationship. First, psychologically and physically well-adjusted persons are more likely to get married and stay married. Second, the favorable socioeconomic status of married persons may explain some of this relationship. Nevertheless, scholars generally agree that marriage has a positive effect on personal adjustment, in both psychological and physical aspects.

If marriages in general affect personal adjustment in a positive fashion, it is likely that well-adjusted marriages lead to well-adjusted lives. Past research shows just this, though the findings should be cautiously interpreted. Some people tend to favorably answer "adjustment" questions, whether the questions are about their marriages, their personal lives in general, or their subjective health. The apparent positive relationship may be spurious. Nevertheless, if the psychological adjustment

is a composite of the adjustments in various aspects of life (i.e., marriage, family, work, health, friendship, etc.), high marital adjustment should lead to high psychological adjustment. In addition, positive effects of well-adjusted marriages on physical health may be accounted for, in part, by psychosomatic aspects of physical health.

This relationship provides an important policy implication of marital adjustment. Well-adjusted marriages may reduce health service costs, involving both mental and physical health. This is in addition to the more obvious reduction in social service costs derived from unstable and/or unhappy marriages. Children of divorce who need special care and domestic violence are just two examples through which poorly adjusted marriages become problematic and incur social services expenses.

Does marital adjustment affect the stability of a marriage? Does a better-adjusted marriage last longer than a poorly adjusted one? The answer is generally yes, but this is not always the case. Some well-adjusted marriages end in divorce, and many poorly adjusted marriages endure. As for the latter, John Cuber and Peggy Harroff conducted research on people whose marriages "lasted ten years or more and who said that they have never seriously considered divorce or separation" (1968, p. 43). They claim that not all the spouses in these marriages are happy and that there are five types of long-lasting marriages. In a "conflict-habituated marriage," the husband and the wife always quarrel. In a "passive-congenial marriage," the husband and the wife take each other for granted without zest, while "devitalized marriages" started as loving but have degenerated to passive-congenial marriages. In a "vital marriage," spouses enjoy together such things as hobbies, careers, or community services, while in a "total marriage," spouses do almost everything together. It should be noted that even conflict-habituated or devitalized marriages can last as long as vital or total marriages. For people in passive-congenial marriages, the conception and the reality of marriage are devoid of romance and are different from other people's.

What then determines the stability of marriage and how the marital adjustment affects it? It

is proposed that although marital adjustment leads to marital stability, two factors intervene; alternative attractions and external pressures to remain married (Lewis and Spanier 1979). People who have both real and perceived alternatives to poorly adjusted marriages—other romantic relationships or successful careers—may choose divorce. A person in a poorly adjusted marriage may remain in it if there is no viable alternative, if a divorce is unaffordable or would bring an intolerable stigma, or if the person is exceptionally tolerant of conflict and disharmony in the marriage. Nevertheless, it should be emphasized that even though marital stability is affected by alternative attractions and external pressures, marital adjustment is the single most important factor in predicting marital stability. Lack of large-scale longitudinal data and adequate statistical technique have hampered scholars' efforts to establish this link between marital adjustment and stability. Given recent availability of longitudinal and technological development, this area of research holds a high promise.

YOSHINORI KAMO

MARRIAGE

The current low rates of marriage and remarriage and the high incidence of divorce in the United States are the bases of deep concern about the future of marriage and the family. Some have used these data to argue the demise of the family in

American Society (Popenoe 1993). Others see such changes as normal shifts and adjustments to societal changes (Barich and Bielby 1996). Whatever the forecast, there is no question that the institution of marriage is currently less stable than it has been in previous generations. This article explores the nature of modern marriage and considers some of the reasons for its vulnerability.

Marriage can be conceptualized in three ways: as an institution (a set of patterned, repeated, expected behaviors and relationships that are organized and endure over time); as rite or ritual (whereby the married status is achieved); and as a process (a phenomenon marked by gradual changes that lead to ultimate dissolution through separation, divorce, or death). In the discussion that follows we examine each of these conceptualizations of marriage, giving the greatest attention to marriage as a process.

MARRIAGE AS INSTITUTION

From a societal level of analysis the institution of marriage represents all the behaviors, norms, roles, expectations, and values that are associated with the legal union of a man and woman. It is the institution in society in which a man and woman are joined in a special kind of social and legal dependence to found and maintain a family. For most people, getting married and having children are the principal life events that mark the passage into mature adulthood. Marriage is considered to represent a lifelong commitment by two people to each other and is signified by a contract sanctioned by the state (and for many people, by God). It thus involves legal rights, responsibilities, and duties that are enforced by both secular and sacred laws. As a legal contract ratified by the state, marriage can be dissolved only with state permission.

Marriage is at the center of the kinship system. New spouses are tied inextricably to members of the kin network. The nature of these ties or obligations differs in different cultures. In many societies almost all social relationships are based on or mediated by kin, who may also serve as allies in times of danger, may be responsible for the transference of property, or may be turned to in times

of economic hardship (Lee 1982). In the United States, kin responsibilities rarely extend beyond the nuclear family (parents and children). There is the possible exception of caring for elderly parents, where norms seem to be developing (Eggebeen and Davey 1998). There are no normative obligations an individual is expected to fulfill for sisters or brothers, not to mention uncles, aunts, and cousins. Associated with few obligations and responsibilities is greater autonomy and independence from one's kin.

In most societies the distribution of power in marriage is given through tradition and law to the male—that is, patriarchy is the rule as well as the practice. For many contemporary Americans the ideal is to develop an egalitarian power structure, but a number of underlying conditions discourage attaining this goal. These deterrents include the tendency for males to have greater income; higher-status jobs; and, until recently, higher educational levels than women. In addition, the tradition that women have primary responsibility for child rearing tends to increase their dependency on males.

Historically, the institution of marriage has fulfilled several unique functions for the larger society. It has served as an economic alliance between two families, as the means for legitimizing sexual relations, and as the basis for legitimizing parenthood and offspring. In present-day America the primary functions of marriage appear to be limited to the legitimization of parenthood (Davis 1949; Reiss and Lee 1988) and the nurturance of family members (Lasch 1977). Recently, standards have changed and sexual relationships outside marriage have become increasingly accepted for unmarried people. Most services that were once performed by members of a family for other members can now be purchased in the marketplace, and other social institutions have taken over roles that once were assigned primarily to the family. Even illegitimacy is not as negatively sanctioned as in the past. The fact that marriage no longer serves all the unique functions it once did is one reason some scholars have questioned the vitality of the institution.

MARRIAGE AS RITE OR RITUAL

Not a great deal of sociological attention has been given to the study of marriage as a rite or ritual that

transfers status. Philip Slater, in a seminal piece published in 1963, discussed the significance of the marriage ceremony as a social mechanism that underscores the dependency of the married couple and links the new spouses to the larger social group. Slater claims that various elements associated with the wedding (e.g., bridal shower, bachelor party) help create the impression that the couple is indebted to their peers and family members who organize these events. He writes,

[F]amily and friends [are] vying with one another in claiming responsibility for having "brought them together" in the first place. This impression of societal initiative is augmented by the fact that the bride's father "gives the bride away." The retention of this ancient custom in modern times serves explicitly to deny the possibility that the couple might unite quite on their own. In other words, the marriage ritual is designed to make it appear as if somehow the idea of the dyadic union sprang from the community, and not from the dyad itself. (p. 355)

Slater describes the ways in which rite and ceremony focus attention on loyalties and obligations owed others: "The ceremony has the effect of concentrating the attention of both individuals on every OTHER affectional tie either one has ever contracted" (Slater 1963, p. 354). The intrusion of the community into the couple's relationship at the moment of unity serves to inhibit husband and wife from withdrawing completely into an intimate unit isolated from (and hence not contributing to) the larger social group.

Martin Whyte (1990) noted the lack of information on marriage rituals and conducted a study to help fill this gap. He found that, since 1925, wedding rituals (bridal shower, bachelor party, honeymoon, wedding reception, church wedding) have not only persisted but also increased in terms of the number of people who incorporate them into their wedding plans. Weddings also are larger in scale in terms of cost, number of guests, whether a reception is held, and so on. Like Slater, Whyte links marriage rituals to the larger social fabric and argues that an elaborate wedding serves several functions. It

serves notice that the couple is entering into a new set of roles and obligations associated with marriage, it mobilizes community support behind their new status, it enables the families involved to display their status to the surrounding community, and it makes it easier for newly marrying couples to establish an independent household. (p. 63)

MARRIAGE AS PROCESS

Of the three ways in which marriage is conceptualized—institution, rite or ritual, and process—most scholarly attention has focused on process. Here the emphasis is on the interpersonal relationship. Changes in this relationship over the course of a marriage have attracted the interest of most investigators. Key issues studied by researchers include the establishment of communication, affection, power, and decision-making patterns; development of a marital division of labor; and learning spousal roles. The conditions under which these develop and change (e.g., social class level, age at marriage, presence of children) and the outcomes of being married that derive from them (e.g., degree of satisfaction with the relationship) are also studied. For illustrative purposes, the remainder of this article will highlight one of these components, marital communication, and one outcome variable, marital quality. We also address different experiences of marriage based on sex of spouse: “his” and “her” marriage.

The Process of Communication. The perception of a “failure to communicate” is a problem that prompts many spouses to seek marital counseling. The ability to share feelings, thoughts, and information is a measure of the degree of intimacy between two people, and frustration follows from an inability or an unwillingness to talk and listen (Okun 1991). However, when the quality of communication is high, marital satisfaction and happiness also are high (Holman and Brock 1986; Burlinson and Denton 1997; Gottman 1994).

The role of communication in fostering a satisfactory marital relationship is more important now than in earlier times, because the expectation

and demands of marriage have changed. As noted above, marriage in America is less dependent on and affected by an extended kin network than on the spousal relationship. One of the principal functions of contemporary marriage is the nurturance of family members. Perhaps because this function and the therapeutic and leisure roles that help fulfill it in marriage are preeminent, “greater demands are placed on each spouse’s ability to communicate” (Fitzpatrick 1988, p. 2). The communication of positive affect and its converse, emotional withdrawal, may well be the essence and the antithesis, respectively, of nurturance. Bloom and colleagues (1985) suggest that one important characteristic of marital dissatisfaction is the expectation that marriage is a “source of interpersonal nurturance and individual gratification and growth” (p. 371), an expectation that is very hard to fulfill.

In the 1990s many studies focused on the relationship between communication and marital satisfaction (Burlinson and Denton 1997). The findings from this body of research suggest that there are clear communication differences between spouses in happy and in unhappy marriages. Patricia Noller and Mary Anne Fitzpatrick (1990) reviewed this literature, and their findings can be summarized as follows: Couples in distressed marriages report less satisfaction with the social-emotional aspects of marriage, develop more destructive communication patterns (i.e., a greater expression of negative feelings, including anger, contempt, sadness, fear, and disgust), and seek to avoid conflict more often than nondistressed couples. Nevertheless, couples in distressed marriages report more frequent conflict and spend more time in conflict. In addition, gender differences in communication are intensified in distressed marriages. For example, husbands have a more difficult time interpreting wives’ messages. Wives in general express both negative and positive feelings more directly, and are more critical. Spouses in unhappy marriages appear to be unaware that they misunderstand one another. Generally, happily married couples are more likely to engage in positive communication behaviors (agreement, approval, assent, and the use of humor and laughter), while unhappy couples command, disagree, criticize,

put down, and excuse more. Recently, Burleson and Denton (1997) explored the complexity of the communication–marital satisfaction relationship and found a variety of moderating factors: skills in communicating (realizing the communication goal, producing and receiving messages, social perception), the context or setting in which communication takes place, and the cognitive complexity of each spouse. They suggest that communication problems are best viewed as a symptom of marital difficulties and should not be seen merely as a diagnostic tool for distressed relationships.

Communication patterns may be class linked. It has long been found that working-class wives in particular complain that their husbands are emotionally withdrawn and inexpressive (Komarovskiy 1962; Rubin 1976). Olsen and his colleagues (1979) assign communication a strategic role in marital and family adaptability. In their conceptualization of marital and family functioning, communication is the process that moves couples along the dimensions of cohesion and adaptability. In another study the absence of good communication skills is associated with conjugal violence (Infante 1989).

Differences between the sexes have been reported in most studies that examine marital communication. The general emphasis of these findings is that males appear less able to communicate verbally and to discuss emotional issues. However, communication is not the only aspect of marriage for which sex differences have been reported. Other components of marriage also are experienced differently, depending on the sex of spouse. The following paragraphs report some of these.

Sex Differences. In her now classic book, *The Future of Marriage* (1972), Jessie Bernard pointed out that marriage does not hold the same meanings for wives as for husbands, nor do wives hold the same expectations for marriage as do husbands. These sex differences (originally noted but not fully developed by Emile Durkheim in 1897 in *Le Suicide*) have been observed and examined by many others since Bernard's publication (Larson 1988; Thompson and Walker 1989; Kitson 1992). For example, researchers have reported differences between husbands and wives in perceptions

of marital problems, reasons for divorce, and differences in perceived marital quality; wives consistently experience and perceive lower marital quality than do husbands.

Sex differences in marriage are socially defined and prescribed (Lee 1982; Blaisure and Allen 1995). One consequence of these social definitions is that sex differences get built into marital roles and the division of labor within marriage. For example, it has been observed that wives do more housework and child care than husbands (Thompson and Walker 1989; Presser 1994). Even wives who work in the paid labor force spend twice as many hours per week in family work as husbands (Benin and Agostinelli 1988; Coltran and Ishii-Kuntz 1992; Demo and Acock 1993). Wives are assigned or tend to assume the role of family kin keeper and caregiver (Montgomery 1992). To the extent that husbands and wives experience different marriages, wives are thought to be disadvantaged by their greater dependence, their secondary status, and the uneven distribution of family responsibilities between spouses (Baca Zinn and Eitzen 1990).

All these factors are assumed to affect the quality of marriage—one of the most studied aspects of marriage (Adams 1988; Berardo 1990). It will be the subject of our final discussion.

Marital Quality. Marital quality may be the “weather vane” by which spouses gauge the success of their relationship. The reader should be sure to differentiate the concept of marital quality from two other closely related concepts: family quality and the quality of life in general, called “global life satisfaction” in the literature. Studies show that people clearly differentiate among these three dimensions of well-being (Ishii-Kuntz and Ihinger-Tallman 1991).

Marriage begins with a commitment, a promise to maintain an intimate relationship over a lifetime. Few couples clearly understand the difficulties involved in adhering to this commitment or the problems they may encounter over the course of their lives together. More people seek psychological help for marital difficulties than for any other type of problem (Veroff et al. 1981). For a

large number of spouses, the problems become so severe that they renege on their commitment and dissolve the marriage.

A review of the determinants of divorce lists the following problems as major factors that lead to the dissolution of marriage: "alcoholism and drug abuse, infidelity, incompatibility, physical and emotional abuse, disagreements about gender roles, sexual incompatibility, and financial problems" (White 1990, p. 908). Underlying these behaviors appears to be the general problem of communication. In their study of divorce, Gay Kitson and Marvin Sussman (1982) report lack of communication or understanding to be the most common reason given by both husbands and wives concerning why their marriage broke up. The types of problems responsible for divorce have not changed much over time. Earlier studies also list nonsupport, financial problems, adultery, cruelty, drinking, physical and verbal abuse, neglect, lack of love, in-laws, and sexual incompatibility as reasons for divorce (Goode 1956; Levinger 1966).

Not all unhappy marriages end in divorce. Many factors bar couples from dissolving their marriages, even under conditions of extreme dissatisfaction. Some factors that act as barriers to marital dissolution are strong religious beliefs, pressure from family or friends to remain together, irretrievable investments, and the lack of perceived attractive alternatives to the marriage (Johnson et al. 1999).

One empirical finding that continues to be reaffirmed in studies of marital quality is that the quality of marriage declines over time, beginning with the birth of the first child (Glenn and McLanahan 1982; Glenn 1991; White et al. 1986). Consequently the transition to parenthood and its effect on the marital relationship has generated a great deal of research attention (Cowen and Cowen 1989; McLanahan and Adams 1989). The general finding is that marital quality decreases after the birth of a child, and this change is more pronounced for mothers than for fathers. Two reasons generally proposed to account for this decline are that the amount of time couples have to spend together decreases after the birth of a child, and that sex

role patterns become more traditional (McHale and Huston 1985).

In an attempt to disentangle the duration of marriage and parenthood dimensions, White and Booth (1985) compared couples who became new parents with nonparent couples over a period of several years and found a decline in marital quality regardless of whether the couple had a child. A longitudinal study conducted by Belsky and Rovine (1990) confirmed the significant declines in marital quality over time reported in so many other studies. They also found the reported gender differences. However, their analysis also focused on change scores for individual couples. They reported that while marital quality declined for some couples, this was not true for all couples: It improved or remained unchanged for others. Thus, rather than assume that quality decline is an inevitable consequence of marriage, there is a need to examine why and how some couples successfully avoid this deterioration process. The authors called for the investigation of individual differences among couples rather than continuing to examine the generally well-established finding that marital quality declines after children enter the family and remains low during the child-rearing stages of the family life cycle.

Finally, the overall level of marital satisfaction is related to the frequency with which couples have sex (Call et al. 1995). The argument states that happy couples have sex more frequently, leading to more satisfying marriage, and that satisfaction in marriage leads to a greater desire for sex and the creation of more opportunities for sex.

Many students of the family have found it useful to consider marital development over the years as analogous to a career that progresses through stages of the family life cycle (Duvall and Hill 1948; Aldous 1996). This allows for consideration of changes in the marital relationship that occur because of spouses' aging, the duration of marriage, and the aging of children. In addition to changes in marital quality, other factors have been examined, such as differences in the course of a marriage, when age at first marriage varies (e.g., marriage entered into at age 19 as opposed to in

the mid-30s), varied duration of childbearing (few versus many years), varied number of children (small family versus large), and the ways in which consumer decisions change over the course of marriage (Aldous 1990).

CONCLUSION

If the vitality of marriage is measured by the extent to which men and women enter marriage, then some pessimism about its future is warranted. Marriage rates are currently lower than during the early depression year 1931 (*Statistical Abstracts* 1998, 1938)—which was the lowest in our nation's recent history (Sweet and Bumpass 1987). One conclusion that might be drawn from reading the accumulated literature on marriage, especially the writings that discuss the inequities of men and women within marriage, the increasing incidence of marital dissolution, cohabitation as a substitute for marriage, and the postponement of marriage, is that the institution is in serious trouble. These changes have been interpreted as occurring as part of a larger societal shift in values and orientations (Glick 1989) that leans toward valuing adults over children and individualism over familism (Glenn 1987; White 1987; see also the entire December 1987 issue of *Journal of Family Issues*, which is devoted to the state of the American family). Supporting this perspective are the data on increased marital happiness among childless couples and lower birth rates among married couples.

Yet every era has had those who wrote of the vulnerability of marriage and the family. For example, earlier in this century Edward Alsworth Ross wrote, "we find the family now less stable than it has been at any time since the beginning of the Christian era" (1920, p. 586). Is every era judged to be worse than previous ones when social institutions are scrutinized? More optimistic scholars look at the declining first-marriage rate and interpret it as a "deferral syndrome" rather than an outright rejection of the institution (Glick 1989). This is because, in spite of declines in the overall rate, the historical 8 percent to 10 percent of never-married people in the population has remained constant: Almost 90 percent of all women

in the United States eventually marry at least once in their lifetimes. Also, projections that about two-thirds of all first marriages in the United States will end in divorce (Martin and Bumpass 1989) do not deter people from marrying. In spite of the high divorce rate, an increased tolerance for singleness as a way of life, and a growing acceptance of cohabitation, the majority of Americans continue to marry. Marriage is still seen as a source of personal happiness (Kilbourne et al. 1990).

More fundamentally, marriage rates and the dynamics of marital relationships tend to reflect conditions in the larger society. What appears clear, at least for Americans, is that they turn to marriage as a source of sustenance and support in a society where, collectively, citizens seem to have abrogated responsibility for the care and nurturance of each other. Perhaps it is not surprising that divorce rates are high, given the demands and expectations placed on modern marriages.

MARILYN IHINGER-TALLMAN

MARRIAGE AND DIVORCE RATES

Marriage and divorce rates are measures of the propensity for the population of a given area to become married or divorced during a given year. Some of the rates are quite simple, and others are progressively more refined. The simple ones are

called *crude rates* and are expressed in terms of the number of marriages or divorces per 1,000 persons of all ages in the area at the middle of the year. These are the only marriage and divorce rates available for every state in the United States. They have the weakness of including in the base not only young children but also elderly persons, who are unlikely to marry or become divorced. But the wide fluctuations in crude rates over time are obviously associated with changes in the economic, political, and social climate.

More refined rates will be discussed below, but the following illustrative crude rates of marriage for the United States will demonstrate the readily identifiable consequences of recent historical turning points or periods (NCHS 1990a, 1990b, 1998).

Between 1940 and 1946 the crude marriage rate for the United States went up sharply, from 12.1 per 1,000 to 16.4 per 1,000, or by 36 percent, showing the effects of depressed economic conditions before, and disarmament after, World War II.

Between 1946 and 1956 the rate went down rapidly to 9.5 per 1,000, or by 42 percent, as the baby boom peaked. The unprecedented increase in the number of young children was included in the base of the rate, and this helped to lower the rate.

Between 1956 and 1964 the rate declined farther to 9.0 per 1,000, or by 5 percent, as the baby boom ended and the Vietnam War had begun. Between 1964 and 1972 the rate went up moderately to a peak of 10.9 per 1,000, or by 21 percent, as the Vietnam War ended and many returning war veterans married.

Between 1972 and 1990 the crude marriage rate declined irregularly to 9.8 per 1,000 persons of all ages and on down to 8.9 in 1997. The factors involved are discussed below.

At the time of this writing, vital statistics annual reports present only *crude* marriage and device rates for the United States and individual states (NCHS 1998). More *refined* rates were last published for 1987 on some subjects and for 1990 on other subjects.

Refined marriage rates show the propensity to marry for adults who are eligible to marry. They exclude from the base all persons who are too young to marry and may also limit the base to an age range within which most marriages occur. The conventional practice of basing these rates on the number of women rather than all adults has the advantage of making the level of the rates correspond approximately to the number of couples who are marrying. Moreover, the patterns of changes in rates over time are generally the same for men and women.

Changes over time in the tendency for adults to marry are more meaningful and may fluctuate more widely if they are reported in refined rather than crude rates. To illustrate, the crude marriage rate declined between 1972 and 1980 from 10.9 per 1,000 population to 10.6, or by only 3 percent, while the refined rate (marriages per 1,000 women 15 to 44 years old) declined from 141.3 to 102.6, or by 27 percent. A change that appeared to be small when measured crudely turned out to be large when based on a more relevant segment of the population. Persons who want to have others believe that the change was small may cite the crude rates, and persons who want to demonstrate that the marital situation was deteriorating rapidly may cite the refined rates. But persons interested in making a balanced presentation may choose to cite both types of results and explain the differences between them.

Still greater refinement can be achieved by computing marriage rates according to such key variables as age groups and previous marital status. Examples appear in Table 1 and Figures 1 and 3 for the United States from 1971 to 1990. Table 1 and Figure 1 show first marriage rates by age for the only marital status category of eligible persons, namely, never-married adults (women) 15 years old and over. Figure 2 shows divorce rates by age for married women, and Figure 3 shows remarriage rates by age for divorced women. The low remarriage rates for widows are not shown here but are treated briefly elsewhere in the article. Rates of separation because of marital discord are also not presented here: Separated adults are still legally married and are therefore included in the base of divorce rates.

MARRIAGE AND DIVORCE RATES

First Marriage Rates per 1,000 Never-Married Women, Divorce Rates per 1,000 Married Women, and Remarriage Rates per 1,000 Divorced Women, by Age: United States, 1970-1990

MARRIAGE AND DIVORCE RATES

Figure 1

NOTE: First marriage rate per 1,000 never-married women, by age: United States, 1971-1990.

The marriage and divorce rates in Table 1 were based on data from reports published by the National Center for Health Statistics (NCHS). These reports contain information, obtained from central offices, of vital statistics in the states that are in the Marriage Registration Area (MRA) and the Divorce Registration Area (DRA). In 1990 the District of Columbia and all but eight states were in the MRA, while the District of Columbia and

only thirty-one states were in the DRA. Funding for the central offices is determined by each state's legislature. But for states not in the MRA or DRA, the NCHS requests the numbers of marriages and divorces from local offices where marriage and divorce certificates are issued. The reports on divorce include the small number of annulments and dissolutions of marriage. Bases for the marriage and divorce rates in Table 1 were obtained

from special tabulations made by the U.S. Bureau of the Census from Current Population Survey data. These are tabulations of adults in MRA and DRA states and classified by marital status, age, and sex. Because not all the population of the United States is included in the MRA and DRA, the detailed marriage and divorce statistics published by the NCHS constitute approximations of the marital situation in the country as a whole. This article contains much numerical information that was published in one or more of the NCHS reports listed in References.

FIRST MARRIAGE RATES BY AGE

Illustrations of first marriage rates appear in table 1. For the United States, the first marriage rates per 1,000 never-married women 15 years old and over were 93 in 1971 and 58 in 1990. In effect, 9.3 percent of the never-married women in 1971 and 5.8 percent in 1990, became married for the first time. For men the corresponding rates were 68 in 1971 and 47 in 1990.

First marriage rates tend to decline with age, and the rates for most of the age groups shown in Table 1 were declining over time. The rates for the age groups under 20 years of age were among the highest, but they dropped so sharply that they were only about one-third as high in 1990 as they had been in 1971. At the oldest ages, the change appears to have been slight. Obviously, the propensity to marry was falling far more abruptly among the young than among the older singles, probably in reaction to the suddenly changing cultural climate.

The generally downward trend in the marriage rate for each young age group was especially rapid during the early 1970s. By 1975, the veterans of the Vietnam War had already entered delayed marriages, and the upsurge in cohabitation outside marriage was only beginning to depress the first marriage rate. During the 1980s the slight upturn in the first marriage rate for women over 30 years of age probably reflected an increase in marriages among women who had delayed marrying for the purposes of obtaining a higher education and becoming established in the workplace.

Research has produced evidence that women who marry for the first time after they reach their thirties are more likely to have stable marriages than those who marry in their twenties (Norton and Moorman 1987). Although first marriage rates among adults in their forties are relatively low, they are by no means negligible.

As first marriage rates declined between the mid-1960s and the late 1980s, the median age at first marriage rose at an unprecedented pace over this short period of time. According to vital statistics, the median age at first marriage for women went up from 20.3 years in 1963 to 24.0 in 1990, for men it went up from 22.5 years to 25.9 years. As age at first marriage increased, the distribution of ages at first marriage also increased (Wilson and London 1987).

One of the consequences of the great delay of first marriage has been a very sharp rise in premarital pregnancy. Only 5 percent of births in 1960 occurred to unmarried mothers, but this increased to 24 percent in 1987 and to 32 percent in 1996. Research by Bumpass and McLanahan (1989) showed that one-half of nonmarital births during the late 1980s were first births, and about one-third occurred to teenagers. Moreover, about one-tenth of brides were pregnant at first marriage. Thus, about one-third of the first births during the late 1980s were conceived before marriage.

As the first marriage rate declined, the proportion of all marriages that were primary marriages (first for bride and groom) also declined. In 1970, two-thirds (68 percent) were primary marriages, but by 1987 the proportion was barely over one-half (54 percent). Meantime, marriages of divorced brides to divorced grooms nearly doubled, from 11 percent to 19 percent, while marriages of widows to widowers went down from 2 percent to 1 percent.

Men and women, regardless of previous marital status, tend to marry someone whose age is similar to their own. But men who enter first marriage when they are older than the average age of men at marriage have a reasonable likelihood of marrying a woman who has been divorced.

Procedures have been developed for projecting the proportion of adults of a certain age who

Figure 2

NOTE: Divorce rate per 1,000 married women, by age: United States, 1970-1990.

are likely to enter first marriage sometime during their lives. This measure is, in effect, “a lifetime first marriage rate.” One of these procedures was used by Schoen and colleagues (1985) to find that about 94 percent of men who were born in the years 1948 to 1950 and who survived to age 15 were expected to marry eventually; for women, it was 95 percent. Their projections for those born in 1980 were significantly lower, 89 percent for men

and 91 percent for women. Despite the implied decline, a level of nine-tenths of the young adults deciding to marry at least once is still high by world standards.

DIVORCE RATES BY AGE

As indicated above, *crude* divorce rates are the only rates available annually for the United States and

Figure 3

NOTE: Remarriage rate per 1,000 divorced women, by age: United States, 1971-1990.

individual states. As recently as 1965, the rate was only 2.5 divorces per 1,000 persons in the United States, but by 1979 the rate reached a peak more than twice that high, 5.3. Then the rate declined gradually until 1997, when it was down to 4.3, the lowest rate since 1973.

The most recent *refined* divorce rates available include those by age and sex in Table 1 for 1990. The report for that year also presented other

refined divorce statistics on the number of divorces occurring among persons in their first marriage, their second marriage, and their third or subsequent marriage (NCHS 1995b). But the required bases for computing first divorce rates and redi-orce rates are not available. During the 1980s, about three-fourths of the divorces were obtained by adults in their first marriage, about one-fifth by

those in their second marriage, and one-twentieth by those who had been married at least three times.

The divorce rates in Table 1 provide illustrations of the magnitude of the rates for the period 1970 to 1990. The divorce rate per 1,000 married women was 14 in 1970 and 19 in 1990. Corresponding rates for men were the same. The rate reached a peak of 20 in 1980, nearly half again as high as in 1970, and declined slightly to 19 in 1987, a level still well above that in 1970.

The divorce rate for married women rose dramatically in every age group during the 1970s and changed relatively little from then through the 1980s. In January 1973 the Vietnam War ended, and at that time the norms regarding the sanctity of marriage were being revised. The advantages of a permanent marriage were being weighed against the alternatives, including freedom from a seriously unsatisfactory marital bond and the prospect of experimenting with cohabitation outside marriage or living alone without any marital entanglements.

By 1994, one-fourth of divorced persons were cohabiting outside marriage, one-third were living alone, and most of the rest were in single-parent families (U.S. Bureau of the Census 1996).

Married women under 25 years of age have consistently high divorce rates resulting largely from adjustment difficulties associated with early first marriage. Noteworthy in this context is the finding that 30 percent of the women entering a first marriage in 1980 were in their teens, while 40 percent of those obtaining a divorce had entered their marriage while teenagers.

More divorces during the 1980s were occurring to married adults 25 to 34 years of age than to those in any other ten-year age group. A related study by Norton and Moorman (1987) concluded that women in their late thirties in 1985 were likely to have higher lifetime divorce rates (55 percent) than those either ten years older or ten years younger. This cohort was born during the vanguard of the baby boom and became the trend setter for higher divorce rates. The lower rate for those ten years younger may reflect their concern caused by the adjustment problems of their older divorced siblings or friends.

Married women over 45 years of age have quite low divorce rates. Most of their marriages

must still be reasonably satisfactory, or not sufficiently unsatisfactory to persuade them to face the disadvantages that are often associated with becoming divorced. Yet, the forces that raised the divorce rate for younger women greatly after 1970 also made the small rate for the older women increase by one-fourth during the 1970s and remain at about the same level through the 1980s.

The median duration of marriage before divorce has been seven years for several decades. This finding is not proof of a seven-year itch. In fact, the median varies widely according to previous marital status from eight years for first marriages to six years for second marriages and four years for third and subsequent marriages. The number of divorces reaches a peak during the third year of marriage and declines during each succeeding year of marriage.

Among separating couples, the wife usually files the petition for divorce. However, between 1975 and 1987, the proportion of husband petitioners increased from 29.4 percent to 32.7 percent, and the small proportion of divorces in which both the husband and the wife were petitioners more than doubled, from 2.8 percent to 6.5 percent. These changes occurred while the feminist movement was becoming increasingly diffused and the birthrate was declining, with the consequence that only about one-half (52 percent) of the divorces in 1987 involved children under 18 years of age and one-fourth (29 percent) involved only one child. It is not surprising that nine-tenths of children under 18 living with a divorced parent live with their mother, far more often in families with smaller average incomes than those living with divorced fathers.

Although only about one-tenth of the adults in the United States in 1988 were divorced (7.4 percent) or separated (2.4 percent), the lifetime experience of married persons with these types of marital disruption is far greater. Based on adjustments for underreporting of divorce data from the Current Population Survey and for underrepresentation of divorce from vital statistics in the MRA, Martin and Bumpass (1989) have concluded that two-thirds of current marriages are likely to end in separation or divorce.

REMARRIAGE RATES BY AGE

Remarriage rates published by NCHS include separate rates for remarriages after divorce and after widowhood as well as for all remarriages. In this article attention is concentrated on remarriages after divorce, which constitute about nine-tenths of all remarriages. As mentioned above, the remarriage rate after divorce is a measure of the number of divorced women who marry in a given year per 1,000 divorced women at the middle of the year. For example, Table 1 shows that the remarriage rate after divorce for the United States was 133 in 1970 and 76 in 1990. Therefore, about 13 percent of the divorced women in 1970 became remarried in that year, as compared with 8 percent in 1990, only three-fifths as much as in 1970.

Divorced men have far higher remarriage rates than divorced women (in 1990, 106 versus 76). This situation and women's greater longevity largely account for the number of divorced women 45 years old and over in 1994 being one and one-half times the number of divorced men of that age (U.S. Bureau of the Census 1996).

Like first marriage rates, remarriage rates tend to decline with age, and the rate for each age group declined after 1970. The especially sharp drop during the first half of the 1970s for women under 40 years of age resulted from the compounding effect of a rapid increase in divorce and a rapid decline in remarriage during that period.

A large majority of divorced persons eventually remarry. In 1980, among persons 65 to 74 years old, 84 percent of the men and 77 percent of the women who had been divorced had remarried (U.S. Bureau of the Census 1989). But because of the declining remarriage rates, a projection based on information from the National Survey of Families and Households conducted in 1987 and 1988 shows that 72 percent of the recently separated persons are likely eventually to remarry (Bumpass, et al. 1989). About 6 percent of those who become separated never become divorced and therefore are not eligible for remarriage. Two-thirds of the remarriages in recent years occurred to women who entered first marriages as teenagers, according to the same study. Moreover, the rate of remarriage declines as the number of young children increases. Among married parents of young children with one or both parents remarried, about

one-third of the children were born after the remarriage, and the others are stepchildren with the usually accompanying adjustment problems (Glick and Lin 1987).

In a given year about two of every three adults who marry are marrying for the first time, but this includes those marrying after widowhood as well as divorce. Among those who remarry after divorce, about three-fourths have been married only once, one-fifth have been married twice, and one-twentieth three or more times. Some couples who remarry had been married to each other previously. According to unpublished data from the National Survey of Families and Households, this occurred in about 3.3 percent of all marriages and closer to 5 percent for those in the age range when most remarriages after divorce occur.

Men are older than women, on the average, when they marry for the first time or when they remarry. Moreover, the gap is considerably wider at remarriage than at first marriage, but it narrowed somewhat between 1970 and 1987. Thus, successive marriages have been happening at older ages but with shorter intervals between them. In this context, the wider gap at remarriage than at first marriage may be less socially significant than an identical gap would have been at first marriage.

A woman in her second marriage is likely to be married to a man who is about ten years older than her first husband when she married him. Therefore, her second husband was probably more advanced in his occupation than her first husband was when she married him. But research has established that her first husband was probably about as far advanced ten years after her first marriage as her second husband was when she married him (Jacobs and Furstenberger 1986).

OTHER MARRIAGE AND DIVORCE RATES

Another rate that differs from the rates shown in Table 1 is the *total marriage rate*. This rate is intended to show the number of marriages that group of 1,000 men and women would have if they experienced in their lives the age-sex marriage rates observed in a given year (NCHS 1990b). It is therefore a hypothetical rate analogous to a total fertility rate. Both first marriage rates and remarriage rates have as the base the total population of the

United States without regard to previous marital status.

The total first marriage rate for the United States in 1987 implied that only 69 percent of men and 70 percent of women would eventually marry. The corresponding remarriage rates were 45 percent for men and 41 percent for women. Because both rates are based on the population regardless of marital status, they are additive. Therefore, the (combined) total marriage rate for 1987 implied that men are likely to have 1.14 marriages during their lifetime and women 1.11. These results may seem low because of the assumptions involved. For instance, if currently about 90 percent of every 100 adults marry, if one-half of the first marriages end in divorce, and if 70 percent of the divorced persons remarry, this would mean that 100 young adults in the 1990s are likely to have 90 first marriages and 32 second marriages after divorce ($.90 + .90 \times .50 \times .70$). In addition, many will redi-vorce and remarry again, and others will become widowed and remarry. Thus, realistically, the average young adult in the 1990s who marries is likely to have more than 1.1 marriages.

Remarriage among widowed adults is not featured in this article. However, the remarriage rate per 1,000 widows declined from 7 to 5 in 1990, while the rate for widowers declined from 32 to 24. The remarriage rate for widowers is much higher than the rate for widows because about one-half of them marry widows, who outnumber them five to one (U.S. Bureau of the Census 1989). Of all men and women who married in 1987, 68 percent had never previously married, 29 percent were divorced, and only 3 percent were widowed.

Divorce rates per 1,000 involving children under 18 published by NCHS shows that in 1987, the rate was 17, implying that 1.7 percent of the children under 18 years of age in the United States were involved in parental divorces in that year. This finding implies further that, if the same rate continued for eighteen years, 30.6 percent of the children would likely experience parental divorce before they reached 18 years of age. Data from the U.S. Bureau of Census used by Norton and Glick (1986) put the estimate at 40 percent. They also estimated that about an additional 20 percent of children become members of one-parent families because of premarital birth, parental separation

that does not end in divorce, or death of a parent. Therefore, about 60 percent of the children born in the 1990's and later may expect to spend a significant amount of time in a one-parent family before they become 18 years of age.

Marriage rates vary among countries as a reflection of dissimilar social, demographic, and economic conditions. An analysis of marriage rates in fifteen developed countries revealed that between 1965 and 1980 the rate per 1,000 unmarried women declined in all but two of the countries (Glick 1989). The marriage rates in English-speaking countries and Israel were above the average for the entire group, but the rates were below the average in the Germanic, French, and Scandinavian countries. A special reason for the differences was the extent to which cohabitation had been accepted as at least a temporary alternative to marriage. The generally downward trend among the marriage rates shows that the changing social conditions related to the propensity toward marriage have become widely diffused.

Divorce rates per 1,000 married women in almost all of the fifteen countries went up between 1965 and 1980 and doubled in the majority of them. Most of the countries with divorce rates above the overall average were English speaking. High divorce rates tended to be associated with high marriage rates because remarriages after divorce make an important contribution to the level of the marriage rates per 1,000 unmarried women.

Remarriage rates have been falling in most of the fifteen countries. In Canada a part of the decline between 1965 and 1980 was attributed to a change in the divorce laws and an increase in the delay of remarriage. The remarriage rate in New Zealand actually rose slightly in the context of a baby boom and an increase in immigration of young adults with subsequent high divorce rates. Countries with the highest remarriage rates were English speaking, and those with the lowest were Scandinavian countries, France and certain other European countries where cohabitation outside marriage had risen sharply.

Variation in the level of marriage and divorce rates among the American regions and states can be documented only by the use of crude rates. The Northeast and Midwest had consistently lower marriage rates than the South and West. The

general pattern is similar for divorce rates. Some of the variations in the rates by states result from differences in the strictness of residence requirements for obtaining a marriage or divorce license. About seven of every eight marriages occur in the state where both the bride and the groom have their usual residence.

SELECTED VARIABLES RELATED TO MARRIAGE AND DIVORCE

Marriage and divorce rates are not presented in the NCHS reports by education and race of those involved. However, some reports do show distributions of first marriages and remarriages by several categories of education and race. The 1987 report documents that those marrying for the first time had more education, on the average, than those who were remarrying. Information from the 1980 census showed that women 25 to 34 years of age who had exactly four years of college training had distinctly the largest proportion of intact first marriages; those with graduate school training had a somewhat smaller proportion; and those with an incomplete college education had a smaller proportion than those in any other education category (U.S. Bureau of Census 1985).

The 1990 report on marriage provided evidence that white adults tend to marry at a younger age than black adults. The difference was two years for both brides and grooms at first marriage and two years at remarriage after divorce. Information for 1988 from the U.S. Bureau of the Census (1989) indicated that 18 percent of black adults had not married by the time they were 40 years old, as compared to 8 percent for white adults of the same age. The pressure to marry and to remain married evidently tends to be less for black adults than for white adults.

Interracial marriage occurs between a small but socially significant proportion of those who marry. In 1987, 2 percent of black brides married white grooms, and 6 percent of black grooms married white brides. Also, nearly 2 percent of black women obtaining divorces were married to white men, and more than 4 percent of black men obtaining divorces were married to white women. Thus, among those who intermarried, the marriages of black men to white women tend to be

more stable than marriages of white men to black women.

Cohabitation outside marriage increased dramatically from only one-half million heterosexual couples in 1970 to 3.5 million in 1993, with about one million of their households maintained by the woman. This numerical growth occurred primarily among adults below middle age and has contributed importantly to the decline in marriage rates as well as to the increase in the number of separated persons. According to the 1987-1988 National Survey of Families and Households, "almost half of the persons in their early thirties and half of the recently married have cohabited" (Bumpass and Sweet 1989, p. 615). In order to provide some balance on the issue, Thornton has concluded that "even though cohabitation will be experienced by many, most people will continue to spend substantially more time in marital unions than in cohabiting unions" (1985, p. 497).

The health of adults is related to marital selection and marital stability, but NCHS does not provide marriage and divorce rates by the health status of those involved. The center does, however, publish current information on several indicators of the health condition of adults by marital status. Nearly all the indicators confirm that people with more signs of good health are likely to marry and remain married or to remarry after marital dissolution (Wilson and Schoenborn 1989). Parental divorce tends to be related to health problems of children but largely through the custodial parents' loss of income and time to spend with the children after divorce (Mauldon 1988). And stress prior to an event such as divorce or premarital breakup may actually reduce the impact of the life transition (Wheaton 1990).

Current trends in marriage and divorce rates do not necessarily indicate whether the rates will tend to stabilize at or near their 1990 levels, to resume their movement in historical directions, or to continue fluctuating in response to future social developments. A few more decades of observing the impact of past changes in marriage and divorce rates on the persons involved may be necessary before a definitive evaluation can be made concerning the longtime effect of these changes on family and child welfare.

PAUL C. GLICK

MARXIST SOCIOLOGY

The concept of a Marxist sociology does not refer to a clearly defined approach to social research; indeed, it is "now employed so widely that it has begun to lose all meaning" (Abercrombie et al. 1988, p. 148). The ambiguity of the term stems from the multiplicity of interpretations of the work of Karl Marx and Friedrich Engels, whose approach to social theory is usually termed *historical materialism*. The most well-known version is that of Soviet communism (Marxism-Leninism) and is identified with the worldview of *dialectical materialism* (a term never used by Marx and Engels), which has served largely the interests of Soviet ideology. The influence of historical materialism in modern sociology, however, stems primarily from the lesser-known independent tradition of European "Western Marxism" and the resulting forms of Marxist sociology (Agger 1979).

Contemporary usage of the term *Marxist sociology* varies considerably. In the United States, for example, the term *Marxist* is often used rather

loosely, to designate virtually any type of radical or critical approach influenced by Marxian concepts (e.g., Ollman and Vernoff 1982; Flacks 1982). In societies with more strongly developed social democratic labor movements, as in Europe, the term is more closely identified with communist parties. Given the inherent ambiguity of the term, it is therefore useful to define Marxist sociology rather narrowly and concretely as a specific form of conflict theory associated with Western Marxism's objective of developing a positive (empirical) science of capitalist society as part of the mobilization of a revolutionary working class.

It is also useful to distinguish three basic types of relations between sociologists and Marxist sociology: those who work directly within the Marxist tradition (Marxist sociology proper) but "incorporate sociological insights, findings, and methodologies"; those who are Marxist-influenced in the sense of being stimulated by its historical approach and the "big questions" Marxists have posed but remain indifferent to "whether the best explanatory answers turn out to be Marxist" (Burawoy and Skocpol 1982, p. vii); and those identifying with highly revisionist critical theories (sometimes still in the name of Marxism) that seek to preserve the emancipatory vision of the Marxist tradition despite abandonment of the conventional notion of working-class revolution (Held 1980; Kellner 1989). It should also be stressed that Marxist sociology in this first sense refers to a historically identifiable—but widely contested—interpretation of the sociological implications of Marx's approach. As the most well-known British Marxist sociologist has concluded with particular reference to the German Frankfurt tradition of critical theory: "The tasks of a Marxist sociology, as I conceive it, are therefore very different from those of a neo-critical theory of society" (Bottomore 1984, p. 81). Marxist sociology in this strict sense thus tends in its most rigid form to resist any eclectic appropriation of sociological concepts: "Marxism has been courted by virtually every conceivable non-Marxist ideology: by existentialism, phenomenology, critical academic sociology, and by several variants of theology. To raise the question of a Marxism of Marxism is to take a resolute stand against all attempts to capture and exploit Marx for non-Marxist purposes; and to adopt as a guiding principle . . . the claim that Marx himself made for his work: that Marxism is a specific science, related to the

working class as a guide to socialist revolution" (Therborn 1976, p. 40).

The distinction between Marxism as "science" and as "critique" provides another way of describing the aspirations of Marxist sociology, which most commonly seeks to develop an objective, political economic science of society rather than a critical philosophy of praxis (Bottomore 1975; Gouldner 1980). Such a project is inherently interdisciplinary and often referred to under the heading of *political economy*, a term designating Marxist-oriented research that may be carried out in various disciplines: economics, political science, and history, as well as sociology (Attewell 1984). Though those identifying with neo-Weberian conflict or critical theories accept many of the empirical findings of neo-Marxist sociology and political economy, they tend to disagree about their broader interpretation and relation to political practice and social change.

ORIGINS

All forms of Marxist sociology trace themselves to the general theoretical approach of historical materialism as developed by Marx and Engels (Marx and Engels 1978; Bottomore and Goode 1983; Bottomore et al. 1983). Standard accounts of Marx's theoretical program stress that it does not constitute a unified system so much as diverse, though interrelated, modes of theorizing.

- Early writings that outline a theory of philosophical critique, an analysis of alienated labor, and a normative vision of human emancipation;
- A general sociology in the form of historical materialism (i.e., a theory of modes of production) as an approach to historical evolution;
- A specific account of capitalism and its economic contradictions deriving from this general theory; and
- A political philosophy and theory of praxis concerned with translating objective crisis tendencies in capitalism into a revolutionary transformation that would bring about a new form of "socialist" and eventually

“communist” society (Giddens 1971, pp. 1–64; Bottomore 1975).

The precise relationship among these areas remains controversial. Though each level of theorizing has sociological implications, Marxist sociology has drawn primarily from the general sociology suggested by historical materialism and the more historically specific analysis of capitalist development that is the empirical focus of Marx’s social theory and historical sociology. The key concept of a mode of production serves as the comparative framework for analyzing different social formations in terms of the contradictory relationship between their forces of production (primarily technology) and relations of production (forms of work organization and exploitation). The resulting mode of production directly shapes the specific structures of the class system and the manner in which the economic base determines the cultural superstructure composed of the state and various ideological institutions such as the mass media, education, law, religion, political ideologies, and so forth. In capitalist societies the contradiction deriving from the unresolvable polarization between labor and capital becomes the basis for revolutionary change under conditions of economic crisis.

As a positive science of society, Marxist sociology emerged in the period following Marx’s death in 1883 through World War I. Strongly influenced by Engels’s conception of “scientific socialism” as elaborated by Karl Kautsky in Germany, it was institutionalized in German Social Democracy and the Second International. Particular stress was placed upon how this approach provided an account of the historical “laws” that explained the causes of changes in modes of production and class formation and struggle. According to these laws a transition to socialism could be deduced from the “necessary” breakdown of capitalism. Extensive further development of such a scientific socialism was carried out by the Austro-Marxists, who deepened the logical analysis of Marxism as a form of causal explanation by drawing upon contemporary debates in the philosophy of science; as well, they extended Marx’s theory to new phenomena such as the analysis of nationalism and the ethical foundations of Marxist sociology (Bottomore 1975, 1978; Bottomore and Goode 1978).

These two traditions of scientific socialism, however, did not develop much beyond the level codified in Bukharin’s textbook of 1921 (*Historical Materialism: A System of Sociology*, translated in 1925). The primary reason was that there was considerable resistance to Marxism in the academy (related in part to identification of Marxism with the Soviet Union), ignorance of the richness of the suppressed tradition of Western Marxism, and a broad post-World War II institutionalization of sociology that virtually excluded Marxist sociology, despite some marginal influences of research in social stratification and change (e.g., Ralf Dahrendorf in West Germany and C. Wright Mills in the United States). For all practical purposes the resurgence of Marxist sociology (often identified as “political economy” as opposed to “critical theory”) coincides with the parallel emergence of radical and critical theories in the late 1960s, along with the recovery of the deeper foundations of Marxian theory with the proliferation of translations of Western Marxist texts in the 1970s.

It is customary to distinguish two basic starting points of a Marxist sociology based on different interpretations of the base–superstructure metaphor that underlies the concept of a mode of production: economistic or instrumental approaches as opposed to structuralist reproduction models. Economistic interpretations—sometimes associated with the idea of orthodox or “vulgar” Marxism—are based on a more or less reductionistic, causal account of the effects of the economic base or infrastructure upon the cultural superstructure, especially as causally derived from the assumed objective consequences of class interests.

Structuralist theories of social and cultural reproduction, in contrast, argue that the base–superstructure relation is more complex, involving functional relations that ensure the relative (if variable) autonomy of cultural factors, even if the economic is determinant in the last instance. Such structuralist interpretations derive primarily from the concept of the social reproduction of labor power developed in Marx’s later works, the theory of cultural hegemony developed by the Italian Marxist leader and theorist Antonio Gramsci (1971) in the 1930s, and the reinterpretation of both Marx and Gramsci by the French philosopher Louis Althusser in the 1960s (Althusser 1971; Althusser and Balibar [1968] 1979).

CONTEMPORARY THEMES IN MARXIST SOCIOLOGY

The most convenient way to speak of contemporary themes in Marxist sociology—thus differentiating it from conflict or critical theory generally—is to restrict the concept to research that continues to adhere to the basic principles of neo-Marxist theory. Such a Marxist sociology would sometimes include adherence to the labor theory of value (which holds that labor is the only source of profit) but more essentially the primacy of economic and class factors, the priority of objective structures over subjectivity and consciousness, and the privileged role of the working class in a transition to socialism as defined by direct state ownership of the means of production (Anderson 1984; Wood 1986; Archibald 1978).

With respect to more recent developments in Marxist sociology, the immense literature and wide national variations make it appropriate to focus primarily—if not exclusively—on the remarkable resurgence of Marxism in American sociology. This phenomenon stems from the 1970s and has been traced to four key influences: the broadened audience of the journal *Monthly Review*, which was founded in 1949 and pioneered the application of Marxist economic theory for an analysis of the United States and its “imperial” role in world politics; Marxist historians who developed a critique of American liberalism and proposed a class-based reinterpretation of American history; the Hegelian Marxism and Critical Theory of the Frankfurt School tradition; and, finally, structuralist Marxism of largely French inspiration that sought to reestablish the credentials of Marx’s theory as a science of society (Burawoy 1982, pp. 4–6). To illustrate the concerns of recent Marxist sociology, it is instructive to review some of the most representative examples of research in four key areas: work and the division of labor, class structure, the state and crisis theory, and culture and ideology. Research on the political economy of the world system and dependency theory have also been important but will not be discussed here (see, however, So 1990).

The Labor Process and the New International Division of Labor. Until the late 1960s, Marxist theory was associated primarily with either communist ideologies or economic theory (Sweezy [1942] 1968). Not surprisingly, the pioneering,

technically sophisticated Marxist research in the United States was concerned with an economic analysis of the new form of “monopoly capitalism” (Baran and Sweezy 1966). Drawing out the sociological implications of such, political economy is most closely associated with subsequent pathbreaking work involving the rediscovery of the labor process (i.e., Braverman 1974; Burawoy 1979) that gave work the central place that had been lost with the sense of consensus in postwar labor relations (Thompson 1983; Attewell 1984, pp. 93–141). Particular attention was given to the logic of capital’s need to cheapen labor costs in ways that degrade and divide workers. More recent work has attempted to emphasize the incorporation of a subjective dimension to the labor process; further, it has developed a comparative perspective through the analysis of factory regimes in different types of economic systems and in relation to the new international division of labor (e.g., Burawoy 1985).

Class. Class analysis of course remains the key aspect of any Marxist sociology, but the focus contrasts sharply with conventional sociological approaches, even those (e.g., Max Weber) that acknowledge the importance of class conflict. Marxist sociology strongly insists on the primacy of the relations of production over the market processes stressed by neo-Weberians (Grabb 1990). The most influential empirical research in this area has stressed the importance of contradictory class locations and of reconnecting the objective and subjective dimensions of class with a theory of exploitation (Grabb 1990, pp. 152–163; Wright 1978, 1985).

Recent Marxist class analysis has been confronted by a number of challenges that pose serious problems for orthodox approaches; for example, the problem of the urban question, the role of ethnicity or race and especially gender as independent sources of domination (Shaw 1985), the emergence of the middle strata and the decline of the traditional “working class” (Walker 1978), the failure of class consciousness and actions to develop in the ways required for revolutionary transition, and other issues. The relation between Marxist and feminist theory has proved most controversial. More orthodox Marxist sociologists have attempted to incorporate gender into the theory of class and modes of production through the concept of unpaid “domestic labor” that contributes to the overall process of social reproduction (Fox

1980). But many feminists have abandoned Marxist sociology precisely because of its insistence on the primacy of class at the expense of gender (and other sources of domination).

The State and Crisis Theory. The contributions of Marxist sociology to the theory of the state have been wide-ranging and influential (Carnoy 1984; Jessop 1982; Holloway and Picciotto 1978). As well, they illustrate most clearly the issues involved in the debate between instrumental and structuralist interpretations of the base-superstructure model. In the context of theories of the state, this issue takes the form of whether the dominant class controls the state directly through its elite connections or indirectly through the functional economic and political imperatives that constrain public policy, regardless of who happens to hold power in a democratic regime. For example, the so-called Miliband-Poulantzas debate sharply defined the different empirical consequences of these two approaches. Miliband ([1969] 1973) stressed the actual empirical link between economic elites and political power of the dominant class, hence the role of the state as an instrument of class rule. Poulantzas ([1968] 1978), on the other hand, analyzed the state as a factor of cohesion that requires relative autonomy in order indirectly to serve the process of social reproduction in the long run.

Another central theme of Marxist sociology has been the relationship between economic crisis tendencies and the state in advanced capitalism (Attewell 1984, pp. 142–206). Research has focused especially on the concept of the “fiscal crisis of the state” (O’Connor 1973). It has been argued that the state is caught between the contradictory pressures of ensuring capital accumulation and legitimating the negative effects of the economy with the safety nets of the welfare state and that these conflicts become the potential basis for the emergence of new class-based oppositional movements.

Culture and Ideology. The most recent flourishing area of research has been in Marxist-influenced analyses of cultural phenomena as manifestations of ideology. The central focus has been on how cultural hegemony (or domination) is formed and the types of resistance that oppressed groups may develop against it. The stress of economic Marxist has been upon the way in which the cultural superstructure of society “reflects” or

“mirrors” economic processes and class relations. This approach often resulted in crude, reductionistic political and class analyses that were often unsatisfactory to those intimately acquainted with both high and popular culture. With the emergence of more sophisticated structuralist models of cultural reproduction, however, the relative autonomy of cultural forms could be acknowledged without obscuring their origins in “material” social relations. In the more extreme form represented by structuralist Marxism, it has been more generally held that all of the cultural institutions of society (e.g., the media, family, law, arts, etc.) functioned in the last instance as “ideological state apparatuses” that served the long-term interests of capital (Althusser 1971). Research based on both instrumentalist and structuralist approaches has been applied to the range of cultural activities (e.g., art, literature, law, sport, etc.), but education and the mass media figure most prominently, and they can serve as illustrations.

In the case of the Marxist sociology of education the result was a shift from an instrumentalist perspective (i.e., the role of capitalist ideology in directly using the educational system to shape consciousness in its interests) to one based on the idea of social reproduction as an indirect form of social control. Initially, structuralist approaches put particular stress upon the formal “correspondence” between the economic base and the hegemonic superstructure, despite the autonomy of the latter. Hence, structuralist research on education attempted to demonstrate the way in which the hidden curriculum of the school “corresponded” to the type of labor required by capital (Bowles and Gintis 1977; Cole 1988). Research on the political economy of the media was more strongly represented by instrumentalist perspectives that stressed the role of the media as instruments of “mind control” on the part of the dominant class and the broader dominance of the American media globally (Schiller 1971; 1973); others argued from a more structuralist perspective that the primary function of the media is the “selling of audiences,” irrespective of the specific ideological content of programming (Smythe 1981).

THE CRISIS OF MARXIST SOCIOLOGY

As a specific theoretical approach that seeks to discover the role of economic and class factors in

social change, Western Marxist sociology will certainly endure, though its significance will vary with the type of social formation and topic examined. As a philosophy of history or general theory of modes of production, and more especially as part of a particular theory of working-class revolution, orthodox Marxist sociology has been seriously called into question, especially in advanced capitalism. It has already collapsed in Eastern bloc countries, where a completely new tradition of social science is in the process of formation. This is not to say that economic and class factors or Marx become irrelevant, though the broader crisis of historical materialism suggests their significance and relation to social, political, and cultural processes will have to be interpreted in more self-critical, flexible, and historically specific ways (Aronowitz 1981). The complex outcome of the crisis of Marxist sociology in advanced capitalism is suggestively anticipated in the response of three contemporary countertendencies.

So-called analytical Marxism is defined more by its methodological stance than its substantive content. It thus differentiates itself from traditional Marxism in its commitment to abstract theorizing (as opposed to more concrete historical analysis), a search for rethinking the foundations by asking heretical questions, and “using state-of-the-art methods of analytical philosophy and ‘positivist’ social science” (Roemer 1986, pp. 1–2). Though these developments will undoubtedly have some impact on social theory, they are clearly too heterogeneous and revisionist to fall under the heading of Marxist sociology in the sense used here.

A second, opposing “poststructuralist” strategy is evident in the work of some former Marxists who have retreated from orthodox class concepts, arguing that a “post-Marxism” is required that involves eliminating the notion of the working class as a “universal class” and resurrecting a new conception of socialist democracy (Laclau and Mouffe 1985). Not surprisingly, this (partial) “retreat from class” has been treated with hostility by many neo-Marxists (Wood 1986), but it has provoked important debates about the role of new social movements and democratic processes in any defensible conception of socialist transformation.

A third tendency has been loosely referred to as “cultural Marxism.” Such critics of the functionalist

tendencies of structuralist Marxism put particular stress upon the contested and uneven character of cultural reproduction in capitalist societies. In particular, various researchers have pointed to how dominated groups resist cultural domination in ways that often become the basis of counterhegemonic social movements. Further, it is argued that a crucial feature of contemporary “postmodern” societies is the distinctive role of the “cultural.” The result has been a flowering of cultural research often identified, especially in the British context, with the notion of “cultural studies” (e.g., the work of Raymond Williams, Richard Johnson, Stuart Hall, et al.; see Brantlinger 1990). A related tendency has been the cultural Marxist historiography of E. P. Thompson (Kaye and McClelland 1990) that has influenced a major reinterpretation of Marx as a historical sociologist (Sayer 1983; Corrigan and Sayer 1985). A distinctive aspect of the cultural Marxist tradition, an aspect that has led it away from Marxist sociology in its more restrictive sense, has been its ability actively to engage in debate with and appropriate concepts from a wide variety of non-Marxist approaches. Much of the recent work carried out in the name of cultural Marxism thus increasingly blends with poststructuralist and critical theories of culture, reflecting the circumstance that “Marxism is no longer a single coherent discursive and political practice” (Nelson and Grossberg 1988, p. 11). One consequence is that it is no longer “possible to talk unproblematically of a ‘Marxist’ sociology, since Marxism has become a major contributor to sociology in general, while Marxist-influenced sociologists increasingly identify with their discipline (Shaw 1985, p. 16).

THE 1990S: THE DECLINE OF MARXIST SOCIOLOGY AND RECONSTRUCTIONS OF MARXIAN CRITICAL THEORY

By the end of the 1990s, several key shifts had redefined the fate of Marxist theory in the social sciences: (1) the collapse of the Soviet bloc; (2) a proliferation of metatheoretical debates—loosely grouped as postmodernist—that called into question the capacity of theory generally, and Marxist theory in particular, to provide general explanations or ethical critiques of social life; (3) a blurring of disciplinary boundaries that contributed to the

flow of Marxist-related concepts into the humanities, especially under the heading of cultural studies; and (4) a substantive focus on globalization as a framework for rethinking the Marxian theory of society and change. The outcome of these tendencies was a decline of Marxist sociology as a clearly identifiable research orientation. Yet these developments also reinforced the three tendencies previously visible in the 1980s: (1) the continuing development of analytical Marxism (Jacobs 1996); (2) the proliferation of poststructuralist critiques of class essentialism that attempted to include standpoints such as race and gender in Marxist theory; and above all, (3) the continuing development of cultural Marxism, especially in the humanities. Many of those who continued to develop such questions had strayed so far from classical Marxist positions that they more often identified with an expanded notion of “critical theory” than with “Marxism” in the strict sense; rather than referring primarily to the Frankfurt School tradition, such an ecumenical reference to critical theory reflected a shared aspiration for a fundamental rethinking of the Marxian tradition.

The disintegration of the Soviet bloc culminating in 1989 marked the end of the failed experiment of “actually existing socialism.” Though Western Marxists had generally rejected the Soviet model as an expression of Marx’s utopian vision, its sudden demise came as a shock and unleashed a complex theoretical debate (Magnus and Cullenberg 1995). Western Marxists greeted this momentous historical transformation with mixed emotions. On the one hand, they were relieved to see the end of this tragic example of state socialism. On the other hand, they were perturbed by the uncritical embracing of the market model of development as the only alternative and the triumphalist heralding of these changes as the “end of Marxism.” Within the ex-Soviet bloc the disillusionment with Marx was so intense that the very idea of Marxist sociology was generally repudiated; partly as a consequence the “Marxist” interpretation of these events (e.g. the important work of Michael Burawoy) has been undertaken, paradoxically, by Western Marxists (Kennedy and Galtz 1996). In Latin America, though Marx remained in influential intellectual force, political debate shifted from revolutionary rhetoric toward pragmatic questions of “democratic transition” (Castañeda 1993). Though many Marxist social scientists moved toward variants of

post-Marxist critical theory in response to these events, others insisted that the collapse of these regimes did not constitute “proofs of the bankruptcy of Marxism as a tradition of social scientific practice,” though conceding that “it must be reconstructed in various ways” (Wright 1996, pp. 121–122). Though Marxist sociology declined precipitously as a specific orientation in the 1990s—hence its absence from leading social theory anthologies, discussion of Marxist theory continued to flourish in a few journals, most notably the *New Left Review* in Britain and *Rethinking Marxism* in the United States. Despite sporadic attempts to defend Marxism as a science (Burawoy 1990) or “test” classic Marxist claims (e.g., Boswell and Dixon 1993; Cockshott et al. 1995; Smith 1994), the revitalization of empirical Marxist research appeared increasingly dependent upon working out the implications of major theoretical reconstructions (e.g., Postone 1993; Wright et al. 1992). Such efforts have also been influenced by “Weberian Marxism,” despite the resistance of more orthodox Marxists (Gubbay 1997; Lowy 1996).

A second major shift that has contributed to the decline of Marxist sociology in the 1990s can be identified with the elusive concept of “postmodernism” and related poststructuralist tendencies. The Marxist tradition was a specific target of epistemological postmodernism which called into question all “meta-narratives” or grand theories of society and history, whether as explanations or as the basis of universalistic ethical claims. Related poststructuralist critiques of essentialism challenged Marxist theories of the working class and called for a decentered conception of the subject that acknowledged the diversity of subject positions, a theme especially central to feminist, gender, and racial research. Some Marxists simply defended classical Marxist theory against these developments, but many felt compelled to revise their positions in the direction of an “emancipatory postmodernism,” a “postmodern Marxism,” or a “poststructuralist materialism.” In this context, various efforts were made to reconcile selective poststructuralist and postmodernist arguments with a reconstructed neo-Marxist, critical theory (e.g., Best and Kellner 1997). On the one hand, such postmodernist-influenced approaches acknowledged that the fundamental cultural shifts linked to the mass media and new information technologies have profound implications for a “postmodern”

society that was not foreseen by Marx. On the other, they also conceded that classic Marxist theory (though not necessarily Marx himself) relied on an inadequate, teleological philosophy of history, economic reductionism, and an essentialist conception of the working-class subject.

A third tendency that has become more clearly defined over the past decade has been the partial erosion of disciplinary boundaries and the diverse impact of Marxist theorizing on the humanities, especially under the heading of cultural studies and poststructuralist textual theories. Paradoxically, though the influence of Marxist theory declined within sociology in the 1990s, it had a continuing renaissance and diffuse effect in other disciplines, especially literary studies. Much of this work has in turn influenced cultural Marxism, as well as sociologists of culture and the media. In its most ambitious form, such neo-Marxist cultural theory has culminated in an account of postmodernity as an historical epoch (Jameson 1991). Another outcome was an expansion and revision of the canons of classical Marxian theory. Though his status as a “Marxist” has been disputed, the Soviet scholar Mikhail Bakhtin (1895–1975) was rehabilitated as a major theorist of culture whose dialogical theory of language anticipated many of the later developments in poststructuralist critiques of Marxism (Bell and Gardiner 1998). Similarly, Antonio Gramsci’s cultural and linguistic writings have been reinterpreted in terms of his poststructuralist anticipations (Holub 1992).

Finally, the most sustained empirical development in the 1990s was the emergence of the problematic of globalization (and aspects of postcolonial theory) as a reference point for an historical materialist account of social change (Hoogvelt 1997; Larrain 1994). From this perspective, “postmodernism” could be read as a symptom of processes better understood from the perspective of a political economy of globalization. Hence it was argued that Marx was the pioneer of globalization theory, given his account of the ceaseless worldwide expansion of markets, a theme elaborated in Wallerstein’s world-system theory. But many other Marxists have joined critical theorists in emphasizing the distinctiveness of more recent developments since World War II, especially the transformation of production processes (e.g., the shift from “Fordism” to “post-Fordism”) and the impact of information technologies, resulting

in changed relations between space and time (Harvey 1989). Unlike those who uncritically celebrated the advent of an “information society” and globalization as the inevitable outcomes of capitalism, such Marxists and critical theorists have pointed to the selective characteristics of this “modernization” and its inadequate vision of the alternatives (Webster 1995). The most elaborate empirical effort to describe this new “informational mode of production” in Marxist-influenced but also innovative sociological terms can be found in Manuel Castells’ three-volume *The Information Age* (Castells 1996–1998). As against various postmodernist currents, neo-Marxist conceptions of globalization (and related variants of critical theory) are united by their political opposition to neoliberalism (or what is often referred to as neoconservatism in the United States) and an empirical concern with analyzing capitalist globalization in terms of its grave implications for marginalized groups and societies, as well as nature itself. For the most part, such researchers no longer appeal to the classic conception of working-class revolution, though they hold out hope for new social movements as the basis of constructive forms of resistance and democratic renewal. As a consequence, Marxist sociologists have increasingly moved toward positions previously staked out by the Frankfurt tradition of critical theory and related poststructuralist French developments (Morrow 1994), though often without consistently acknowledging the full implications for the “death of Marxism” as an oppositional political discourse (Fraser 1998).

MASS MEDIA RESEARCH

The interest of sociologists in mass communication was stimulated by developments in technology allowing the reproduction and speedy transmission of messages. It began with the rise of the popular press, followed by the invention of film, sound broadcasting (or radio), and the audiovisual, including television and cable television. In the past decade, this interest has grown to embrace computer-influenced adaptations of these traditional mass media, the latest being the World Wide Web (www), which is part of the Internet, or the Information Superhighway.

All of us live in a world of media-constructed images that, presumably, significantly influence what we think and how we partition our attention, time, and other scarce resources. So pervasive has been the media presence that issues relating to these influences have also drawn the attention of researchers from disciplines other than sociology.

It is to Harold Lasswell (1947), an empirically oriented political scientist, that the social science community owes a succinct formula that lays out the major elements within the field of communication research: *Who says what in which channel to whom and with what effects?* Only some channels lend themselves to *mass* communication, which can be defined, in the terms of the above formula, as the transmission by professional communicators (who) of a continuous flow of a uniform content (what) by means of a complex apparatus (channel, or how) to a large, heterogeneous, and geographically dispersed audience (to whom), the members of which are usually anonymous to the communicator and to each other.

Not included in this definition of mass communication are its effects or, more broadly speaking, its consequences, toward which most of the sociological research effort has been directed. The physical or electronic transmission of message content does not in itself suffice for communication. Communication is indisputably social, in that it consists of a meeting of minds between communicator and audience, in the sense of mutual accommodation. Yet the nature and extent of effects

have been, over the years, the central problem of sociological interest in media research.

Effects, however, do not stand alone as a separate and independent dimension for research. More accurately, scholars have investigated the effects of each element in Lasswell's formula. For example, there has been analysis of what effects the different kinds of communicator controls may have, whether the *who* be defined by demographic characteristics and professional values of the communicator (Weaver and Wilhoit 1996; Weaver with Wu 1998) or as the growing big-business controls over mass media through concentration of ownership by not more than ten corporations (Bagdikian 1997). In other research, the effects of different kinds and amounts of media content have been analyzed to determine what was likely to have influenced particular audience behavior, as has been what difference it makes whether news is obtained from radio, television, or newspapers.

Media effects have been studied on three levels: the atomistic, the aggregate, and the societal. Effects on the atomistic level involve the cognitive processes and behavioral responses of *individuals* who make up the various mass audiences. By contrast, aggregate measures take into account only *distributions* that produce changes in averages usually expressed as net effects. Consequences for society have more to do with the political, cultural, and other *institutional* changes that represent cumulative adaptations over time to the dominance of a particular mass medium. Inferences based on the observation of effects on one level when ascribed to effects on a different level have often turned out to be invalid.

THE ATOMISTIC LEVEL

Much of the media research effort has been a response to the operational needs of communicators and propagandists, or of those who wished to defend the public against what was perceived as the pernicious influence of the media. The basic problem has been that of precisely pinpointing effects: What were the characteristics of the potential audience? Who among them was susceptible? What were the determinants of their reactions?

To answer these and similar questions, audience research has typically focused on the situations in which mass communications are received

and on the habits and cognitive processes that underlie the responses of individuals either to specific media messages or to some significant part of the media fare. The responses under scrutiny have ranged from the arousal of interest, gains in knowledge, the recognition of dangers, changes of opinion, and other attitudinal measures to such behavioral indicators as consumer purchases, electoral decisions, and the "elevation" of cultural taste.

Precisely because of its focus on the individual, this line of research tends to stress the diversity of ways in which individuals relate to media content. First of all, audiences are found to be stratified by education, interest, taste, habits, gender, and age. Taken together, education and age tend to account for considerable variance in media use. The observation that some content had only minimal audience penetration helped explain why some information campaigns failed. Consistent patterns of exposure to different kinds of content further suggested that members of the mass audience, by and large, found what suited their needs and interests.

Second, even common exposure turns out to be a less strong predictor of response than expected. Not everyone understands or understands fully, and reactions are affected by the preconceptions with which people approach the content, by preconceptions rooted in past socialization experience but also reflecting the perspective of groups with which they are associated or identify themselves. Audiences are obstinate and people have options in how they orient themselves to any particular set of messages. They can ignore, misunderstand, accept, find fault with, or be entertained by the same content. In other words, there is no assurance that anyone other than those, for whatever reason, already so disposed will accept the facts, adopt the opinion, or carry out the actions suggested by the mass communicator (Schramm 1973).

This downplaying of the importance of content elements by a methodical partitioning of the mass audience received systematic formulation in the "minimal effects" theorem, derived from Joseph Klapper's review (1960) of certain empirical research findings of studies conducted mostly during the 1940s and 1950s. He generalized that certain factors, such as audience characteristics and a pluralistic media structure, which mediated

between content and response, worked primarily in the service of reinforcement of prior attitudes. Changes triggered by exposure were pretty much limited to people whose situations already impelled them to move in that direction. Klapper did, however, acknowledge the power of mass communication to move people on matters with which they were unfamiliar and concerning which they had no distinct views of ingrained habits.

Strong evidence in favor of not-so-minimal effects has come from observations made in the laboratory, especially through the series of experimental studies on children, reported in *Television and Social Behavior*, conducted under the auspices of the U.S. Surgeon General (Murray and Rubinstein 1972). After exposure to programs that included "violent" behavior, subjects often engaged in similar behavior during their play, and were more likely than subjects not so exposed to commit other violent acts.

Such experiments generally have been set up to maximize the possibility of demonstrating direct effects. Thus, in this instance, children, especially young children, would be inclined to model their own behavior on what they see. Moreover, such findings of short-term effects observed in a play situation have to be considered within the context of the whole socialization experience over many years. Longitudinal studies and experimental studies of older children in a more natural setting have yielded results that are more ambiguous (Milavsky et al. 1973). Laboratories do not fully replicate communication situations of real life (Milgram 1973).

Over years of study, conflicting evidence emerged about the relation between mass media (largely televised) violence and its influence on aggressive behavior. Operational definitions of key variables, research designs, and support for research having come from the television industry or not, all have been viewed as possible influences on the research results themselves.

The media-violence effects issue is one in which research results have played an important role in public policy debates involving the broadcast industry often pitted against public interests. Decades of debate eventually led to passage of the Telecommunications Act of 1996, authorizing an electronic device called the V-chip, that would

allow blocking programs with violent programming from television viewing (Rowland 1997).

In recent years, concern over the media-violence effects issue has been “exported” to the rest of the world through the multiple means of transmission and aggressive marketing by multinational corporate media interests. Public opinion surveys in all corners of the globe indicate disturbance by the ubiquitousness of television violence (Maherzi 1997).

The challenges posed by experimental studies have to be faced. Casual but repeated exposure to televised messages results in incidental learning. For example, content of advertising appeals gradually intrude into our consciousness until we associate a product with a particular brand name, or issues dominating the news become the criteria by which we measure the effectiveness of a political leadership. Insofar as the various mass media sources transmit similar content and play on similar themes, such limited effects, if they are cumulative, can produce shifts of significant proportions.

AGGREGATE EFFECTS

Because the responses of persons are so diverse, the effect of communication en masse has to be conveyed in some kind of summary measure—as an average, a trend, a general movement. From this perspective, the magnitude of the shift in the responses of individuals, or whether this represents reinforcement or a reversal, matters less than the general picture, taken over time.

How differently effects can appear when viewed from different perspectives, and at different periods of time, may be illustrated by reference to studies of the diffusion of innovations (Rogers 1995). Detailed documentation in the more than fifty-year tradition of diffusion studies has spanned many disciplines and many nations, bringing revision and fine-tuning to the original concepts. The early diffusion model was applied to post-World War II development programs in agriculture, family planning, public health, and nutrition. Today, the model is being applied to areas as diverse as acquired immunodeficiency syndrome (AIDS) and the Internet.

The process by which innovations are adopted and spread suggests that early adopters, also called

“influentials” or “opinion leaders,” depending on context, are more cosmopolitan in their orientation and hence more attuned to certain media messages. They select from the total stream the messages that best meet their needs and interests. Others will adopt an innovation only after its success has been demonstrated or, if that is precluded—as it would be in most political decisions—out of trust in the expertise of the pacesetters. One can account for the different behavior of leaders and followers in such situations—that is, why one person moves ahead and another is content to wait—in terms of personal characteristics and social relationships. Aggregate effects, on the other hand, have to do with whether or not there has been a general movement toward acceptance or rejection of the innovation.

The most direct measures of aggregate effects are to be found in two-variable relationships designed to show cause and effect, with one variable functioning as an indicator of media presence and the other representing the response. Many such combinations are possible. One can use media penetration (e.g., newspaper circulation, or the proportion of homes with a television set) or content characteristics (e.g., the number of violent acts in children’s programs, editorial endorsements, or issues emphasized in the news). This rules out media behavior, which is voluntary for individuals in the audience, and may bring into question the influence of still other, often unmeasured, variables that also account for the presumed effect.

As the age of television dawned, opportunities for “controlled” observation—comparing two matched areas, one receiving television and the other not yet within reach of the broadcast signal—were never fully exploited. Rarely did findings about the advent of television go beyond documenting the rather obvious fact that television viewing cut into the use of some other media, especially radio and to a lesser degree movie attendance and children’s comic book reading. Nor were the consequences of this reallocation of time at all clear.

A study of children in “Teletown” and “Radiotown,” the latter community still without television but comparable in other respects, concluded that before television, many children (had gone) through the same type of change as today

from fantasy-seeking media behavior toward reality-seeking media behavior (Schramm et al. 1961).

For another natural experiment, a researcher was able to identify a Canadian town that was to get television within a year, after being unable to obtain reception because of geographic location. Comparisons were made with two other communities, one that would receive a second television channel and one that remained the same that year, with four channels. Results showed that the arrival of television did make a difference in children's reading skills, aggression levels, sex role stereotyping, and attendance at social events outside the home (Williams 1986).

Any such cause-effect evidence from natural experiments is lacking on matters relating to citizen participation among adults in national elections. Systematic comparisons between the turnout and overall responsiveness to "party" issues during the 1952 presidential election in counties with high TV penetration and low TV penetration revealed no consistent differences, probably because other media were already saturated enough with campaign material to have produced a high level of interest. Situations subject to such "ceiling" effects prevent further research in response to the presence of a new medium.

Variations in content, when they occur, have offered far more opportunities for controlled observations, many of which have challenged the conventional wisdom. That voters on the west coast of the United States would be dissuaded from voting in the presidential election once television, based on early returns, had declared a winner seemed only logical. Yet studies showed that westerners continued to cast ballots in roughly the same proportions as their compatriots in states where polls had already closed. In voting, they were evidently moved by considerations other than practical utility and by other competing media messages. Whatever the effects of such broadcast returns on the decision to vote or not to vote, they have been too small for detecting with present techniques of measurements (Lang and Lang 1984, ch. 5). As regards editorial endorsements, where the range of variations is greater, research has shown that such support gives candidates for minor offices, many of whom are only names on a ballot, an incremental but nevertheless

distinct advantage over other minor candidates on the same slate.

Correlations that pair media use variables with some measure of response always imply change over time. The alternative is to conduct before-and-after studies in response to events as they are being communicated via the mass media: a televised speech by a political leader, the announcement of an unexpected reversal of government policy, news of foreign crisis, or simply the flow of information about economic conditions and problems facing the country.

Polls before and after an appropriately timed speech have documented the power of a head of state to move opinion through appeals directed to the public. Speeches can create greater awareness. They are designed to focus attention on those issues and actions from which the politician stands to benefit. The effectiveness of such media events is apt to be greatest when an issue is just surfacing. Leaders also have the ability to make news. Even without an undisputed success, their public appearances, diligently reported by the news media, are used to dramatize their own role in promoting solutions to matters believed to be of general concern, thereby conferring status on themselves, as well as on the matters they seek to promote.

Careful analysis of the impact of many such events over the years again challenges the conventional wisdom. Neither speeches nor foreign travel by American presidents over the many administrations have, by themselves or in combination, *uniformly* shored up public support. Public response to these events has been highly dependent on the political context—that is, on whether they coincided with other events that tended to enhance the president's standing or whether his administration was plagued by intractable problems, such as public concern about a declining economy, an indignation over American hostages whose release it could not effect, or revelations of governmental wrongdoing such as those that surfaced during Watergate and led to the resignation of Richard Nixon as chronicled by Lang and Lang (1983).

What stands out in a long line of studies is the general correspondence over time between the overall amount of attention a topic, an issue, or a personality enjoys in the media and the audience's awareness, interest in, and concern about these. Mass communication influences not so much *what*

people think (opinion) but what they think *about* (recognition). Insofar as there is enough common emphasis, the media perform an “agenda-setting” function (McCombs and Shaw 1972, 1976; Iyengar and Kinder 1987). Collectively, the media and the audience define the terms of public debate. Media attention also confers status on some of the many voices clamoring to be recognized.

Agenda-setting research requires at least two steps; that is, content analysis is conducted to define the media agenda, and surveys are used to identify the public or audience agenda. This simple formulation, which has been a central focus of effects research in political communication for some years, attributes to the media at one and the same time too much and too little influence. On the one hand, the media do not, all on their own, dictate or control the political agenda. Neither public awareness nor recognition of a problem is sufficient to stir a controversy on which people take sides. On the other hand, access to the media is a major resource for the advocates of particular policies. Concerns become issues through discussion in which political leaders, government officials, news and commentary in the press, and the voices of citizens reciprocally influence one another in a process more aptly characterized as “agenda building” (Lang and Lang 1984). In fact, three agendas—those of the media, the public, and the policy makers—all influence each other in a rather interactive political process (Rogers and Dearing 1988).

THE SYSTEMIC PERSPECTIVE

The dissemination of content via the mass communication system occurs in a highly selective fashion. Some information is privileged; other information is available only to those with the interest and resources to pay for it, thereby stratifying societies into the “haves” and have-nots,” or into the information rich and the information poor. The upshot of all the efforts to direct communication flow is a repertoire of images of events and ongoing social activities. Media organizations are themselves producers of content. The mass communications through which the world is brought into focus are, in the broadest sense, cultural creations that incorporate the perspectives of the

producers and of others whose views have to be taken into account. This influence of the communications system on content, intended or not, is a source of bias often unrecognized by those responsible for it.

One has to differentiate between two sources of bias: technological and social. Technological bias stems from the physical characteristics of the medium. Harold Innis (1951), the Canadian institutional economist, distinguished between bias toward space and bias toward time. Paper, he averred, because of its light weight, was easily transported but also perishable, and so supported the development of centralized administration. The uniformity thus imposed over a given area (space) was usually at the expense of continuity (time). A more flexible medium could adapt to an oral tradition that favored spontaneous cooperation among autonomous units. Indeed, signs continue to point in the direction that cheaper and smaller electronic devices may be radically increasing the control individuals have over the information available to them and what to do with it (Beniger 1986). Information is central to the control individuals have over the social events of the world in which they live.

Applied mechanistically, without regard to who is in control, these categories lead to a simple-minded media determinism. Social bias has to do with how the capabilities intrinsic to the dominant medium are exploited. Television, in and of itself, may not have had a demonstrable effect on voter turnout but nevertheless contributed indirectly. Thus, a nonpartisan political coverage, designed not to offend but with an insatiable appetite for scandal, was implicit in the economic logic of aiming at the largest possible audience while the American regulatory system opened the way for a well-financed candidate could buy nearly unlimited time to air well-targeted, and often negative, political messages. Both trends fed into an already existing distrust of government. Meanwhile, campaign strategies adapted to the medium of television helped undermine the power of party machines to deliver votes. The nominating conventions in which political bosses once traded votes have been transformed into showpieces, played for a national audience as the curtain raiser for the U.S. presidential election campaign.

More generally, its penetration into the spheres of other institutions—political, cultural, educational, and so on—is what makes mass communication a potentially powerful influence on the societal level. It hardly matters whether the media are viewed as a resource or as a threat. The publicity generated through mass communication brings the norms of the larger society to bear on actions that once might have been considered privileged or at least shielded from public scrutiny. Conversely, the competition for visibility is an inducement for elite institutions to adopt at least some of the conventions of the media culture.

There remains the question of who sets these norms and standards. Some scholars have argued that repeated exposure to a sanitized media culture results in “mainstreaming” (Gerbner et al. 1986), or what has been commonly referred to as homogenizing consequences. Accordingly, all but a few of the diverse currents that feed into the kaleidoscope of minority United States cultures, including women and racial and ethnic minorities, receive comparatively little or no recognition. Lacking an effective institutional representation, they are more readily marginalized. Content analyses of character portrayal and the values espoused by heroes and villains, victims and perpetrators of violence in the popular entertainment fare, as well as by surveys of adults, adolescents, and children in the United States, have lent some support to the charge of “mainstreaming.” Such cultivation analysis in cross-cultural settings also is finding support for these kinds of media effects (Signorielli and Morgan 1990). Despite the premium on novelty, most media organizations are inclined not to stray too far from what is popularly accepted but will be likely to eagerly imitate any demonstrated success.

The representation of political views is similarly constrained. Despite the independence of the press and a few celebrated instances where a small number of persistent journalists initiated an inquiry, as when the Woodward and Bernstein team pursued the Watergate story, the more typical pattern is to wait until political actors have highlighted a problem. Usually, it is they, rather than the press, who define the terms of controversies over policy, as was the case in the much-studied limited role of the media, largely American and mostly Cable News Network (CNN), in the 1991 Persian Gulf conflict (Dennis et al. 1991; *Media*

Development, 1991). To paraphrase W. Lance Bennett (1988), when the institutional voices speaking in protest are stilled, all but the more radical media are inclined to drop the issue as well. Discussion and diversity exist but usually within self-imposed limits.

It should be clear that major media organizations, though important players, are less than fully separate from other establishments. Their influence on events is greatest when they act in conjunction with other agencies.

INTERNATIONAL, OR GLOBAL, RESEARCH

Into the 1950s, mass communication research was very much a product of the United States: U.S. media programming and news events, U.S. media practices and policies, with necessary consideration of U.S. politics and society. There was a tendency for mass media research to concentrate on one aspect of the communication process originally outlined by Lasswell, namely effects. Later, research refocused some attention on other elements of the communication process—on what was produced and how it was produced.

Research also began exploring dimensions of mass media influence outside the United States. Some studies were international extensions of research already being conducted in the United States, as with the media-violence issue, diffusion of innovations, and cultivation analysis. For other research, the international perspective was the question under investigation: What should be considered when news, television entertainment programming, and other media products cross geopolitical boundaries?

In the 1950s, the identification of four theoretical perspectives of the press—authoritarian, communist, libertarian, and social responsibility—focused attention on the social, political, cultural, and philosophical underpinnings that determine how and why the mass media of various parts of the world are different (Siebert et al. 1956). Here, the press was defined as all available mass media responsible for dissemination of news. Some country-specific case studies have helped to elucidate these differences (Mickiewicz 1988; Alot 1982; Howkins 1982).

The post-World War II era was concerned with reconstruction and development of the so-called Third World and spawned a developmental perspective of the mass media (Schramm 1964; Lerner and Schramm 1967). A fifth concept of the press focused on revolutionary goals of the mass media, with China's transitions over the past century and the recent emergence of terrorism as examples of present-day extensions of this perspective (Chu 1977; Lull 1991; Nacos 1994).

Debate over international communication issues has been strongly influenced by the political and economic imbalances among the nations of the world. So-called North-South debates juxtapose the concerns of the politically independent, industrialized, and developed part of the world against those of the newly independent countries, which have been trying to shed their colonial pasts and, because they have missed out on the Industrial Revolution, are still developing. Other debates between the East and the West have been reflections the cold-war conflicts between the former Soviet Union and the United States, in which an emergent group of nonaligned countries, largely in the developing world, have refused to take sides.

In the 1970s, the United Nations Educational, Scientific and Cultural Organization (UNESCO) became an outspoken supporter of efforts by this developing Third World to create a New World Information and Communication Order (NWICO) as the counterpart to calls for a less well known New World Economic Order. UNESCO formed an advisory commission of international scholars, diplomats, and specialists, headed by Irishman Sean MacBride, to study the world's communications problems, and to address Third World protests against the domination of news flow from industrialized countries of the West to the rest of the world. It was also concerned with issues as diverse as governmental controls, censorship, cultural dominance or imperialism, concentration of media ownership and powerful control of transnational corporations, freedom and responsibility of the press, commercialization of mass media, protection of journalists when they are at work in countries other than their home, access to technology and infrastructure development, and rights to communication (International Commission for the Study of Communication Problems 1980).

Studies proliferated in relation to the various issues posited by the UNESCO report. "Cultural imperialism" that reflected political imperialism of older models from historical colonialism was the theoretical perspective from which empirical studies documented imbalances in the world's media infrastructures and contents. The "media imperialist" was decidedly Western, and largely American. UNESCO together with professional organizations of scholars and practitioners supported large multicountry studies of international news flow (Sreberny-Mohammadi 1984; Kirat and Weaver 1985). These studies analyzed images, distortion in content, and the role of news agencies, and also explored factors that determine what becomes news (Galtung and Ruge 1965).

This research showed that certain factors do influence news production, such as economic considerations in distribution of news-gathering resources and ease of reporting; importance to the country producing the news in terms of trade, social and cultural ties, geographic proximity, and relative standing or status of nations in the eyes of others. Such findings have influenced shifts in mass media structures and output, such as the increase in national and regional news through agencies like the New China News Agency, also known as Xinhua, and the Caribbean News Agency (CANA).

In these nearly twenty years, the UNESCO debate over NWICO has faded and resurfaced more than once, and UNESCO-sponsored round table discussions continue on a regional basis to provide a forum for discussion of research on global communication issues. A recent UNESCO report on the status of the world's mass media and how they are handling the challenges of new technologies claims that the problems identified by the MacBride Commission "still remain a burning issue" and are likely to continue to be the focus of research efforts at national, regional, and international levels (Maherzi 1997).

One issue highlighted in the original UNESCO report that has received considerable national and multinational research attention is the inequality of women and girls in societies around the globe, their disproportionate representation in media-related employment, and their stereotyped images in news and entertainment media portrayals. More than a decade behind the U.S. civil rights and

women's movements that triggered considerable mass media research with implications for local media practices, programming decisions and U.S. policy, this UNESCO report was to become pivotal in pitching these issues to the rest of the world for research and analysis.

The United Nations Fourth World Conference on Women, held in Beijing in 1995, included women and media among the thirteen major substantive areas for consideration. There were reports on country-specific surveys of media practices, characteristics and attitudes of those holding jobs in the media, and program content (All-China Journalists Association and Institute of Journalism, Chinese Academy of Social Sciences 1996) and studies that involved the coordination of data collection in many countries. For example, the Global Media Monitoring Project gathered data from news media—radio, television and newspapers—in seventy-one countries for representation and portrayal of women at one point in time: January 18, 1995. Based on the data, an overall report and separate regional reports were produced. The study provides a large database with policy implications for UNESCO and for media systems in many countries. A benchmark for measuring future change, the Media Monitoring Project's study remains the most extensive survey of portrayals of women in the world's news media that has been undertaken to date (Media Watch 1995).

On balance, however, it remains unclear from available research whether women and men working in the mass media take different approaches on issues or events, even if women and men have a different range of interests they select for media attention. Though there has been an increase in the number of women working in the media in the past few years, surveys also show that the world of media remains strongly male (Maherzi 1997).

Most recently, research questions emerging in international communications are centering on the concept of globalization of mass media producers and their products. The concentration and control of media industries into fewer and fewer transnational corporations has long been a concern in research that points to the negative effects of increasing global "homogenization." It is not without some irony that, on the one hand, the results of mass media investigations have brought

about international pressure for diversifying media products with voices of women and minorities of all kinds, while on the other hand, ownership of the world's media is concentrated in the hands of a few corporate giants.

NEW MEDIA TECHNOLOGIES

One of these corporate giants in the media world is Time Warner. Years ago, Warner Brothers produced films and Time produced a news magazine. Together, they are now also involved with other aspects of the media environment, including newspapers, magazines, television, cable television, radio, video games, telephones, and computers in the United States and around the world. Understanding why such a corporate giant was created is key to understanding the impacts of new media technologies: "Convergence" of technical infrastructures is leading to consolidation of media products and services.

The Internet, or the Information Superhighway, with the World Wide Web (www), is the most recent development, which has the potential to offer any or all of the aforementioned media products and services through on-line information networks. Current Internet services are transmitted via computer-telephone connections, but explorations of other methods of transmissions are under way, such as cable television and direct satellite links. Obviously, the corporate giants wish to be positioned to take their share of any new media offerings and to provide new delivery systems. What technology will deliver news and entertainment, as well as other information and services, in the future remains an open question.

Regardless of how the infrastructure question is decided, will the definition of "news" remain the same? Because of the vast storage capacity of computers, the role of editors and gatekeepers may change. With the ability of computers to allow more personalized reception of news offerings, will the "newspaper" still be considered a *mass* medium?

Internet-related services and e-mail already are providing new possibilities for on-line public opinion polls. But so far, such surveys are similar to volunteer call-in or write-in polls and are limited to Internet users. While the number of new Internet users grows daily, by the year 2000 the numbers of

U.S. adults on-line is expected to reach only 60 million (Pew Research Center 1996). Increasingly, on-line users are “decidedly mainstream,” according to a nationwide telephone survey, and for now, television is losing in their allocations of time (Pew Research Center 1998).

At the atomistic level, researchers have conducted ethnographic and clinical observation on how people relate to computers and how they may be reconstructing their basic sense of identity (Turkle 1995).

How will the traditional mass communication conceptualizations of diffusion of innovations, agenda-setting and agenda-building, cultivation, and mainstreaming help us to understand the new media environment?

Is our new world more global or more local (Sreberny-Mohammadi et al. 1997)? Are we moving into Marshall McLuhan’s long-promised “global village”? Or is it a global megalopolis? Are we moving from UNESCO’s “many voices, one world” to many worlds, one voice?

These are some of the many questions that will occupy media researchers in the near future.

MASS SOCIETY

The mass society theory, in all its diverse formulations, is based on a sweeping general claim about "the modern world," one announcing a "breakdown of community." The leading nineteenth-century proponents of this position were Louis de Bonald, Joseph de Maistre, and, from a different perspective, Gustave Le Bon. These formulations argue the collapse of the stable, cohesive, and supportive communities found in the days of yore. In modern times, as a consequence, one finds rootlessness, fragmentation, breakdown, individuation, isolation, powerlessness, and widespread anxiety (Giner 1976; Halebsky 1976).

The original formulations of this position, those of the nineteenth century, were put forth by conservatives, by persons identified with or defending the old regime. These were critiques of the liberal theory or, more precisely, of liberal practice. The basic aim of the liberals was to free individuals from the restraints of traditional institutions. That aim was to be accomplished by the dismantling of the "irrational" arrangements of the old regime. Liberals, understandably, were enthusiastic about the achievement: Free men could do things, achieve things, create things that were impossible under the old arrangement. The collective benefits, they argued, were (or would be) enormous. The conservative critics agreed about some aspects of the history. They agreed about the general process of individuation. They, however, called it fragmentation or a decline of community. More important, they provided very different assessments of the consequences. At its simplest, the

liberals argued an immense range of benefits coming with the transformation, a conclusion signaled, for example, in Adam Smith's title, *The Wealth of Nations*. The mass society theorists agreed with the basic diagnosis but drew strikingly opposite conclusions pointing to a wide, and alarming, range of personal and social costs.

The modern world begins, supposedly, with an enormous uprooting of populations. Ever greater numbers are forced from the small and stable communities into the large cities. In place of the strong, intimate, personal supports found in the small community, the large cities were characterized by fleeting, impersonal contacts. The family was now smaller. The isolated nuclear family—father, mother, and dependent children—was now the rule, replacing the extended family of farm and village. The urban neighborhoods were and are less personal. The frequent moves required in urban locales make deep, long-lasting friendships difficult if not impossible. As opposed to the support and solidarity of the village, instrumental and competitive relationships are typical in the large cities and this too makes sustained social ties problematic. In the mass society people are “atomized.” The human condition is one of isolation and loneliness. The claims put forth in this tradition are typically unidirectional—the prediction is “more and more.” There is ever more uprooting, more mobility, more societal breakdown, more isolation, and more anxiety.

The nineteenth-century versions of this theory focused on the insidious role of demagogues. In those accounts, traditional rulers, monarchs, aristocracy, and the upper classes did their best to govern fundamentally unstable societies. But from time to time, demagogues arose out of “the masses,” men who played on the fears and anxieties of an uneducated, poorly informed, and gullible populace. The plans or programs offered by the demagogues were said to involve “easy solutions.” But those, basically, were unrealistic or manipulative usages, ones providing no solutions at all. The demagogues brought revolution, which was followed by disorder, destruction, and death. The traditional patterns of rule were disrupted; the experienced and well-meaning leaders were displaced, either killed or driven into exile. The efforts of the demagogues made an already-desperate situation worse.

Conservative commentators pointed to the French Revolution as the archetypical case with Robespierre and his associates as the irresponsible demagogues. Mass society theorists also pointed to the experience of ancient Greece and Rome. There too the demagogues had done their worst, overthrowing the Athenian democracy and bringing an end to the Roman republic. The republic was succeeded by a series of emperors and praetorians, men who, with rare exceptions, showed various combinations of incompetence, irresponsibility, and viciousness.
